D Administrative Record User's Guide

1 INTRODUCTION

The requirement for the Administrative Record is established under Section 113 of the *Comprehensive Environmental Response, Compensation, and Liability Act* of 1980 (CERCLA), as amended by the *Superfund Amendments and Reauthorization Act* of 1986. Section 113(k)(1) of CERCLA and Subpart I of the *National Oil and Hazardous Substance Pollution Contingency Plan* (EPA 1992) require the establishment of an Administrative Record upon which the selection of a response action is based.

The Administrative Record (AR) is a body of documents that "forms the basis" for the selection of a particular response action at a site. Documents that are included in the AR are relevant documents that were relied upon in selecting the response action, including documents that contain alternatives or options that were considered, but were ultimately rejected.

1.1 Purpose

The CERCLA Administrative Record serves a dual purpose. The record documents the decision for the selection of a response action, and the record serves as a vehicle for public participation in the selection of the response action. Judicial review of any issue concerning the adequacy of a response selection is limited to the record. For purposes of administrative and judicial review, the record contains documents that reflect the participation of the public and the DOE's consideration of the public's concerns.

1.2 Public Participation

Section 113(k) of CERCLA requires that the public have the opportunity to participate in developing the Administrative Record for response selection. Section 117 of CERCLA also includes provisions for public participation in the remedial action selection process.

2 WSSRAP ADMINISTRATIVE RECORD

In accordance with *Comprehensive Environmental Response, Compensation and Liability Act* (CERCLA) the *National Oil and Hazardous Substance Polution Contingency Plan*, and the *Final Guidance on Administrative Records for Selecting Comprehensive Environmental Response, Compensation and Liability Act Response Actions* (EPA 1990), a simple and comprehensive system has been developed for establishing and maintaining the Administrative Record and record files for the Weldon Spring Site Remedial Action Project (WSSRAP) response actions. This system permits the WSSRAP to achieve the judicial review and public participation goals of the Administrative Record by the most efficient and practical means possible.

The administrative record file (ARF) should be distinguished from the administrative record (AR). The ARF refers to the documents as they are being compiled. Until a response action decision has been selected, there is no complete AR for that decision. Thus to avoid creating the impression that an AR is complete at any time prior to the final decision, the set of documents compiled for the response action is referred to as the administrative record file rather than the administrative record.

2.1 Responsibility for the Administrative Record

The overall responsibility for the establishment of the Administrative Record rests with the lead agency, which is the Department of Energy (DOE) at WSSRAP. The Project Management Contractor (PMC) for the DOE then compiles the WSSRAP AR/ARFs and maintains the Administrative Record File System (ARFS). The responsibility for long-term maintenance lies with the DOE as explained in Section 5.

2.2 Objective

The objective of establishing the WSSRAP Administrative Record File System is to provide a system of maintaining concise records that contains the events, studies, data, and other pertinent information documenting the decision process upon which WSSRAP removal and remedial actions are based.

2.3 Scope

This plan applies to all WSSRAP personnel using and/or reviewing documents which are part of the ARFS.

This plan supports procedure RC-8, *Administrative Record Development and Management*.

This plan will be reviewed annually and maintained according to procedure RC-45a/3, *Document Hierarchy Procedure*.

The ARFS comprises Administrative Record and Administrative Record files and the database used to track and compile documents for inclusion into the record file.

Administrative Record File System - provides a systemic approach for the overall scope, work, preparation, and maintenance of the WSSRAP Administrative Record and Administrative Record files.

Database - An electronic method in dBase IV of cataloging and indexing documents included in the AR/AFRs.

2.4 Administrative Record Coordinator

The ARC has the primary responsibility for coordinating the development and maintenance of the ARFS. The system established at the WSSRAP to maintain and implement the Administrative Record requirements includes the following activities:

- Managing the AR master file and copies.
- Creating, maintaining and distributing the administrative records indexes.
- Submitting the administrative record indexes to DOE on a quarterly basis.
- Ensuring availability of the Administrative Record to the public.

- Coordinating with the Administrative Record Committee to ensure that all relevant new documents and correspondences are reviewed by the committee for inclusion/exclusion into the proper Administrative Record file. The AR committee periodically meets to review documents for inclusion in the ARF and consists of the ARC and assistant, and a representative of the Environmental Documentation/ Conceptual Design Department.

- Ensuring that sampling and testing data, quality control and quality assurance documentation, and Chain of Custody Forms would be available for public inspection.

2.5 Administrative Record Requirements

The following sources and authorities mandate the establishment and maintenance of an administrative record.

CERCLA (42 USC Section 9601 et seq.)

- Section 9613 (k), Administrative Record and participation procedures.
- Section 9617 Public Participation.

National Oil and Hazardous Substance Pollution Contingency Plan (40 CFR 300)

- Community Relations provisions in Parts 300.155, 300.415(m), 300.430(c) and (f)(3) and (6) and 300.435(c).

- Administrative Record for Selection of Response Action provisions in Subpart I (300.800 - 300.825).

OSWER Directive No.9833.3A-1 (December 1990)

- *Final Guidance on Administrative Records for Selection of CERCLA Response Actions.*

Federal Facility Agreement (January 1992)

- If requested, a copy of each AR document will be provided to the U.S. Environmental Protection Agency (EPA).

- An index of documents in the AR file will be provided to the EPA on a quarterly basis.

- The above records and documents will be preserved 10 years beyond Federal Facility Agreement (FFA) determination.

3 WSSRAP ADMINISTRATIVE RECORD FILE

The Weldon Spring Site Remedial Action Project (WSSRAP) Administrative Record File System contains the following five separate files:

- Quarry Bulk Wastes Administrative Record (complete).
- Chemical Plant Area Administrative Record File.
- Quarry Residuals/Groundwater Administrative Record File.
- Site Ground Water Administrative Record File (future).
- Interim Response Actions Administrative Record File.

The Quarry Bulk Wastes Administrative Record file is complete. The *Record of Decision* was signed March 1991, and subsequently included in the Quarry Bulk Wastes Administrative Record. This record is now complete, and documents may not be added or deleted from the Quarry Bulk Wastes Administrative Record. The Chemical Plant Area Administrative Record file has been established for the chemical plant area remedial action; it will be complete when the Record of Decision is finalized. The Quarry Residuals/Groundwater Administrative Record file and Site Ground Water Administrative Record file will be established for their respective remedial actions. The Interim Response Actions (IRA) Administrative Record contains the documentation for all removal actions at the WSSRAP. The IRAs are contained in one Administrative Record rather than in separate records for each IRA, at the request of the U.S. Environmental Protection Agency (EPA) Region VII.

3.1 Compilation

The administrative record file (ARF) for a new response action is made available to the public at the time the remedial investigation/feasibility study (RI/FS) work plan for a remedial action or the engineering evaluation/cost analysis (EE/CA) for a removal action is made available to the public. However, the compilation of a WSSRAP ARF begins during the remedial investigation process to ensure that all documents are captured. Documents that would be included in a future ARF are compiled in an "unofficial", pre-public file until the RI/FS work plan is complete.

A time-critical removal action is a removal action for which a period of less than 6 mo exists before on-site removal activities must be initiated (EPA 1990). The administrative record

file for these actions is made available for public inspection no later than 60 days after the initiation of an on-site removal activity. If possible, the record file is made available earlier.

A non-time-critical removal action is a removal action for which a planning period of at least 6 mo exists before on-site removal activities must be initiated [40 CFR 300.415(b)(4)]. The administrative record file for a non-time-critical removal action is made available for public inspection when the engineering evaluation/cost analysis is made available for public comment.

3.2 Content of the Administrative Record

3.2.1 Remedial Actions

According to the *Final Guidance* (EPA 1990), documents such as those listed below should be included in the AR for a remedial action. The term "documents" covers a variety of documents, such as letters of correspondence, data reports, plans, newspaper articles and notices, as well as *Comprehensive Environmental Response, Compensation and Liability Act* (CERCLA) documents. Documents included in the WSSRAP AR/ARFs for remedial actions do contain the following documents, as appropriate.

- Preliminary Assessment/Site Investigation Reports.
- Remedial Investigation/Feasibility Study (RI/FS) Work Plan.
- Amendments to the final work plan.
- Sampling and Analysis Plan (SAP) consisting of a Quality Assurance Project Plan (QAPP) and a Field Sampling Plan.
- Sampling data: data verified during the RI/FS, or any data collected for previous actions such as removal actions which were considered or relied on in selecting the remedial action. Unvalidated data is included only if relied on in the absence of validated data.
- Chain Of Custody Forms.

- Data Summary Sheets.
- Data submitted by the public.
- Technical studies performed for the site (may be included as technical literature in the reference listing of the AR file).
- Memoranda on site-specific or issue-specific policy decisions. Examples include memoranda on off-site disposal availability, special coordination needs, applicable or relevant and appropriate requirements (to the extent not in the RI/FS), cost effectiveness, and utilization of permanent solutions and alternative treatment technologies.
- Risk evaluation/endangerment assessment and underlying documentation (i.e., WSSRAP Baseline Risk Assessment).
- Remedial Investigation/Feasibility Study (as available for public comment and as final, if different).
- Proposed plan.
- Guidance documents.
- Technical literature.
- Community Relations Plan.
- Newspaper articles showing general community awareness.
- Public notices (i.e., notices of availability of information, notices of meeting, and notices of opportunities to comment).
- Documentation of informal public meetings.
- Public comments.

- Transcripts of formal public meetings.
- Responses to significant comments.
- Responses to comments from the State and Other Federal agencies.
- Documentation of State involvement (documentation of the request and response on applicable and/or relevant and appropriate requirements (ARARs) Section 121(f)(1)(G) *Notices and Responses*, a statement of the State's position on the proposed plan, opportunity to concur in the selected remedy.)
- Agency for Toxic Substances and Disease Registry Health Assessments Reports.
- Natural Resource Trustee notices and responses, findings of fact, final reports, and natural resource damage assessments.
- Record of Decision (ROD) (including Responsiveness Summary).
- Explanations of significant differences and underlying information.
- Amended ROD and underlying information.
- Index.

3.2.2 Removal Actions

According to the *Final Guidance* (EPA 1990), documents such as those listed below should be included in the administrative record for a removal action. The WSSRAP AR/ARFs contains the following documents, as appropriate.

- Preliminary Assessment/Site Investigation Reports.
- Sampling Plan.

- Sampling data: verified data obtained for the removal action, or any data collected for previous actions, such as other response actions which are considered or relied on in selecting the removal action. Unvalidated data is included only if relied on in the absence of validated data.

- Chain Of Custody Forms.

- Engineering Evaluation/Cost Analysis (EE/CA).

- Technical studies performed for the site (may be included as technical literature in the reference listing of the AR file).

- Risk evaluation/endangerment assessment and underlying documentation (i.e., WSSRAP Baseline Risk Assessment).

- Data submitted by the public.

- Memoranda on site-specific or issue-specific policy decisions. Examples include memoranda on off-site disposal availability, compliance with other environmental statutes, special coordination needs.

- Guidance documents.

- Technical literature.

- Community Relations Plan.

- Newspaper articles showing general community awareness.

- Public notices (i.e., notices of availability of information, notices of meeting, and notices of opportunities to comment).

- Documentation of public meetings.

- Public comments.

- Transcripts of formal public meeting.
- Responses to significant comments.
- Responses to comments from the State and other Federal agencies.
- Documentation of State involvement.
- Agency for Toxic Substances and Disease Registry Health Assessments Reports.
- Natural Resource Trustee notices and responses, findings of fact, final reports, and natural resource damage assessments.
- EE/CA Approval Memorandum.
- Action Memorandum or Response Action Decision Document.
- Amended Action Memorandum or Amended Response Action Decision Document.
- Other documents which embody the decision for selection of a removal action.
- Index.

The ARFs include only numeric revision documents (i.e., Revision 0, Revision 1, etc.) for the preceding documents. Drafts (or portions of drafts) and internal memorandums are incorporated into the record only in the following instances:

- If a draft document or internal memorandum is the basis for a response decision, the draft document or internal memorandum is placed in the record file. This may occur if (a) the draft contains factual information which was relied upon but is not included in a final document, (b) a final document does not exist, or (c) a final document did not exist when the response decision was made.
- If a draft document or internal memorandum is circulated by the U.S. Department of Energy (DOE) to other persons (e.g., Federal/State agencies or the general

public), who then submit comments that the decision maker considers or relies upon when making a response action decision, relevant portions of the draft document or the memorandum and comments on that document, are included in the record file.

- If a draft document or internal memorandum explains or conveys decisions on the procedures for selecting the remedy or substantive aspects of a proposed or selected remedy (e.g., the scope of a site investigation or the identification of potential applicable and/or relevant and appropriate requirements [ARARs], the document is placed in the record file, even though the document was signed by a person other than the DOE, and generated long before the decision document was signed.

3.3 Special Documents

According to the *Final Guidance* (EPA 1990), certain documents that are included in the AR file do not have to be maintained in the ARFs. Documents in this category must be included in the AR index or referenced in an AR document included in the record file. Exceptions are described for each special category as follows:

- Chain of custody -- These forms may be left in the original storage location. Chain of custody may be viewed by the public by appointment.

- Data packages.

- Computer models and technical databases --The software is available on site for public inspection.

- Privileged Documents -- These documents can be maintained in the confidential portion of the file located in the Document Control. The title and location of the information, as well as a short description of the information and the reason for the privilege, is maintained by the Administrative Record Coordinator. Currently WSSRAP has no privileged documents.

- Confidential documents -- See Privileged Documents

- Guidance documents -- The guidance documents that comprise the *Compendium of CERCLA Response Selection Guidance Documents Users Manual* (EPA 1988) are located at the EPA Region VII office. The compendium list is included in the WSSRAP AR/ARFs.

- Publicly available documents -- Documents that not site-specific and are publicly available need not be physically located in the ARF, if the documents are referenced in the index to the ARF.

3.4 Post-Decision Information

In general, documents generated or received after signing the decision document are kept in a post-decision document file. This file is not part of the administrative record file and is maintained in a separate file.

However, documents kept in the post-decision document file may be added to the record file when:

- A decision document does not address, or reserves a portion of the decision to be made at a later date, e.g., a decision document that does not resolve the type of treatment technology. In such cases, these documents are added to the record file which forms the basis of the unaddressed or reserved portion of the decision.

- There is a significant change in the selected response action. Changes that result in a significant difference to a basic feature of the selected remedial action (e.g., timing, ARARs), with respect to scope, performance, or cost are addressed in an explanation of significant differences.

- The changes are so significant that they fundamentally alter the very nature or basis of the overall response action and require an amended decision document.

- Comments containing significant information are submitted by interested persons after the close of the public comment period. Documents meeting this criteria are included in the record file, along with the DOE's responses to the significant

comment (whether or not such information results in a change to the selected decision.

- The DOE holds public comment periods after the selection of the response action.

4 WSSRAP ADMINISTRATIVE RECORD FILE SYSTEM

The Weldon Spring Site Remedial Action Project (WSSRAP) Administrative Record File System (ARFS) was developed to select, catalogue, index, and file documents that are incorporated into an Administrative Record File (ARF). The system includes administrative record (AR) document file numbering, instructions for completing database document information, data entry of this information, and generation of the index.

A User's Guide is available (Appendix D) for use by the public and the WSSRAP staff in the Reading Room. The Guide simply explains the Administrative Record requirements and the WSSRAP Administrative Record files.

4.1 Document Selection

The selection process involves the identification of documents for review by the Administrative Record Coordinator (ARC). This selection process is performed on a monthly basis. During a public comment period, the selection process may take place as documents are generated. In this selection process the ARC shall:

- **Review** the incoming and outgoing DOE correspondence logs and the WSSRAP Reference Library Listing of documents printed by Document Control.

- **Select** documents from the DOE logs and Reference Library Listing, and produce the Administrative Record Document Tracking Log (Appendix C) for these documents.

- **Request** copies of the above selected documents for review.

- **Request** AR committee review of documents for which inclusion in an ARF is uncertain.

- **Catalogue** documents approved by the ARC/AR committee by using the AR Document Concurrence/Input Form (see Appendix C).

The AR Document Selection Flowchart (Appendix C) describes the flow of the document selection process from reviewing logs to inclusion of documents in the ARFs.

4.2 Index Generation

Once the document is approved, the document information is added to the index, and the document is placed in the appropriate ARF. The index contains the document information as data fields in the computerized system, as explained in the Document Information and dBase Field (Appendix C). Appendix C also contains an example of the index entry for a document. The index is used to verify that the information entered in the database is correct and it can be used as a cursory review of documents. The current version of the index is kept in the AR file, and is considered a draft index until the Record of Decision is completed and the administrative record is finalized.

The AR document file numbering system is a unique collection of numbers for each document identified in the AR files. Each document is given an unique number for identification and easy retrieval from the files. Below is an explanation of the numbering system:

EXAMPLE: DOCUMENT NUMBER C-100-101-1.01

C - One digit alpha designation to identify to which ARF the document belongs. In this case, C belongs to the Chemical Plant ARF.

100 - Three digit numeric designation for the identification of which general section in the table of contents the document belongs.

101 - Three digit numeric designation for the specific section in which the document belongs.

1.01 - Three digit (with decimal) numeric designation for the sequential number assigned the document. The number is assigned according to the chronological order of the documents in that specific section.

4.3 Technical Literature Review

References listed in primary documents (i.e., Engineering Evaluation/Cost Analysis [EE/CA], Remedial Investigation/Feasibility Study [RI/FS], Baseline Risk Assessment, Proposed Plan) are reviewed as technical literature for inclusion in the ARF. The references are cataloged in the database. Certain non-site-specific references that are publicly available are not required to be placed in the AR. All other references are collected and processed into the ARF under the Technical Sources section of the Table of Contents.

5 RECORD PRESERVATION

The *Federal Facility Agreement* (FFA) (pg. 27) requirements for the preservation of the Weldon Spring Site Remedial Action Project (WSSRAP) Administrative Records as follows:

> "The DOE shall, without regard to any document retention policy to the contrary, preserve during the duration of this Agreement and for a minimum of ten (10) years after its termination, all records and documents in its possession, custody or control which relate in any way to hazardous substances generated, stored, treated or disposed of on the site, the release or threatened release of hazardous substances from the site or work performed pursuant to this Agreement. After this ten-year period has lapsed, DOE shall notify U.S. EPA at least sixty (60) calendar days prior to the destruction of any such document. DOE shall, as directed by U.S. EPA, either provide to U.S. EPA the documents or copies of such documents or retain them for an additional time period specified by U.S. EPA."

6 LOCATION

The Weldon Spring Site Remedial Action Project (WSSRAP) Administrative Record files (ARFs) are located on site at 7295 Highway 94 South, St. Charles, Missouri. One copy of the AR/ARF is located in the WSSRAP Public Reading Room. It provides the community and local officials easy access to the AR/ARF. The master file copy is considered the official file copy and is maintained in fireproof, locking filing cabinets in the Compliance Department. The keys to the master file are kept and controlled by the Compliance Department. Both the Community Relations Department and the Compliance Department hold keys to the file cabinets and bookcases in the Public Reading Room. Both sets of files (the master file copy and the Reading Room copy) are to be kept locked at all times unless being used. Only authorized WSSRAP individuals (Community Relations Department and the ARC) are allowed entry of the Reading Room AR files. Only the Administrative Record Coordinator (ARC) is authorized to gain entry to the master file copy.

In the future, another copy of the ARF may be located at the Kisker Branch Library (in the Government Section), of the St. Charles County Library System which is in Saint Charles, Missouri. The library may be more accessible to the general public than the Reading Room. The address of the Kisker Branch Library is 1000 Kisker Road, Saint Charles, Missouri.

B How to Find a Document in the Administrative Record Files

1 INTRODUCTION

The Weldon Spring Site Remedial Action Project (WSSRAP) Administrative Records are managed in accordance with Section 113(j) and (k) of the *Comprehensive Environmental Response Compensation and Liability Act* (CERCLA), as amended by the *Superfund Amendments and Reauthorization Act of 1986*; Subpart I of the *National Oil and Hazardous Substance Pollution Contingency Plan* (NCP) (EPA 1992); and the U.S. Environmental Protection Agency OSWER Directive 9833.3A-1, *Final Guidance on Administrative Records for Selection of CERCLA Response Actions* (EPA 1990).

The purpose of this User's Guide is to facilitate the use of the WSSRAP Administrative Record files by the public or the WSSRAP staff. The Guide explains the breakdown of the Administrative Record files and how and where to find specific information. A site representative, either a Community Relations Specialist or the Administrative Record Coordinator (or designee), will be present during public inspection of the Administrative Records in order to facilitate public use of the record files and to answer questions about the record or the site.

Prior to viewing the Administrative Record files, the log book must be signed, including all pertinent information.

2 WSSRAP ADMINISTRATIVE RECORDS

The purpose of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) Administrative Record (AR) is two-fold: first, to accurately document the basis for response actions, since any judicial review is limited to the Administrative Record, and second, to provide a vehicle for public participation in the selection of response actions.

Cleanup of the Weldon Spring site is being conducted as CERCLA remedial and removal actions. A separate administrative record must be compiled for each remedial action. The Weldon Spring Site Remedial Action Project (WSSRAP) removal actions are filed in one Administrative Record. The following is a list of the current and future WSSRAP Administrative Records:

Quarry Bulk Waste Excavation and Removal (complete)
Chemical Plant Area
Quarry Residuals/Groundwater (future)
Site Groundwater (future)
Interim Removal Actions

The Administrative Record for the Quarry Bulk Waste Removal has been completed. (Administrative Records are considered complete when the decision document for that response action is approved.) The Administrative Record for the chemical plant area is in the process of being compiled; it will be completed when the Record of Decision is finalized. Remedial investigations have not yet begun for the quarry residuals/groundwater or site groundwater, and therefore, Administrative Record files for these will be established and made available for public inspection when the Remedial Investigation/Feasibility Study (RI/FS) work plans are approved.

One AR file has been established that includes all WSSRAP interim response or removal actions (IRAs). The following is the current listing of WSSRAP removal actions contained in the IRA AR file:

- IRA 1 Electrical Transformers
- IRA 2 Ash Pond/Isolation Dike
- IRA 4 Army Property 7
- IRA 6 Overhead Piping/Asbestos Removal

- IRA 7 Containerized Chemicals
- IRA 8 Electrical Pole/Line Removal
- IRA 9 Debris Consolidation
- IRA 10 Building 409 Dismantling
- IRA 11 Building 401 Dismantling

- IRA 21 Quarry Water Treatment Plant

2.1 Location of the Administrative Record

Section 113(k)(1) of CERCLA requires that the Administrative Record be available to the public "at or near the facility at issue." Duplicates of the record file may be kept at any other location. The WSSRAP Administrative Records are available in the WSSRAP Public Reading Room for public review during business hours, i.e., Monday through Friday from 8am to 4:30 pm. Appointments are preferred.

Information repositories have been established at local libraries, so that the public can view documents at their convenience. The repositories contain various documents and information on WSSRAP activities, e.g., sampling data, informational bulletins, CERCLA/ National Environmental Policy Act (NEPA) documents. However, official copies of the WSSRAP Administrative Records have not been established at any of the repositories.

3 CONTENTS

3.1 Types of Documents

WSSRAP AR files are comprised of various types of documents. Examples of AR documents are correspondence, reports, information bulletins, public notices (newspaper), and decision documents. The documents are compiled and added to the AR files as they are generated and issued.

3.2 Index

A computerized index of each administrative record file is maintained as part of the record. This index contains basic information about the document, i.e., the AR document file number, title, issue date, author, recipient, and the physical location. The AR document file number found in the index is assigned to all documents as they are added to the AR files and are assigned based on the table of contents section. A copy of the index is also sent to EPA Region VII, on a quarterly basis.

3.3 Locating Documents

Specific AR documents can be located by either browsing the files or using the index. Appendix B contains the instructions on how to find a document in the administrative record files.

4 COPYING

The Weldon Spring Site Remedial Action Project (WSSRAP) Administrative Records (AR) are made available to the public for review. Documents comprising any AR file may not be removed from the Reading Room by the public. Authorized personnel may temporarily remove documents from the Reading Room for copying purposes only.

Copies of AR documents may be obtained by request to the authorized site representative. Copies of less than 20 pages may be obtained immediately. Copies of more than 20 pages, or large documents, may require more time. Turn-around time for copying large amounts would be determined on a case-by-case basis. A copying fee of $.20 per page may be charged.

5 GLOSSARY

Administrative Record Coordinator - Person assigned the responsibilities of establishing and maintaining the WSSRAP Administrative Records.

Administrative Record - A body of documents that is considered or relied upon to form the basis for the selection of a response action.

Administrative Record File - The body of documents that will constitute the Administrative Record for a response action once the record of decision is finalized.

Administrative Record File System - The system developed for the process of selecting, cataloging, indexing, and filing of documents constituting the Administrative Record.

Remedial Action - A permanent remedy taken in the event of a release or threatened release of a hazardous substance into the environment, to prevent or minimize the release so that the hazardous substance(s) does not migrate to cause substantial danger to present or future public health or welfare or the environment.

Removal Action - A short-term, immediate action taken to remove a release of hazardous substances into the environment. Removal actions may be performed as part of a remedial action.

5.1 Acronyms

AR	Administrative Record
ARF	Administrative Record File
ARFS	Administrative Record File System
CERCLA	Comprehensive Environmental Response, Compensation and Liability Act of 1980 (42 USC 9601 et seq.)
CFR	Code of Federal Regulations
EE/CA	Engineering Evaluation/Cost Analysis
IRA	Interim Response Actions
NEPA	National Environmental Policy Act
ROD	Record of Decision

RI/FS	Remedial Investigation/Feasibility Study
WSSRAP	Weldon Spring Site Remedial Action Project

APPENDIX B
How to Find a Document in the Administrative Record Files

1. If you know the Document Title.

   a. Go to the index section listed chronologically by section.
   b. Find the Administrative Record (AR) document number next to the correct title.
   c. Go to the file cabinet with the AR document file number or section number in the table of contents in each AR folder.
   d. Turn to the tab with the AR document file number or section number on it.
   e. Inside the file folder is the list of documents (in order) contained in the file folder.

2. If you know the Document Date.

   a. Go to the index section listed chronologically by date.
   b. Find the AR document file number.
   c. Go to the file cabinet with the AR document file number or section number in the table of contents in each AR folder.
   d. Turn to the tab with the AR document file number or section number on it.
   e. Inside the file folder is the list of documents (in order) contained in the file folder.

3. If you know the remedial action.

   a. Find the remedial action unit code number from the table of contents on each file folder.
   b. Go to the index section listed by AR document numbers.
   c. Go to the AR document numbers beginning with (each unit 1st letter) (i.e. C"= chemical plant).
   d. Find the complete AR document number of the document you want.
   f. Go to the file cabinet with the AR document number on the outside label.
   g. Turn to the AR document within the folder.

4. If you know the removal action.

   a. Find the removal action unit code number from the table of contents on each file folder.

b. Go to the index section listed by AR document number.

c. Go to the file cabinet with the AR document number in the table of contents inside the AR file folder.

d. Turn to the AR document in the AR file.

Re: Acknowledgment of Notification and Registration of Hazardous Waste Activity

Dear Generator:

This is to acknowledge that you have filed hazardous waste activity forms for the installation located at the address shown in the box below to comply with Section 260.380 of the Missouri Hazardous Waste Management Law and Section 3010 of the Resource Conservation and Recovery Act (RCRA). The identification numbers must be included on all hazardous waste manifest documents for transporting hazardous wastes; on all reports that generators of hazardous waste are required to maintain, and reports that owners and operators of hazardous waste treatment, storage and disposal facilities must file with the State of Missouri and the Federal EPA; on all applications for a state and federal hazardous waste permit; and other required hazardous waste management reports and documents.

Missouri Emergency Response Commission
ATTN: Jim Long
Missouri Department of Natural Resources
Jefferson City, Missouri 65102

Dear Mr. Long:

This letter is intended to serve as the notification to your Commission as required by the Superfund Amendments and Reauthorization Act of 1986, Title III Sec. 302 (C). Our facility is located near Weldon Spring, Missouri, about 30 miles west of St. Louis. It is surrounded by large tracts of land owned by the federal government and the state of Missouri. The site was used by the U.S. Department of the Army from 1941 to 1944 for the production of explosives. In 1957, a 220-acre portion of the site was released to the U.S. Atomic Energy Commission, which used the site for processing of uranium and thorium concentrates from 1957 to 1966. The site is comprised of four areas: raffinate pits, chemical plant, quarry, and vicinity properties. The raffinate pits and chemical plant are on adjoining land about 2 miles southwest of the junction of Missouri Route 94 and U.S. Route 40/61. The raffinate pits and chemical plant areas are accessed from Route 94. The quarry is located in a comparatively remote area about 4 miles south-southwest of the raffinate pits area; the quarry is also accessed from State Route 94. The contaminated vicinity properties are located in the proximity of these three areas.

DOE is presently preparing documentation for cleanup of the site in accordance with the National Environmental Policy Act (NEPA). Actual cleanup work will begin when that process is completed. In support of the NEPA process a containerized chemical inventory will be made and detailed site characterization work will be performed. We are not sure that Sec. 302 would apply to this facility since it is not an operating facility, however, we will keep you informed of our characterization findings and will cooperate with decisions on applicability of the 302 requirements.

If you have any questions please contact myself or Ken Lawver at 314-441-8978.

Sincerely,

R. R. Nelson
Project Manager
Weldon Spring Site

CHEMICAL PLANT
101-1.03

March 24, 1989

Dr. Wanda McDaniel, Superintendent
Francis Howell School District
7001 Highway 94 South
St. Charles, Missouri 63303

Dear Dr. McDaniel:

FORMER USES OF THE UNIVERSITY OF MISSOURI AGRICULTURAL EXTENSION CENTER, WELDON SPRING, MISSOURI

According to a U. S. Army Toxic and Hazardous Material 1977 report the facilities at the former University of Missouri Agricultural Extension Center was constructed as a part of the Weldon Spring Ordnance Works in 1941. The buildings were the "Box Factory" which produced boxes for the explosives to be packed in. The packing of the boxes apparently occurred in a series of buildings located in the explosives production areas to the west of the Extension Center.

The Box Factory was transferred to the University of Missouri in 1949. The University used the facilities for storage of materials used at their experimental farm prior to and during the operation of their extension office. The experimental farm operated until 1978 when 7200 acres were sold to the Missouri Department of Conservation. The Extension Center operated until 1988.

The Department of Army transferred land to the Atomic Energy Commission in 1954 for construction of a uranium feed materials plant which converted processed ore into uranium metal until 1966. During this time, the University operated the Extension Center. No radioactive materials were taken onto or stored at the Extension Center. In 1985-86 Oak Ridge Associated Universities performed a detailed radiological survey of the area surrounding the uranium processing facility. This survey included the roads, rail line and fenced perimeter of the Extension Center. No elevated levels of radiation were observed and, based on the use of the property, no additional studies were required.

The Extension Center is located uphill of all Ordnance Works and uranium processing facilities and therefore could not receive run-off from these areas.

If you have any additional questions please call.

POTENTIAL HAZARDOUS WASTE SITE

IDENTIFICATION AND PRELIMINARY ASSESSMENT

This form is completed for each potential hazardous waste site to help set priorities for site inspections. The information submitted on this form is based on available records and may be updated on subsequent forms as a result of additional inquiries and on-site inspections.

SITE IDENTIFICATION

Site number (to be assigned by Headquarters) 00000005C

Site Name Weldon Springs Chemical Plant (Rockwell Int. Ace Contractor, Army)

Street (or other identifier) Mo. 94 2 miles S. of U.S. 40

City, State, Zip

County Name St. Charles County, Mo.

Owner/Operator (if known) Kansas City Engineering District, U.S. Army Corps of Engineers and Telephone

/X/ Federal /__/ State /__/ County

/__/ Municipal /__/ Private /__/ Unknown

Site Description Former DuPont plant & Former Feed Materials Production Plant. Present Storage Site, Department of Energy

How Identified (i.e. Citizen's complaints, OSHA Citations, etc.) Date Identified

Decontamination and Decommission Operations Jun. 1963

Principal State Contact Robert Robinson Telephone 314-751-2041

Fill in pages 2-5 of this form as completely as possible. Then indicate the preliminary assessment in the boxes below:

PRELIMINARY ASSESSMENT

Apparent Seriousness of Problem /__/ High /__/ Medium /X/ Low /__/ None /__/ Un

/X/ No action needed - ~~no hazard~~

/__/ Immediate site inspection needed Tentatively Scheduled for _____
Will be performed by _____

/__/ Site inspection needed Tentatively Scheduled for _____
Will be performed by _____

/__/ Site inspection needed - low priority

File this form in the Regional Hazardous Waste Log File and submit a copy to:

List all drinking water wells within 1/4 mile radius of site:

Well	Depth	Location (proximity to population/buildings)	Non-Community
		Unknown	/__/
			/__/
			/__/
			/__/
			/__/

Receiving Waters /__/ Sewers /X/ Streams/Rivers

Name Missouri and Mississippi Rivers /__/ Lakes/Reservrs /__/ Other

Specify use and classification of receiving waters Navigable Streams

SOIL AND VEGETATION DATA

Location of Site is in:

/__/ Known Fault Zone

/__/ Karst Zone

/__/ 100 Year Floodplain

/__/ Wetland

/__/ A Regulated Floodway

/__/ Critical Habitat

/__/ Recharge Zone or Sole Source Aquifer

TYPE OF GEOLOGICAL MATERIAL OBSERVED

/X/ Overburden	/X/ Bedrock (specify)	/__/ Other (specify)
/__/ Sand	Limestone	
/X/ Clay		
/__/ Gravel		

SOIL PERMEABILITY

/__/ Unknown

/__/ Very High (100000-1000 ft/day)

/__/ High (1000-10 ft/day)

/__/ Moderate (10 to .1 ft/day)

/__/ Low (.1 to .001 ft/day)

/X/ Very Low (.001 to .00001 ft/day)

Recharge Area /__/ Yes /X/ No Comments: Under valley side hills

Discharge Area /X/ Yes /__/ No Comments: 3 small streams cross surface

Slope (estimate % of slope) unknown Specify direction of slope, condition of slope, etc.

Other Geological Data See U.S. Army Assessment study, March 1976

PERMIT INFORMATION

List all Applicable Permits held by the site:

Permit Type (E.g. RCRA, State, NPDES, etc)	Issuing Agency	Permit Number	Date Issued	Expirtn date	In Complian Yes	In Complian No
Radioactive Material Storage	NRC	SMB 1314	1977		/_/	/X/
					/_/	/_/
					/_/	/_/
					/_/	/_/
					/_/	/_/
					/_/	/_/

PAST REGULATORY OR ENFORCEMENT ACTIONS

/__/ None

/X/ Yes If yes, summarize: NRC amended permit in May 1977 to require Buildings Decontamination and Decommission Plan by Nov. 15 1979

Based on the information on pages 2 through 13, fill out the projected date of the Tentative Disposition on the first page of this form.

SUPPLEMENTAL FORM

SURFACE IMPOUNDMENTS

Answer and Explain as Necessary:

1. Type of Impoundment 4 Ruthenate Pits
   1 Ash Pit
2. Stability/Condition of Imbankments: Slide observed on
   repaired on Pit #4 in 1975
3. Evidence of Site Instability (Erosion, Settling, Sink Holes, etc.)
   Yes ( ) No (X)
4. Evidence of Disposal of Ingnitable or Reactive Waste
   Yes ( ) No (X)
5. Waste Compatible with Impoundment Yes (X) No ( )
6. Records Checked for the Contents and Location of Each Surface Impoundment Yes (X) No ( )
7. Impoundment has Liner System Yes ( ) No (X)
   Integrity of Liner System Checked Yes ( ) No ( )
   Findings: _____
8. Soil Structure and Substructure Clay over limestone
9. Monitoring Wells Yes (X) No ( )
10. Length, Width and Depth Combined estimated surface area greater than 100 acres
11. Calculated Volumetric Capacity unknown
12. Percent of Capacity Remaining unknown
13. Estimate Freeboard: unknown
14. Solids Deposition Yes (X) No ( )
15. Dredging Disposal Method _____
16. Other Equipment _____

POTENTIAL HAZARDOUS WASTE SITE
IDENTIFICATION AND PRELIMINARY ASSESSMENT

REGION: VII | SITE NUMBER (To be assigned by HQ): MO

NOTE: This form is completed for each potential hazardous waste site to help set priorities for site inspection. The information submitted on this form is based on available records and may be updated on subsequent forms as a result of additional inquiries and on-site inspections.

GENERAL INSTRUCTIONS: Complete Sections I and III through X as completely as possible before Section II *(Preliminary Assessment)*. File this form in the Regional Hazardous Waste Log File and submit a copy to: U.S. Environmental Protection Agency; Site Tracking System; Hazardous Waste Enforcement Task Force *(EN-335)*; 401 M St., SW; Washington, DC 20460.

I. SITE IDENTIFICATION

A. SITE NAME: Raffinate Pits — Weldon Springs Chemical Plant

B. STREET *(or other identifier)*: Mo. 94, 2 miles S. of U.S. 40

C. CITY: St. Charles

D. STATE: MO

E. ZIP CODE:

F. COUNTY NAME: St. Charles

G. OWNER/OPERATOR *(If known)*

1. NAME: Technical Services Department, U.S. D.O.E.

2. TELEPHONE NUMBER: FTS: 626-0947

H. TYPE OF OWNERSHIP

[X] 1. FEDERAL [ ] 2. STATE [ ] 3. COUNTY [ ] 4. MUNICIPAL [ ] 5. PRIVATE [ ] 6. UNKNOWN

I. SITE DESCRIPTION

Former Uranium Feed Material Plant, raffinate pits.

J. HOW IDENTIFIED *(i.e., citizen's complaints, OSHA citations, etc.)*

Decommissioning Study

K. DATE IDENTIFIED *(mo., day, & yr.)*: Jan. 1968

L. PRINCIPAL STATE CONTACT

1. NAME: Robert Robinson

2. TELEPHONE NUMBER: 314/751-3241

II. PRELIMINARY ASSESSMENT *(complete this section last)*

A. APPARENT SERIOUSNESS OF PROBLEM

[ ] 1. HIGH [ ] 2. MEDIUM [X] 3. LOW [ ] 4. NONE [ ] 5. UNKNOWN

B. RECOMMENDATION

[X] 1. NO ACTION NEEDED *(no hazard)*

DOE exerting efforts for timely remedial actions

[ ] 2. SITE INSPECTION NEEDED
a. TENTATIVELY SCHEDULED FOR:
b. WILL BE PERFORMED BY:

[ ] 2. IMMEDIATE SITE INSPECTION NEEDED
a. TENTATIVELY SCHEDULED FOR:
b. WILL BE PERFORMED BY:

[ ] 4. SITE INSPECTION NEEDED *(low priority)*

C. PREPARER INFORMATION

1. NAME: W.L. Brinck

2. TELEPHONE NUMBER: FTS: 758-3307

3. DATE *(mo., day, & yr.)*: Nov. 1, 1979

III. SITE INFORMATION

A. SITE STATUS

[ ] 1. ACTIVE *(Those industrial or municipal sites which are being used for waste treatment, storage, or disposal on a continuing basis, even if infrequently.)*

[X] 2. INACTIVE *(Those sites which no longer receive wastes.)*

[ ] 3. OTHER *(specify)*: *(Those sites that include such incidents like "midnight dumping" where no regular or continuing use of the site for waste disposal has occurred.)*

B. IS GENERATOR ON SITE?

[X] 1. NO [ ] 2. YES *(specify generator's four-digit SIC Code)*:

C. AREA OF SITE *(in acres)*: 52

D. IF APPARENT SERIOUSNESS OF SITE IS HIGH, SPECIFY COORDINATES

1. LATITUDE *(deg.-min.-sec.)*: 38/30/--

2. LONGITUDE *(deg.-min.-sec.)*: 90/37/--

E. ARE THERE BUILDINGS ON THE SITE?

[ ] 1. NO [X] 2. YES *(specify)*: 1 minor

T2070-1 (10-79)

DOCUMENT

IV. CHARACTERIZATION OF SITE ACTIVITY

Indicate the major site activity(ies) and details relating to each activity by marking 'X' in the appropriate boxes.

	A. TRANSPORTER		B. STORER		C. TREATER		D. DISPOSER
	1. RAIL		1. PILE		1. FILTRATION		1. LANDFILL
	2. SHIP	X	2. SURFACE IMPOUNDMENT		2. INCINERATION		2. LANDFARM
	3. BARGE		3. DRUMS		3. VOLUME REDUCTION		3. OPEN DUMP
	4. TRUCK		4. TANK, ABOVE GROUND		4. RECYCLING/RECOVERY	X	4. SURFACE IMPOUNDMENT
	5. PIPELINE		5. TANK, BELOW GROUND		5. CHEM./PHYS. TREATMENT		5. MIDNIGHT DUMPING
	6. OTHER (specify):		6. OTHER (specify):		6. BIOLOGICAL TREATMENT		6. INCINERATION
					7. WASTE OIL REPROCESSING		7. UNDERGROUND INJECTIO
					8. SOLVENT RECOVERY		8. OTHER (specify):
					9. OTHER (specify):		

E. SPECIFY DETAILS OF SITE ACTIVITIES AS NEEDED

V. WASTE RELATED INFORMATION

A. WASTE TYPE

☐ 1 UNKNOWN ☒ 2. LIQUID ☐ 3. SOLID ☒ 4. SLUDGE ☐ 5. GAS

B. WASTE CHARACTERISTICS

☐ 1 UNKNOWN ☐ 2. CORROSIVE ☐ 3. IGNITABLE ☒ 4 RADIOACTIVE ☐ 5 HIGHLY VOLATILE
☐ 6 TOXIC ☐ 7 REACTIVE ☐ 8 INERT ☐ 9 FLAMMABLE

☐ 10. OTHER (specify):

C. WASTE CATEGORIES

1. Are records of wastes available? Specify items such as manifests, inventories, etc. below.

Partial, stored at DOE Technical Services, Oak Ridge, Tenn.

2. Estimate the amount (specify unit of measure) of waste by category; mark 'X' to indicate which wastes are present.

a. SLUDGE	b. OIL	c. SOLVENTS	d. CHEMICALS	e. SOLIDS	f. OTHER
AMOUNT	AMOUNT	AMOUNT	AMOUNT	AMOUNT $.6 \times 10^6$	AMOUNT 2×10^7
UNIT OF MEASURE	UNIT OF MEASURE	UNIT OF MEASURE	UNIT OF MEASURE	UNIT OF MEASURE ft^3	UNIT OF MEASU gallons

1958 (BEGINNING YEAR) | 1965 (ENDING YEAR) ☐ UNKNOWN

04 DESCRIPTION OF SUBSTANCES POSSIBLY PRESENT, KNOWN, OR ALLEGED
Wastes present onsite include Raffinate sludges from uranium and thorium processing operations, including uranium and thorium decay products and radium contaminated water. Also onsite are solid rubble and debris from destruction of the Weldon Spring Chemical Plant.

05 DESCRIPTION OF POTENTIAL HAZARD TO ENVIRONMENT AND/OR POPULATION
Wastes have been found to be low level radioactive. Sludges and waters are contained in unlined pits constructed directly in native soils. Several small areas of soil outside the pits have shown gamma levels above background.

V. PRIORITY ASSESSMENT

VI. SOURCES OF INFORMATION (Cite specific references, e.g., state files, sample analysis, reports)

Radiological Survey Report for the Weldon Spring Raffinate Pits Site, Weldon Spring, Missouri – Bechtel National, Inc., August 1984.

EPA

POTENTIAL HAZARDOUS WASTE SITE
PRELIMINARY ASSESSMENT
PART 3 - DESCRIPTION OF HAZARDOUS CONDITIONS AND INCIDENTS

I. IDENTIFICATION	
01 STATE	02 SITE NUMBER
MO	2210090005

II. HAZARDOUS CONDITIONS AND INCIDENTS

01 ☒ A. GROUNDWATER CONTAMINATION — 02 ☐ OBSERVED (DATE: _____) — ☒ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: 61,400 — 04 NARRATIVE DESCRIPTION

Some nitrates have been detected in ground water. May not be attributable to Raffinate Pits, but to the former Weldon Spring Chemical Plant site.

01 ☐ B. SURFACE WATER CONTAMINATION — 02 ☐ OBSERVED (DATE: _____) — ☒ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____ — 04 NARRATIVE DESCRIPTION

NONE DIRECTLY ATTRIBUTABLE TO THE RAFFINATE PITS SITE HAS BEEN OBSERVED.

01 ☒ C. CONTAMINATION OF AIR — 02 ☐ OBSERVED (DATE: _____) — ☒ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: Unknown — 04 NARRATIVE DESCRIPTION

Walkover gamma surveys have detected gross CPM gamma levels in excess of background (approx. 6,000 counts/min.) is several localized spots. Potential contamination of airways onsite.

01 ☐ D. FIRE EXPLOSIVE CONDITIONS — 02 ☐ OBSERVED (DATE: _____) — ☒ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____ — 04 NARRATIVE DESCRIPTION

NONE OBSERVED, BUT POTENTIAL MAY BE PRESENT DUE TO TNT AND DNT CONTAMINATION DETECTED AT ADJACENT CHEMICAL PLANT, AND TRAINING AREA SITES.

01 ☐ E. DIRECT CONTACT — 02 ☐ OBSERVED (DATE: _____) — ☐ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: _____ — 04 NARRATIVE DESCRIPTION

Site is enclosed by a 7 ft high security fence. In addition, each pit is enclosed by a smaller interior fence.

01 ☒ F. CONTAMINATION OF SOIL — 02 ☐ OBSERVED (DATE: _____) — ☒ POTENTIAL — ☐ ALLEGED
03 AREA POTENTIALLY AFFECTED: Unknown (ACRES) — 04 NARRATIVE DESCRIPTION

Wastes are contained in unlined impoundments directly in native soils. Potential for migration of contaminants into surrounding soils. Walkover gamma surveys, bore holes gamma logs, and surface soil samples have shown radionuclide levels exceeding background levels in several localized spots.

01 ☒ G. DRINKING WATER CONTAMINATION — 02 ☐ OBSERVED (DATE: _____) — ☒ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: 61,400 — 04 NARRATIVE DESCRIPTION

None observed attributable to the Raffinate Pits Site, but location and construction of pits (unlined) present some potential.

01 ☐ H. WORKER EXPOSURE/INJURY — 02 ☐ OBSERVED (DATE: _____) — ☐ POTENTIAL — ☐ ALLEGED
03 WORKERS POTENTIALLY AFFECTED: _____ — 04 NARRATIVE DESCRIPTION

No workers onsite

01 ☒ J. POPULATION EXPOSURE/INJURY — 02 ☐ OBSERVED (DATE: _____) — ☒ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: ~3,000 — 04 NARRATIVE DESCRIPTION

Francis Howell high school is located within one mile east of the site. Potential exists for exposure to radiological contaminants via airways. In addition, Army Reserve/National Guards personnel are in the Training Area, west of the site.

EPA

POTENTIAL HAZARDOUS WASTE SITE
PRELIMINARY ASSESSMENT
PART 3 - DESCRIPTION OF HAZARDOUS CONDITIONS AND INCIDENTS

I. IDENTIFICATION	
01 STATE	02 SITE NUMBER
MO	2210090005

II. HAZARDOUS CONDITIONS AND INCIDENTS (Continued)

01 ☒ J. DAMAGE TO FLORA — 02 ☐ OBSERVED (DATE: _____) ☒ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION
None observed, but proximity of wild-life areas to site presents a potential for adverse impact to area flora.

01 ☒ K. DAMAGE TO FAUNA — 02 ☐ OBSERVED (DATE: _____) ☒ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION (Include name(s) of species)
None observed, but proximity of wildlife areas (Busch Wildlife Area, and Weldon Spring Wildlife area) presents potential for adverse impact to area fauna. Bald Eagle is known to inhabit and nest along the Missouri River

01 ☒ L. CONTAMINATION OF FOOD CHAIN — 02 ☐ OBSERVED (DATE: _____) ☒ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION
The proximity of water bodies from which fish are caught presents a potential for contamination of food chain in the event of a release of contaminants from the site.

01 ☒ M. UNSTABLE CONTAINMENT OF WASTES (Spills, runoff, standing liquids, leaking drums) — 02 ☐ OBSERVED (DATE: _____) ☒ POTENTIAL ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: Unknown — 04 NARRATIVE DESCRIPTION
Sludges are contained in open, unlined impoundments constructed in native soil. Potential for emigration of contaminants into surrounding soils.

01 ☐ N. DAMAGE TO OFFSITE PROPERTY — 02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION
None Documented

01 ☐ O. CONTAMINATION OF SEWERS, STORM DRAINS, WWTPs — 02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION
None Documented

01 ☐ P. ILLEGAL/UNAUTHORIZED DUMPING — 02 ☐ OBSERVED (DATE: _____) ☐ POTENTIAL ☐ ALLEGED
04 NARRATIVE DESCRIPTION
None Documented

05 DESCRIPTION OF ANY OTHER KNOWN, POTENTIAL, OR ALLEGED HAZARDS
None Documented

III. TOTAL POPULATION POTENTIALLY AFFECTED: ~3,000

IV. COMMENTS
Water samples collected from the St. Charles County well field have shown radionuclide levels within exceptable levels. However, it may not be attributable to the Weldon Spring sites.

V. SOURCES OF INFORMATION (Cite specific references, e.g., state files, sample analysis, reports)
- Hazard Ranking System analysis prepared for the Weldon Spring Chemical Plant (including Raffinate Pits); by NUS Corporation, 7/3/85
- Radiological Survey Report for the Weldon Spring Raffinate Pits Site, Bechtel Natl., Inc. - 8/84
- Assessment of the Weldon Spring Chemical Plant, Dept. of the Army, 3/1/76

COMBINED NOTIFICATION OF HAZARDOUS WASTE ACTIVITY

Send to: Missouri Department of Natural Resources, Waste Management Program, P.O. Box 176, Jefferson City, MO 65102

For Official Use Only

Comments

Installation's EPA ID Number	Approved	Date Received (yr. mo. day)
MOG21092281330		

I. Name of Installation: WELDON SPRING SITE REMEDIAL ACTION PROJECT

II. Installation Mailing Address

Street or P.O. Box: Route 2 Highway 94 South

City or Town: St. Charles | State: MO | ZIP Code: 63303

III. Location of Installation

Street or Route Number: Route 2 Highway 94 South

City or Town: St. Charles | State: MO | ZIP Code: 63303

IV. Installation Contact

Name and Title (last, first, and job title): Rodney Nelson | Phone Number (area code and number): 314 441 8978

V. Ownership

A. Name of Installation's Legal Owner: DOE Dept of Energy | B. Type of Ownership (enter code): FC

VI. Type of Regulated Waste Activity (Mark 'X' in the appropriate boxes. Refer to instructions.)

A. Hazardous Waste Activity

- [X] 1a. Generator
- [ ] 1b. Less than 1,000 kg/mo.
- [ ] 2. Transporter
- [ ] 3. Treater/Storer/Disposer
- [ ] 4. Underground Injection
- [ ] 5. Market or Burn Hazardous Waste Fuel (enter 'X' and mark appropriate boxes below)
  - [ ] a. Generator Marketing to Burner
  - [ ] b. Other Marketer
  - [ ] c. Burner

B. Used Oil Fuel Activities

- [ ] 6. Off-Specification Used Oil Fuel (enter 'X' and mark appropriate boxes below)
  - [ ] a. Generator Marketing to Burner
  - [ ] b. Other Marketer
  - [ ] c. Burner
- [ ] 7. Specification Used Oil Fuel Marketer (or On-site Burner) Who First Claims the Oil Meets the Specification

VII. Waste Fuel Burning: Type of Combustion Device (enter 'X' in all appropriate boxes to indicate type of combustion device(s) in which hazardous waste fuel or off-specification used oil fuel is burned. See instructions for definitions of combustion devices.)

- [ ] A. Utility Boiler
- [ ] B. Industrial Boiler
- [ ] C. Industrial Furnace

VIII. Mode of Transportation (transporters only — enter 'X' in the appropriate box(es))

- [ ] A. Air
- [ ] B. Rail
- [ ] C. Highway
- [ ] D. Water
- [ ] E. Other (specify)

IX. First or Subsequent Notification

Mark 'X' in the appropriate box to indicate whether this is your installation's first notification of hazardous waste activity or a subsequent notification. If this is not your first notification, enter your installation's EPA ID Number in the space provided below.

- [ ] A. First Notification
- [X] B. Subsequent Notification (complete item C)

C. Installation's EPA ID Number: MO 6210022830

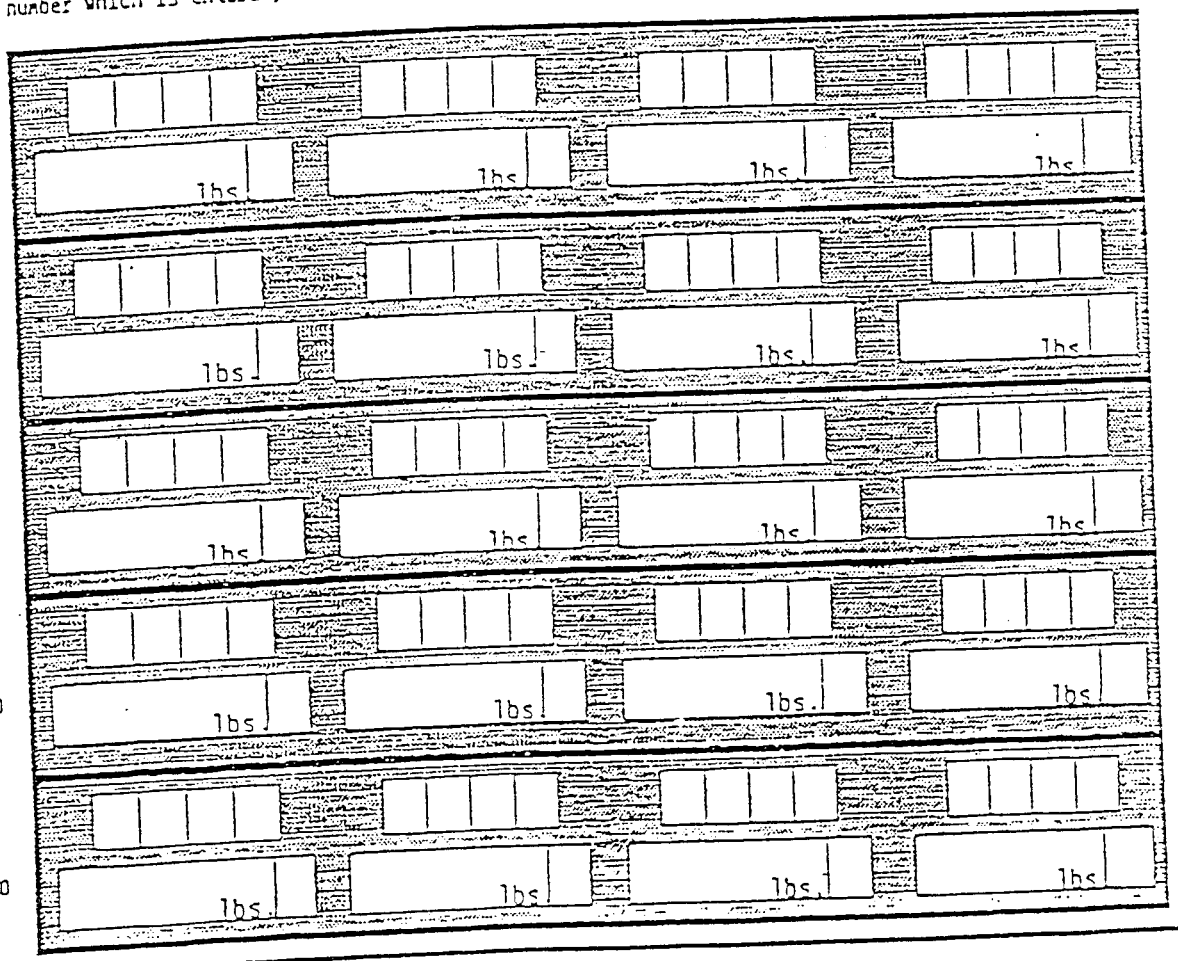
IV. Hazardous Waste Description

Enter the four-digit EPA waste number from 40 CFR Part 261 for each additional waste stream. Below each EPA waste number which is entered, enter the monthly generation amount in pounds and frequency code A, B, or C.



V. Certification

I certify under penalty of law that I have personally examined and am familiar with the information submitted in this and all attached documents, and that based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the submitted information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment.

Signature	Name And Official Title(Type Or Print)	Date Signed

Instructions for Completion of HWG — 1A Form

General Instructions — Type or print in black ink. This form is to be used as additional space for "Description of Hazardous Waste" (Item X), of the EPA/DNR Combined Notification of Hazardous Waste Activity form (EPA 8700 —12/MDNR HWG —1), only if additional space is necessary. This form is valid only when attached to a completed EPA 8700 —12/MDNR HWG —1 form.
SPECIAL NOTE: When adding or deleting a waste, a new Combined Notification of Hazardous Waste Activity Form must be completed and submitted. Be certain to accurately reflect all waste streams each time you notify, as the most recent form in our files will be considered as your legal registration.

Item I — Name of Installation — Enter the name of your business or organization as you have on your completed and attached EPA 8700 —12/MDNR HWG —1, item I.

Item II — Location of Installation — Enter the location as you have on your completed and attached EPA 8700 — 12/MDNR HWG —1, item III.

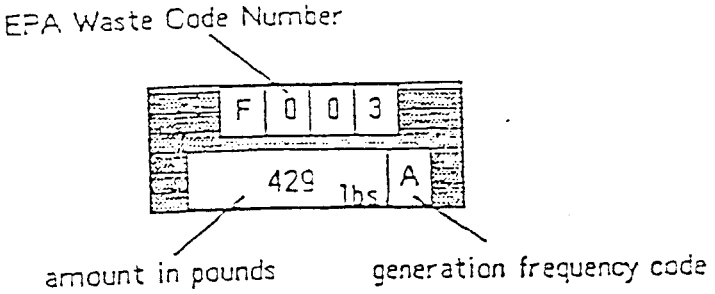
Item III — Identification Numbers — If previously assigned, enter your 12—digit EPA identification number and 5—digit Missouri identification number in the boxes provided.

Item IV — Hazardous Waste Description — Enter the four—digit EPA waste number from 40 CFR Part 261 for each waste stream. Below each EPA waste number which is entered, give the monthly generation rate in pounds and frequency code A, B, or C.

In completing this section use the following generation frequency codes:

A= Continual Generation
B= Intermittent Generation
C= One time only Generation

To assist you in the completion of this section note the following example:



Item V — Certification — This certification must be signed by the owner, operator, or an authorized representative of your installation. An "authorized representative" is a person responsible for the overall operation of the facility, i.e., a plant manager or superintendent, or a person of equal responsibility. *All notifications must include this certification to be complete.*

Instructions for Completion of Combined Notification of Hazardous Waste Activity
Form EPA 8700 -12 / MONR HWG - 1

General Instructions - Type or print in black ink except item XI, "Signature". Leave a blank box between words. If you must use additional sheets, indicate clearly the number of the item on the form to which the information on the separate sheet applies. If you need additional space for item X, attach a completed form DNR HWG-1A (continuation sheet).

SPECIAL NOTE: When adding or deleting a waste, a new Combined Notification of Hazardous Waste Activity form must be completed and submitted. Be certain to accurately reflect all waste streams each time you notify, as the most recent form in our files will be considered your legal registration.

Items I-III - Name, Mailing Address, and Location of Installation - Complete Items I-III. Please note that the address you give for Item III, "Location of Installation", must be a physical address, *not a post office box or route number.* If the mailing address and physical facility location are the same, you can print "Same" in box for Item III.

Item IV - Installation Contact - Enter the name, title, and business telephone number of the person who should be contacted regarding information submitted on this form.

Item V - Ownership

A) Name: Enter the name of the legal owner(s) of the installation, including the property owner. Use additional sheets if necessary to list more than one owner.

B) Type: Using the codes listed below, indicate the legal status of the owner of the facility:

FF=Federally Owned, Federally Operated
FC=Federally Owned, Operated by a Private Contractor to Federal Government
FP=Federally Owned, Privately Operated
PF=Privately Owned, Constructed for Use by The Federal Government and Operated by The Federal Government
PL=Privately Owned, Leased and Operated by The Federal Government
PI=Privately Owned, Indian Land
FI=Federally Owned, Indian Land
C =County
D =District
M =Municipal
P =Private
S =State

Item VI - Type of Regulated Waste Activity

A) Hazardous Waste Activity: Mark the appropriate box(es) to show which hazardous waste activities are going on at this installation.

1) Generator:

a) If you generate a hazardous waste this is identified by characteristic or listed in 40 *CFR* Part 261, mark an "X" in this box.

b) In addition, *if you generate less than 1000 kilograms of non-acutely hazardous waste per calendar month, mark an "X" in this box.*

2) Transporter: If you move hazardous waste by air, rail, highway, or water mark an "X" in this box. All transporters must complete Item VIII. Transporters do not have to complete Item X of this form, but must sign the certification in Item XI. Refer to Part 263 of 40 *CFR* for an explanation of the federal regulations for hazardous waste transporters.

3) Treater/Storer/Disposer: If you treat, store, or dispose of regulated hazardous waste, mark an "X" in this box. You are reminded to contact the Missouri Department of Natural Resources, Waste Management Program, to request Part A of the RCRA permit application. Refer to Parts 264 and 265 of 40 *CFR* for an explanation of the federal regulations for hazardous waste facility owners/operators. Be sure to also check applicable state regulations.

4) Underground Injection: Persons who generate and/or treat, store, or dispose of hazardous waste must place an "X" in this box if an injection well is located at their installation. An injection well is defined as any hole in the ground, including septic tanks, that is deeper than it is wide and that is used for the subsurface placement of fluids.

5) Market or Burn Hazardous Waste Fuel: If you market or burn hazardous waste fuel, place an "X" in this box. Then mark the appropriate boxes to indicate your specific activity. *If you mark "Burner" you must complete Item VII - "Type of Combustion Device".*

Note: Generators are required to notify for waste-as-fuel activities only if they market directly to the burner.

"Other Marketer" is defined as any person, other than the generator marketing his hazardous waste, who markets hazardous waste fuel.

B) Used Oil Fuel Activities

Mark an "X" in the appropriate box(es) below to indicate which used oil fuel activities are taking place at this installation.

6) Off-Specification Used Oil Fuel: If you market or burn off-specification used oil, the place an "X" in this box. Then mark the appropriate boxes to indicate your specific activity. *If you mark "Burner" you must complete Item VII - "Type of Combustion Device".*

Note: Used oil generators are required to notify only if marketing directly to the burner.

"Other Marketer" is defined as any person, other than a generator marketing his or her used oil, who markets used oil fuel.

7) Specification Used Oil Fuel: If you are the first to claim that the used oil meets the specification established in 40 *CFR* Part 266.40(e) and is exempt from further regulation, you must mark an "X" in this box.

Item VII — Waste—Fuel burning. Type of Combustion Device — Enter an "X" in all appropriate boxes to indicate type(s) of combustion devices in which hazardous waste fuel or off—specification used oil fuel is burned. (Refer to definition section for complete description of each device.)

Item VIII — Mode of Transportation — Complete this item only if you are a transporter of hazardous waste. Mark an "X" in each appropriate box to indicate the method(s) of transportation you use.

Item IX — First or Subsequent Notification — Place an "X" in the appropriate box to indicate whether this is your first or a subsequent notification. If you have filed a previous notification, enter your EPA Identification Number in the boxes provided.

Note: When the owner of a facility changes, the new owner must notify of the change even if the previous owner has already received a U.S. EPA Identification Number. Because the U.S. EPA number is "site specific", the new owner will keep the existing ID number. If the facility moves to another location, the owner/operator must notify of this change. In this instance, a new U.S. EPA Identification Number will be assigned, since the facility has changed locations.

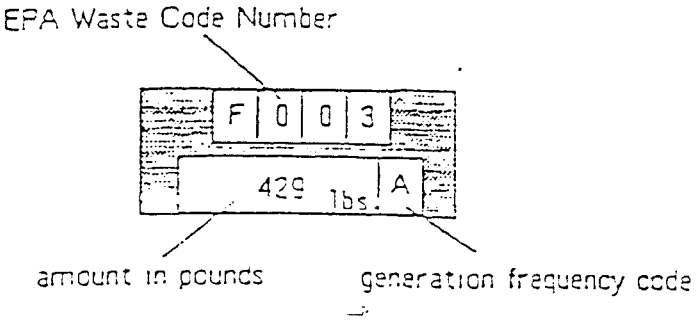
Item X — Description of Hazardous Waste — Only persons involved in hazardous waste activity [Item VI(A)] need to complete this item. Transporters requesting a U.S. EPA Identification Number do not need to complete this item, but must sign the "Certification" in Item XI.

You will need to refer to the federal regulations, Title 40 *CFR* Part 261 in order to complete this section. Part 261 identifies those wastes that EPA defines as hazardous. You must also refer to Missouri chapter 10 CSR 25—4.261 for any additional state listed waste streams.

In completing this section use the following generation frequency codes:

A= Continual Generation
B= Intermittent Generation
C= One time only Generation

To assist you in the completion of this section note the following example:



Section A — If you handle hazardous wastes that are listed in the "nonspecific sources" category in Part 261.31, enter the appropriate 4—digit numbers in the

boxes provided. Below each waste code number, enter the monthly generation rate in pounds, and, the generation frequency code.

Section B — If you handle hazardous wastes that are listed in the "specific industrial sources" category in Part 261.32, enter the appropriate four—digit numbers in the boxes provided. Below each waste code number, enter the monthly generation rate in pounds, and, the generation frequency code.

Section C — If you handle any of the "commercial chemical products" listed as wastes in Part 261.33, enter the appropriate four—digit numbers in the boxes provided. Below each waste code number, enter the monthly generation rate in pounds and, the generation frequency code.

Section D — Disregard, Since EPA has not yet published infectious waste regulations.

Section E — If you handle hazardous wastes which are not listed in any of the categories above, but do possess a hazardous characteristic, you should describe these wastes by their hazardous characteristic. An explanation of each characteristic is found in Part 261.21—261.24. Place an "X" in the box of each characteristic waste that you handle. Below each waste code number, enter the monthly generation rate in pounds and, the generation frequency code.

If you need space for additional waste streams use the Continuation Sheet Form MDNR HWG —1A.

Missouri Required Information

Missouri Generator ID Number — If your business has been previously assigned a 5—digit Missouri Generator Identification Number enter it here.

Principle Business Activity — Enter a description of the activity which best typifies your business, i.e., manufacture steel chairs and related products.

Standard Industrial Classification Number — Enter the 4 — digit standard industrial classification number(s) in order of descending importance.

Generate Less Than 100 kilograms (220 pounds)/month — Check this box if the total of all hazardous waste streams is less than this amount.

Item XI — Certification — This certification must be signed by the owner, operator, or an authorized representative of your installation. An "authorized representative" is a person responsible for the overall operation of the facility, i.e., a plant manager or superintendent, or a person of equal responsibility. *All notifications must include this certification to be complete.*

1.0 INTRODUCTION

The Weldon Spring Site (WSS) is a U.S. Department of Energy (DOE) surplus facility located in St. Charles County, Missouri. This document presents a description of the study plan and work scope to determine and characterize the level of potential human exposure to radionuclides and nitroaromatics from the food pathways at the WSS. This will be accomplished by a statistically significant sampling effort of biota available for human consumption from various locations around and within the WSS. The final report will describe the methods in performing the survey, summarize the results, and discuss their significance. This effort represents the first step in those analyses which are typically performed in an Endangerment Assessment as part of an RI/FS process under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA).

The analysis of the food pathway for the surrounding populations is necessary in assessing the risks to human health from pathway ingestion of biota living in or near these contaminated sediments and waters. Chemical and radiological exposure in humans and the relevance of data in establishing design and action limits will be reviewed.

The study will combine estimates of average consumption by humans with measured contamination levels in edible tissues for input into a metabolic model. The approach taken will be to measure the actual uptake of edible aquatic and terrestrial biota with a calculation of the uptake from human consumption of contaminated tissue based on assumed ingestion rates.

The sampling program will consist of the collection of approximately forty-one (41) kilograms of sunfish, twenty-seven and one-half (27.5) kilograms of catfish, two and one-half

(2.5) kilograms of minnows, fifteen (15) kilograms of largemouth bass, five (5) kilograms of crappies, and a minimum of eight (8) kilograms of both rabbits and squirrels.

Electrofishing methods will be utilized for the collection of aquatic samples. This method will provide randomness in fish samples. Individual samples weighing approximately less than 50-75 grams will not be kept, assuming these samples would not be kept for consumption by typical members of the public.

Biota samples will consist of small mammals such as rabbits and squirrels. Since the population of these mammals is limited, the traps will be set adjacent or above the areas of contamination. The samples collected will be assumed to live and intake steady or chronic amounts of contaminants.

All samples will be analyzed for total uranium and nitroaromatics. In addition, samples collected from the Raffinate Pits and Quarry Sump will be analyzed for radium-226 and thorium-230. Surface water exiting the site via drainage pathways have elevated amounts of uranium with very small amounts of radium and thorium.

Since certain uranium compounds are soluble and can migrate in soil and water, the spread of contamination is primarily uranium. Uranium is also more soluble than radium and thorium in the body, therefore it is more likely to be present in soft tissues in addition to the bone.

For the nitroaromatics, dinitrotoluenes (DNT) are probable carcinogens and are believed to be more toxic than trinitrotoluenes (TNT). Acute toxicity to human beings has been observed for 2,4,6-TNT. Chronic toxicity has not been observed for any of the nitroaromatic contaminants to human beings. Nitroaromatic contamination has been found in locations where either process lines and buildings stood or in

surface water and drainage locations. All samples will be analyzed for nitroaromatics since TNT and DNT are similar to each other with respect to solubility and properties affecting adsorption.

2.0 SITE HISTORY AND ENVIRONMENTAL SETTING

From 1941 to 1944, the U.S. Department of the Army (DA) operated the Weldon Spring Ordnance Works for production of trinitrotoluene (TNT) and dinitrotoluene (DNT). During this operation, smaller areas of the 17,000-acre site were contaminated by TNT process materials. In the mid-1950's 220-acres of the Ordnance Works property was transferred to the U.S. Atomic Energy Commission (AEC). From 1957 to 1966, the AEC operated a uranium processing facility at the site. During the operation of this Feed Materials Plant, the buildings, equipment, and immediate terrain of the plant (220-acres) became contaminated with radionuclides in the Uranium transformation series.

After closure by the AEC, the Feed Materials Plant was reacquired by the Army in 1967. The Army partially decontaminated the buildings, dismantled some of the equipment, and began converting the facilities to produce herbicides. In 1969, prior to the Chemical Plant (WSCP) becoming operational, the herbicide project was canceled. In 1985, the custody of the WSCP was transferred from the DA to the Department of Energy (DOE). In conjunction with this transfer, the Weldon Spring Site Remedial Action Project (WSSRAP) was created as DOE Major Project Number 182.

Surface water runoff from the north and west sides of the WSCP, as well as potential overflow from an onsite water tower, flow to Ash Pond (Figure 1). Water from Ash Pond travels through an overflow conduit for approximately 100 m, surfaces, and then flows to Lake 35 on the August Busch Wildlife Area, to Schote Creek, Dardenne Creek, and eventually the Mississippi River (Figure 2). Water from Ash Pond also discharges via underground connections to Burgermeister Spring, Lake 34, Dardenne Creek, and eventually the Mississippi River. Since

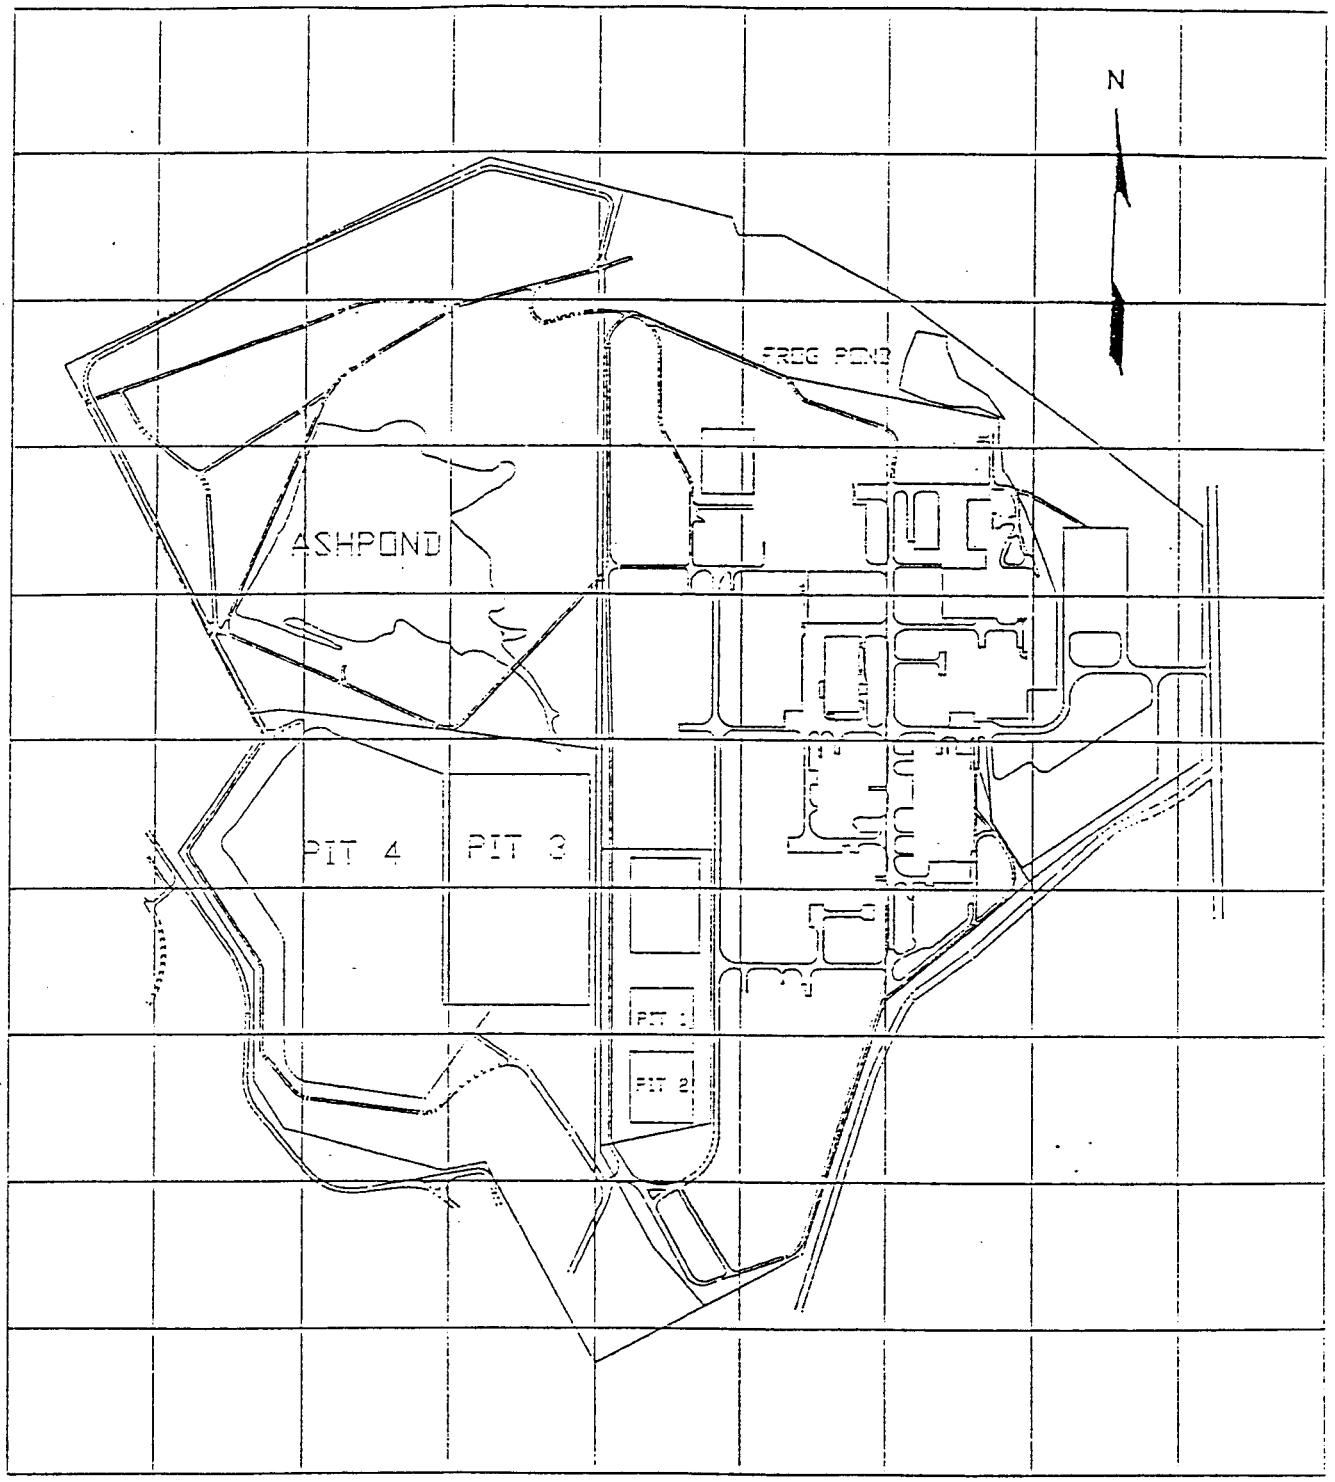

FIGURE 1

MAP OF WSCP/WSRP

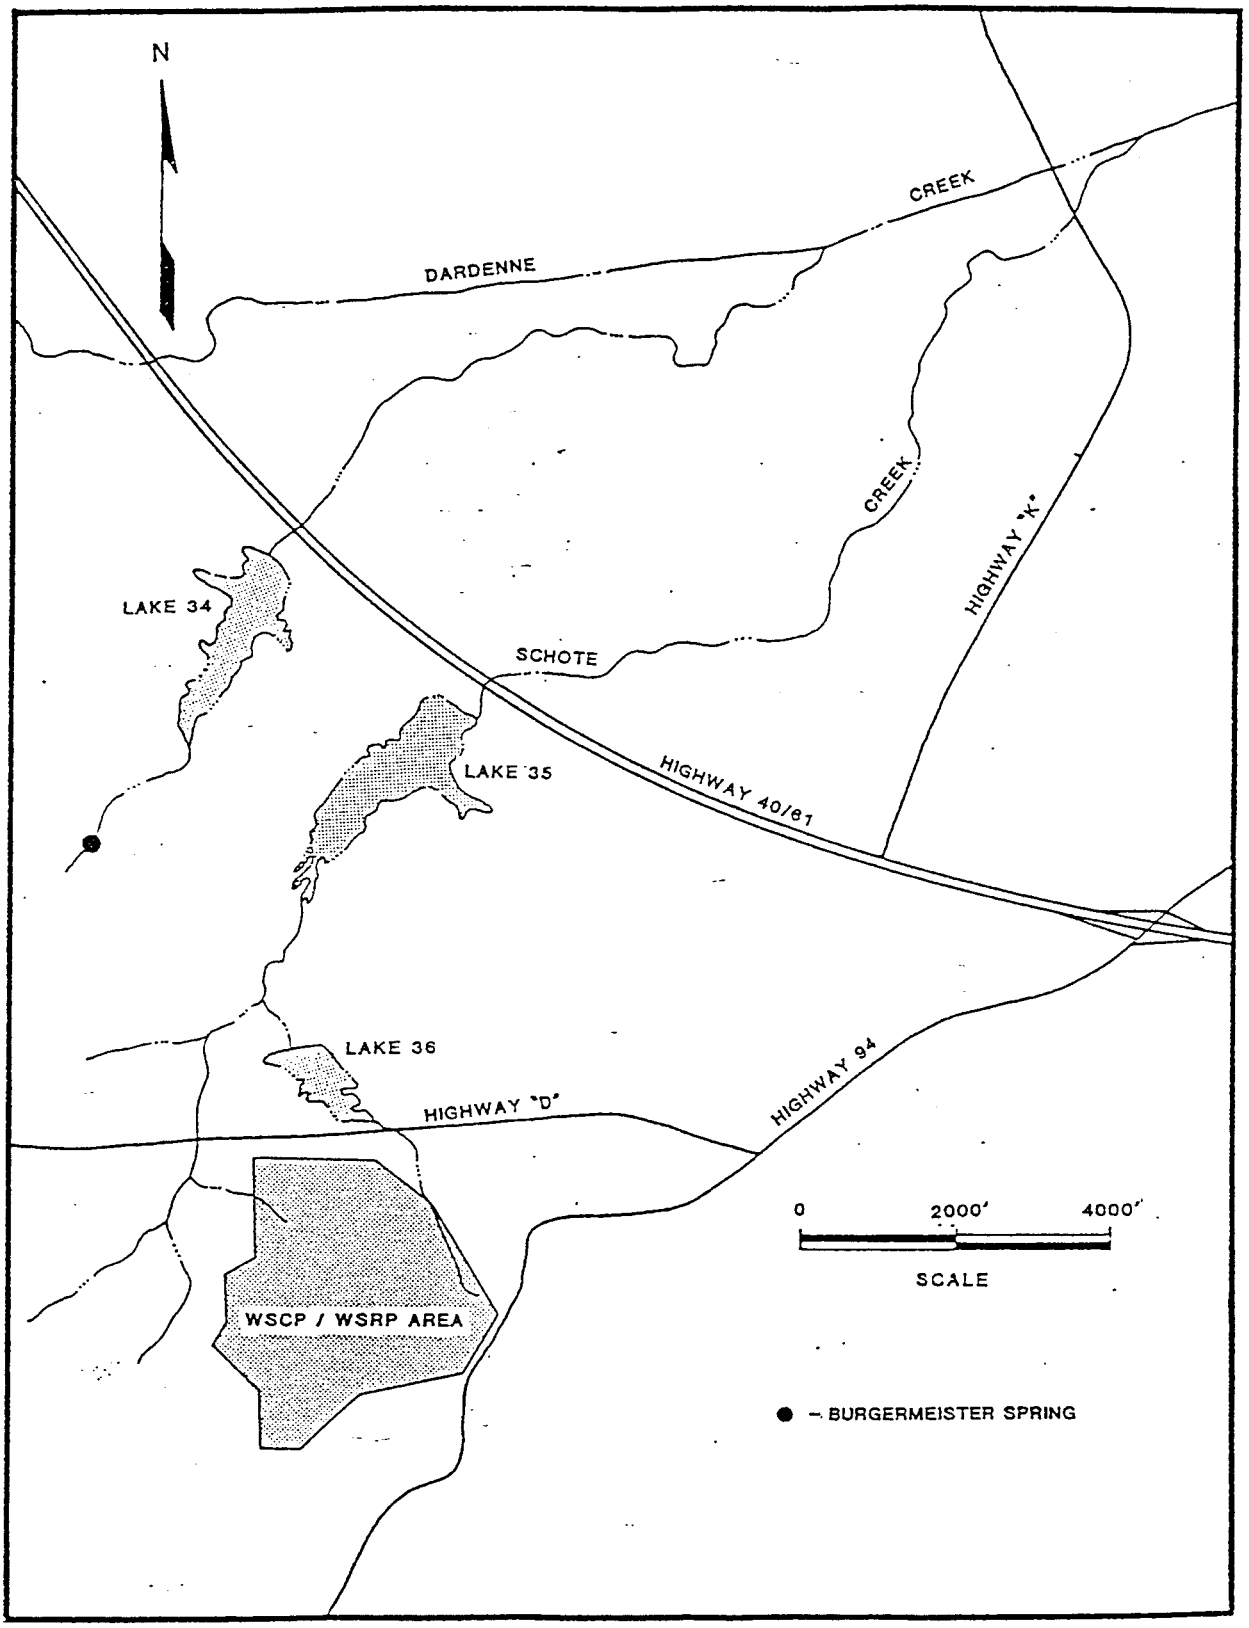

FIGURE 2

MAP OF THE WSCP/WSRP SURROUNDING PROPERTIES

operations in 1967 ceased, the discharge from Ash Pond has become an intermittent stream.

Surface water runoff from the northeast portion of the WSCP drains into Frog Pond. An intermittent stream out of Frog Pond flows north to Lake 36 and then into Lake 35, Schote Creek, Dardenne Creek, and eventually the Mississippi.

On the southeast corner of the WSCP, the outfall of the Imhoff Tank, the former WSCP sanitary sewage system, flows down a drainage ditch to the Missouri River. This drainage contains numerous areas of elevated radionuclides. Currently, flow through the Imhoff Tank results from the infiltration of storm water inflow into the sewer system. Sanitary wastes no longer enter the sewer system.

From 1941 to 1944, the Army used the Weldon Spring Quarry (WSQ) for disposal of rubble contaminated with TNT. The WSQ is approximately 4 miles to the south-southwest of the WSCP. Radioactive wastes were disposed of in the WSQ by the AEC from 1957 to 1966. (Figure 3)

The Femme Osage Slough, located south-southeast of the WSQ, has elevated concentrations of radionuclides (Figure 4). Contaminants are believed to be carried by groundwater movements from the WSQ sump to the slough, eventually reaching the Missouri River.

MAP OF WSQ SURROUNDING PROPERTIES

3.0 TECHNICAL DISCUSSION AND BACKGROUND INFORMATION

Lake 35 is located in the Busch Wildlife Area. It is the closest lake receiving effluent from Ash Pond in an unrestricted area. Lake 35 is used for recreational activities such as fishing and boating. Dye tests have shown that water from Ash Pond also discharges via underground connections to Burgermeister Spring. Burgermeister Spring discharges to Lake 34 in the Busch Wildlife Area (Figure 2). At present, there is no recreational use of Burgermeister Spring, but Lake 34 is used for recreational purposes similar to Lake 35. These streams or lakes are not used as drinking water or irrigation sources.

Lake 36, located in the Busch Wildlife Area is the closest lake receiving effluent from Frog Pond in an unrestricted area. Frog Pond discharges via an intermittent stream into Lake 36. Lake 36 is also used for recreational activities such as fishing and boating.

The Femme Osage Slough is located approximately 500-feet SSE of the WSQ sump in an unrestricted area (Figure 3). The sump is believed to be hydraulically connected to the slough. This slough is not used as a source for drinking water or irrigation, but is frequently used for fishing (Figure 4).

Average radioactivity levels in surface and runoff water samples taken from in and around the WSS in 1986 are presented in Table 1. Nitroaromatic concentrations are presented in Table 2. The activity levels in waters decrease rapidly with the increase of distance from site mainly due to dilution by lake waters and/or other water sources.

Important considerations for determining body content of a radionuclide after it is ingested are time and age dependence of the intake. For purposes of the present analysis, it may be

TABLE 1

RADIONUCLIDE CONCENTRATIONS FROM 1986 ENVIRONMENTAL MONITORING DATA.

LOCATION	RADIONUCLIDE CONCENTRATIONS (pCi/l)

TABLE 2

Nitroaromatic Concentrations from March 1987. National Pollutant Discharge Eliminate System (NPDES) Sampling.

LOCATION	Nitroaromatic Concentrations (ug/l)	
	2,4 DNT	2,6 DNT
Frog Pond	<0.2	<0.6
Ash Pond	1.5	<0.6
Raffinate Pit #4	<0.2	<0.6
Burgermeister Spring	<0.2	1.4
SE Drainage (WSCP)	<0.2	0.8

assumed that organ concentrations remain constant at an equilibrium value with a fixed daily intake. The consumption of biota by humans will have the same assumptions applied. Since dietary composition and its source can change, this may lead to an oversimplification. Also, some of the metabolic parameters may change due to age dependence over the course of intake.

The International Commission on Radiological Protection has developed mathematical models which determine body content of a radionuclide after it is ingested. The bone is the major site for uranium, radium, and thorium accumulation. The turnover or half life of some fraction of these is slow, therefore, skeletal cancer will be regarded as the major potential radiobiological effect of ingestion by humans. The metabolism of the biota has the primary effect in these calculations. Unfortunately, most studies focus on relating the metabolic rates to humans rather than different species. There is a wealth of data for metabolism in human beings, so the primary focus will be given to the careful dissection and sample analysis of only food parts from the biota to determine their uptake. From this study, the action levels adopted to control radiological risk are to limit the likelihood of bone cancer induction for the nearby population, though calculations will be based on a hypothetically maximum exposed individual.

The quantitative relationship between uranium intake and kidney damage have been measured in several species. Proximal renal tubule cells are killed by high acute or lower chronic dosages of soluble uranium compounds. The limiting concentration for chronic intake is 120 ug per day. From this level of intake, the toxic effects should be sufficiently low in the kidney. Kidney damage may be expected to occur gradually, above some critical uranium concentration.

The primary site of effect for TNT is the blood system. TNT can cause toxic hepatitis, aplastic anemia, and methemoglobinemia.

The most serious systemic effect of acute TNT poisoning in humans are toxic jaundice and toxic hepatitis. There is growing evidence from research that DNT's are carcinogenic, although the potency of the different isomers in cancer induction has not been well characterized. The acceptable dose for DNT is based on EPA ambient water quality criterion, 0.11 ug/L or 3.2×10^{-6} mg/kg/day.

By comparing actual contaminant levels with these criteria, the actual risks incurred from ingestion of biota tissue containing these nitroaromatics can be estimated. The development of criteria is still based on a variety of conservative assumptions and safety factors so that exceedence of the criteria does not imply that adverse health effects are expected.

4.0 SAMPLE COLLECTION

Biota samples will be collected from locations both on and off the WSS. Locations of fish and small mammal collection areas are shown in Figures 5, 6, 7, and 8. Fish will be collected using electrofishing methods and minnow traps, while small mammals will be collected using live traps. Electrofishing involves the use of a gas powered electric generator to introduce an electric current into the water near the boat. This temporarily stuns fish long enough to be netted and placed in a container in the boat. Electrofishing will be conducted by Missouri Department of Conservation (MDOC) personnel for all sites located on the Busch and Weldon Spring Wildlife Areas. Electrofishing will continue at each site until a sufficient quantity of fish is collected to fulfill the sample requirements. (Table 2)

Four composite samples will be collected at each site. Three of the four composites will be composed of skinned and filleted specimens representing the following fish; largemouth bass, sunfish, and catfish. These three composites will represent only edible portions of fish flesh. In Lake 35, the largemouth bass composite will be replaced by crappie since this lake has an overabundance of crappie and few bass. It is currently being managed with special regulations to reverse this trend. The fourth composite will consist of sunfish that have been cleaned and scaled but not skinned or filleted. This composite will represent fish used to make fishcakes, a common method of preparation for small edible fish.

Approximately 500 grams of fish tissue per composite sample will be required for the laboratory analyses. Fish will be cleaned or filleted, depending on the composite, at the end of each day. Fish flesh samples will be stored in labeled plastic bags and frozen prior to shipment to the lab. At the lab, each composite will be homogenized and extracted as required for the specific analyses to be performed.

Two separate sampling locations have been selected at Lakes 34 and 35 on the Busch Wildlife Area due to the large size of these lakes. The locations are at the inlet and outlet ends of these two lakes. Lakes 36 and 37 will be sampled only at the inlet ends. Lake 37 has been chosen for use as a background location. This lake does not receive runoff from either the WSCP/WSRP or the Army Ordnance Works property.

Two locations will also be sampled in the Femme Osage Slough. The first location is just below the WSQ near the confluence of the Little Femme Osage Slough. The second location is in the eastern end of the Femme Osage Slough on the other side of the access road crossing the Slough (see Figure 8).

	Sunfish, fillets	2500 g	1000 g
Lake 37 (Background location)	Sunfish, fillets	2500 g	1000 g
	Catfish, fillets	2500 g	1000 g
	Largemouth bass, fillets	2500 g	1000 g
	Sunfish, cleaned	1500 g	1000 g

SAMPLE TYPES

AREA	SPECIES	MINIMUM AMOUNT OF SAMPLE COLLECTED	MINIMUM AMOUNT OF SAMPLE SUBMITTED
Ash Pond Area	Rabbit	4000 g	1000 g
	Squirrel	4000 g	1000 g
Quarry Area	Rabbit	4000 g	1000 g
	Squirrel	4000 g	1000 g
Frog Pond Area	Rabbit	4000 g	1000 g
	Squirrel	4000 g	1000 g
Imhoff SE Drainage Easement	Rabbit	4000 g	1000 g
	Squirrel	4000 g	1000 g

A total of 48 samples will be submitted.

Locations that will be sampled on-site include Frog Pond, the quarry sump, and Raffinate Pits 3 and 4. Fish are not positively known to occur in these on-site waterbodies. However, sightings have been reported of minnows and possibly sunfish by Project employees. Electrofishing will therefore be utilized in an attempt to obtain samples from these locations. In addition, minnow traps will be set so that a composite sample of whole minnows can be collected if larger fish are unavailable. Some type of fish sample from on-site locations is important since this represents a "worst case" situation of radionuclide uptake.

Small game mammals, such as squirrels and rabbits, will be collected by live traps set at various locations around the Weldon Spring Site. Traps located on the WSCP and WSQ will be focused at boundary areas where animals can migrate on and off site being accessible to hunters. Figure 5 shows the proposed locations where traps will be set in the WSCP area. Figure 6 illustrates the locations for the WSQ area. Figure 7 shows the area in the Weldon Spring Wildlife Area where traps will be set in the vicinity of the southeast drainage easement.

Live traps will be set in the approximate locations shown on the figures where suitable habitat exists. Traps will be baited and checked daily until the sampling effort has been completed. Only small mammals commonly eaten by hunters will be kept. Others, such as opossums and raccoons, will be released unharmed. Animals kept for analysis will be killed using a pellet gun at close range, skinned, and cleaned, so that flesh samples represent only edible portions (Table 2).

Composite samples of each species, rabbit and squirrel, will be collected at four areas: Frog Pond, Ash Pond, Quarry, and the Imhoff (southeast) drainage easement. Each composite will consist of a minimum of 3 individuals. At the Quarry and Imhoff drainage easement locations, rabbits will probably be

difficult to obtain since these locations are densely wooded with little open or brushy habitat suitable for rabbits. Should this be the case, the rabbit composites from these two locations will be deleted.

Small mammal composite samples will be handled similarly as the fish. Composites will be made after skinning and cleaning the animals, stored in labeled plastic bags and frozen prior to shipment to the lab. Chain of Custody records will be utilized for a written record of sampling effort. These records will verify that the samples were not tampered with or altered prior to laboratory analysis.

The laboratory analyses with unit costs are estimated below:

TYPE OF ANALYSIS	UNIT COST	ESTIMATED NUMBER
Total Natural Uranium	120.00	48
Radium-226	200.00	6
Thorium-230	200.00	6
Total Nitroaromatics	300.00	48

Approximately 500 grams (minimum) will be required per sample for the analysis. The analysis for uranium, radium, and thorium should have a lower limit of detectability of 0.01 pCi/g. The level of activity expected to be seen from the offsite lakes will be in this range. Nitroaromatics will have a lower limit of detectability of approximately 0.2-0.5 parts per billion (ppb).

The estimated amount of time required to complete the sampling operation are as follows:

AREA	MAN-HOURS
Lake 34 *	12
Lake 35 *	12
Lake 36 *	12
Lake 37*	12
Frog Pond	12
Raffinate Pit #3	12
Raffinate Pit #4	12
Femme Osage Slough *	24
Quarry Sump	24
Total Man-Hours	132

* Locations will be assisted by MDOC personnel.

Sampling efforts will begin after July 1, 1987. MDOC personnel will be notified well in advance of operation. Small mammal traps will be set after July 1, 1987. Traps will be checked on a daily basis until minimum sample number obtained.

The following is a numbered list of equipment and materials needed for the sampling operation.

1. Small mammal traps (18)
2. Boat or raft for onsite
3. Electroshock apparatus for onsite
4. Small mammal dissection kits
5. Fish filet equipment
6. Sample collection bags
7. Radiation monitoring equipment
8. Life preservers
9. Rubber boots & gloves
10. Rain suits
11. Transport for boat or raft

5.0 DATA ANALYSES

The set of data along with assumptions made on dietary intake will be used to calculate the radiation dose from internally deposited radionuclides. Cumulative risk estimates from lifelong intakes will assume a linear dose-response relationship for cancer induction at environmental levels.

If the biota sampling results in significant findings, routine collection and analysis may be added to the Environmental Monitoring Plan. The radiation dose calculated from edible parts of biota samples and measured data for water concentrations will be compared.

If measured offsite concentrations increase and conditions drastically change in future operations, the need may arise for another study. Sampling efforts in higher radionuclide concentrations located on-site may provide better estimates and determinations for outcomes of such releases.

The DOE radiation dose limit for an unrestricted area is 100 mrem/yr above background for whole body exposure. The DOE Administrative action level is 25 mrem/yr above background. A hypothetical individual consuming such biota from the vicinity of WSS receives internal exposure via the food pathway and by ingestion of contaminated water.

If calculations suggest the radiation dose to an individual is greater than 50 percent of the administrative action level, then a second study for verification of results may be developed.

Available data pertaining to DNT exposure is limited at this time, calculation of an acceptable dosage is extremely difficult. In research, animal studies indicate significant species and strain differences in the excretion of DNT isomers.

The potency of DNT varies in studies, so to assure the protection of public health from carcinogenic effects, a 10^{-6} cancer risk level is generally assumed at the dosage of 6.4×10^{-7} mg/kg/day. With the primary site for TNT being the blood system and liver, studies have provided no evidence of carcinogenicity, so an Allowable Daily Intake (ADI) is used for a no-observed-adverse-effect level (1.4×10^{-3} mg/kg/day). Conclusions from the assessment and subsequent determinations regarding the levels of contamination will be reviewed for actual risks incurred by the exposed population.

St. Charles, Missouri 63303

Dear Mr. Nelson:

Ed Skowronski, ATSDR representative working with EPA, reviewed the Biouptake and Sediment Sampling Plans. His comments are as follows:

1. Plan for the Sampling of Sediment Influenced by Weldon Spring Chemical Plant Drainage.

Table 4-1 - Are some of the sample locations truly background?

5.0 - I would like to see more of the QA/QC procedures detailed in the body of the plan.

6.0 - Who will get a copy of the results? Will we get a chance to input into deciding the necessity for cleanup? This is not clear.

2. Plan for Determination of Biological Uptake of Radionuclides and Nitroaromatics in Species in the Food Pathway at the Weldon Spring Site.

Are there any other contaminants that may be expected to appear in the food pathway at the Weldon Spring Site? Page 14, paragraph 2 - FDA procedures for determining edible portions of fish flesh call for filleted with the skin left on. Page 21 - Frogs have been found at other site to have very high levels of contamination. They should probably be included.

Please call Ed at 913/236-2856 if you have any questions or need further information.

Sincerely yours,

Katie

October 26, 1987

Ms. Katie Biggs, Chief
Environmental Review Branch
U.S. Environmental Protection Agency
727 Minnesota Avenue
Kansas City, Kansas 66101

Dear Ms. Biggs:

The Missouri Department of Natural Resources (MDNR) has reviewed four interim response actions which the U.S. Department of Energy (DOE) has proposed for the Weldon Spring site.

These actions are:

1) Removal of overhead piping and asbestos insulation

2) Disposal of containerized chemicals

3) Remedial action on the Army Reserve Property

4) Power line/pole removal.

The MDNR supports the initiation of these actions at this time with the qualifications noted in the October 26, 1987 letter from Dr. Frederick A. Brunner, Director of MDNR, to Mr. Rod Nelson, Weldon Spring Site Manager. Therefore, MDNR approves initiation of these actions but the DOE should initiate discussions with the MDNR regarding the issues raised in Dr. Brunner's letter, specifically:

1) DOE should provide information to MDNR to allow us to determine whether the on-site handling, processing and storage of solid waste is subject to the Missouri Solid Waste Management Law.

2) When an off-site solid waste landfill is selected for the disposal of asbestos or other solid waste, the landifll operator and the DOE must apply for special waste disposal approval.

3) In regard to containerized chemical waste disposal, the subcontractor's work plan should be submitted to MDNR for review, when it is available.

The MDNR has also reviewed the "Work Plan for Determination of Biological Uptake of WSS Contaminants by Species in Food Pathways." MDNR agrees that this study should be immediately initiated. However, we note that deer, turkey, geese and ducks will not be sampled at this time because of their mobility. While we agree that it would be difficult to interpret sampling results from these species, we believe that further thought should be given to determining whether these species, particularly the waterfowl, might be contaminated by feeding on the site. If any methods of making this determination can be devised, we would recommend further studies at that time.

Please contact me if you have any further questions on these matters.

Sincerely,

DEPARTMENT OF NATURAL RESOURCES

Kansas City, Missouri 66101

Dear Ms. Biggs:

PLAN FOR DETERMINATION OF BIOLOGICAL UPTAKE OF WSS CONTAMINANTS BY SPECIES IN FOOD PATHWAYS

Pursuant to our discussion on November 5, 1987, we will modify the subject plan to include PCB and Metal Analyses for on-site terrestrial mammal samples.

Regarding your question concerning analysis of off-site fish samples for levels of Ra 226 and Th 230 we do not plan to include such sampling at this time. We base this plan on previous findings of no elevated levels of Th 230 in off-site water bodies. The mobility of Ra 226 is similar to Th 230 and, similarly, we would not expect to find elevated levels of this radionuclide in off-site water bodies. We will add in the Biouptake Plan that if elevated levels of RA 226 or Th 230 are discovered during the upcoming lake and stream sediments sampling program then it will be necessary to analyze for these radionuclides on fish samples designed to represent consumption of fishcake (i.e., including bones). Our plan does include analyses for Ra 226 and Th 230 on fish samples from on-site water bodies.

We appreciate EPA's comments and encourage you to call if you have any further questions.

Sincerely,

Stephen H. McCracken

November 6, 1987

Mr. Rodney R. Nelson
U.S. Department of Energy
Weldon Spring Site Remedial
Action Project/Office
Route 2, Highway 94, South
St. Charles, Missouri 63303

Dear Mr. Nelson:

We have reviewed the revised work plan for determination of biological uptake at the Weldon Spring Site (WSS). Generally, the plan is well written and contains all the necessary elements to reach the stated objectives. We concur with the revised plan and agree you should undertake the sampling as planned. The Missouri Department of Natural Resources (MDNR) also agrees this work should be immediately implemented.

As you prepare the report for this work, there are some items that need more detailed discussion or clarification. These points are addressed in the following comments.

1. It is stated that the data will be used in an Endangerment Assessment under CERCLA, but no reference to a guidance document is given. The specific documents to be used should be referenced.

2. On page 2, reference is made to a "metabolic model," but no reference or other discussion is given concerning the type of model to be used; i.e., computer, pharmacokinetic, etc.

3. The term "uptake" may be erroneously used in this document. What is really being measured are residues of compounds already ingested, distributed, metabolized and/or stored. "Uptake" implies that not only is the exposure quantified but that the metabolic dynamics of the chemicals in question are well understood. We suggest that the term "residue" be used in place of "uptake" to denote that the compounds in tissues are of environmental origin but not to imply that complete information regarding pharmacokinetics under natural conditions are known.

4. The revised work plan does not address on-site sampling for PCBs and metals. Based on our discussion, it is my understanding you plan to conduct these analyses and will send a letter to confirm this.

001853
11-17-87

5. Composite samples made up of cleaned but not filleted fish suggest radium and thorium analysis since the bones would also be present in a fish cake. Your report should address why these anlyses are not included.

6. The difficulty in interpreting the analytical results of nitroaromatic coumpounds in tissue should not necessarily deter you from looking for these compounds. It is correct that biodegradation studies as well as true "uptake" studies appear to be unavailable and recoveries of nitroaromatic compounds may be less than 60 percent. However, the mere presence of nitroaromatics in fish tissues would be of significance. It is suggested that, once the TNT/DNT levels in and around the WSS are sifficiently known, the report evaluate the need for additional biological sampling to analyze tissues for the presence of TNT, DNT and other nitroaromatic residues.

7. The plan cites CLP and other analytical methods; however the plan does not specify any tissue extraction procedures. Also, no analytical laboratory is identified.

If you have any questions regarding these comments, please contact me or Dan Wall.

Sincerely yours,

Katie

Dear Ms. Biggs:

RESPONSIVENESS SUMMARY ON WSS BIOLOGICAL UP-TAKE SAMPLING AND ANALYSIS WORK PLAN

Enclosed is a responsiveness summary to comments in your November 6, 1987 letter. The final report will reflect responses to the comments and no changes will be made to the sampling plan.

If you have any questions, please call.

Sincerely,

R. R. Nelson
Project Manager
Weldon Spring Site
Remedial Action Project

Enclosure:
As stated

cc: D. Bedan, MDNR
J. Hammond, MK-Ferguson/Document Control

Responsiveness Summary to Comments on the WSS Biological Up-Take Sampling and Analysis Work Plan - Reference: Letter from K. Biggs to R.R. Nelson dated 11/06/87.

Comment No. 1:

It is stated that the data will be used in baseline risk assessment under CERCLA, but no reference to a guidance document is given. The specific documents to be used should be referenced.

Response:

A baseline risk assessment (formerly an Endangerment Assessment) will be conducted to assess the impacts of the no action alternative and the information incorporated into the remedial investigation report. The baseline risk assessment will follow the methodology described in the Superfund Public Health Evaluation Manual.

Comment No. 2:

On page 2, reference is made to a "metabolic model", but no reference or other discussion is given concerning the type of model to be used; i.e., computer, pharmacokinetic, etc.

Response:

Based upon a preliminary review of potential indicator compounds at the WSS, the dominant risk is associated with the ingestion of radiological species. For this reason, the metabolic model used will be that found in the International Commission on Radiological Protection (ICRP) Publications No.'s 23, 26, and 30. All calculations and assumptions will be based on this methodology.

If further evaluation of indicator compounds indicates the need for additional metabolic model(s), the types and rationale for selection of these models will be discussed with EPA before implementation.

Comment No. 3:

The term "uptake" may be erroneously used in this document. What is really being measured are residues of compounds already ingested, distributed, metabolized and/or stored. "Uptake" implies that not only is the exposure quantified, but that the metabolic dynamics of the chemicals in question are well understood. We suggest that the term "residue" be used in place of "uptake" to denote that the compounds in tissues are of environmental origin but not to imply that complete information regarding pharmocokinetics under natural conditions are known.

Response:

The final report will carefully use terms describing the metabolic behavior of the various hazardous substances. The ICRP currently uses the term "uptake" to describe ingestion, distribution and metabolism of radiological species. However, the term "residue" will be incorporated into discussions of compounds in tissue that are of environmental origin in order to not imply complete understanding.

Comment No. 4:

The revised work plan does not address on-site sampling for PCB's and metals. Based on our discussion, it is my understanding you plan to conduct these analyses and will send a letter to confirm this.

Response:

Pursuant to the letter from Stephen McCracken to K. Biggs dated November 6, 1987, analyses for PCBs' and CLP metals for on-site terrestrial mammal samples will be performed. The results will be presented in the final report, however, we do not envision modification and formal reissuance of the work plan document.

Comment No. 5:

Composite samples made up of cleaned but not filleted fish suggest radium and thorium analysis since the bones would also be present in a fish cake. Your report should address why these analyses are not included.

Response:

Previous samples of the surface water in off-site water bodies showed no elevated levels of Ra-226 or Th-230 present. In addition, no elevated levels of Th-230 in sediment from Lakes 34, 35 and 36 and the Femme Osage Slough have been detected in previous preliminary sampling efforts and the mobility of Ra-226 is similar to Th-230. A more intensive Stream and Lake Sediment Sampling Plan is to be initiated in the winter/spring of 1988. Should elevated levels of Ra-226 or Th-230 be discovered during this upcoming program, then the biological uptake plan will be revised to collect and analyze for these radionuclides on fish samples designed to represent consumption of fish cake (i.e., including bones). The current work plan does include analyses for Ra-226 and Th-230 on samples from on-site water bodies.

Comment No. 6:

The difficulty in interpreting the analytical results of nitroaromatic compounds in tissue should not necessarily deter you from looking for these compounds. It is correct that biodegradation studies as well as true "uptake" studies appear to be unavailable and recoveries of nitroaromatics compounds may be less than 60 percent. However, the mere presence of nitroaromatics in fish tissues would be of significance. It is suggested that, once the TNT/DNT levels in and around the WSS are sufficiently known, the report evaluate the need for additional biological sampling to analyze tissues for the presence of TNT, DNT and other nitroaromatic residues.

Response:

Once the nitroaromatic levels in and around the WSS are sufficiently known, the final report will evaluate the need for additional biological sampling to analyze tissues for the presence of these compounds.

Comment No. 7:

The plan cites CLP and other analytical methods; however the plan does not specify any tissue extraction procedures. Also, no analytical laboratory is identified.

Response:

The analytical laboratory which will perform the analyses on samples collected for the biological uptake work plan is metaTrace, in St. Louis, MO. This laboratory has performed the majority of analyses for all determinations made at the WSS in 1987. The laboratory participates in the Contract Lab Program and meets USATHAMA requirements. We would be glad to provide more details on the Quality Assurance and other capabilities of this laboratory at your request.

Tissue extraction procedures are based on guidance provided in the EPA Interim Methods for the Sampling and Analysis of Priority Pollutants in Sediments and Fish Tissue. Modifications to these procedures were made to improve detection limits and percent recovery. These procedures will be cited in the final report.

1.0 INTRODUCTION

The Weldon Spring Site (WSS) is a U.S. Department of Energy (DOE) surplus facility located in St. Charles County, Missouri. This document presents a description of the study plan and scope of work to determine and characterize the level of potential human exposure to radionuclides, polychlorinated biphenyls (PCB's), and EPA-CLP Metals from the food pathways at the WSS. This will be accomplished by a statistically representative sampling effort of biota available for human consumption from various locations around and within the WSS. The final report will describe the methods used in performing the survey, summarize the results, and discuss their significance. This effort is fundamental in providing data used in an Endangerment Assessment as part of an RI/FS process under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA).

The analysis of the food pathways for the surrounding population is necessary in assessing the risks to human health from pathway ingestion of biota living in or near contaminated sediments and water. Chemical and radiological exposure in humans and the relevance of data in establishing design and action limits will be reviewed.

The study will combine estimates of average consumption by humans with measured contamination levels in edible tissues for input into a metabolic model. The approach taken will measure the actual uptake by edible aquatic and terrestrial biota and then calculate the human uptake from consumption of contaminated tissue based on assumed ingestion rates.

The goal of the sampling is to collect approximately thirty-nine (39) kilograms of sunfish, twenty-eight (28) kilograms of catfish, two (2) kilograms of minnows, sixteen (16) kilograms of largemouth bass, five (5) kilograms of crappies, thirty-two (32) kilograms of frogs, and a minimum of seven (7) kilograms of both rabbits and squirrels.

Electrofishing methods will be utilized for the collection of aquatic samples. This method will provide randomness in fish samples. Individual samples weighing approximately less than 50-75 grams will not be kept, assuming these samples would not be kept for consumption by typical members of the public and uptake would be minimal compared to more adult samples. Frogs will be collected using hand-held nets.

Terrestrial biota samples will consist of small mammals such as rabbits and squirrels. Live traps will be used for the capture of these mammals. Since the population of these

mammals is limited, the traps will be set adjacent or above the areas of contamination. The samples collected will be assumed to live and intake representative amounts of contaminants for populations living near the site(s).

Deer, turkey, geese, and ducks will not be sampled at this time. These animals are very mobile, readily moving on and off the Weldon Spring Site. For this reason, it would be extremely difficult to interpret both positive and negative results since no estimate of the percentage of their time spent on site can be substantiated.

Investigations of offsite radiological migration in soil and water have focused on uranium, due in part to its higher solubility and quantity compared to the other radionuclides present at the WSS. These uranium compounds are also soluble in the body and will incorporate into the soft tissues and bone. Thus, all onsite and offsite samples will be analyzed for uranium.

Surface water outfall sample results from the WSS have background concentrations of radium and thorium. Radium and thorium compounds are insoluble and incorporate primarily in the bone. Therefore, samples from the offsite waterbodies will not be analyzed for radium and thorium because their

uptake in tissue samples are expected to be below detectable levels.

Composite samples collected from the Raffinate Pits, Frog Pond, Quarry Sump, Lake 37, and from small mammals will be analyzed for radium and thorium. Detectable quantities of radium and thorium may exist in the onsite samples due to the higher concentrations of the radionuclides in the waterbodies.

One composite fish sample from each off-site water body will also be analyzed for PCB's and CLP metals. Since the WSCP was operational at a time when PCB's were routinely used, the potential exists for the presence of the contaminants. Many of the old electrical transformers contain PCB's in varying concentrations. In addition, ongoing investigations have indicated PCB's to be present in low concentrations on floors, equipment, and in hydraulic lines at the WSCP. These releases were a result of accidental spills and careless use, not routine releases due to operational procedures.

Draft versions of the Biological Uptake Plan included the analysis of biota samples for nitroaromatics. This was based on the potential for the laboratory to perform such

analyses. Subsequent research indicates the general lack of knowledge about the uptake and bio-degradation and metabolism of nitroaromatic compounds by animals and humans. It would, therefore, be very difficult to interpret analytical results. Second, there is no accepted methodology for analysis of nitroaromatic compounds in tissue. Recovery of target compounds following accepted extraction procedures is expected to be extremely low. In addition, bio-degradation products may not be detected and the lower limits of detection will not be low enough to consistently detect the concentrations anticipated. Therefore, nitroaromatic analyses have been deleted from this plan.

The additional analyses of semi-volatiles were considered, but were discounted for the same factors as discussed for nitroaromatics. Sufficient information concerning uptake, biodegradation and metaboles is inadequate and an acceptable methodology has not been developed.

2.0 SITE HISTORY AND ENVIRONMENTAL SETTING

From 1941 to 1944, the U.S. Department of the Army (DA) operated the Weldon Spring Ordnance Works for production of trinitrotoluene (TNT) and dinitrotoluene (DNT). During this operation, smaller areas of the 17,000-acre site were contaminated by TNT process materials. In the mid-1950's 220-acres of the Ordnance Works property were transferred to the U.S. Atomic Energy Commission (AEC). From 1957 to 1966, the AEC operated a uranium processing facility (Mallinckrodt Chemical Works) at the site. During the operation of this Feed Materials Plant, the buildings, equipment, and immediate terrain of the plant (220-acres) became contaminated with radionuclides in the Uranium transformation series.

After closure by the AEC, the Feed Materials Plant was reacquired by the Army in 1967. The Army partially decontaminated the buildings, dismantled some of the equipment, and began converting the facilities to produce herbicides. In 1969, prior to the Chemical Plant (WSCP) becoming operational, the herbicide project was canceled. In 1985, the custody of the WSCP was transferred from the DA to the Department of Energy (DOE). In conjunction with this transfer, the Weldon Spring Site Remedial Action Project (WSSRAP) was created as DOE Major Project Number 182.

Surface water runoff from the north and west sides of the 220-acre WSCP, as well as potential overflow from an onsite water tower, flow to Ash Pond (Figure 1). Water from Ash Pond travels through an overflow conduit for approximately 100 m, surfaces, and then flows to Lake 35 on the August Busch Wildlife Area, to Schote Creek, Dardenne Creek, and eventually the Mississippi River (Figure 2). Lake 35 is the closest lake receiving effluent from Ash Pond in an unrestricted area. Lake 35 is used for recreational activities such as fishing and boating.

Water from Ash Pond also discharges via underground connections to Burgermeister Spring, Lake 34, Dardenne Creek, and eventually the Mississippi River. At present, there is no recreational use of Burgermeister Spring, but Lake 34 is used for recreational purposes similar to Lake 35. Lakes 34 and 35 are not used as drinking water or irrigation sources. Since operations in 1967 ceased, the discharge from Ash Pond has become an intermittent stream.

Surface water runoff from the northeast portion of the WSCP drains into Frog Pond. An intermittent stream out of Frog Pond flows north to Lake 36. The outfall of Lake 36 discharges into Lake 35, Schote Creek, Dardenne Creek, and eventually the Mississippi River. Lake 36, located in the Busch Wildlife Area is the closest lake receiving effluent from Frog Pond in an unrestricted area. Lake 36 is also

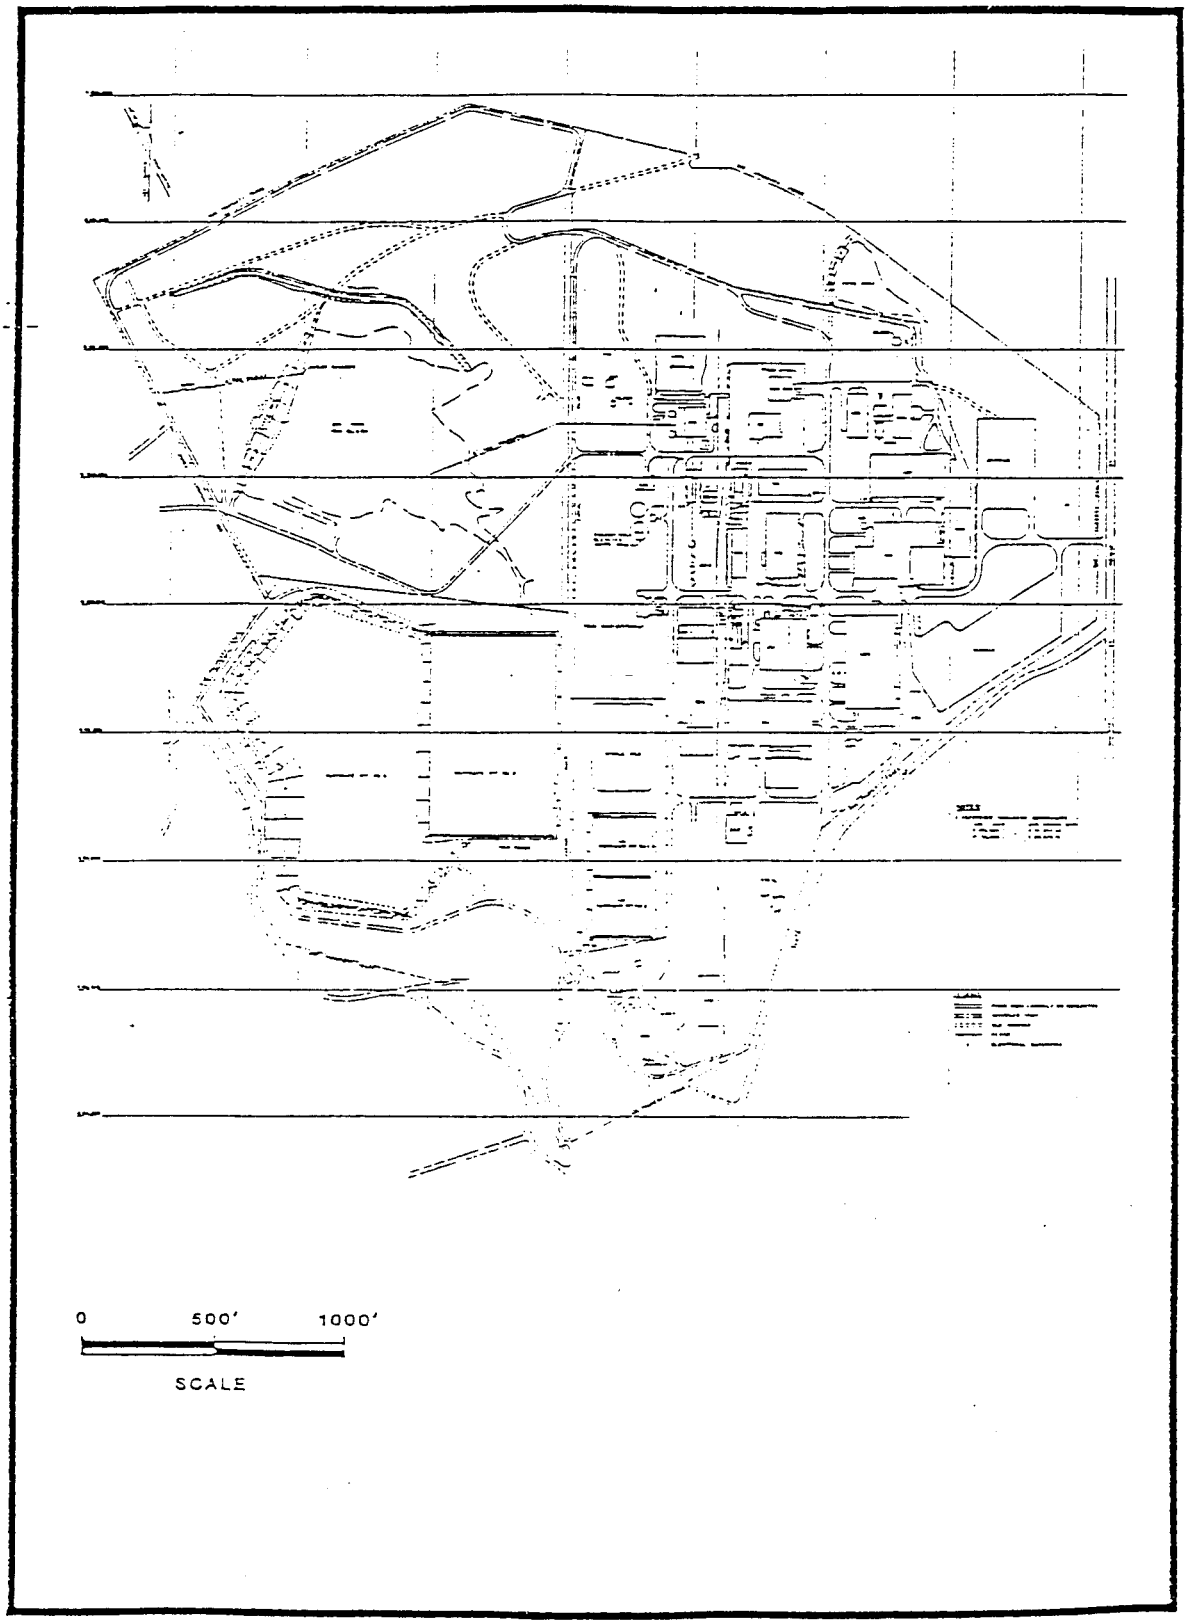

FIGURE 1
MAP OF WSCP/WSRP

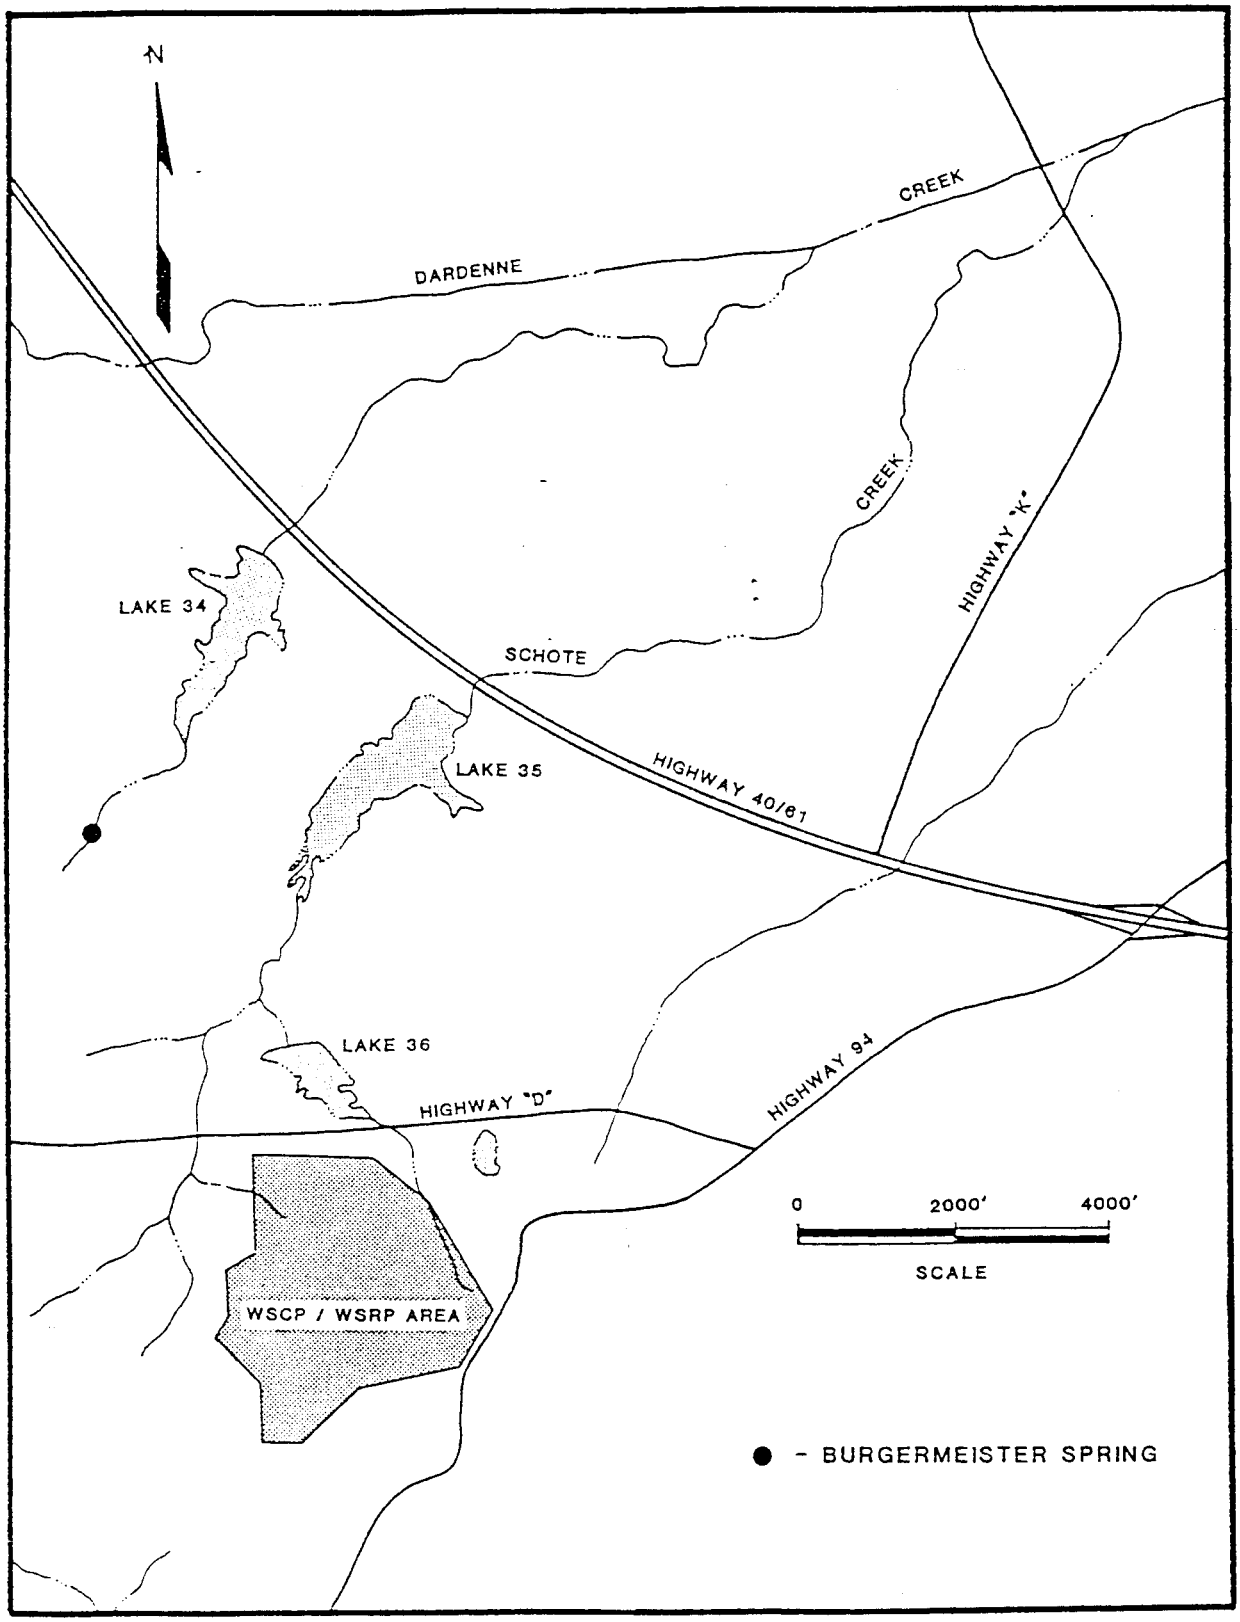

FIGURE 2
MAP OF THE WSCP/WSRP SURROUNDING PROPERTIES

used for recreational activities such as fishing and boating but not as drinking water or irrigation sources.

On the southeast corner of the WSCP, the outfall of the Imhoff Tank, the former WSCP sanitary sewage system, flows down a drainage ditch to the Missouri River. This drainage contains numerous areas of elevated radionuclide concentrations. Currently, flow through the Imhoff Tank results from the infiltration of storm water inflow to the sewer system. Sanitary wastes no longer enter the sewer system.

The Weldon Spring Quarry (WSQ) is approximately 4 miles to the south-southwest of the WSCP. Radioactive wastes were disposed of in the WSQ by the AEC from 1957 to 1966 (Figure 3). The DA also disposed of TNT process wastes into the WSQ. A large portion of the AEC radioactive wastes were from Mallinckrodt Chemical Works' Destrehan Street Feed Plant in St. Louis. Materials from this plant were contaminated with radionuclides in the uranium transformation series.

The Femme Osage Slough is located in the Weldon Spring Wildlife Area, approximately 500-feet SSE of the WSQ sump in an unrestricted area (Figure 3). The sump is believed to be hydraulically connected to the slough. The slough is not used as a source for drinking water or irrigation, but is frequently used for fishing (Figure 4).

Lake 37, located at the western end of the Busch Wildlife Area, will be used as a background location for fish and frog samples. This lake does not receive runoff from either the Army Ordnance Works or the Weldon Spring site and should therefore be free of contaminants. In addition, Lake 37 is generally upwind of the Weldon Spring site and over three miles away.

Average radioactivity levels in surface and runoff water samples taken from in and around the WSS in 1986 are presented in Table 1. These average values are presented in the WSS 1986 Environmental Monitoring Report. The data represents samples taken at quarterly intervals which are then averaged over the entire year. The activity levels in waters will decrease with the increase of distance from site mainly due to dilution by lake waters and/or other water sources.

3.0 SAMPLE COLLECTION

Biota samples will be collected from locations both on and off the WSS. Locations of fish, frog, and small mammal collection areas are shown in Figures 5, 6, 7, and 8. Fish will be collected using electrofishing methods and minnow traps, while small mammals will be collected using live traps.

Electrofishing involves the use of a gas powered electric generator to introduce an electric current into the water near the boat. This temporarily stuns fish long enough to be netted and placed in a container in the boat. Electrofishing will be conducted by Missouri Department of Conservation (MDOC) personnel for all sites located on the Busch and Weldon Spring Wildlife Areas. Electrofishing will continue at each site until a sufficient quantity of fish is collected to fulfill the sample requirements. (Table 2)

Five composite samples will be collected, if possible, at each of the offsite locations. Three of the five composites will be composed of filleted specimens representing the following fish; largemouth bass, sunfish, and catfish. These three composites will represent only edible portions of fish tissue. In Lake 35, the largemouth bass composite will be replaced by crappie since this lake has an overabundance of crappie and few bass. It is currently being managed with special regulations to reverse this trend. The fourth composite will consist of sunfish that have

	Squirrel	1600 g	800 g

A total of 65 samples will be submitted.

been cleaned and scaled but not filleted. This composite will represent fish used to make fishcakes, a common method of preparation for small edible fish. The fifth composite sample will be made up of representatives of all species collected, equally represented by weight. These samples will be filleted and analyzed for PCB's and CLP metals.

Locations that will be sampled on-site include Frog Pond, the quarry sump, and Raffinate Pits 3 and 4. While fish have been sited at some onsite surface bodies, it is uncertain that sufficient samples can be collected positively known to occur in these on-site waterbodies. Electrofishing will therefore be utilized in an attempt to obtain samples from these locations. In addition, minnow traps will be set so that a composite sample of whole minnows can be collected if larger fish are unavailable. Some type of fish sample from on-site locations is important since this represents a "worst case" situation of a high radionuclide uptake.

Two separate fish sampling locations have been selected at Lakes 34 and 35 on the Busch Wildlife Area due to the large size of these lakes. The locations are at the inlet and outlet ends of these two lakes. This is being done to see if there is any dilution factor or difference in fish uptake. Higher concentrations might be expected at or near the inlets. Lakes 36 and 37 will be sampled only at the inlet ends. Lake 37 has been chosen for use as a background location. This lake does not receive runoff from either

the WSCP or the DA Ordnance Works abandoned facility.

Two locations will also be sampled in the Femme Osage Slough. The first location is just below the WSQ near the confluence of the Little Femme Osage Slough. The second location is in the eastern end of the Femme Osage Slough on the other side of the access road crossing the Slough (see Figure 8).

4.0 METHODS OF ANALYSIS

Approximately 100 grams of fish tissue per sample will be required for the laboratory analyses per radionuclide. Fish will be cleaned or filleted, depending on the sample, at the end of each day. Fish samples will be stored in labeled plastic bags and frozen prior to shipment to the lab for radionuclide analysis. The composite samples that will be analyzed for PCB's and CLP Metals will be stored in aluminum foil instead of plastic bags. At the laboratory, each composite will be homogenized and extracted as required for the specific analyses to be performed. A summary of the appropriate analysis to be performed on samples are presented in Table 3.

Samples of frogs will be collected from each of the water-body locations. Frogs will be collected using hand-held nets. If this sampling cannot be accomplished in daylight, it will be attempted at night with lights. This method is often used by sportsmen to gig frogs. Frog specimens will be prepared by removing the legs, skinning them, and cutting the meat from the bones. These samples will represent the edible portion of frog tissue. Samples will be bagged, labeled and frozen prior to shipment to the laboratory.

Small game mammals, such as squirrels and rabbits, will be collected by live traps set at various locations around the

Weldon Spring Site. Traps located on the WSCP and WSQ will be focused at boundary areas where animals can migrate on and off site being accessible to hunters. Figure 5 shows the proposed locations where traps will be set in the WSCP area (Frog and Ash Pond). Figure 6 illustrates the locations for the WSQ area.

Live traps will be set in the approximate locations shown on the figures where suitable habitat exists. Traps will be baited and checked daily until the sampling effort has been completed. Only small mammals commonly eaten by hunters will be kept. Others, such as opossums and raccoons, will be released unharmed. Animals kept for analysis will be killed using a pellet gun at close range, skinned, and cleaned, so that tissue samples represent only edible portions.

Each small mammal composite sample will consist of a minimum of 3 individuals. At the WSQ and southeast drainage easement locations, rabbits will probably be difficult to obtain since these locations are densely wooded with little open or brushy habitat suitable for rabbits. Should this be the case, the rabbit composites from these two locations will be deleted.

Small mammal composite samples will be handled in a similar manner as the fish. Composites will be made after skinning and cleaning the animals. The animals will then be stored in

labeled plastic bags and frozen prior to shipment to the lab. Chain of Custody records will be utilized for a written record of the sampling effort. These records will verify that the samples were not tampered with or altered prior to laboratory analysis.

The analysis for uranium, radium, and thorium should have a lower limit of detectability of 0.01 pCi/g. The level of uranium activity in soft tissues is expected to be slightly above this range from the offsite waterbodies. Polychlorinated biphenyls (PCB's) and metals analyses only require 25 and 5 grams for analysis respectively and have a lower limit of detectability in water as listed below:

METALS	DETECTION LEVEL (ug/L or ppb)
Aluminum	200
Antimony	60
Arsenic	10
Barium	200
Beryllium	5
Cadmium	5
Calcium	5000
Chromium	10
Cobalt	50
Copper	25
Iron	100
Lead	5
Magnesium	5000
Manganese	15
Mercury	0.2
Nickel	40
Potassium	5000
Selenium	5
Silver	10
Sodium	5000
Thallium	10
Vanadium	50
Zinc	20

PCB'S	DETECTION LEVEL (ug/L or ppb)
PCB-1016	0.5
PCB-1221	0.5
PCB-1232	0.5
PCB-1242	0.5
PCB-1248	0.5
PCB-1254	1.0
PCB-1260	1.0

Environmental Protection Agency (EPA) Contract Laboratory Program (CLP) Test Method 608 will be used to analyze samples for PCB's. This is a gas chromatographic (GC) method applicable to the determination of the compounds listed above.

EPA-CLP method for inorganic analysis based on Caucus Inorganics Protocol will be used to analyze samples for Metals. These metals are determined by inductively coupled plasma emission or Atomic Absorption Spectroscopy.

Uranium will be analyzed per EPA Method 908-ASTN. Radium-226 will be analyzed per EPA Methods 903.0 and 903.1. Thorium-230 will be analyzed per the procedure developed by the EPA Eastern Environmental Radiation Facility (EERF 00/07).

5.0 DATA ANALYSES

The set of data along with assumptions made on dietary intake will be used to calculate the radiation dose from internally deposited radionuclides. Cumulative risk estimates from lifelong intakes will assume a linear dose-response relationship for cancer induction at environmental levels.

Important considerations for determining body content of a radionuclide after it is ingested are time and age dependence of the intake. For purposes of the present analysis, it may be assumed that animal and fish tissue concentrations remain constant at an equilibrium value with a fixed daily intake of contaminant. The consumption of these biota by humans will have the same assumptions applied. Since dietary composition and its source can change, this may lead to a conservative oversimplification. Also, some of the metabolic parameters may change due to age dependence over the course of intake. The present analysis will assume metabolic parameters of reference man (ICRP No. 23).

The International Commission on Radiological Protection has developed mathematical models which determine body content of a radionuclide after it is ingested. The bone is the major site for uranium, radium, and thorium accumulation. The biological turnover or half life of a fraction of these is slow, therefore, skeletal cancer will be regarded as the major

potential radiobiological effect of ingestion by humans. The metabolism of the biota and the concentration of the contaminant in their tissue has the primary effect in these calculations. The primary focus will be given to the careful dissection and sample analysis of only food parts from the biota to determine the biota uptake. There is a wealth of data for the assumptions made on uptake and the metabolism in human beings. From this study, the action levels adopted to control radiological risk are to limit the likelihood of bone cancer induction for the nearby population, though calculations will be based on a hypothetically maximum exposed individual.

The quantitative relationship between uranium intake and kidney damage have been measured in several species of animals. Proximal renal tubule cells are killed by high acute or lower chronic dosages of soluble uranium compounds. The limiting concentration for chronic intake is 110 ug per day (Wrenn, 1985). From this level of intake, the toxic effects should be sufficiently low to nonexistent in the kidney. Kidney damage may be expected to occur gradually above this uranium concentration.

Radiobiological Effects of Uranium

The concentration determined in the fish tissue will be multiplied by 4086 grams per year (USDA, 1986) to give the total activity ingested by a hypothetical individual in a one

year time interval. Using the methodology described in ICRP's 26 and 30, the 50-year committed dose equivalent and effective dose equivalent will be calculated.

Example: The Effective Dose Equivalent for a hypothetically exposed individual who consumes fish tissue contaminated with uranium. Assume 1.0 pCi/g total Uranium in fish tissue is found by laboratory analysis :

Radiobiological Dose (mrem) = (1.0 pCi/g) X (4086 g)
X (1.0E-06 uCi/pCi)
X (0.25 rem/uCi) X (1.0E+03 mrem/rem)
= 1.0 mrem (whole body) or 1.0 E-05 Sv.

Example: The 50-year Committed Dose Equivalent to the bone for a hypothetically exposed individual. Assume 1.0 pCi/g total uranium in fish tissue is found by laboratory analysis:

Radiobiological Dose to Bone (mrem) = (1.0 pCi/g) X (4086 g)
X (1.0 E-06 uCi/pCi) X (4.2 rem/uCi)
X (1.0 E+03 mrem/rem) = 17 mrem (bone) or 1.7E-04 Sv.

The radiosensitive cells in bone have been identified as the endosteal cells and epithelial cells on bone surfaces. For purposes of radiation protection, the number of excess cancer

fatalities for bone cancer is 5 per 10000 individuals per Sievert (Sv) (ICRP No. 26).

Example: Bone cancer risk

Bone cancer fatalities per 10000 exposed individuals =

(1.7 E-04 Sv) X (5 fatalities/Sv)

= 9.0 E-04 fatalities/10000 individuals exposed to this level.

The number of excess cancer fatalities is dependent upon the number of individuals consuming 4086 grams of fish from a contaminated lake. If 100 million individuals caught fish from a lake with this amount of contaminant in the fish tissue, then 9 of these individuals would die of bone cancer.

Chemical Toxicity Effects of Uranium

The concentration determined in the fish tissue will be multiplied by 11.2 grams per day (USDA, 1986)* to give the average intake. Gastrointestinal absorption of uranium as a function of intake will decrease with increases in intake. Therefore, a daily average or chronic intake is used for conservatism in these calculations.

According to recent studies, the fractional gastrointestinal (GI) absorption from the GI tract to the blood is 1.4 percent.

* Rabbit, squirrel and frog - assume 2000 grams per year.

A blood-to-kidney transfer factor of 11 percent (Wrenn, 1985) is assumed, with a 15-day half-time in the kidney. The amount of uranium in the kidney at equilibrium would then be as follows:

$$A_e = (f_1/\ln 2) \times (f_{21})\ (T_1) = (0.014/\ln 2) \times (0.11)(15)$$

$$= 0.033 \text{ or } 3.3 \text{ percent}$$

where: A_e = amount of uranium in the kidney at equilibrium

f_1 = fractional GI absorption from GI tract to blood

f_{21} = fractional transfer from blood to kidney

T_1 = half-time in kidney compartment

Using 0.6 ug/g as the limiting concentration (C_L) in the kidney (below the injury threshold, Wrenn, 1985), a safety factor(S) of 50(NAS-77) and kidney mass (m= 310 g), the limiting daily intake (I_L) would be derived as:

$$I_L = (C_L/S)(A_e/m) = (0.6/50)/(0.033/310)$$

$$= 110 \text{ ug per day}$$

If the measured concentration in the fish tissue is 1.0 pCi/g then the percent of the limiting daily intake would be calculated as:

$$I_L\% = \frac{(C) \times (CF) \times (A) \times 100\%}{I_L}$$

$$= \frac{(1.0 \text{ pCi/g})(0.677 \text{ ug/pCi})\ (11.2 \text{ g}) \times 100\%}{110 \text{ ug}}$$

$$= 7\%$$

where: C = Assumed concentration in fish tissue

CF = Conversion Factor for a mass of natural uranium to its activity

A = Amount of fish tissue ingested daily

I_L = Limiting Daily intake

Nitroaromatic Toxicity Effects

Available data pertaining to DNT and TNT exposure is limited at this time. Animal studies indicate significant species and strain differences in the excretion of DNT isomers. There is growing evidence from research that DNT's are carcinogenic, although the potency of the different isomers in cancer induction is not well characterized. The primary site for TNT toxicity is the blood system and liver. The most serious systemic effects of acute TNT poisoning in humans are toxic jaundice and toxic hepatitis.

The potency of DNT varies in studies, so to assure the protection of public health from carcinogenic effects, a 10^{-6} cancer risk level has been assumed by the EPA at the dosage of 6.4×10^{-7} mg/kg/day. Since studies have provided no evidence of TNT carcinogenicity, an Allowable Daily Intake (ADI) has been used for a no-observed-adverse-effect level at 1.4×10^{-3} mg/kg/day.

By comparing actual contaminant levels with these criteria, the actual risks incurred from ingestion of biota tissue containing these nitroaromatics could be estimated. The development of criteria is still based on a variety of conservative assumptions and safety factors so that no adverse health effects would be expected.

At the WSS, determinations regarding the levels of contamination in water are being reviewed and studied. Again, until the different TNT and DNT isomers are better characterized and the breakdown products in tissues reviewed for carcinogenic effects, contaminant levels in tissues along with the variety of assumptions and safety factors will make the criteria and an acceptable risk far lower than the present day detection limits for these nitroaromatics in tissues.

Discussion

If the biota sampling results in significant findings, routine collection and analysis may be added to the Environmental Monitoring Plan. The radiation dose calculated from edible parts of biota samples and measured data for water concentrations will be compared. The chemical toxicity and percent of Limiting Daily Intake from edible parts will be reviewed. The findings from this program will be summarized and interpreted in the Endangerment Assessment section of the RI/FS.

If measured offsite concentrations increase and conditions change significantly in future operations, the need may arise for additional studies. Sampling efforts at onsite locations with higher radionuclide concentrations may provide better estimates and determinations for outcomes of such releases.

The DOE radiation dose limit for an unrestricted area is 100 mrem/yr above background for whole body exposure. The DOE Administrative action level is 25 mrem/yr above background. A hypothetical individual consuming such biota from the vicinity of WSS would receive internal exposure via the food pathway and by ingestion of contaminated water. If calculations suggest the radiation dose to an individual is greater than 50 percent of the administrative action level, then biological sampling will be included in the Environmental Monitoring Plan based on radiological concerns.

An administrative action limit for chemical toxicity to uranium has not been developed. If calculations suggest the chemical toxicity to an individual is significant, then biological sampling will be included in the Environmental Monitoring Plan based on chemical toxicity concerns.

In the Appendix, Table A-1 lists the estimated costs for laboratory analysis of the samples. An increase in cost is due to a much lower limit of detection required in the analyses of radionuclides. The total number of man-hours required to

complete the sampling, mobilization of equipment, and sample preparation are estimated in Table A-2 in the Appendix. MDOC will be supplying equipment and personnel for the sampling on the Busch Wildlife Area, however, sampling on the WSS will require the use of Project equipment and materials. A list of the necessary equipment and materials needed for the entire sampling operation are listed in Table A-3 in the Appendix.

1.0 INTRODUCTION

This document presents the Field Sampling and Analysis Plan for the collection of sediments from lakes and streams influenced by drainage from the Weldon Spring Site. The plan describes the scope of activities to be performed by the Project Management Contractor (PMC) and its subcontractors during sediment collection and analysis.

Results of this study and any subsequent sediment investigations will be incorporated into the Site Characterization Report. In addition, the risks associated with any discovered contaminant deposition will be assessed as part of the Environmental Impact Statement.

1.1 Background

A survey of sediments near the Weldon Spring Site will be performed in 1988. Surface drainage from most of the combined Weldon Spring Chemical Plant (WSCP) and Weldon Spring Raffinate Pit (WSRP) areas flows in a northerly direction, toward Lakes 35 and 36 on the August A. Busch Memorial Wildlife Area (Busch Area) (Figure 1.1). The remaining surface drainage flows southward down a drainage easement to the Missouri River, through the Weldon Spring Wildlife Area (WSWA). The drainage easement also carried process and sanitary sewer outfall to the Missouri River.

The 7,000-acre Busch Area and 7,200-acre WSWA are managed by the Missouri Department of Conservation and are open throughout the year to the general public. Several of the intermittent streams draining portions of the WSCP/WSRP areas are losing streams. A portion of this drainage resurfaces at Burgermeister Spring which is upstream from Lake 34 on the Busch Area. Radiological activity above background was detected in the waters of these three lakes at levels ranging from 11 pCi/L to 36 pCi/L (DOE, 1986 Environmental Monitoring Report).

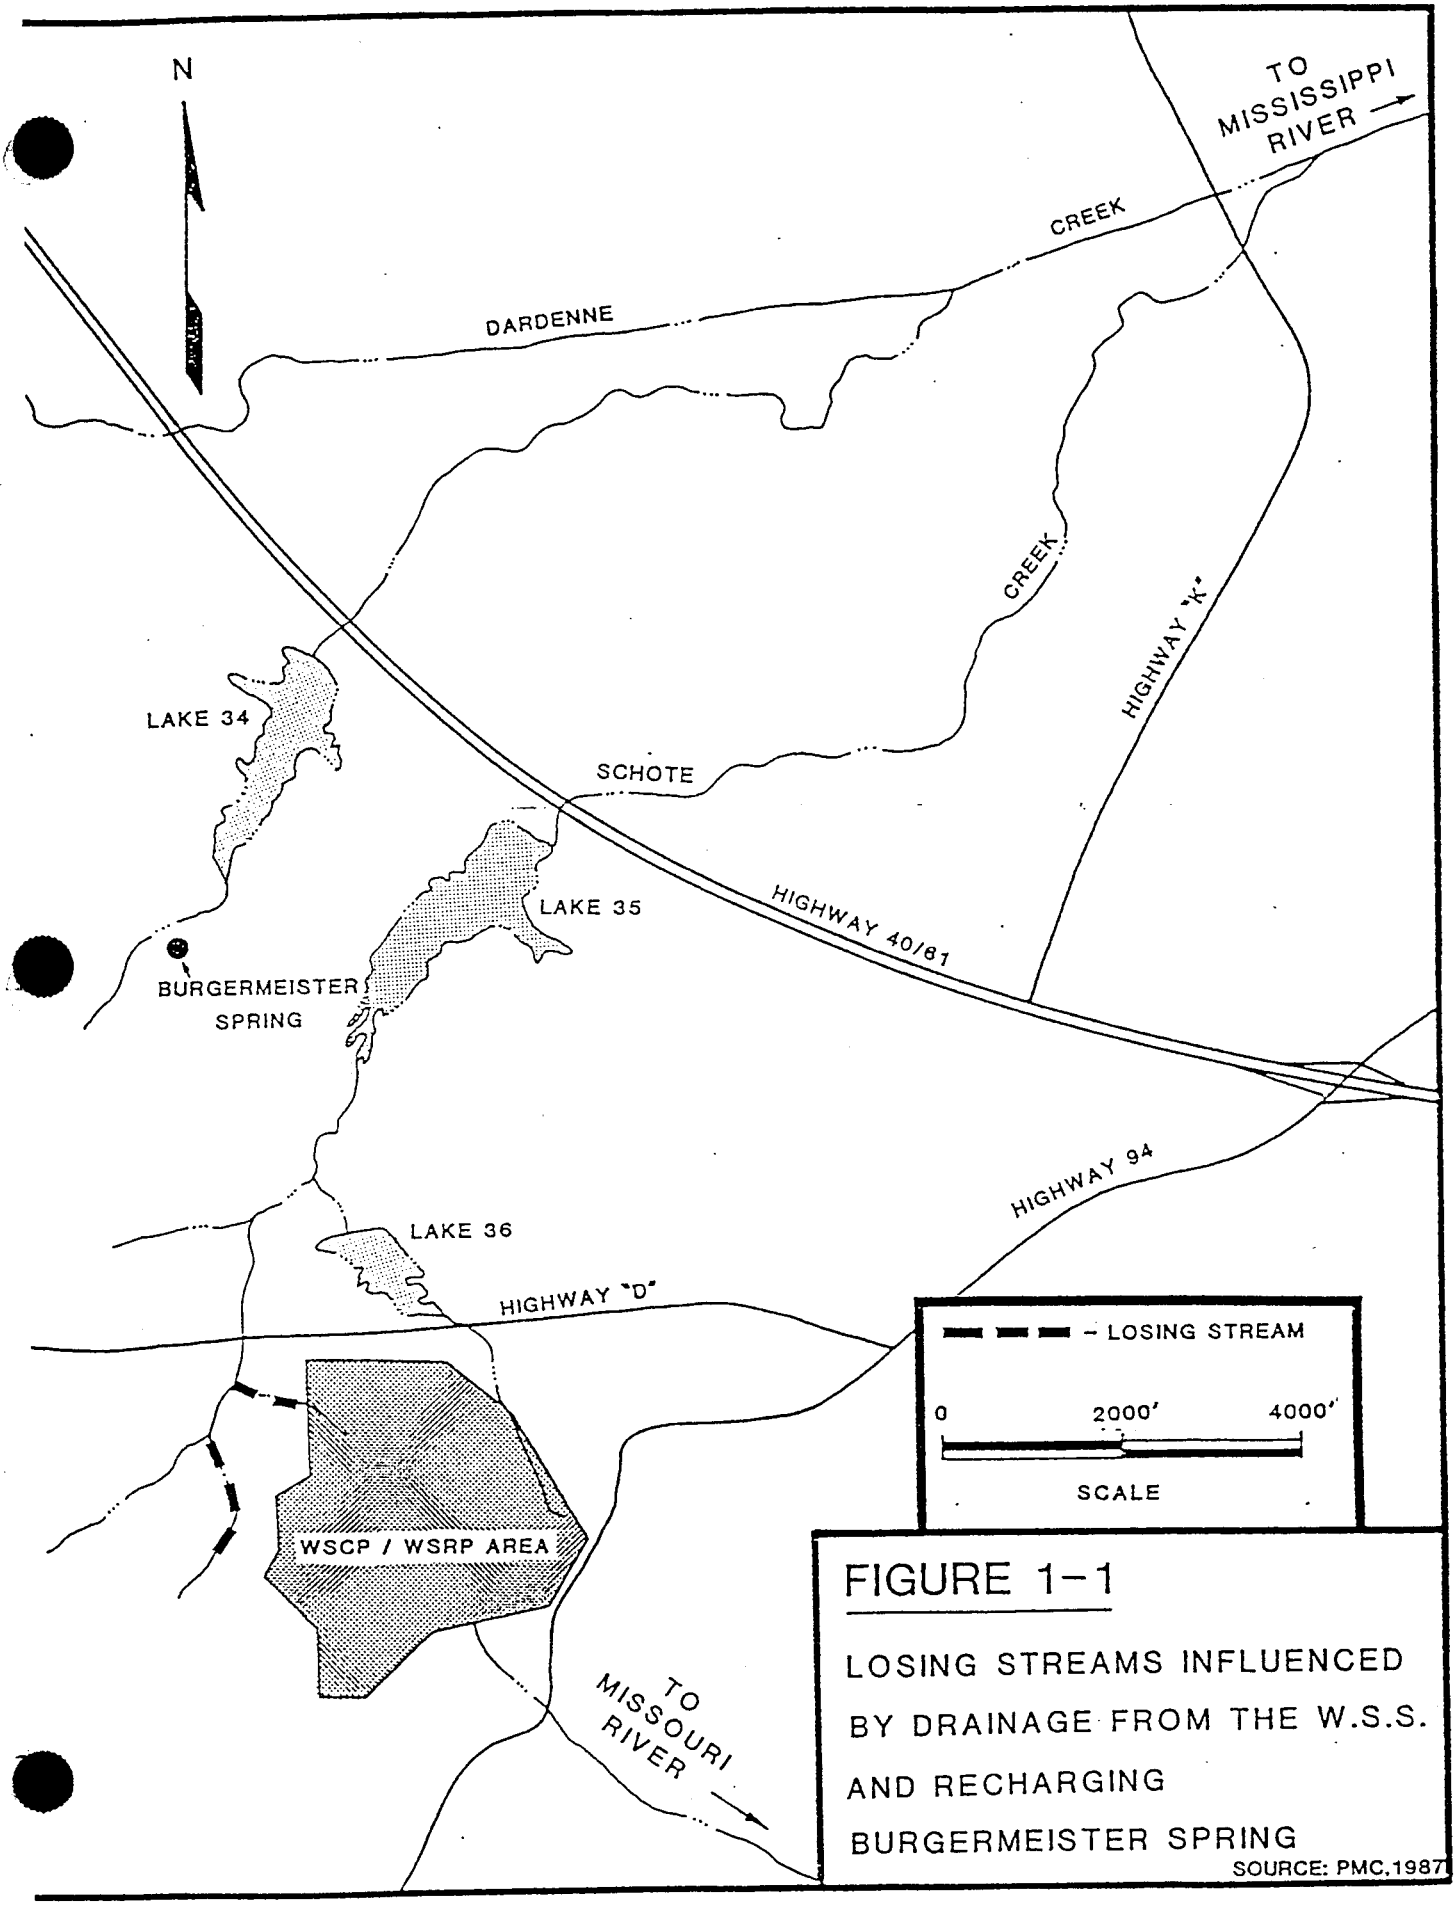

FIGURE 1-1

LOSING STREAMS INFLUENCED BY DRAINAGE FROM THE W.S.S. AND RECHARGING BURGERMEISTER SPRING

SOURCE: PMC,1987

In addition, limited lake and stream sediment sampling conducted in 1986 (ORAU: Radiological Survey of the August A. Busch and Weldon Spring Wildlife Areas.) and in 1978 (Rykman, Edgerly, Tomlinson and Associates: Phase III Report: Assessment of Deposition Alternatives) indicated uranium activity in several lake and stream sediment samples exceeding the remedial action guidelines of 60 pCi/g for U-238 and U-234 respectively. These data suggest that the underlying sediments in these lakes may require remedial action.

In addition, five sediment samples were collected in 1983 from Dardenne Creek by a local citizens group and analyzed for radiological parameters. While analyzed results of these samples technically indicated background levels, the report concludes that samples from downstream of the WSS exhibited higher activity than background. However, insufficient quality control analyses do not allow adequate assessment of the validity of the report's conclusion. In August of 1987, eight sediment samples were collected from the proposed NPDES storm water discharge points around the perimeter of the WSS. Samples were collected from the top 6 inches of sediment from each outfall. The data indicate above background levels of uranium, nitroaromatics and several semi-volatiles related to coal burning.

Nitroaromatics are also known to be present in the soil at the WSCP/WSRP area. Tributary and receiving streams from these areas as well as the drainage easement, also may be contaminated and require investigation. Lakes 35 and 36 drain into Schote Creek which joins Dardenne Creek just east of Highway K. Lake 34 flows directly into Dardenne Creek just west of Highway K. Dardenne Creek, in turn, flows north to the Mississippi River.

1.2 Objectives

The purpose of this activity is to determine the extent and magnitude of potential chemically and radiologically contaminated sediment under off-site streams and surface water bodies. This determination will be performed by the collection and analysis of a significant number of samples to limit uncertainty and achieve a proper level of confidence required to evaluate the no action and various remedial action alternatives. Limited analysis for PCB's, semi-volatiles and metals will also be performed to document any presence of these compounds in sediments compared to background.

The field sampling and analysis activities will comply with all applicable WSSRAP procedures including:

- Soil/Sediment Sampling
- Sample Number
- Chain of Custody
- Sample Packaging and Shipment
- Decontamination

1.3 Overview of Program

This sampling effort will determine the uranium activity and nitroaromatic, PCB's, semi-volatiles, and metals concentrations in lake and stream sediments influenced by the WSS drainage. Areas receiving direct runoff or subsurface recharge will be considered in this study. Based on data from the RETA report and knowledge of the types of materials processed during uranium refinement, radium-226, thorium-230, and thorium-232 activity levels exceeding DOE remedial action guidelines in these sediments are not expected. However, at least 30 percent of all sediment samples collected will be analyzed for these additional radiological parameters.

Stream sediments below the Busch Area Lakes (with the exception of 2 locations) will not be sampled for nitroaromatics, PCB's, semi-volatiles, or metals since contaminated sediment should have settled in the lakes. Since no documentation exists for chemical species in the lake sediments, a single composite sample from each of 3 six inch sediment intervals will be collected. These composites, coupled with results from upstream locations, should confirm the absence of these compounds.

Table 1.1 describes the area, the number of sampling stations, and estimated number of samples, and analysis to be performed on each sample. Samples will be collected from a total of 66 stations.

TABLE 1.1

SUMMARY OF PROPOSED LAKE & STREAM SEDIMENT SAMPLING PROGRAM[1]

AREA	NO. OF SAMPLING STATIONS	TOTAL NUMBER OF SAMPLES[2]	ANALYTICAL PARAMETERS
Lakes 34, 35, & 36	10 (per lake)	90	Uranium
		30	Nitroaromatics
		9	Radium & Thorium
		9 Composites	PCBs, Semi-volatiles, Metals
Lake 37	3	9	Uranium
		3	Nitroaromatics
		3	Radium & Thorium
		1 Composite	PCBs, Semi-Volatiles, Metals
Dardenne Creek & Peruque Creek	12	36	Uranium
		12	Radium & Thorium
Schote Creek	10	30	Uranium
		24	Nitroaromatics
		10	Radium & Thorium
		24	PCBs, Semi-volatiles, Metals
Burgermeister Spring, and Stream	5	15	Uranium

2.0 SAMPLING PROGRAM

Samples will be collected from several depth intervals at each location. Each interval will be a maximum of six inches thick, beginning with the 0 to 6 inch interval. A minimum of three depth intervals will be collected at each location, if sediments are 18 inches thick and recoverable. Samples will be collected by a subcontractor to the Project Management Contractor (PMC) using a PMC-approved method based on the criteria stated below. Sampling equipment will be thoroughly decontaminated between samples following EPA guidance documents.

After collection, the samples will be packaged and shipped to the subcontractor's laboratory for analysis. Field data shall be recorded on the Sediment Sampling Data Form (Figure 2-1) which records all relevant sample collection data, such as depth of sample, analytical parameters, location diagram, etc. Completed forms will be included in the final data report as an appendix.

The exact sampling methods and procedures will be supplied by the selected subcontractor for approval by the DOE before sampling commencement. In order to avoid limiting competition among potential subcontractors, exact methods have not been defined. However, in the Technical Instructions to potential bidders, EPA procedures, WSSRAP Standard Operating Procedures, and applicable guidance documents have been provided. Bidders have been instructed to propose sampling methods which will comply with both EPA and DOE requirements.

2.1 Sampling Locations

Sampling locations have been selected in both lakes and streams as described below. The rationale for sampling each location is presented in Table 2-1.

2.2 Stream Sampling Locations

Stream sediments will be collected at, or as near as possible to, the marked locations for each stream. Areas of sediment deposition will be sampled preferentially. Depth interval samples will be taken at stream locations to the extent possible, depending on sediment type and depositional environment. Samples from locations near highway crossings will be taken far enough upstream of the crossing to avoid influences from casual private dumping.

2.2.1 Schote Creek

Sediment samples will be collected from 10 locations (SD-4001 to SD-4010) shown on Figure 2-2.

2.2.2 Unnamed Tributary To Dardenne Creek

Five locations (SD-4011 to SD-4015) along the Burgermeister Spring stream will be sampled. The approximate locations are shown in Figure 2-2.

2.2.3 Dardenne Creek

Sediment samples will be collected from 11 locations (SD-4016 to SD-4026) along Dardenne Creek. An additional background sample (SD-4027) will be collected from Peruque Creek. These locations are shown in Figure 2-3.

TABLE 2-1

STREAM SEDIMENT REMEDIAL INVESTIGATIONS

LOCATION NO.	LOCATION DESCRIPTION	SAMPLING RATIONALE
*SD-4001	Inflow to Lake 36 - 100' north of Highway D	Assess sediment prior to entering lake
*SD-4002	Ash Pond drainage 100' west of DOE fence	Assess sediment in outfall stream
*SD-4003	Unnamed tributary to Schote Creek	Establish background conditions
*SD-4004	Unnamed tributary to Schote Creek just south of Army Reserve Training Area	Assess sediment entering Busch Area
*SD-4005	Schote Creek - 200' east of Ahden Knight Memorial Lake	Establish background conditions
*SD-4006	Lake 36 outfall stream north of gravel road	Assess sediment below lake
*SD-4007	Schote Creek - 600' above Lake 35	Assess sediment prior to entering Lake 35
*SD-4008	Schote Creek at Hwy 40-61	Assess sediment below Lake 35

2.2.4 Southeast Drainage Easement

Six locations (SD-4061 to SD-4066) along the drainage easement will be sampled. The locations are shown on Figure 2-4.

2.3 Lake Sampling Locations

Samples will be collected from 10 locations in each of the three affected lakes. Three background locations will be sampled in Lake 37 on the Busch Area. The approximate locations within the lakes are shown in Figures 2-5, 2-6, 2-7 and 2-8 for Lakes 34, 35, 36 and 37 respectively. At all locations, measurements of water depth and depth of sediment will be recorded on the Sediment Sampling Data Form (Figure 2-1) during sample collection. All samples will be analyzed for natural uranium. At least three samples per lake will be analyzed for radium-226 and thorium-230. One-third of all lake sediment samples will be analyzed for nitroaromatics. Three composite samples will be prepared from Lake 34, 35 and 36 respectively. One composite sample will be prepared from Lake 37. Each composite will be prepared by combining sediments from three to four sampling locations and sediments from the same sampling interval (i.e. 0-6", 6-12" etc.) Each composite will be analyzed for PCB's, semi-volatiles and metals.

3.0 ANALYTICAL PROCEDURES

Samples will be analyzed as described in Table 1.1. Metals and semi-volatiles analyses will be performed using methodology, chain of custody, and detection limits required in the USEPA Contract Laboratory Program Statement of Work. Nitroaromatic analyses will be performed according to USATHAMA methodology. Radiologic parameters will be determined following the methods and meeting the minimum detection and accuracy limits shown in Table 3-1.

4.0 QUALITY ASSURANCE

The integrity of all sediment samples shall be maintained in accordance with WSSRAP ES&H Standard Operating Procedure No. 4.01.02 (Chain of Custody). A minimum of 5 percent of the total number of samples shall be duplicates to assess analytical precision.

5.0 DATA DOCUMENTATION

Proper documentation is a fundamental element for quality assurance of this program. All sampling activities including sampling location, identification, sampling techniques and methods, decontamination procedures, and shipment of samples will be extensively documented in the field on a daily basis.

5.1 Sample Collection

Prior to sample collection, the sample location will be checked to verify that the sampling ID code used corresponds to the sampling plan station. For each sample collected, a Sediment Sampling Data Form will be completed. The data form (Figure 2.1) includes the name(s) of the person(s) collecting the sample, the time of collection, the mechanism for sampling, depth of sample, location, and discription of the sample. Sample numbering will be as defined in ES&H WSSRAP SOP 4.01.01 (Environmental Numbering System).

5.2 Chain of Custody

Custody of Samples will be maintained and documented from the time of collection to completion of analysis and reporting of data. Chain of Custody procedures are specified in the ES&H WSSRAP Standard Operating Procedure 4.01.02 (Chain of Custody).

5.3 Field Notebook

All field sampling activities will be documented through written entries into a field notebook. Field activities will be logged in on a daily and event-oriented basis.

Entries will be as detailed as possible so that, at a later date, the reader could reconstruct each event without reliance on the

memories of the field team members.

All field notebooks will be hardbound with numbered pages. Responsibility for note-taking will be assigned to specific field team personnel. Each notebook will be identified by the project-specific information recorded on the front cover:

Project Name:	WSSRAP Lake/Stream Sediment Characterization
Start Date:	
End Date:	
Responsibility:	Name of person to whom the notebook is assigned.

Entries into the notebook will contain a variety of information. At the beginning of each entry, the date, start time, weather, all field personnel present, level of personal protection being used onsite, and the signature of the person making the entry will be entered. The names of property owners approached for access, agency personnel present, and all field sampling team personnel will be recorded in the field notebook.

All measurements made and samples collected will be recorded. All entries will be made in waterproof ink and no erasures will be allowed. If an incorrect entry is made, the information will be crossed out with a single strike mark. Wherever a sample is collected or a measurement is made, a detailed description of the location of the station, which includes compass and distance measurements, shall be recorded. The film roll number and number of photographs taken of the station will also be noted. All equipment used to make measurements will be identified, along with the date of calibration.

5.4 Photographs

Photographs will be taken of each sampling location at the time

of sampling (except lake locations). These photographs will document the position of each location in relation to local surroundings and prominent reference points. Photographs will be taken of groups of soil sampling locations where each location is clearly visible. The frame, roll number and compass heading (e.g., N, NE, NW, etc.) of each picture will be logged into the field sampling notebook along with the other site location information.

In addition to documenting each sampling location with photographs a photographic record also will made of the sediment collected at each location. A reference (such as a ruler) and identification label will be used to identify the sample, depth and physical description of the interval sampled.

6.0 REPORTING REQUIREMENTS

After the analytical results are received from the laboratory, a data report will be prepared to present the findings from this study and to interpret the data. This report will show actual sampling locations, sampling method, field data, and analytical results. It will also be used to make recommendations regarding further sampling and/or continued monitoring. This report will provide information from which a decision can be made regarding the necessity for cleanup of sediment in these surface water bodies.

1.0 INTRODUCTION

1.1 Purpose

The purpose of this Chemical Soil Investigation Sampling Plan is to provide a systematic approach for chemically characterizing soils at the Weldon Spring Chemical Plant/Raffinate Pits (WSCP/WSRP) areas in support of the overall Site Characterization Plan. The Chemical Soil Investigation Sampling Plan is designed to determine the extent and magnitude of chemically contaminated soil, evaluate contaminant migration pathways, document uncontaminated areas, and identify soil contaminant concentrations in qualitative and quantitative terms.

1.2 Scope

This sampling plan reviews historical information, identifies data needs and uses, and outlines sampling and analytical procedures, quality assurance methods, and data documentation and reporting requirements for soil investigations at the Weldon Spring Site (WSS).

The scope of this sampling plan is limited to the chemical characterization of soil contaminants in the 220-acre area of the WSCP/WSRP. The Weldon Spring Quarry (WSQ) and vicinity properties will be addressed as Interim Response Actions (IRAs) and are not included under this plan. This plan is not intended

to provide a vadose zone characterization or geotechnical information. Radiological soils characterization was completed in 1987, the conclusions of which are summarized in this sampling plan.

The area in and under the raffinate pits is not addressed in this sampling plan. The raffinate pit wastes will be characterized under the Waste Sampling Plan - Raffinate Pits. Any characterization of soil underlying the raffinate pits will be performed following waste removal to avoid risk of leakage from the WSRP. All waste material will be excavated to meet applicable guidelines and standards determined in the Baseline Risk Assessment. The need for chemical characterization of soils underlying the pits will be evaluated upon completion of soils data interpretation.

The need for chemical characterization of soils underlying existing buildings and along process sewer lines will be evaluated based on the results of this investigation. Any required characterization will be performed following removal of buildings and process sewers.

2.0 BACKGROUND

2.1 Site Description

The WSCP/WSRP is located in St. Charles County, Missouri, approximately 30 miles west of St. Louis and 14 miles southwest of St. Charles as shown in Figure 2-1. The site is situated on Missouri State Highway 94, about two miles southwest of the junction of Highway 94 and U.S. Routes 40 and 61. The WSCP/WSRP is surrounded by state and federally owned lands. It is adjoined on the west by the Weldon Spring Training Area (WSTA) and on the east, north and south by Missouri Department of Conservation (DOC) lands.

The communities of Weldon Spring and Weldon Spring Heights are located approximately two miles from WSCP/WSRP with a combined population of 200. A significantly larger population within close proximity of WSCP/WSRP includes the St. Louis metropolitan area with a population exceeding 2.5 million, and St. Charles with a population of over 36,000.

The geology of the area is predominantly clayey and silty soils overlying weathered limestone bedrock. The limestone bedrock contains solution-enlarged joints and fractures. In general, groundwater movement in the area is toward the north.

The best aquifer for potable water is the St. Peter Sandstone,

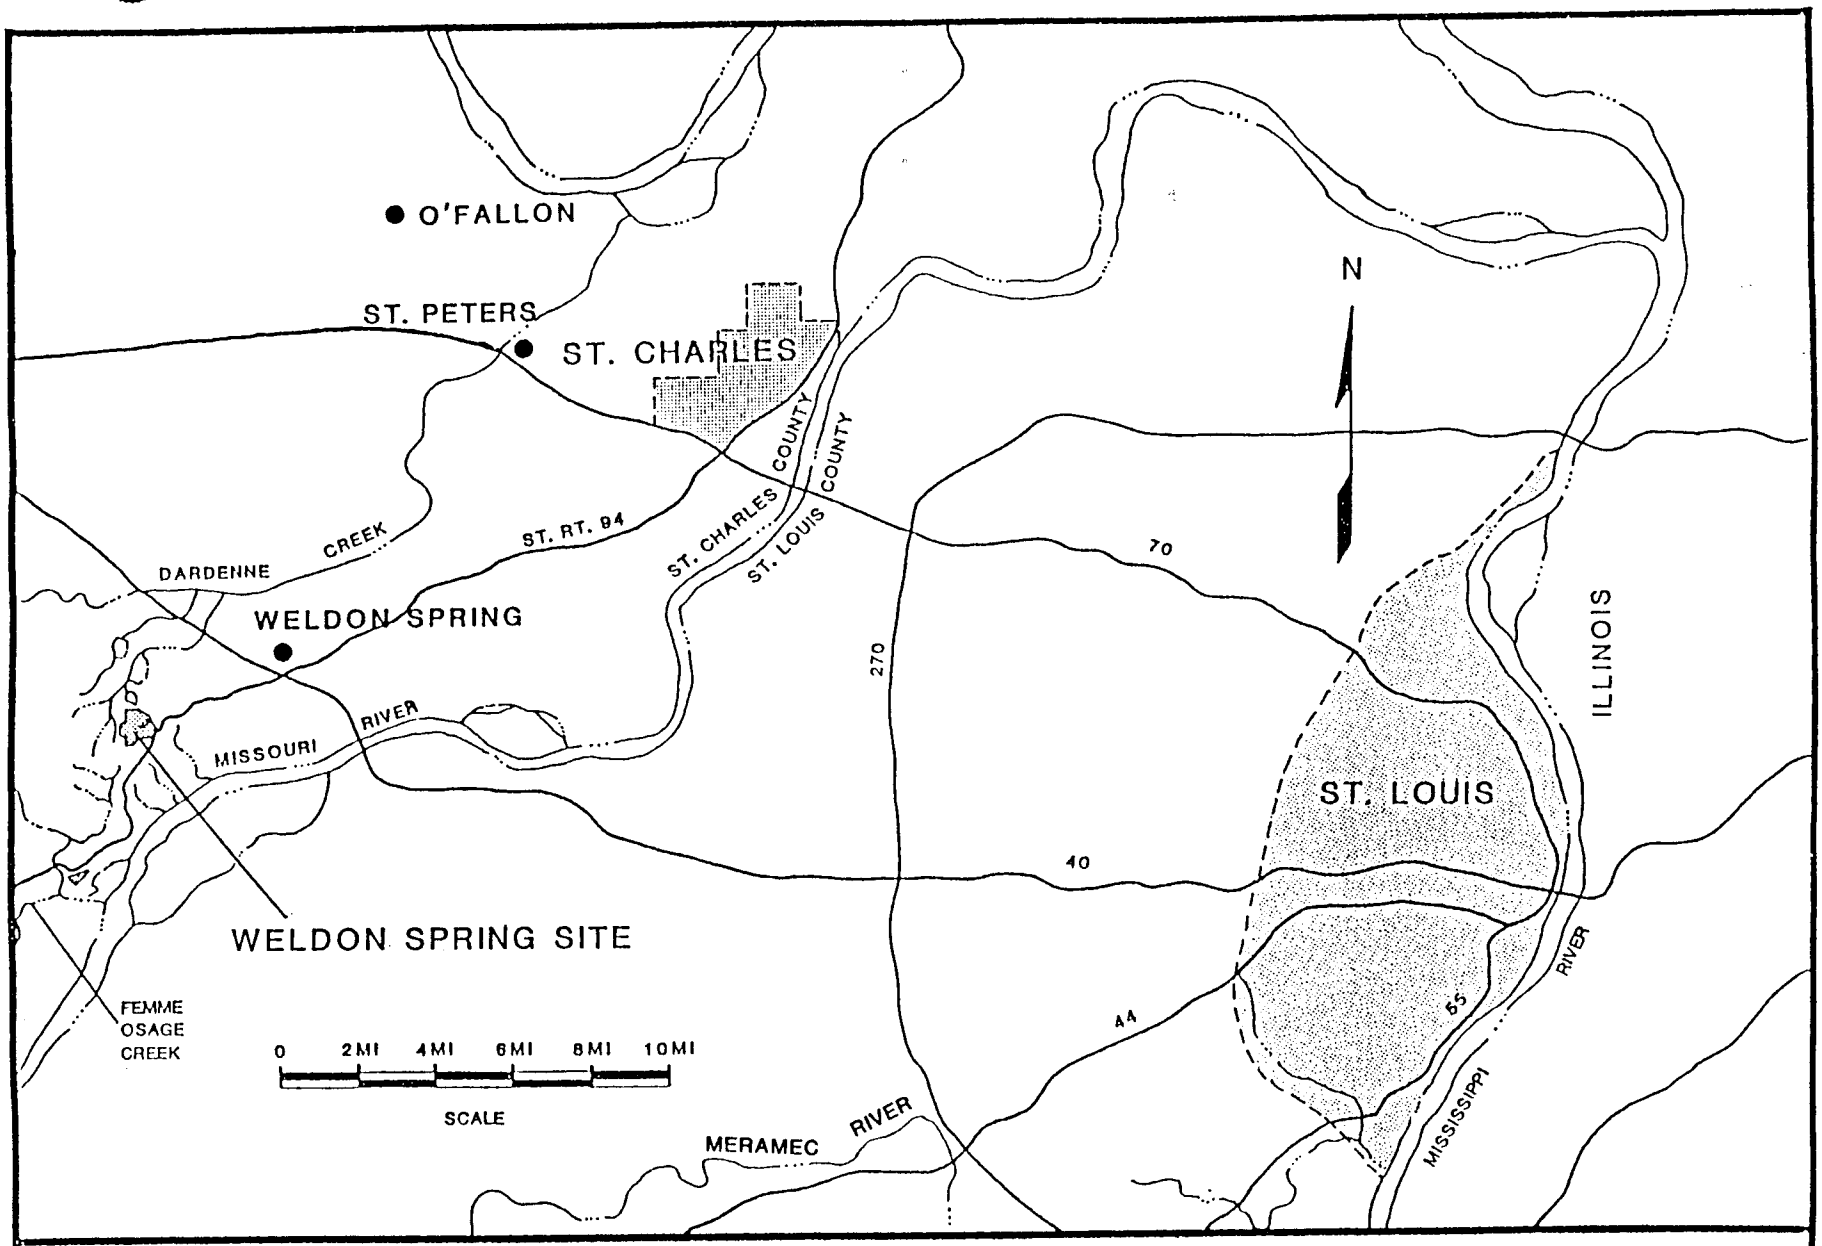

FIGURE 2-1

LOCATION OF THE WELDON SPRING SITE

approximately 600 feet below the surface at WSCP/WSRP. Two other aquifers of significance are the Burlington-Keokuk, about 200 feet thick and 60 feet below the surface, and the Sulfur Springs (Bushberg Sandstone), about 50 feet thick and 400 feet below the surface.

2.2 Site History

The site history, including previous decontamination efforts from 1941 to 1987 is summarized below. A more detailed history of WSS operations is included in Sections 2.2.1 - 2.2.4.

In April of 1941, the Department of the Army (DA) acquired 17,232 acres of land, and from November 1941 through January 1944, Atlas Powder Company operated a trinitrotoluene (TNT) and dinitrotoluene (DNT) explosives production facility known as the Weldon Spring Ordnance Works (WSOW). The 17,232-acre WSOW was closed and declared surplus to Army needs in April 1946. By 1949, all but approximately 2,000 acres had been transferred to the State of Missouri (August A. Busch Memorial Wildlife Area) and the University of Missouri (agricultural land). Except for several small parcels transferred to St. Charles County, the remaining property became the Weldon Spring U.S. Army Reserve and National Guard Training Area (WSTA).

Through a Memorandum of Understanding between the Secretary of the Army and the General Manager for the Atomic Energy Commission

(AEC) in May 1955, 205 acres of the former WSOW were transferred to the AEC for construction and operation of the Weldon Spring Uranium Feed Materials Plant (WSUFMP) to process uranium and thorium ore concentrates. Considerable explosives decontamination was performed by Atlas Powder and the DA prior to WSUFMP construction (DA, 1976).

The WSUFMP processed uranium and thorium ore concentrates from 1957 to 1966 with Mallinckrodt Chemical Works - Uranium Division as the AEC Operating Contractor. This facility consisted of 13 major process buildings and approximately 30 support structures as shown in Figure 2-2. The AEC closed the WSUFMP in December of 1966 when the facility was determined to be in excess of their needs.

On August 7, 1967, the AEC facility was selected as the site for a herbicide production facility, later known as the Weldon Spring Chemical Plant (WSCP). The Army was granted a license from the Nuclear Regulatory Commission (NRC) for the source material that was present as contamination throughout the site. On December 31, 1967, 169 acres of property and improvements were transferred to the Kansas City District-U.S. Corps of Engineers, which was responsible for the design and construction of the herbicide facility. The 52-acre WSRP and the WSQ remained under AEC control.

Decontamination and dismantling operations were initiated in

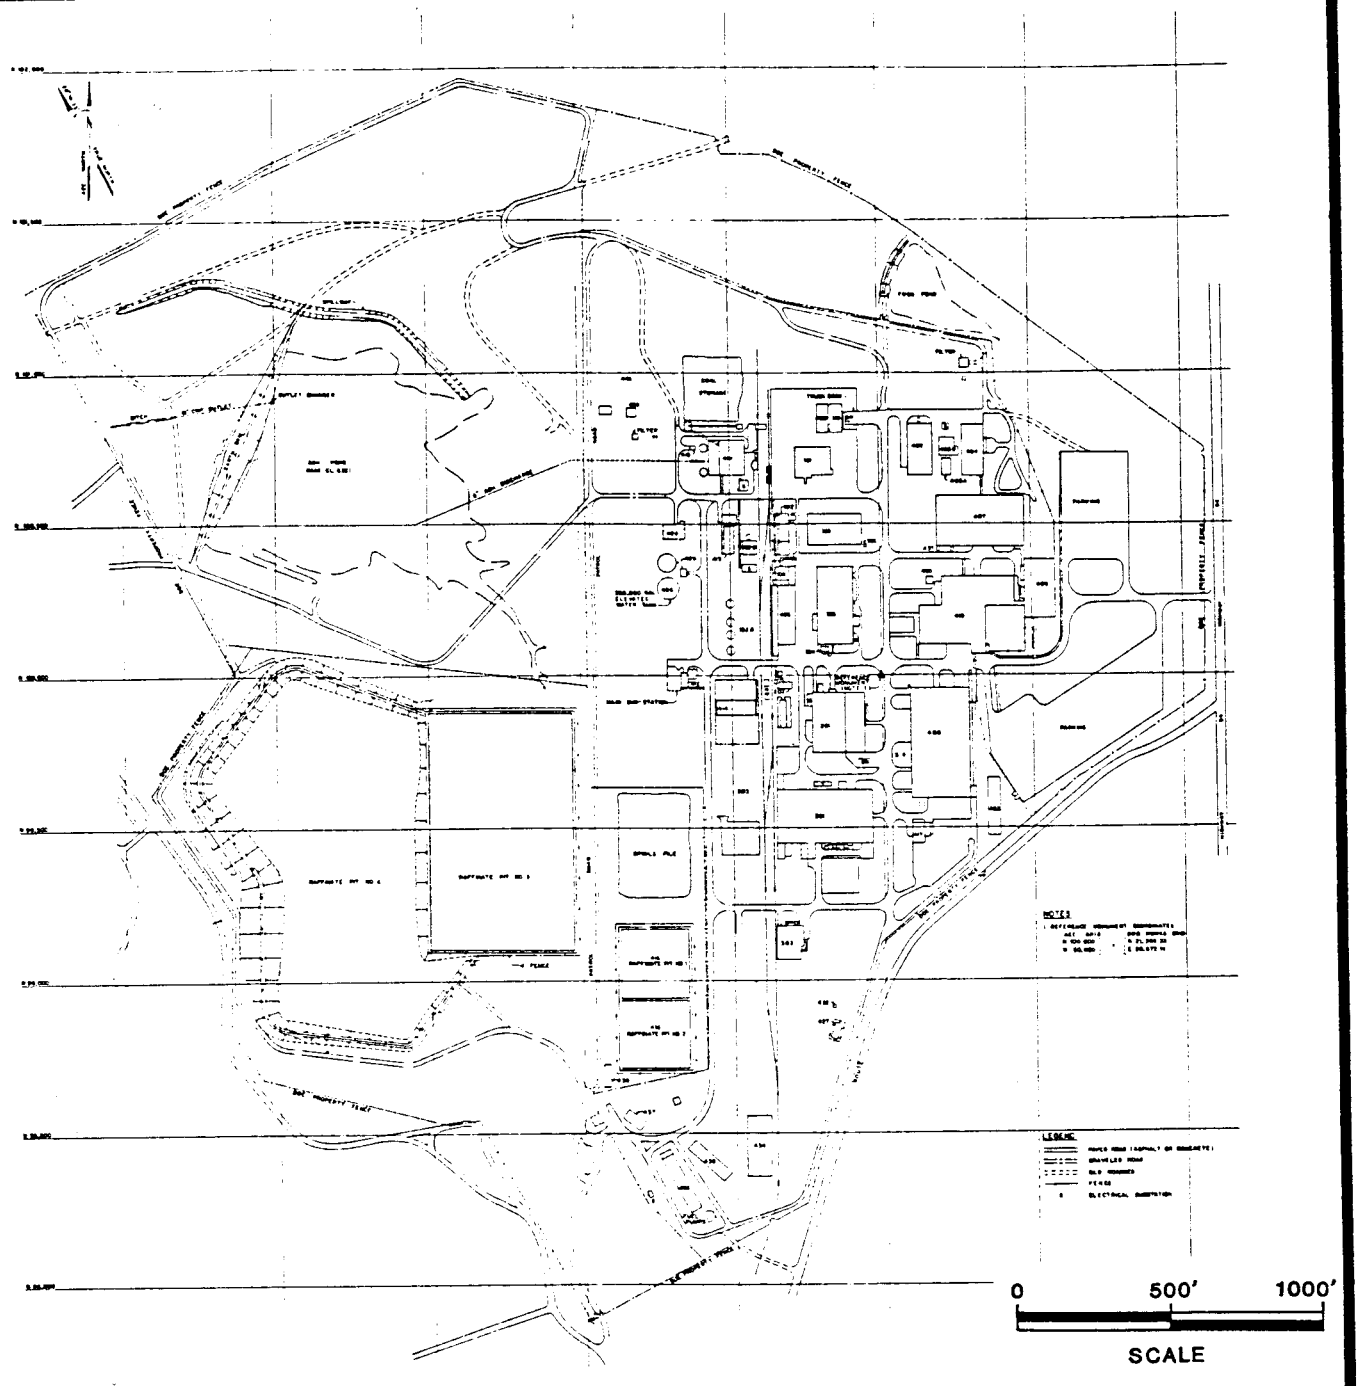

FIGURE 2-2

WSCP / WSRP

January 1968, by Thompson-Stearns-Roger Corporation (TSR), the Army's prime contractor for design and construction of the herbicide facility. Although some progress was made in decontaminating areas required for herbicide production equipment, the project was cancelled in February 1969 due to costs required to meet radiological contamination limits imposed on the facility and to the reduction of the military's requirements for herbicide.

The herbicide project was cancelled before any process equipment was installed for production. The DA retained the responsibility for the land and facilities at the WSCP.

The AEC contracted with National Lead Company of Ohio (NLO) to periodically visit the WSRP to perform environmental monitoring, maintain the pit embankments, and perform maintenance and surveillance tasks as necessary. In October 1981, Bechtel National, Incorporated (BNI), under contract to DOE (successor to AEC), assumed management responsibility for the WSRP and WSQ from NLO.

In November 1984, the DOE was directed by the Office of Management and Budget to assume custody and accountability for the WSCP from the DA. This transfer occurred on October 1, 1985.

In February 1985, DOE proposed designating the control and decontamination of the WSRP, WSCP, and WSQ as a major project.

Designation was effected by DOE Order 4240.1E dated May 14, 1985. A Project Management Contractor (PMC) for the Weldon Spring Site Remedial Action Project (WSSRAP) was selected in February 1986. In July 1986, a DOE Project Office was established on site. The PMC, MK-Ferguson Company, assumed control of the WSS on October 1, 1986.

2.2.1 Weldon Spring Ordnance Works: 1941-1949

The Atlas Powder Company operated the WSOW from November 1941 through January 1944. The complex consisted of 18 TNT and two DNT explosives manufacturing plants which were built within the borders of what is now the WSCP and WSTA. Figures 2-3 and 2-4 display the original WSOW layout and the current ownership, respectively. The first three TNT plants, and a portion of a fourth were built on what is now the WSCP/WSRP. Plate 1, bound at the back of this report, shows the locations of the TNT plants, roads, and process lines relative to the current WSCP/WSRP location.

At peak operation, the WSOW required 48 to 50 million gallons of water per day. In addition to the great quantities of water used for washing and mixing the chemicals, the process of manufacturing TNT and DNT also requires large quantities of nitric and sulfuric acids, and a chemical solution called sellite (sodium sulfite). The huge volume of wastewater generated at the WSOW caused the surface waters to become

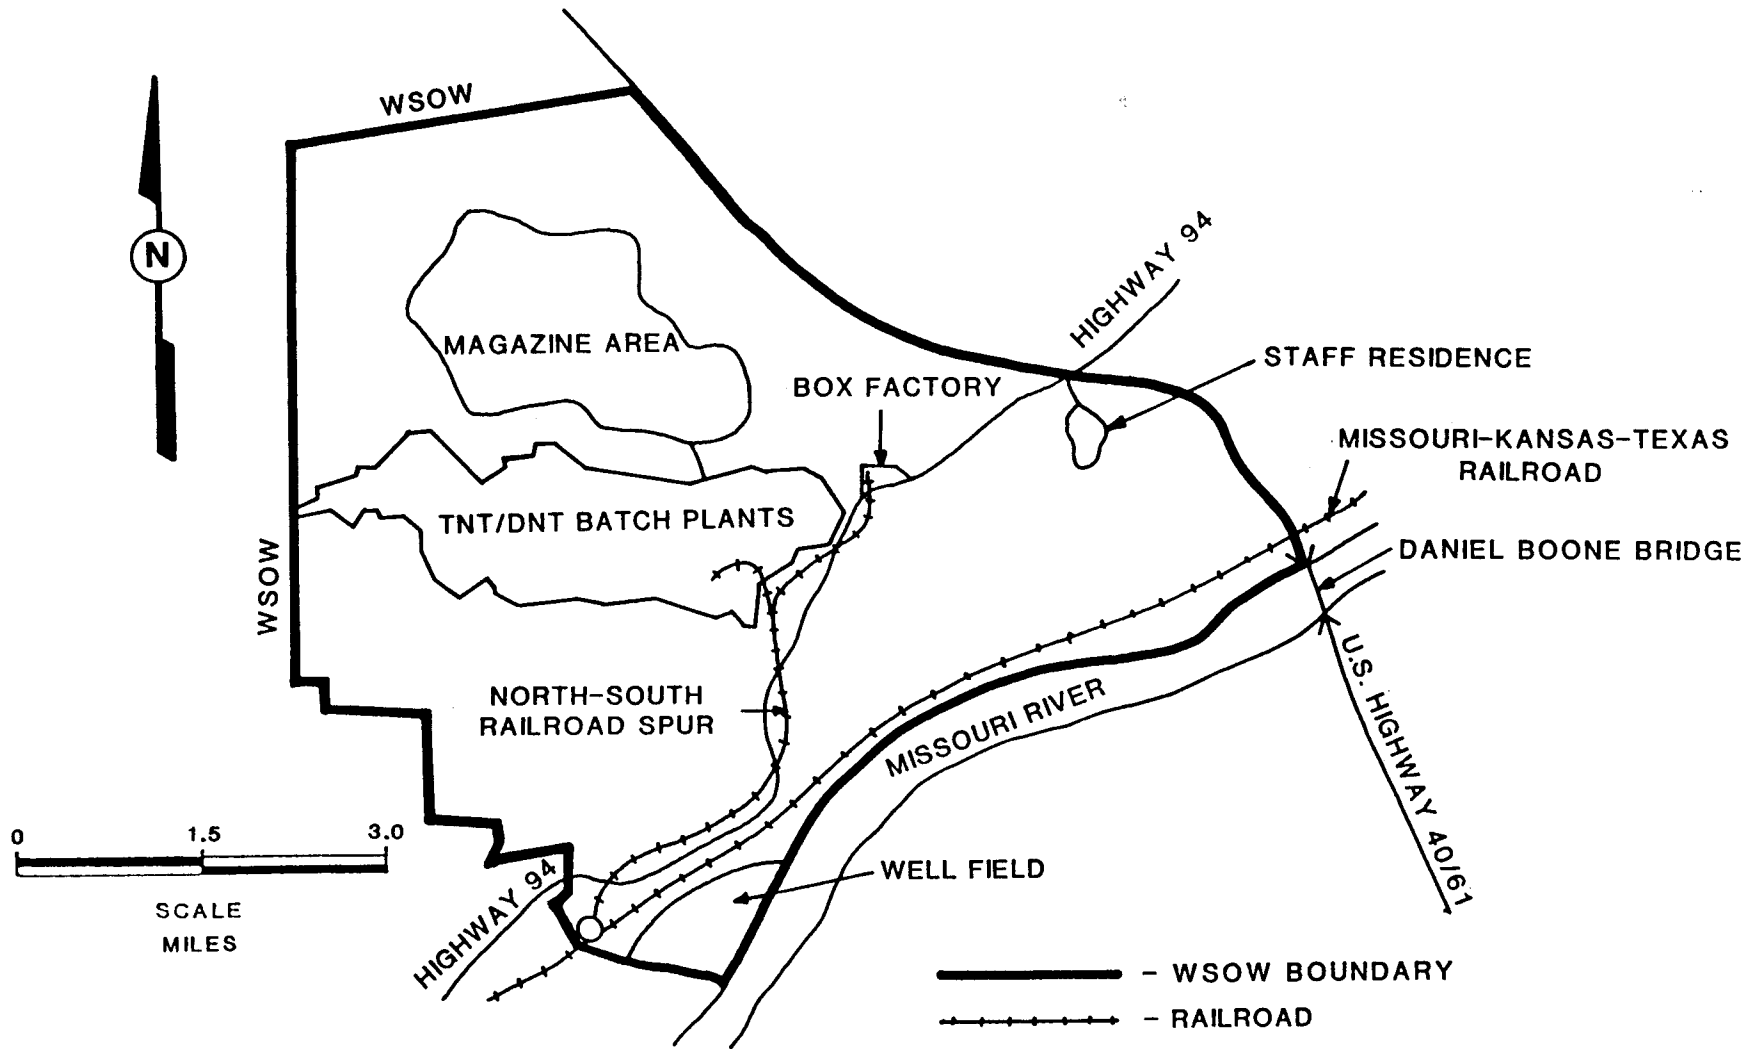

FIGURE 2-3

ORIGINAL WSOW LAYOUT

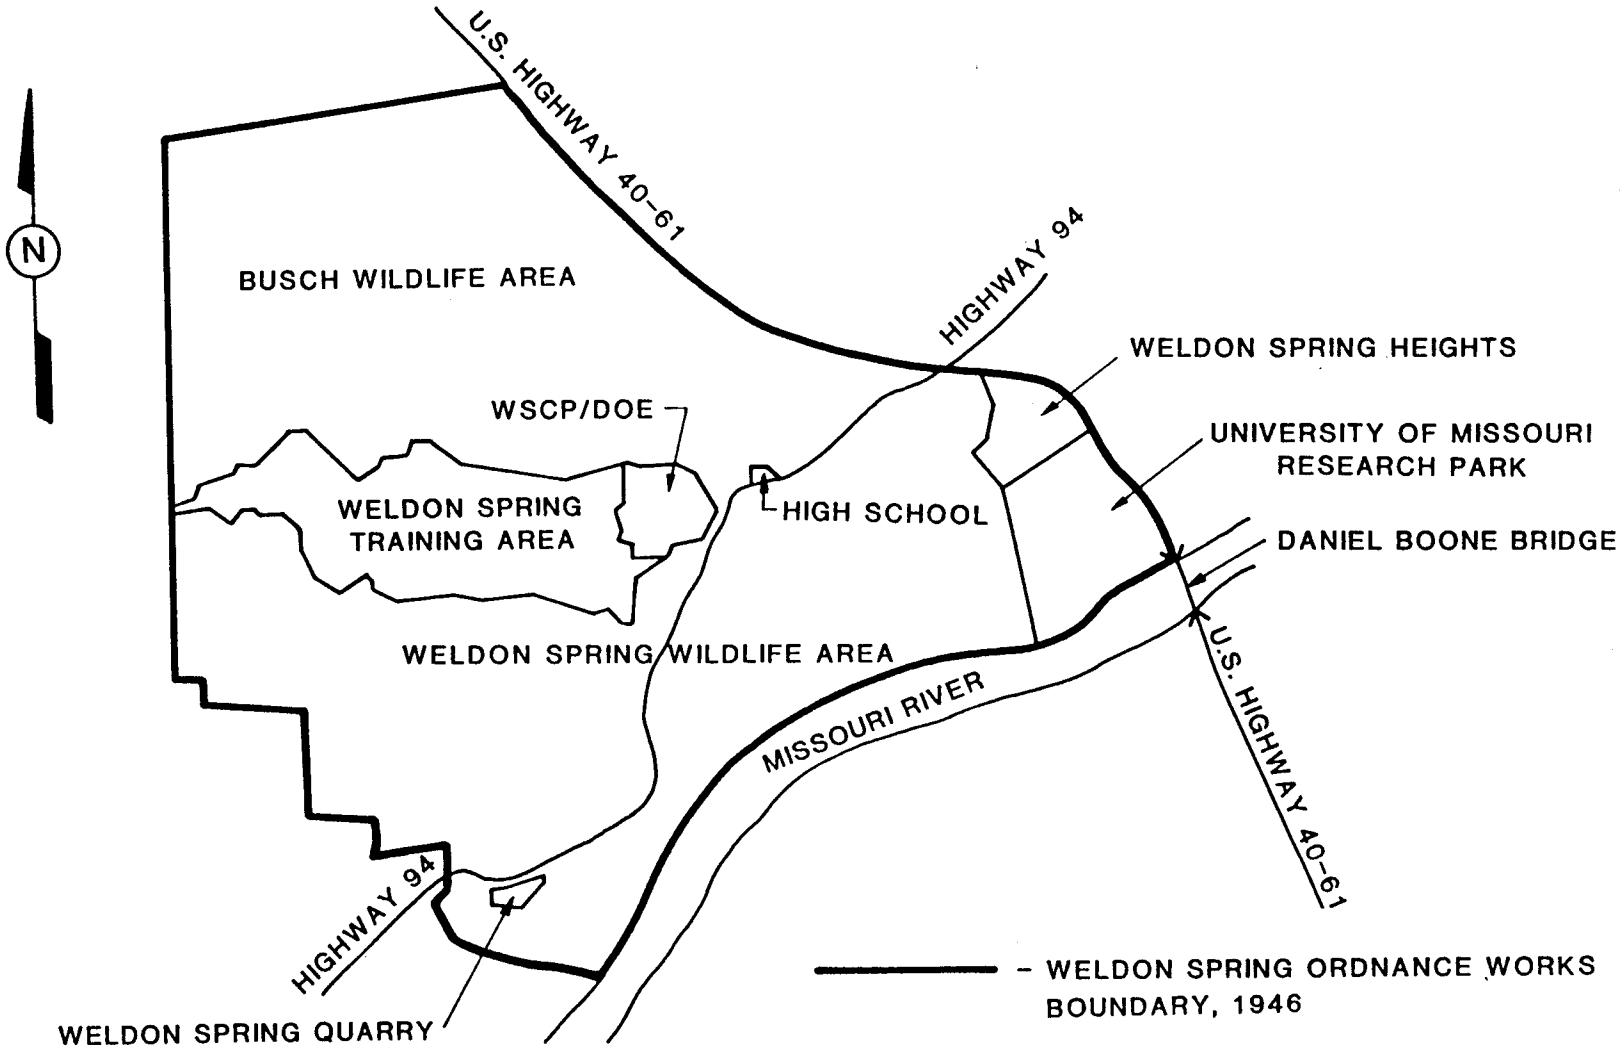

FIGURE 2-4

CURRENT DISPOSITION OF WSOW PROPERTY

polluted with TNT and DNT. Prior to construction of wastewater treatment plants in 1943, wastewater was discharged into seven lagoons for temporary storage. In December 1943, the Army drained and earth-filled four lagoons. The remaining three were drained but not filled at this time (USGS, 1944).

Water and wastewater lines served each batch plant. Separate wastewater lines were used for chemical waste and for sewage. The chemical wastewater lines carried red and yellow wastewater from each batch plant to various locations where the lines terminated. An estimated 66,000 linear feet of wooden wastewater lines were laid at the WSOW. The pipelines were generally made of cypress wood constructed similar to barrels with metal bands for support and were 10 feet or less in length. The lines discharged into wastewater treatment plants used to collect wastes for land disposal.

At the request of the War Department, the USGS conducted an investigation of groundwater and surface water contamination from TNT and DNT waste products. The contamination source was originally believed to be waste lagoons constructed to store wastewater. Subsequent field observations by the USGS revealed that wastewater was also discharged into ditches and streams, and that wastewater lines and catchment tanks frequently overflowed. A 1944 report by Fishel & Williams titled "The Contamination of Ground and Surface Waters by Liquid Wastes from the Weldon Spring Ordnance Works, Missouri," indicates a potential for soil

contamination along wastewater lines, in surface drainages, near production areas, at waste lagoons and wastewater catchment tanks.

The wastewater treatment plants were used to evaporate the wastewater into a sludge. The sludge was then hauled to open burning grounds for incineration. Eight burning grounds were used at WSOW. Seven of these areas are located off of the WSCP. One area, number five of the original eight, is thought to be located within the WSCP area and is shown in Figure 2-5. The WSOW temporarily ceased operations in January 1944, for approximately six months; then the DA reactivated it and operated it until the end of World War II.

Under the reactivation program at the WSOW, equipment in line No. 18 was cannibalized for use in other lines. Lines No. 2 and No. 3 were reassembled, but were never placed in operation. In addition, the WSOW produced a new type of TNT under the reactivation program. In January 1946, an Ordnance Review Board (ORB) was created to determine the disposition of contaminated buildings and equipment at various ordnance plants. In April 1946, the ORB declared the WSOW surplus property and transferred it to the War Assets Administration (WAA) on September 1, 1946. The WAA was organized to dispose of surplus U.S. government property.

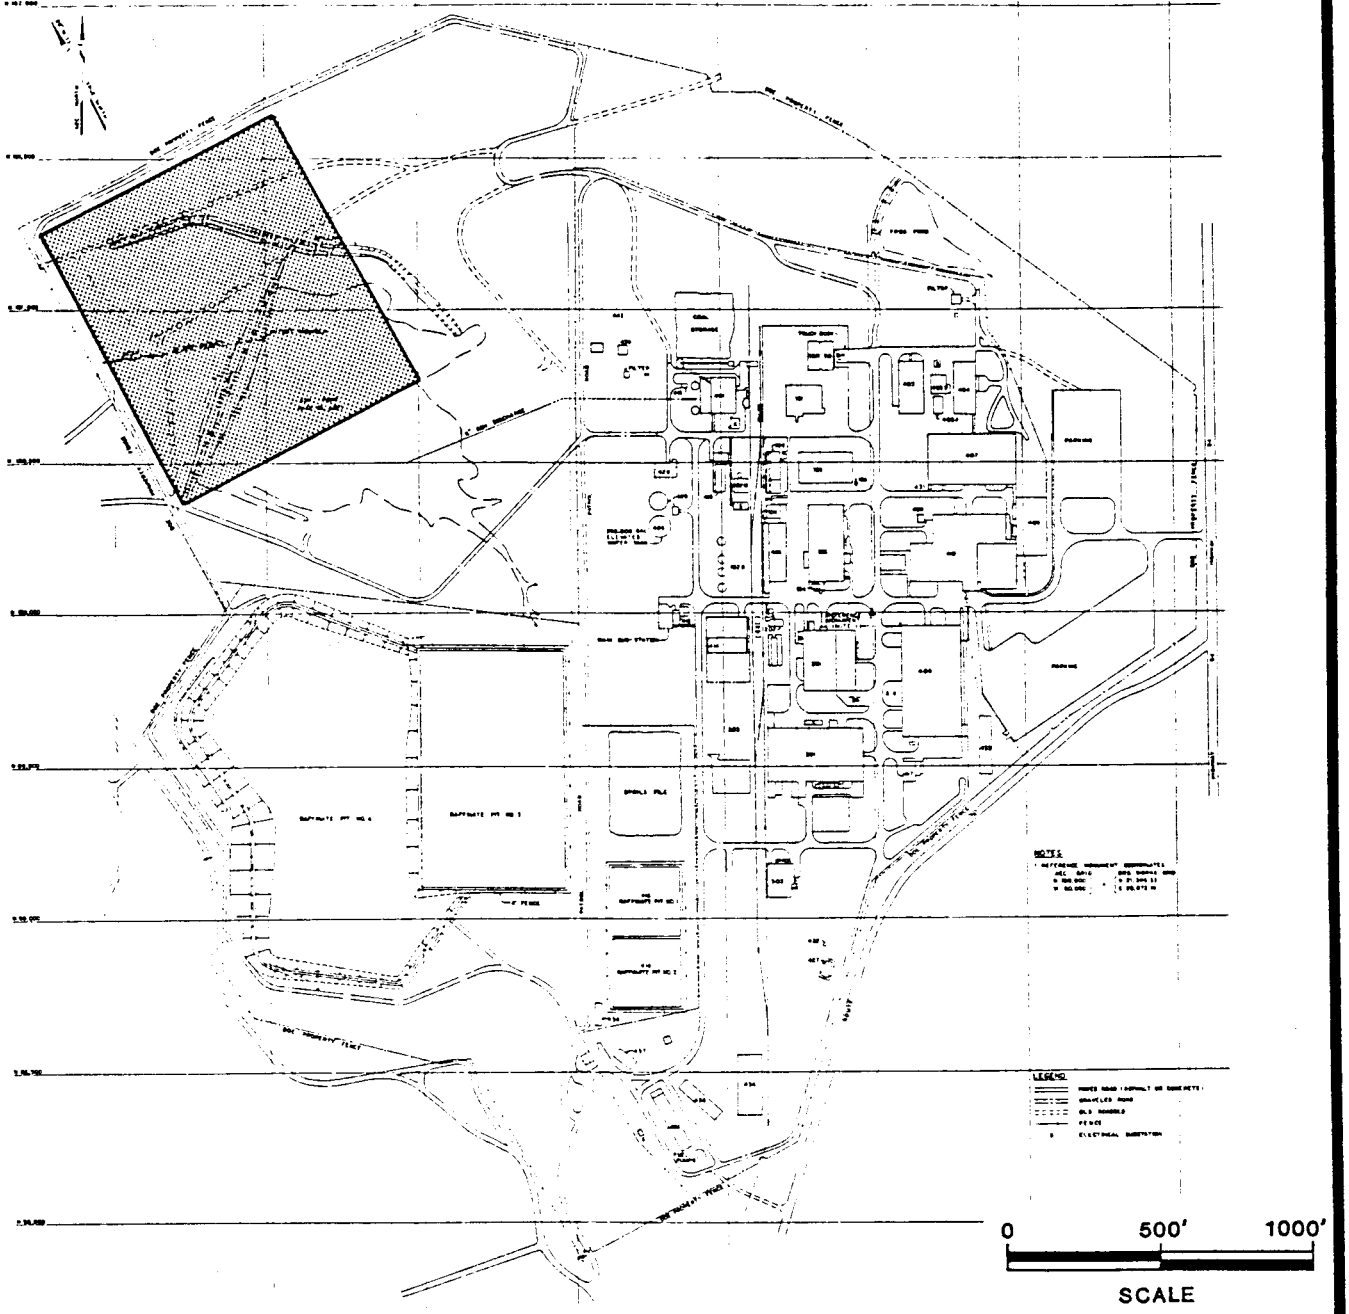

FIGURE 2-5

BURNING GROUND AREA

The first effort to decontaminate the WSOW was made by Atlas Powder Company in 1946. Atlas presumably decontaminated all equipment in accordance with accepted standards for stand-by service. In the fall of 1946, however, several fatalities occurred as a result of using improperly decontaminated equipment. Therefore, the ORB recommended that any processing equipment in direct contact with TNT, DNT or their intermediates be considered hazardously contaminated. In addition, the Board recommended removal of all earth known to be contaminated around processing buildings, catch tanks and similar areas. In 1946, following these recommendations, the Kansas City District of the Army Corps of Engineers removed 3,512 cubic yards of earth, burned 113,005 pounds of hand-picked TNT and 40 tons of TNT and other residues in place. It is not known if the Corps deposited this earth in the magazine area, the quarry, the burning grounds or somewhere else. In addition, many buildings were burned or otherwise destroyed. At the conclusion of this decontamination effort, the Corps published a report entitled: "Survey Covering Salvageable Equipment and Buildings in TNT Area at Weldon Spring Ordnance Works," Kansas City District Corps of Engineers, December 7, 1946 (USATHAMA, 1977). Of the more than 800 buildings comprising the WSOW, the Corps burned or demolished approximately 200 buildings. These 200 buildings were considered contaminated with explosives. It has been discovered much later that many of the 800 buildings at the WSOW contained asbestos insulation. This suggests the possibility of asbestos contamination in the remains of destroyed buildings.

2.2.2 Land Transfers: 1949-1954

In 1949, much of the original WSOW was sold to the public. The University of Missouri received approximately 8,000 acres for agricultural use (southern half of the WSOW). Subsequently, this land was purchased by the Missouri Department of Conservation (DOC)--the present owners. The DOC received about 7,000 acres and created the August A. Busch Memorial Wildlife Area (Busch Area- northern half of WSOW). St. Charles County Public Schools received about 40 acres, where Francis Howell High School now stands. The WAA was the grantor in all these transactions. In 1950, the General Services Administration (GSA), as successors of the WAA, took custodial control of the remaining 2,000 acres at Weldon Spring. The GSA conducted a renovation project to restore some buildings and equipment.

The GSA transferred the remaining 2,000 acres of WSOW land to the DA in July 1954, as part of the National Industrial Plant Reserve.

2.2.3 Uranium Feed Materials Plant: 1954-1966

In 1954, the Atomic Energy Commission (AEC) expressed an interest in using the area for the Weldon Spring Uranium Feed Materials Plant (WSUFMP). The Army agreed to transfer 205 acres to the AEC in 1955. Prior to transfer, decontamination operations were performed. These operations were limited to decontaminating only the 205-acre area transferred to the AEC. As a result of this

decontamination operation, it was assumed that all underground wastewater lines were removed from the WSCP/WSRP to the perimeter of the WSTA fence (USATHMA, 1977).

To ensure complete decontamination of underground process lines, trenches were dug 360 degrees around each foundation to locate any remaining underground lines that might be contaminated. Additional trenching was performed in adjacent areas where there was a potential for underground lines or contaminated residue collection points. Contaminated lines and materials located were removed and destroyed by flashing (burning with a flamethrower). It was discovered that as many as four underground lines remained around certain buildings because broken lines were neither repaired nor removed when bypass lines were installed. The new replacement lines were probably never mapped since production of explosives was top priority while the installation of waste lines was occurring. Large deposits of explosive materials were found in the pipelines that were located and removed in 1955. It was also reported that chunks of TNT, measuring approximately 36 inches in diameter and 18 inches thick, were removed from catch basins. (Campbell, 1986)

Contaminated materials were burned (presumably in the burning grounds area) and conveyed to designated storage areas as noncombustibles. Uncontaminated useful materials such as wood, utility poles and fire hydrants were salvaged for future use. Excess materials were accumulated and later sold as scrap. The

following list indicates the major work items performed (USATHAMA, 1977):

o Structures burned	59
o Structures removed by wrecking	8
o Structures remaining (uncontaminated)	2
o Underground piping removed, linear feet (estimated)	21,500
o Poles and supports removed (estimated)	1,600
o Poles salvaged	815
o Process equipment delivered to U.S. Army, items	33
o Contaminated earth removed, cubic yards (estimated)	28,250
o Concrete foundations removed, cubic yards (estimated)	1,400

The decontamination work above is described in very general terms in an AEC document on site preparation for construction of the WSUFMP (DA, 1976). After decontamination was completed, the DA transferred 205 acres to the AEC in August 1956. This land was to revert back to the DA whenever the AEC operations ceased.

To prepare the site for construction after the decontamination process, extensive cut and fill grading was performed across the site. Plate 2 shows the location of cut and/or fill grading relative to the current WSCP locations and topography.

The AEC contracted with Mallinckrodt Chemical Works to operate the WSUFMP. Operations which produced uranium metal from processed uranium ore began in June 1957, and ceased on December 31, 1966. The plant consisted of numerous buildings and four waste pits, called "raffinate" pits. The AEC also acquired the WSQ located four miles south of the WSCP/WSRP which was used to dispose of radiologically contaminated waste materials.

The WSUFMP, as first constructed, contained only two raffinate pits. The third and fourth pits were constructed in 1958 and 1964, respectively. The pits were used to deposit radioactive process waste from the WSUFMP. The Army transferred another 15 acres to the AEC for construction of the fourth pit. The land was carefully chosen to avoid taking any land contaminated with explosives, avoiding another decontamination operation. All waste pits were elevated to prevent surface drainage from entering the pits. Although the pits are located on the north side of the drainage divide between the Mississippi and Missouri rivers, indicating drainage into the Mississippi River watershed, the pits were designed in such a manner that allowed discharge into the Missouri River watershed, south of the divide. Decant from the pits (supernatant liquid after deposition of raffinate sludge) originally flowed into plant effluent and then to the southeast drainage easement. (When the AEC acquired the land for the WSUFMP in 1956, they obtained a drainage easement for the plant sewer outfall. This easement begins at the southeast corner of the plant and continues to the Missouri River. The DOC

owns the intervening land comprising this sewer outfall, however, the Army has retained control of the easement.)

The WSCP was transferred back to the Army in 1967 after the WSUFMP closed.

2.2.4 Weldon Spring Chemical Plant: 1967-1969

In August 1967, WSCP was selected for a herbicide orange (also known as "Agent Orange") facility because of the immediate need for herbicide in Southeast Asia. The Kansas City District-U.S. Corps of Engineers was responsible for design and construction of the facility and contracted with TSR Corp. for design and construction. The Army received a license to possess the radioactive material present as contamination on the site, but the WSQ and the WSRP remained under AEC control. However, the Army received permission from the AEC to dispose of radiologically contaminated equipment in the quarry and to pump plant waste into Raffinate Pit No. 4 with prior clearance from the AEC (DA, 1976).

In an amendment to the license, the Army specified that levels of radioactivity after decontamination were to be below the approved standards at the time. Due to these limits, the project was delayed and costs increased.

In January 1968, TSR Corporation took occupancy of the WSCP, and by February, decontamination and equipment removal had begun in Buildings 103 and 105 (Figure 2-2). Although progress was made, by January 1969, the estimated costs for completing the project had risen to 293% of the original bid, from approximately $10 million to over $30 million. At the same time, military demands for the herbicide were reduced. As a result, the project was cancelled in February 1969.

During decontamination operations, 20 railcars of stainless piping were shipped to National Lead Company of Ohio and about 900 truckloads containing 6,000 cubic yards of uranium-contaminated material were buried at the quarry. Furthermore, an unknown quantity (something less than 80 railcars) of radioactive material was shipped to Tennessee for reclamation.

2.2.5 Current Status: 1969-1988

Following the cancellation of the herbicide project in 1969, the WSCP remained under DA control and the WSRP was administered by the AEC. Only general maintenance activities such as mowing were performed from 1969 to 1987. Various characterization activities were performed by both the DA and AEC during this time. No decontamination or decommissioning efforts were performed during this period.

2.3 Physical Properties of Soil

Two previous studies at the WSCP/WSRP have established the current understanding of area soils and their physical properties. These studies, performed by Bechtel National in 1983-84 and 1986-87, defined on-site geology at the WSRP and WSCP respectively. The 1983-84 study focused on the 52-acre WSRP area. Soil samples were analyzed for grain size, laboratory hydraulic conductivity and several strength tests. The 1986-87 study evaluated the 169-acre WSCP and incorporated data from the previous report. Additional soil samples were collected and analyzed for liquid and plastic limit, grain size, unit weight, specific gravity, moisture content, centrifuge moisture equivalent, effective cation exchange capacity (CEC) and distribution ratio. Additional soil parameters were calculated including: void ratio, porosity, specific retention, specific yield, saturation and activity.

These studies defined WSCP/WSRP soils and their physical properties. Soils at the WSCP/WSRP area consist of six distinct units:

- Topsoil/Fill
- Loess
- Ferrelview Formation
- Clay Till
- Basal Till
- Residuum

The topsoil/fill unit is the first soil unit encountered on-site. Topsoil ranges in thickness from a few inches up to one foot. Topsoil is typically a dark, organic-rich silty clay to clayey silt. Fill at the WSCP/WSRP is highly variable in nature, ranging from silts and clays to gravel and debris. Up to 26 feet of fill is present in some locations at the WSCP/WSRP. Related to the fill are cut areas. Up to fourteen feet of material was cut from various areas and used as fill for low areas. Cut and fill relationships are displayed in Plate 2.

Loess deposits are present over portions of the site. Their areal distribution is highly variable due to predepositional topography and postdepositional erosion. Loess thickness ranges from 0 to 10 feet.

Underlying the topsoil and/or loess units is the Ferrelview Formation, which consists of orange-yellow to brown silty clay. The Ferrelview Formation developed as a weathering product of the underlying clay till and its lateral extent is controlled by the presence of the till. Figure 2-6 presents an isopach map of the Ferrelview Formation (BNI, 1987). Thickness ranges from 0 to more than 15 feet.

The clay till unit is a glacial till deposited during Kansan glaciation composed of a yellow-brown silty clay with minor

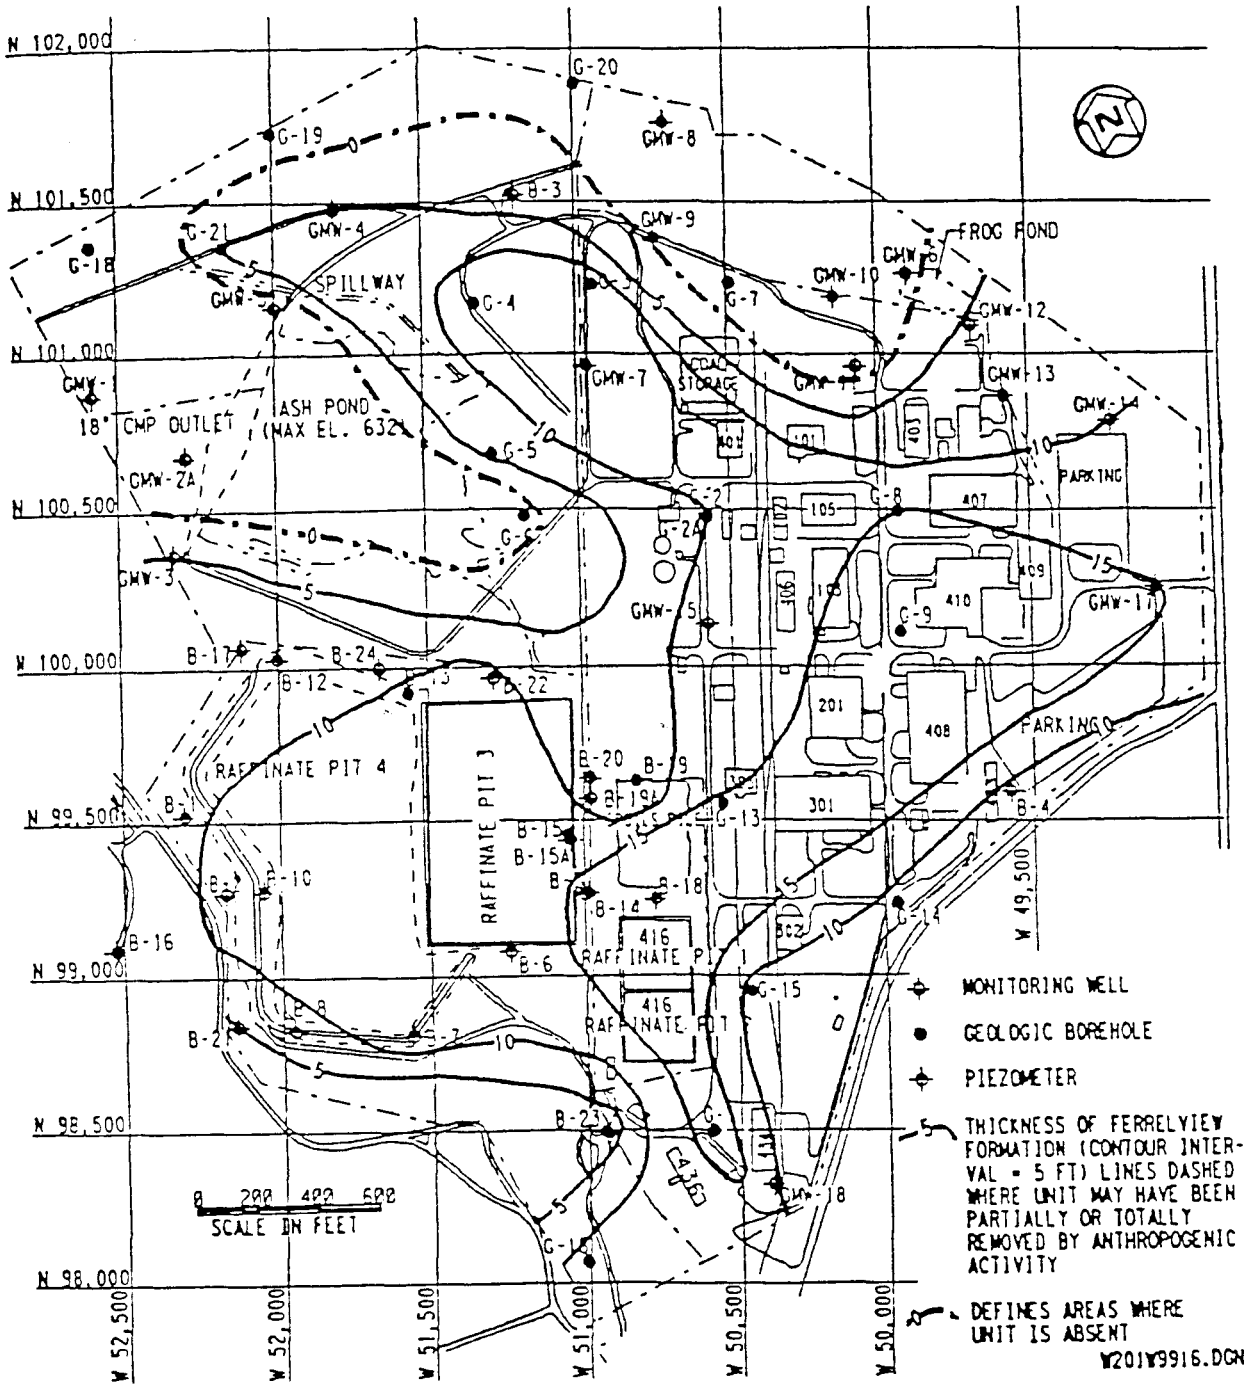

FIGURE 2-6

FERRELVIEW ISOPACH

amounts of sand and gravel. Up to 35 feet of clay till is present beneath the site, with the thickest deposits in the northern portion of the WSCP. Figure 2-7 presents an isopach map of the clay till unit (BNI, 1987).

Underlying the clay till is the basal till unit which contains greater amounts of gravel and angular chert in a clayey silt matrix. The basal till is thinnest (or absent) in areas with higher bedrock elevations. Figure 2-8 displays a basal till isopach map (BNI, 1987).

Residuum is present immediately overlying bedrock and consists of red and yellow clays with substantial quantities of chert. Thickness ranges from 0 to 23 feet for the residuum layer with the thickest deposits present in the Ash Pond area.

The average grain size distributions and Unified Soil Classification System (USCS) description for the soil units above the residium is presented in Table 2-1. Average moisture content (BNI, 1987) is also presented in this table.

Cation exchange capacity (CEC) was measured for both till units and the Ferrelview Formation. CEC values averaged 60.3 meq/100g for the Ferrelview Formation, 69.0 meq/100g for the clay till unit and 29.0 meq/100g for the basal till. The CEC is a measure of the propensity of the soil to exchange cations and retain contaminants. CEC tests indicate that the Ferrelview Formation

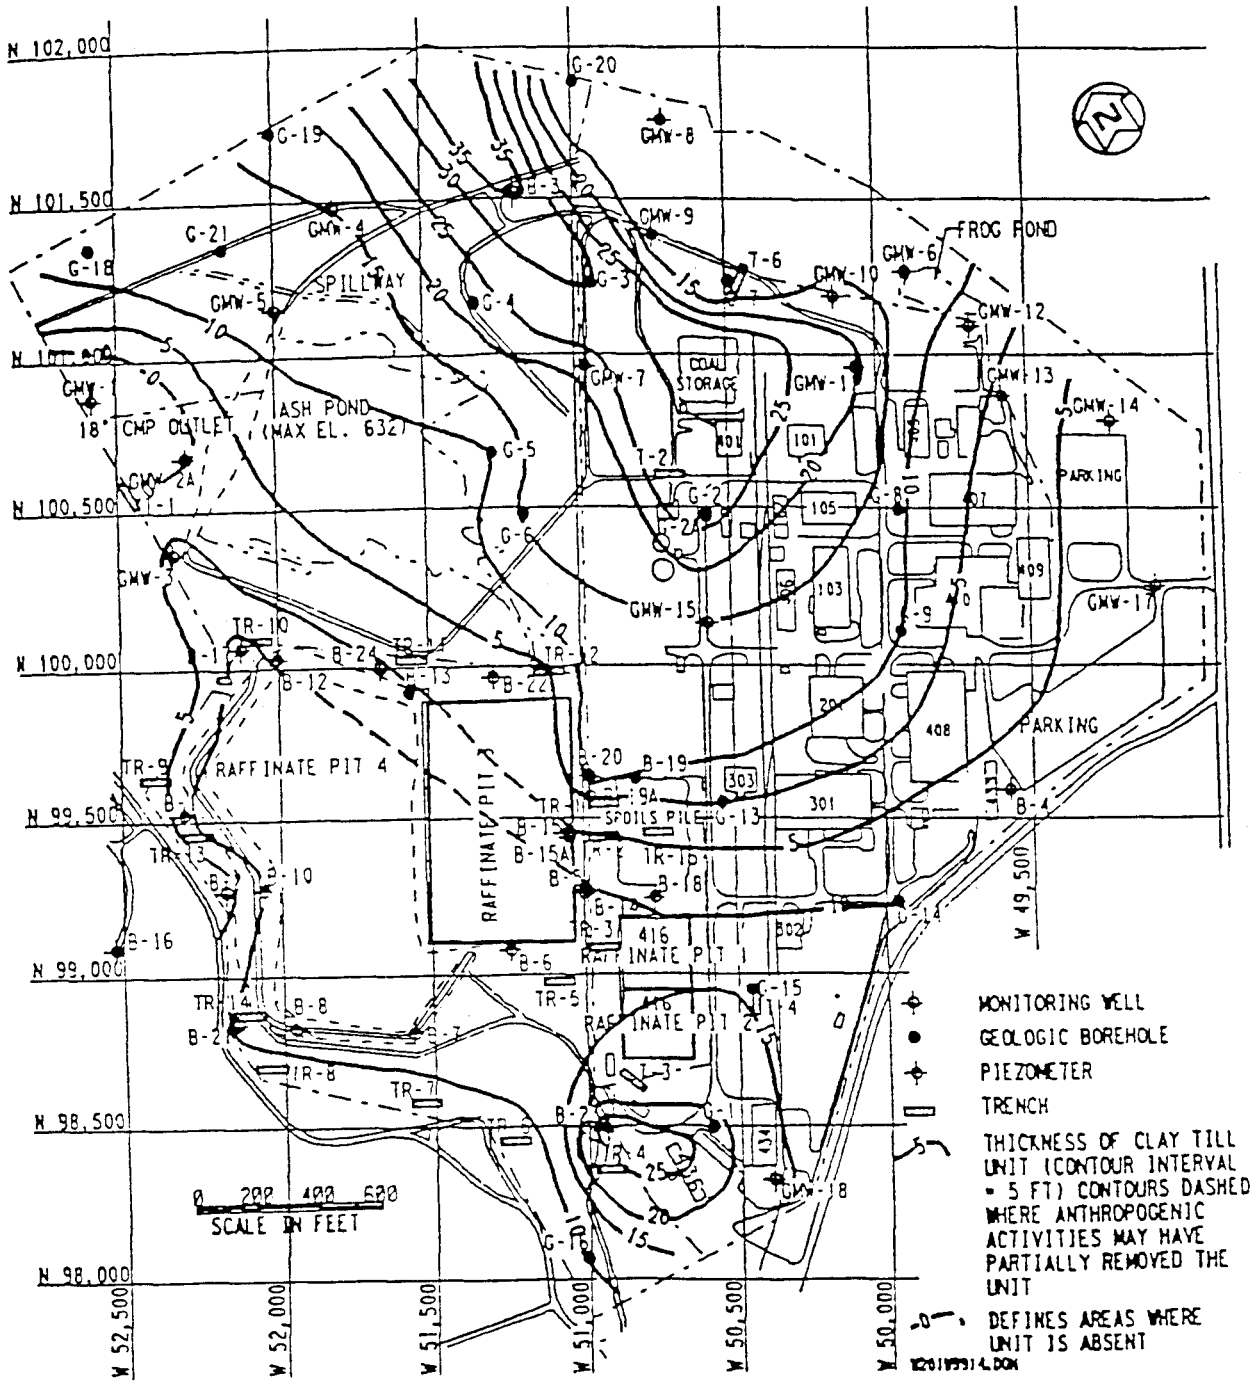

FIGURE 2-7

TABLE 2-1

GRAIN SIZE DISTRIBUTION FOR

SOIL UNITS

UNIT	USCS Classification	PERCENTAGE OF GRAIN SIZES GRAVEL	SAND	SILT	CLAY	MOISTURE CONTENT
Loess	CL	0	4.4	64	31.6	N.M.
Ferrelview Formation	CL-CH	2.8	9.8	49.6	39.6	24.7
Clay Till	CL	0.4	22.4	31.7	45.6	19.3
Basal Till	GC-CL	10.7	18.7	39.8	30.8	20.9
Residuum	**					

N.M. - not measured

Compiled from "Hydrogeological Characterization Report For Weldon Spring Chemical Plant," BNI 1987.

** Residuum information not available.

and the clay till are the primary soil units that can retain significant amounts of contaminants.

During the geological characterization of the WSRP performed by Bechtel National in 1983-84, soil samples were collected and analyzed for physical properties such as strength, grain size, and permeability. Since soil strength is of very limited usefulness in assessing contaminant migration, it will not be discussed in this work plan. Geotechnical properties of the soil will be addressed in detail under the Disposal Facility Siting Work Plan.

Laboratory testing indicated soil permeabilities ranging from 10-6cm/sec to 10-9cm/sec. These values are within the expected range for clay soils and clay tills. These values should be viewed as "ideal" conditions. The permeability of a clay soil unit can be increased by a number of factors including desiccation cracks, root penetration, soil jointing and chemical alteration. Individual samples may or may not be indicative of the whole unit.

Overall, natural soils above the residium at the WSCP/WSRP are low plasticity silty clays with a high CEC. They are generally "tight" and do not transmit significant amounts of water to the underlying bedrock. More permeable, preferred migration pathways may exist in the form of desiccation cracks, old borings, etc., and could potentially transmit contamination from source areas

into the groundwater. The residuum unit may also be extremely permeable.

3.0 DATA NEEDS AND USES

Soil investigations at the WSS will be performed to satisfy defined data needs. The data obtained from these investigations, applied in concert with existing data, will be used to identify contamination source areas, determine the extent and magnitude of contamination, evaluate migration pathways and document uncontaminated areas.

Section 3.1 provides information on the possible chemical contamination sources from both the WSOW and the WSUFMP. An assessment of existing chemical soil data is given relative to both operations and is followed by a discussion of data validity and the need for further data collection. Section 3.2 discusses the data needed to further define the extent and magnitude of contamination. Section 3.3 discusses potential migration pathways and the known environmental fate of specific contaminants. Section 3.4 discusses the data needed for documentation of uncontaminated areas.

3.1 Contamination Sources

The WSOW and WSUFMP operations are the two primary sources for soil contamination at the WSCP/WSRP. Since the processes at each of these plants are known, and no other materials are known to have been disposed of on-site, a detailed list of suspected contaminants can be prepared.

3.1.1 Weldon Spring Ordnance Works

WSOW TNT and DNT production consisted of treating liquid toluene with mixed nitric and sulfuric acid.

Three complete TNT production lines, and a portion of a fourth, were originally constructed in the 220-acre portion of the WSOW that later became the WSCP/WSRP. The primary suspected contaminants from WSOW are nitroaromatic residues, nitrate, sulfate, and metals. Table 3-1 lists the chemicals used in TNT and DNT production. Potential source areas include WSOW building locations, old wooden wastewater lines, spill areas, and surface drainages from process buildings.

Plate 1 presents WSOW features superimposed on existing site features.

3.1.1.1 Data Assessment of WSOW Sources

Twenty surface soil samples were taken in 1975 by the U.S. Army Chemical Demilitarization and Installation Restoration (DACDIR) team to provide a general assessment of the residual explosives present on site from previous WSOW operations. The majority of the surface and subsurface sampling points were located in areas suspected of containing the highest level of nitroaromatic contamination on-site, from building foundations, wastewater

TABLE 3-1

CHEMICALS USED IN TNT AND DNT PRODUCTION AT THE WSOW

CHEMICALS	USE(S)
Ammonia	Nitric acid production
Caustic Soda	Neutralize acidic wastewater
Chlorine*	Water treatment
Coal*	Burned for power generation
Fuel Oil	Sulfuric acid concentrating and wastewater treatment
Oleum	Used in TNT lines

lines, or in and around the burning ground area. Sampling locations are provided in Figure 3-1.

The samples were transported to the Battelle-Columbus Laboratories, Columbus, Ohio, for analyses (gas chromatography-electron capture). A known positive sample was also provided to verify analytical detection.

Eight subsurface soil samples (Figure 3-1) were also collected at this time by the St. Louis District - U.S. Corps of Engineers. Seven of these samples were consolidated soil taken from the top three feet of earth. The eighth sample was taken from the interface where the Ash Pond dam construction material meets the original soil surface at a depth of approximately 25 feet below the top of the dam. Ash Pond was constructed for WSUFMP use. These samples were treated identically to previously collected soil samples and were also transported to and analyzed by Battelle-Columbus Laboratories.

Sample analyses were performed by the Battelle-Columbus Laboratories. The analyses were directed toward quantitative determination of 2,6-DNT, 2,4-DNT, and TNT. The analytical results indicated low-level (low ug/kg) contamination of the soil by all three nitroaromatic compounds.

Of the 20 surface soil samples submitted, seven samples (and the known positive sample which was also submitted) were not

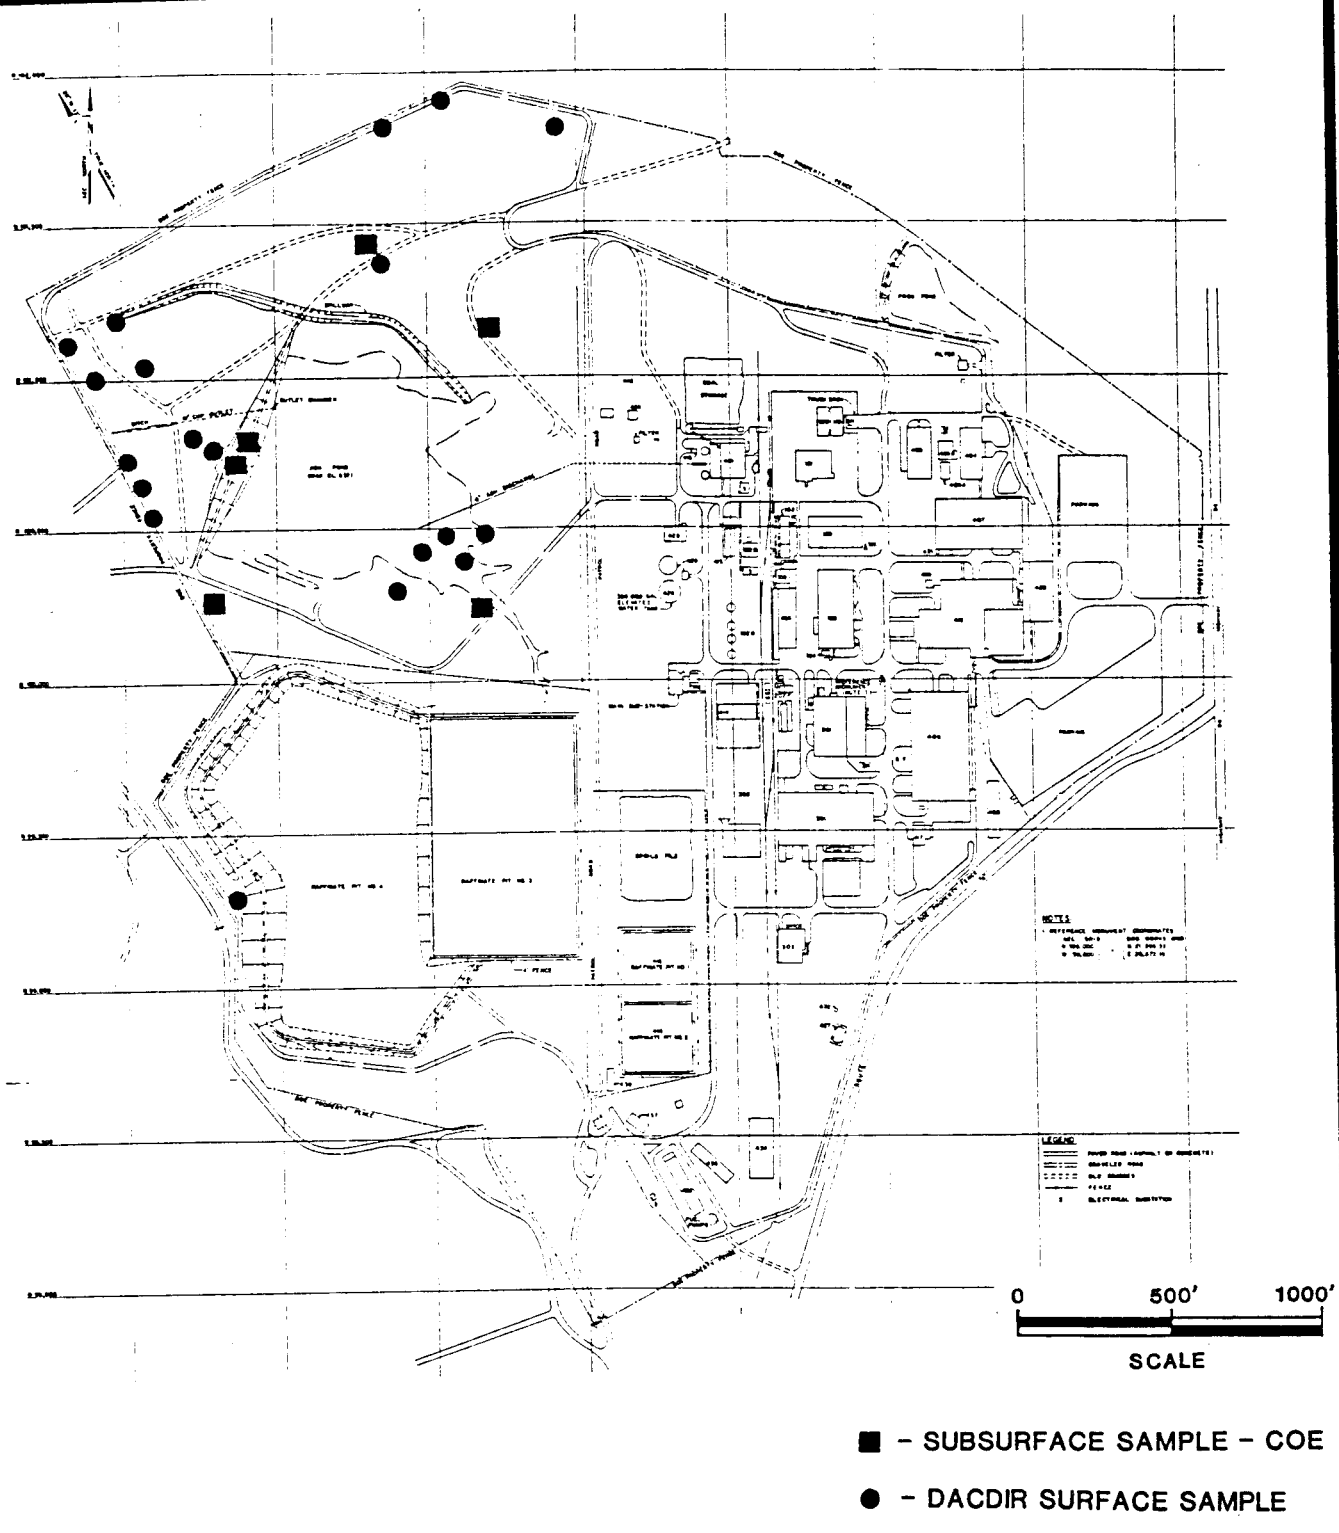

FIGURE 3-1

DACDIR SAMPLING LOCATIONS

analyzed "due to presence of some major interfering material(s) appearing in extracts of these samples." The 13 remaining samples were analyzed for 2,4 DNT, 2,6 DNT and TNT.

For the 2,6 DNT, six samples had non-detectable concentrations, and four samples had tentative identification, but less than the method detection limit of 1.0 ug/kg. The highest level detected in surface soil was 2.9 ug/kg.

For 2,4 DNT, only one sample had non-detectable concentrations, and 2 samples showed tentative identifications, but less than the method detections limit of 2.0 ug/kg. The highest level detected in surface soil was 38.3 ug/kg which was collected in the vicinity of TNT Production Line No. 4, located west of Raffinate Pit No. 4.

For TNT compounds, seven samples had non-detectable levels, and one sample had tentative identification, but was less than the method detection limit of 3.0 ug/kg. The highest TNT level detected was 32.4 ug/kg.

In the eight subsurface soil sampling locations, no interferences were found in the analytical matrixes. Seven of the eight subsurface soil samples were consolidated from the upper 1-3 feet of soil. The remaining subsurface sample was taken from 25 feet below the top of Ash Pond dam at the original WSOW topographic level.

The 2,6 DNT sample results ranged from <1.0 ug/kg to 12.9 ug/kg. For TNT, the sample results ranged from non-detectable to 292 ug/kg. Overall, the highest concentrations of nitroaromatics were identified in the Ash Pond dam (the area of the WSOW burning grounds).

This investigation established the presence of nitrated toluene compounds in WSCP/WSRP soils at concentrations in the lower microgram per kilogram range. Cross trenching operations failed to expose any remaining underground wastewater lines. Comparison of photographs taken during WSUFMP construction to WSOW wastewater lines indicate that WSUFMP construction would have encountered any unexcavated lines. While the analytical results presented do not meet current standards (see data validation discussion), significant deposits of nitroaromatics were not detected. This sampling effort did not incorporate cut and fill relationships between WSOW and WSUFMP topographies (Plate 2). This study concluded that a more extensive effort was required to assure total decontamination and removal of hazardous explosives material.

3.1.1.2 Data Validity and Assessment

Complete Quality Assurance/Quality Control (QA/QC) information is unavailable for the soil sampling efforts performed by the DACDIR in 1975. Limited analytical information is available in the 1976 Assessment of Weldon Spring Chemical Plant (DA, 1976).

The procedures utilized by the Battelle-Columbus Laboratories in 1975 are not consistent with the current semi-volatile analyses for 2,4 DNT and 2,6 DNT identified in SW-846 - Method 8090 for nitroaromatics (9/86) or USEPA Contract Laboratory Program methodology for the determination of extractable semi-volatiles (based on EPA Method 625). The analytical procedures employed also differ from the current USATHAMA High Pressure Liquid Chromotography (HPLC) method.

Furthermore, documentation of sample collection, handling, preservation, storage and transport by the DACDIR and QA procedures performed by Battelle-Columbus laboratories, including precision, accuracy, etc. was not included with the reported data.

The data presented in this report are useful in establishing areas of contamination and contaminant levels. However, the data presented cannot be validated according to the Quality Assurance Project Plan (QAPP) and will not be used in Risk Assessment analyses and/or final soil contamination interpretations. The data will be used to guide WSOW biased sampling.

3.1.2 Weldon Spring Uranium Feed Materials Plant

Uranium processing at the WSUFMP consisted of converting uranium ore concentrates to uranium metal with several intermediate

metallurgical steps. Figures 3-2, 3-3 and 3-4 depict the processing sequence and chemicals used in each stage.

The primary potential contaminants associated with uranium processing include: nitric acid, tributyl phosphate in hexane, ammonia, hydrogen fluoride, magnesium, uranium, radium, thorium and other trace metals. Table 3-2 lists the chemicals used for uranium processing and support operations.

To date, no soils investigation has been conducted specifically for chemicals associated with uranium production. However, in 1987, the DOE conducted a preliminary chemical soil contamination assessment and site investigation (PA/SI).

The preliminary assessment was based on the Phase I Water Quality Assessment. The Water Quality Assessment established baseline groundwater and surface water conditions at the WSS. All existing monitoring wells were sampled for the complete Hazardous Substance List, nitroaromatics, inorganic anions and radionuclides. The Phase I Water Quality Assessment detected the presence of nitrate, sulfate and nitroaromatics in the groundwater. No other organic or inorganic contaminants were observed in the groundwater, implying the lack of significant soil contamination by these compounds. The Phase I Water Quality Assessment was used in developing the Phase I Soil

Investigation. This site investigation was designed to provide baseline data of areal coverage across the site in areas absent of any chemical soils data.

This initial effort consisted of the collection of 135 samples from 32 locations within the 220 acres of the WSCP/WSRP. Five other boreholes were drilled immediately adjacent to the WSCP, four of which were drilled into the WSOW waste lagoon no. 1, which is located just northeast of Frog Pond, and one borehole was located between the WSCP property and WSOW waste lagoon no. 1. Borehole locations are shown in Figure 3-5.

Phase I soil samples were analyzed for nitroaromatics, metals, nitrate, sulfate, fluoride, chloride and percent moisture.

Analytical results indicated elevated levels of lead, zinc, barium, nitrate and sulfate in WSCP/WSRP soils. Nitroaromatics were not detected on-site. However, percent levels of nitroaromatics were observed in WSOW waste lagoon no. 1.

On-site background metal concentrations were statistically determined during the Phase I soil investigation. Table 3-3 presents the statistical information. This statistical background determination indicated potential contamination consisting of: aluminum, antimony, barium, iron, lead, magnesium, manganese, nickel, vanadium and zinc. This statistical determination was performed to evaluate the

concentration distributions for each metal. Metals with normal distribution may not be contaminants in on-site soils. These on-site background values will be compared with off-site background samples to determine true background conditions as detailed in Section 4.5.2.

3.2 Extent and Magnitude of Contamination

Previous studies have not adequately defined the extent and magnitude of chemical contamination at the Weldon Spring Site. As discussed in the Site History (Section 2.2), the normal operations of the WSOW produced large quantities of "red water" as well as acid waste, bad batches of TNT, and other miscellaneous waste streams. Waste disposal practices during the operation of the WSOW appear to have been driven mainly by expediency. As a result, the potential exists for soil contamination from normal operations, as well as from the leaks and spills that may have occurred during operations.

Existing site sampling locations, when compared with the site history, indicate unsampled areas that could be potential areas of contamination. A statistically developed random sampling program and biased sampling program are required to define the extent and magnitude of contamination.

Elevated nitrate and sulfate levels were observed in locations near potential WSOW source areas. No elevated inorganic anion levels were detected near potential WSUFMP sources.

A more detailed discussion of this effort is presented in "Phase I Chemical Soil Investigation at the WSCP/WSRP" (MK-Ferguson, 1988).

The data presented in this report were collected using acceptable techniques and methods. Chain of custody was maintained according to approved WSSRAP procedures. Sample analyses were performed according to U.S. EPA approved methods or USATHAMA methods (for nitroaromatics). The data presented in this report will be validated according to procedures described in the QAPP and will be used in final data interpretation.

The Phase I data will be used to guide and focus this larger sampling event. Particularly useful is the nitroaromatic data collected from WSOW waste lagoon no. 1. These data demonstrated the nitroaromatic binding to soil particles as concentrations decreased from percent levels to below detection limits in eight feet. This information will be used to focus WSOW biased sampling and random area sampling.

Overall, this baseline effort supplied essential information to guide and focus the Chemical Soil Investigation Sampling Plan.

3.3 Soil Migration Pathways

There are three potential mechanisms for migration of contaminants at the WSCP: groundwater transport, volatilization, and wind or surface water erosion of contaminated soil particles. Groundwater transport is likely to be the most important, especially for the nitroaromatics and inorganics.

Contaminants considered in this section are: inorganics (primarily nitrates and sulfates), metals (principally lead), nitroaromatics, and PCBs. Their migration pathways and mobility are discussed below.

3.3.1 Nitrate

The significant migration pathway for nitrate is movement with groundwater. Nitrate is very mobile in groundwater due to its anionic negative charge and high water solubility (ESE, 1986). It is likely that nitrate will move with the groundwater, without significant soil attenuation (ESE, 1986). Concentrations at the WSCP/WSRP can be lowered mainly by hydrodynamic dispersion.

3.3.2 Sulfate

Like nitrate, the primary significant migration pathway for sulfate is movement with groundwater. Also like nitrate, sulfate is an anion and very mobile (ESE, 1986). Unlike nitrate, sulfate is less subject to biological transformation. Sulfate is susceptible to reduction only at extremely low anaerobic Eh which is unlikely to occur in groundwater beneath the WSCP. Sulfate may also be removed from groundwater by precipitation as a mineral such as gypsum. Sulfate would be expected to be slightly less mobile than nitrate, but is still considered to be a very mobile anionic species. (ESE, 1986)

3.3.3 Lead

Lead is the principal nonradioactive metal contaminating soils at the WSCP/WSRP site. Lead was used extensively in WSOW production facilities because it is resistant to corrosion and sparking. Phase I soil sampling has detected isolated areas of elevated lead concentrations. It is expected that lead contamination will remain in discrete pockets of elevated concentration in the soil. This is due to the usage of lead only in particular areas of production and its hydrogeochemical behavior in the soil.

Lead is strongly adsorbed to soils with a pH above 5. Lead adsorption increases with pH, cation exchange capacity, organic carbon content, and phosphorus levels (ESE, 1985). Movement of lead in the groundwater is unlikely to be the dominant mode of transport, although some lead may be found in groundwater near localized areas of high concentration. The primary migration pathway for lead is expected to be wind or surface water erosion of soil particles containing adsorbed lead. The vegetative cover on the WSOW site should greatly abate this migration pathway by reducing soil erosion.

3.3.4 Nitroaromatics

3.3.4.1 2,4,6 - Trinitrotoluene (TNT)

Migration pathways for TNT are controlled by adsorption (ESE, 1986). However, TNT is not as tightly bound to the soil as lead, so the migration pathways include transport by groundwater as well as direct transport of TNT or TNT-contaminated soil particles.

TNT's reported water solubility is 117-200 mg/l (ESE, 1985). It is unlikely that TNT transport in groundwater will be limited by solubility. Retardation factors (Rd) are a function of the organic carbon content of the soil with higher organic carbon content causing more adsorption resulting in a higher Rd. Horizontal and vertical migration rates in contaminated soil of

as little as one inch per year have been estimated for TNT (ESE, 1985) in clay soils and climatic conditions similar to the WSCP/WSRP.

TNT has a relatively low vapor pressure and a low Henry's Law constant; therefore, volatilization is not expected to be a significant migration pathway.

Biodegradation could be an important mechanism for the attenuation of nitroaromatics and nitrates. Important factors controlling biodegradation rates are: pH, Eh, nutrient availability, and temperature. As a nitroaromatic such as TNT moves through the groundwater regime, it could be transformed microbially and eventually mineralized to ammonia. The ammonia could then be rapidly nitrified to nitrate. Finally, as the groundwater declines in redox potential, nitrate can be reduced to N_2 by denitrification. Unfortunately, data is not available to make a quantitative assessment of the importance of biological degradation processes at the WSCP/WSRP and WSOW.

Photolysis (chemical decomposition due to exposure to light) is a dominant degradation process in surface waters (Spanggord et al, 1980) and is a likely process that may suppress TNT concentrations to undetectable levels in ponds receiving ground water discharge with measureable TNT. Photolytic decomposition products include 1,3,5-TNB.

3.3.4.2 1,3,5 - Trinitrobenzene (TNB)

TNB may be more resistant to degradation than TNT. Sufficient evidence is not available to estimate degradation rates in environmental systems, but the limited data that are available indicate that TNB is resistant to hydrolysis and is neither photolytically nor biochemically degraded as readily as TNT. The environmental behavior of TNB is expected to be very similar to that of TNT. Adsorption to soil particles should be a major factor in controlling TNB migration pathways. Migration pathways will be by groundwater transport and movement of contaminated soil.

The Henry's Law constant for TNB is approximately an order of magnitude greater than for TNT (ESE, 1985). Thus, volatilization could be more of a factor in TNB transport than for TNT.

TNB movement with groundwater is likely to be the most significant migration pathway for TNB at the WSOW.

3.3.4.3 Dinitrotoluenes (DNT)

The DNT isomers (DNTs) are relatively more mobile, volatile and degradable than TNT (ESE, 1985). Retardation factors are estimated as low as 1.2 for DNTs. This implies that DNT isomers would move through the soil with essentially the same velocity

as groundwater. Thus, this is expected to be the primary migration pathway for DNT.

DNT isomers are also quite volatile, with a Henry's Law constant nearly three times that of TNB. Volatilization, especially from surface soils, may be a significant means of DNT migration. Volatilization and degradation by photolysis would be important factors in reducing DNT concentrations in surface soils or water (ESE, 1985).

Photolysis is an important process affecting DNTs in surface waters, with reported half-lives of a few hours to approximately 1 week (Spanggord et al, 1980). Photolytic decomposition and volatilization may account for failure to observe DNTs in surface waters that receive groundwater discharge from the TNT manufacturing area.

3.3.4.4 Dinitrobenzenes (DNB)

DNB isomers should behave very similarly to DNT with respect to volatility and absorption (Spanggord et al, 1980). Transport with groundwater should be the primary migration pathway, with volatilization an important factor in surface soil or water.

3.3.5 Polychlorinated Biphenols (PCB)

PCB migration will be through direct contact with PCB oil and/or through erosion of contaminated soil because PCBs bind tightly to soil particles and are not transported with groundwater (CRC, 1982). PCBs are very stable and do not transform or biodegrade easily in soil (CRC, 1982).

3.3.6 Asbestos

Asbestos fibers are mobile only by wind, surface water, and direct soil mixing. The vegetative cover present at the WSCP/WSRP should control and minimize asbestos migration. The degree and nature of this control is not known and would be extremely difficult to quantify.

3.4 Documentation of Uncontaminated Areas

Knowledge of site history, previous studies, Phase I sampling results, and knowledge of the likely routes of migration for chemical contaminants on-site all indicate potentially contaminated areas. The areas of the site with no implicating factors pointing to chemical contamination must be sampled in a systematic way so they can be shown to be free of contamination. In addition, areas known to be free of contamination, but similar geologically to the contaminated

areas on-site, must be sampled to establish background levels for metals and inorganics to allow a true and valid assessment of on-site contamination.

Sampling locations in these areas have been selected on a random basis. Proper statistical methods have been applied to insure that the number of samples will be adequate to provide a statistically valid coverage of the area and establish the mean and standard deviation of background concentrations of naturally occurring constituents. A detailed description of the statistical approach selected to characterize areas not suspected of being contaminated is presented in Section 4.5.

4.0 SAMPLING PROGRAM

4.1 Sampling Objectives

Soil sampling for chemical characterization will be conducted to meet several objectives. The objectives are to:

1) Determine the extent and magnitude of chemical contamination.

2) Locate potential chemical contamination sources.

3) Document uncontaminated areas.

4) Provide a data base sufficient for consideration of remedial action options.

5) Provide data base sufficient for preparation of risk assessment.

6) Establish background concentrations in native soils.

4.2 Sampling Rationale

The focus of this soils investigation is to quantify the nature and extent of chemical contamination in terms of the specific objectives stated in Section 4.1. Because of the size of the

site and the diversity of activities that have occurred over the last 45 years, two sampling approaches--biased and unbiased sampling--are proposed to provide a comprehensive soil contamination characterization. The biased sampling locations are based on historical documentation and recent site investigation results presented in previous sections. Specific sampling locations were selected based on association with either the WSUFMP operations or the WSOW operations. Areas of known radiological contamination are defined in Section 4.3.1. Specific sampling locations are discussed and identified by site coordinates, along with sampling depths, analytical parameters, and a brief rationale. All soil sampling locations are presented in Plate 3.

Unbiased sampling will be conducted over the entire site in order to provide a statistically valid data base for soils characterization and to document uncontaminated areas. The statistical approach to unbiased sampling is presented in Section 4.5.

4.3 WSUFMP Biased Sampling

Sampling locations discussed in the following sections were selected based on site history, plant operations, and previous data. Soil samples will be collected from 71 locations. Analytical parameters were selected based on contaminant source characteristics and previous data. A total of 191 samples will be collected. The locations, depths, analytical parameters and

rationale are presented in Table 4-5. Collected samples will be analyzed for chemical parameters only and not for radiological constituents since radiological characterization is complete. However, the areas of radiological contamination are of concern for both safety and handling procedures. Section 4.3.1 discusses areas known or suspected to be radiologically contaminated. These areas will be chemically characterized. Section 4.3.2 discusses plant operations in relation to chemical source areas, provides rationale for sample locations, details borehole depths and describes analytical parameters.

4.3.1 Radiological Investigations

RADCON Survey - 1975

A radiological survey was conducted in September 1975, by the U.S. Army Radiation Control team (RADCON), to determine outdoor areas of contamination, identify contaminants and assess the potential radiological hazard to the properties surrounding the site. Natural uranium and its decay products were anticipated to be the major source of contamination. The RADCON team surveyed the perimeter of the site at the fence and 10 meters inside the fence. Measurements were taken on the ground surface at 250-foot intervals.

The survey conducted around the Weldon Spring Chemical Plant buildings indicated that the areas around buildings 428, 429, 437, 439, and 443 were free of detectable contamination. The

areas surrounding the remainder of the buildings were contaminated to varying levels from background to more than 500 times background. Three pieces of uranium metal were found alongside major support buildings. Although the most heavily contaminated areas are characteristically located near major process buildings and the pilot plants, some support buildings were found to be surrounded by significant contamination. For example, visible uranium oxide and uranium fluoride deposits were found alongside the Paint Shop (Bldg. 417). The area in front of the Administration Building (Bldg. 409) was found to be contaminated to approximately eight times the background in portions of the parking lot. Apparently automobile lubricants collected on the parking lot and trapped low-level airborne contaminants during plant operations. All expansion joints between surface materials on-site which contain tar have likewise collected and concentrated contamination.

WSSRAP Survey - 1987

In February, 1985, the DOE established the Weldon Spring Site Remedial Action Program (WSSRAP) to effect remedial action at the site. Because additional radiological information and data were needed to complete the Environmental Impact Statement (EIS), DOE developed a radiological characterization plan for the WSCP/WSRP.

This field work was performed from April through July 1987. The intent of this program was to determine the horizontal and

vertical extent of radioactive contamination within the WSCP/WSRP area that exceeds guidelines for remedial action.

A combination of surface and subsurface radiometric measurements, and surface and subsurface soil samples were collected. Exact sampling and measurement locations were determined by an on-site survey utilizing the AEC coordinate system to positively locate sampling location.

Boreholes were drilled at 317 locations. Samples were collected from each borehole in one-foot increments to a minimum depth of five feet. Boreholes were then logged with a gamma-ray spectrometer. Elevated spectrometer readings triggered subsequent radium and thorium-232 analyses. Selected samples were archived for possible future uranium and/or thorium-230 analysis if the spectrometer log indicated no elevated gamma activities. The following paragraphs briefly discuss the radiological contamination findings at specific locations. Each area is shown in Figure 4-1. Residual soil guidelines are presented in Table 4-1.

A complete description of the radiological characterization can be found in the final report entitled "Radiological Characterization Report of the WSS."

Source: WSSRAP, 1987

North Dump Area

A borehole drilled near the western boundary of the dump indicates that the contamination extends deeper than five feet. The eastern half of the dump is contaminated to a 36-inch depth. Results indicated Ra-226 contamination slightly below surface soil guidelines in a small region east of the dump area.

North, Northwest, Northeast, and North Central Areas

All in-situ measurements and soil sample results indicate that these areas are below soil guidelines.

Frog Pond Area

In-situ measurements and soil sample results indicate that a large portion of this area is above soil guidelines. The inlet to Frog Pond is contaminated to a depth of 36 inches. A drainage area located NNE of Frog Pond is contaminated to a depth of 12 inches.

The grounds south of Frog Pond contain a mixture of radionuclides exceeding guidelines.

Building 403 Area

Boreholes and surface soil sample results indicate that the grounds surrounding the buildings are contaminated to a depth of

12 inches with the exception of a small area east of building 404 where the contamination extends to 24 inches.

Building 101 Area

Several areas on the concrete dock have elevated gamma radiation readings.

Building 401 Area

A large portion of the grounds in this area are below guidelines. Historical information has indicated feed material spills occurred along the railroad tracks. The contamination within this area is surficial and is predominantly uranium. The area below the coal pile is known to have radionuclides above residual soil guidelines. Drainage from the coal pile area leads into the northeast site area and the outfall from Frog Pond extends across the northern portion of this area.

East Site and PMC Area

All in-situ measurements and soil sample results indicate that these areas are below the residual soil guidelines.

Building 410, 103, and 105 Areas

A borehole drilled in Building 103 area indicates contamination to a depth of 24 inches beneath the building. A borehole drilled in Building 105 showed no contamination above the guidelines. A borehole drilled to the southeast of Building 105 showed considerable contamination. The surface soil in the Building 410 area showed detectable contamination.

102B Area

Boreholes and surface soil samples have indicated contamination in this area above soil guidelines.

Water Tower Area

A major portion of this area is below residual soil guidelines. However, an isolated area around the tank farm and water tower has elevated uranium concentrations.

Ash Pond Inlet Area

This area contains isolated areas of contamination.

East Ash Pond and Ash Pond Areas

No radiological contamination is present in these areas.

South Ash Pond Area

This area is radiologically contaminated to a depth of eight feet.

West Ash Pond Area

The Ash Pond outfall is contaminated at a depth of 60 inches (15 pCi/g U-238) and at 36 inches (60 pCi/g U-238). An area of Th-230 contamination is present at one borehole location.

Building 408 Area

The grounds in this area show contamination to a depth of 12 inches. All sample results for this area are above the residual soil guidelines.

Building 417 Area

Portions of this area are above the residual soil guidelines.

Building 201 and 301 Areas

A borehole drilled in Building 201 is contaminated to a depth of 12 inches. The grounds surrounding the buildings show contamination exceeding guidelines.

Imhoff Tank Area

A large portion of the grounds is below residual contamination guidelines. Isolated areas of contamination exist including one area of Th-230 contamination.

4.3.2 WSUFMP Biased Sampling Approach

This section discusses the use of chemicals associated with the production of uranium trioxide, uranium tetraflouride and uranium metal. Specifically it discusses the site locations where certain chemicals were used, disposed of or spilled during operations and relates the information to the selection of potential contaminant source areas. By combining potential source information with historical soils data, Phase I Water Quality Assessment data, and the containerized chemical inventory conducted in the buildings by PMC personnel in 1987, site-specific soil sampling will be conducted. This sampling will verify the contaminant sources, characterize the extent of these sources, determine the extent of any contaminant migration and provide an assessment of the rate of contaminant migration. All sampling locations, rationale, depths and analytical parameters are presented in Table 4-5 following the discussion of WSCP facilities.

Discussion of the chemical plant is divided into three general areas: Major Building Structures, Yard and Yard Structures, and Surrounding Land Areas.

Major Building Structures. The contents of the buildings are quite variable. Certain buildings have been emptied and partially decontaminated. Most of the buildings contain original process equipment and several have been used to store material removed from other buildings. Major building structures are listed in Table 4-2.

Yard and Yard Structures. These include smaller process buildings and utility structures as well as loose equipment, drums, piping, vehicles, vessels, etc., scattered randomly throughout the yard area. Table 4-3 lists items situated in the yard areas. The major structures consist of small buildings or structures used intimately with the process. However, many of the structures involve utilities which traverse most of the yard. The major fixed yard structures include overhead piping and underground piping. The overhead piping is concentrated near the process buildings and the steam plant, although steam piping connects most buildings in the plant area. Substantial amounts of the insulation used on these overhead pipes contain asbestos and have deteriorated to the point of falling off the pipe to the ground. The underground piping system includes sanitary sewers, process sewers, storm drains, potable and fire water lines, etc. The sanitary system originally fed two septic tanks with filters and an Imhoff tank which discharged effluent by outfall to a

drainage easement leading to the Missouri River. The process sewer system also discharges to this easement through the same outfall pipe. Surface drainage that collects on the site is discharged through pipes and open ditches to several outfall ditches leading to off-site areas. Surface water enters the site from small watersheds to the south and northeast.

Surrounding Land Areas. These lie outside the building and yard areas and include: the Frog Pond area to the northeast, the northern boundary area, the Ash Pond area to the northwest, the raffinate pit area to the southwest, and the southern boundary area. Table 4-4 lists the areas comprising the Surrounding Land Areas. Figure 4-2 gives a general delineation of the areas as well as an indication of where surface water moves to and from the site.

The Frog Pond area includes its watershed area and discharge stream exiting the site. This area, specifically the pond and outfall stream, were used by the WSUFMP for stormwater discharge and process wastes from buildings 403 and 404. The area still contains features of the WSOW including a tram line and process wastewater surface conveyance.

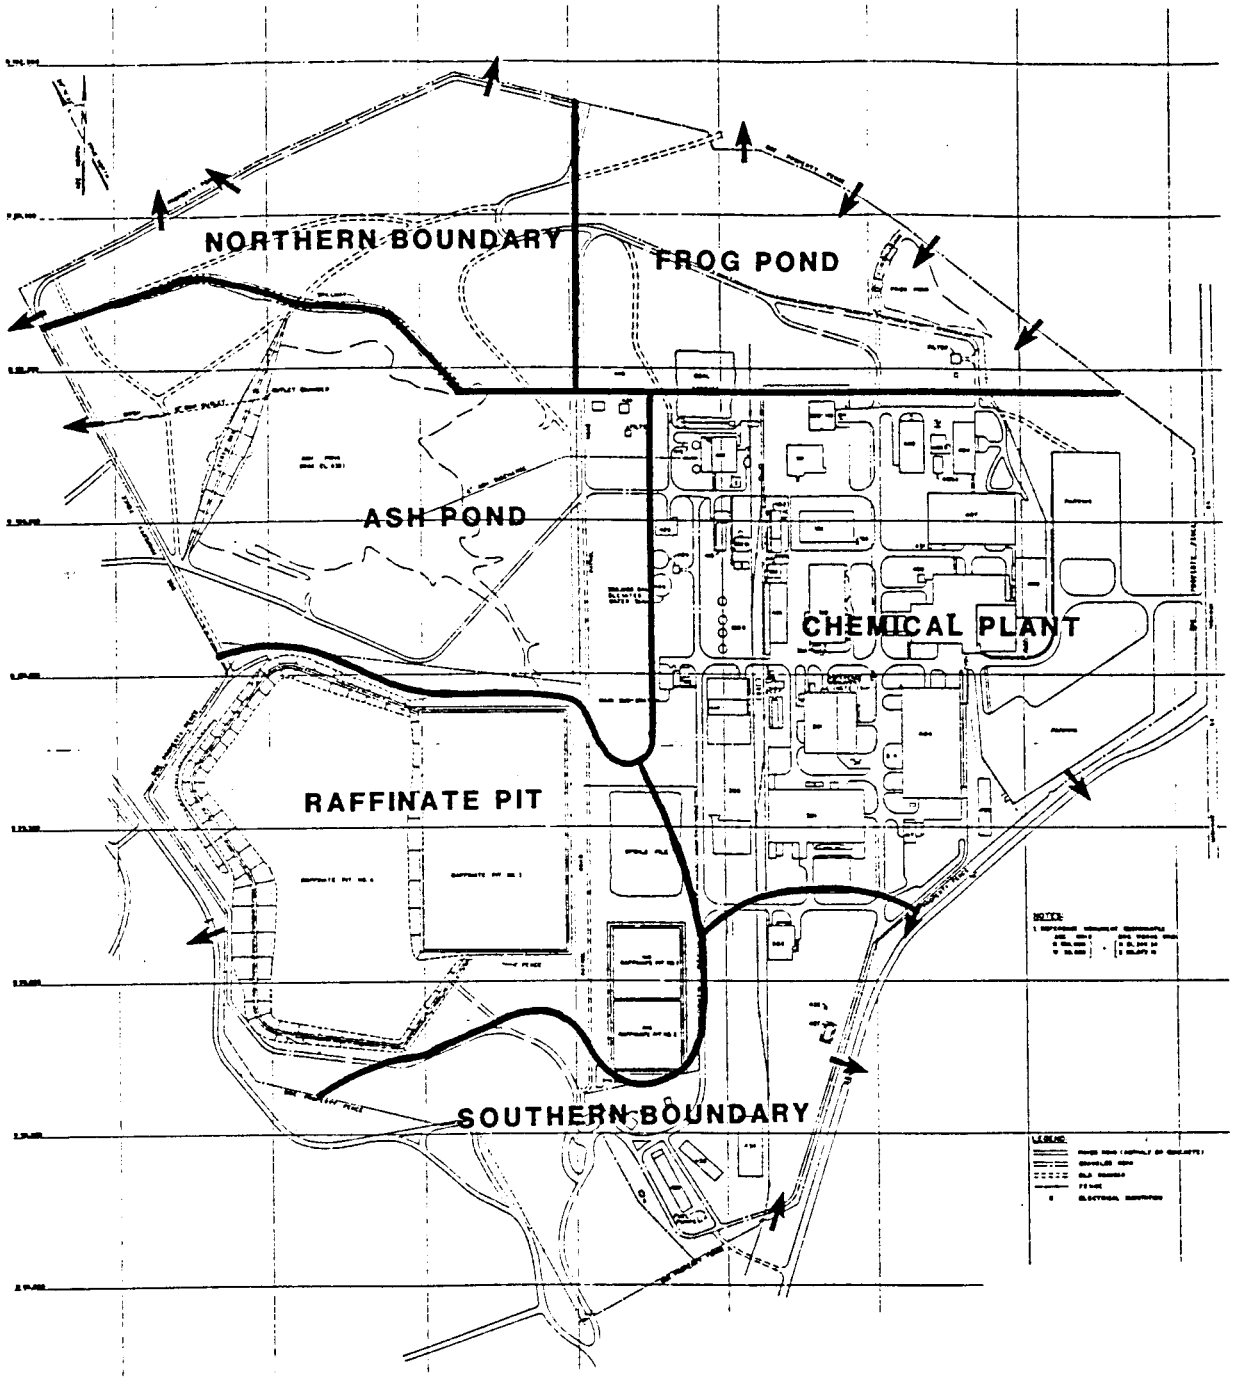

FIGURE 4-2

DELINEATION OF MAJOR AREAS OF THE SITE

The Ash Pond is another major area. Spent ash from the steam plant was slurried to this surface impoundment for settling prior to discharge of the water. The area below the dam contains rubble from the WSOW. Along the south upstream shore of the pond, radiologically contaminated material was dumped.

Areas along the northern boundary, just west of the Frog Pond area, also have been untouched since the WSOW operations except for surface storage of discarded equipment and rubble, (not waste products). Most of this stored material has been removed but remnants still exist. The area was also used by the WSOW as a burn area for TNT waste disposal.

The area south of the raffinate pits was partially modified when the WSUFMP was constructed and has been used for surface dumping of solid waste material. Most material has been removed except for debris close to the remaining buildings. The Imhoff tank for treatment of sanitary sewage and the buildings used during construction are also located in this area but are discussed with yard structures. The eastern part of this area is the watershed for surface drainage southeast to the Missouri River.

The following sections describe WSUFMP process facilities. The need for sampling is discussed along with analytical parameters and sampling locations. Three samples will be collected from each location unless noted. Sample intervals at each location are: 0 to 6 inches, 24 to 30 inches, and 54 to 60 inches, unless otherwise noted. A more detailed description of sample location,

sampling interval, analytical parameters and location selection rationale is presented in Table 4-5, located at the end of this section.

FEED PREPARATION AND SAMPLING PLANT - BUILDING 101, AREA 109, 110

The Feed Preparation and Sampling Plant was designed to process approximately 75 tons per day of the low assay feed material concentrates.

The plant consisted basically of equipment and facilities for drying, grinding, screening, blending and sampling of both wet and dry ore concentrates and process residues. The three major functions performed in the building were to:

- Prepare representative samples of feed material for accountability purposes;
- Eliminate tramp metal, wood and foreign material from feed material; and
- Eliminate ammonia and/or residual organics from feed materials by oxidation and heating.

In addition, a 68,800-square-foot storage pad (Areas 109 and 110) was provided for the storage of incoming drummed feed material. An unloading dock was provided in the storage area.

The storage pad is poured concrete construction with a hardened surface, sloped, and provided with a complete trench drainage system which collects the rain and wash-water drainage from both the pad and Building 101 in a common sump. Sampling will be performed in the wash-water drainage area based on the potential for residual organic contamination. These locations are:

DIGESTION AND DENITRATION - BUILDING 103

Building 103 is composed of two major sections: the Digestion Section and the Denitration Section. In the Digestion Section, sampled ore concentrates were digested and transferred as slurry to Refinery Building 105 where the solution was purified by solvent extraction. The second section of Refinery Building 105 then received the purified uranium nitrate trioxide. The content and function of the two sections is more fully outlined below.

Digestion Section. The digestion portion of the refinery was designed to dissolve uranium concentrates in nitric acid. The

concentrates were received either in the form of oxides of uranium or in the form of sodium, magnesium and calcium salts of uranium. They were normally free-flowing powders that were transported from the Feed Preparation and Sampling Plant (Building 101) to the refinery in transfer hoppers and were fed directly into the four digesters. The resulting slurry was then transferred and stored in holding tanks from which it was pumped to the extraction plant (Refinery Building 105).

Denitration Section. After purification, the uranyl nitrate solution from the extraction plant (Refinery Building 105) was pumped to the denitration section where it was further concentrated in steam-heated tanks and finally transferred to gas-fired denitration pots.

The resultant dry product, uranium trioxide powder, also known as orange oxide, was pneumatically conveyed from each pot to the penthouse section where it dropped by gravity through a pulverizer, vibrating screen, one-stage sampler, and finally into transfer hoppers for movement to the Green Salt Plant (Bldg. 201). The oxides of nitrogen generated during the denitration cycle were collected and returned to the nitric acid recovery facility.

Sampling will be performed in the vicinity of Building 103 based on the use of nitric acid and metal acids. The sampling locations are:

#	Coordinates W	N	Analytical Parameters

TBP AND ETHER EXTRACTION - BUILDING 105

The Refinery Building (Building 105) removed essentially all uranium from the digested slurry received from Building 103 and returned the uranium as purified uranyl nitrate solution to the Denitration Section of Building 103. The process consisted of a two-stage solvent extraction operation in which tributyl phosphate (TBP)-hexane was used as the first stage solvent and diethyl ether as the second stage solvent.

The impurities contained in the digest slurry were concentrated and removed as raffinate from the TBP-hexane extractors in the form of an acid slurry. This slurry was transferred to the raffinate neutralization system prior to disposal in the raffinate pits.

The aqueous re-extract liquor containing the bulk of the uranium present in the feed concentrates was washed with hexane in a spray column to remove entrained TBP. It was then heated to flash off all remaining hexane. The solvent-free re-extract liquor was finally concentrated in a triple effect evaporator

located in the boil-down section and pumped to the Denitration Section of Building 103 as pure uranyl nitrate solution.

Raffinate from the first stage extraction was washed with hexane in a spray-type wash column to remove TBP and then stripped of hexane by boiling off the solvent in a stripping tank. The solvent-free raffinate was pumped to the raffinate neutralization system in the Denitration Section of Building 103 and on to the raffinate pits. All sump liquors in this first-stage extraction section were collected and stripped of TBP and hexane in a similar manner. The solvent-free sump liquor was then pumped to the sump liquor concentration system located in the Digestion Section of Building 103. All TBP and hexane recovered from the extract, raffinate, and sump liquor was adjusted to the proper TBP concentration by boiling off excess hexane in a still. The evaporated hexane was condensed and re-used.

Sampling will be performed in the vicinity of Building 105 based on the use of TBP, hexane, nitric acid, and diethyl ether. Sampling locations are:

#	Coordinates W	N	Analytical Parameters

10)	50,150	100,425	VOA, SV, IO

GREEN SALT PLANT - BUILDING 201

The Green Salt Plant (Building 201) was designed to convert uranium trioxide (UO_3 or orange oxide), the product of Building 103, to uranium tetrafluoride (UF4), known as green salt.

Orange oxide powder was received from the Refinery Building (Building 105) in portable hoppers. The oxide was fed to a reduction reactor where the uranium trioxide (UO_3) was continuously reduced at an elevated temperature to uranium dioxide (UO_2 or brown oxide) with hydrogen gas. The uranium dioxide was then converted to uranium tetrafluoride by contacting it countercurrently at high temperature with hydrogen fluoride (HF) gas in three hydrofluorination reactors operating in series.

Basically, this process contains six reactor banks, each with four horizontal reactors arranged one above the other, a re-run bank similar to the reactor banks, a green salt reverter, and a pilot bank, consisting of three smaller reactor tubes. Uranium trioxide was reduced continuously to uranium dioxide by the countercurrent flow of hydrogen in a tubular reactor.

The hydrogen for the reduction step was made by the catalytic dissociation of anhydrous ammonia in special package units. Hydrofluoric acid for the hydrofluorination step was received from the tank farm (Area 202) as a liquid and was vaporized in steam jacketed tanks. Auxiliary facilities included six dust

collection and four vacuum cleaning systems for handling dusts, a lime scrubbing system for removing the last traces of HF from gases being vented to the atmosphere, two Freon refrigeration systems and a nitrogen producer.

Sampling will be performed in the vicinity of Building 201 based on the use of hydrofluoric acid, a lime scrubbing system, Freon, and asbestos.

The sampling location is:

#	Coordinates W	N	Analytical Parameters
11)	50,225	99,850	MTL, VOA, SV, pH, IO

METALS PLANT - BUILDING 301

The Metals Plant (Building 301) was designed to convert uranium tetrafluoride (UF_4) received from Building 201 to metal. The conversion was accomplished by a batch process, involving a thermite-type reduction of the uranium tetrafluoride with magnesium.

The reduction was carried out in large refractory-lined containers, known as "bombs," which were heated in a furnace for several hours in order to bring the reactants to a temperature at which the reaction, once ignited, occurred spontaneously. After removal from the furnace, the bombs were cooled and disassembled. The metal, which settled to the bottom of the bomb

and solidified, was removed from the slag in a so-called "breakout" operation. The cylindrical metal shape produced in this process was fabricated without recasting and was therefore considered a direct ingot and given the designation of "dingot". The magnesium fluoride slag produced by the reaction was crushed, ground and a portion recycled for use as the refractory liner for the bombs. The chips of metal removed during the machining of the dingot were segregated and collected for reclamation.

Sampling will be performed in the vicinity of Building 301 based on the use of caustics, magnesium, and solvents. Sampling locations are:

#	Coordinates W	N	Analytical Parameters
12)	50,375	99,650	MTL, VOA, SV, pH, IO
13)	50,075	99,400	MTL, VOA, SV, pH, IO
14)	50,225	99,400	MTL, VOA, SV, pH, IO

MAGNESIUM BUILDING - BUILDING 302

The Magnesium Building (Building 302) served as an important auxiliary facility to the Metals Plant (Building 301). It provided facilities (1) for unloading the finely divided magnesium metal chips received either by rail or truck in returnable 22-gallon drums, (2) for pelletizing and storing an inventory of drums in carload lots, and (3) for processing the magnesium through a magnetic separator and repackaging it in weighed lots of 55-gallon drums for use as a single charge in the

metals plant. Because of the hazards involved in storing large quantities of finely divided magnesium, it was necessary to isolate the building from other operating areas. Sampling will be performed in the vicinity of Building 302 based on the use of magnesium and lead.

Sampling location:

#	Coordinates W	N	Analytical Parameters
15)	50,390	99,175	MTL, IO

STEAM PLANT - BUILDING 401

The Steam Plant and its auxiliary facilities furnished the WSUFMP with steam, refrigerated brine, soft water, compressed air, and emergency electric power. The yard structures include coal and ash handling facilities, salt storage, coal storage and ash disposal areas.

The boilers were located outside the building and were supported by individual structural steel frames. The induced draft fans were located to the east of the building and discharged into two ground-supported steel stacks. A stack was used also for a small incinerator installed to the west of the steam plant. Two plant air receivers, a diesel exhaust muffler, an acid storage tank, and a diesel oil storage tank were located outside the building walls. Sampling will be performed in the vicinity of Building

401 based on the use of asbestos, barium chloride, coal, chlorine, hydrofluoric acid, diesel oil, fuel oil, lube oil, gasoline, oxalic acid, phosphate, sulfite and salts.

Sampling locations are:

#	Coordinates W	N	Analytical Parameters
16)	50,575	100,725	MTL, VOA, SV, IO
17)	50,550	100,950	MTL, SV, TOX
18)	50,550	101,070	MTL, SV, TOX
19)	50,550	101,210	MTL, SV, TOX
20)	50,660	100,940	MTL, SV, TOX

WET AND DRY CHEMICAL PILOT PLANT - BUILDING 403

The Wet and Dry Chemical Pilot Plant (Building 403) was designed to house pilot plant equipment for performing operations similar to those carried out in the digestion, extraction, and denitration areas of the operating plant. Sampling performed in the vicinity of Building 403 will be based on the use of nitric acid, magnesium, lime, iron, aluminum, hexane, and TBP. Sampling location is:

#	Coordinates W	N	Analytical Parameters
21)	49,800	100,675	MTL, VOA, SV, IO

METALS PILOT PLANT - BUILDING 404

The Metals Pilot Plant (Building 404) houses the metallurgical pilot plant and includes such facilities as blenders, jolters, breakout equipment, reduction furnaces, vacuum casting equipment and a small ceramics laboratory. The building was designed for maximum flexibility of equipment installation. It is located immediately north of the laboratory (Building 407). Sampling in the vicinity of Building 404 will be based on the use of barium fluoride, lithium chloride, and lithium fluoride. Sampling location is:

#	Coordinates W	N	Analytical Parameters
22)	49,725	100,675	MTL, VOA, SV, IO

WAREHOUSE - BUILDING 406

The Warehouse (Building 406) provides storage space for dry chemicals, recycled and special feed materials, intermediate products and miscellaneous materials. Both railroad car and truck unloading docks are provided. Since most dry chemicals were used in the refinery area, the warehouse is equipped with a ramp so that materials can be moved to other buildings by fork truck. No sampling is proposed in this area due to the presence of large areas of concrete.

SUPPORT FACILITIES

LABORATORY BUILDING - BUILDING 407

Building 407 provided the necessary laboratory facilities for the plant. Approximately two-thirds of the building housed analytical facilities with the remaining third housing development facilities.

Although many chemicals were used in Building 407, there is no historical information indicating routine transport of chemicals from Building 407 to other buildings, nor are there any documented spills in the area. Therefore sampling in the vicinity of Building 407 will not be performed.

MAINTENANCE AND STORES BUILDING - BUILDING 408

The Maintenance and Stores Building (Building 408) provided the on-site maintenance facilities. The building housed maintenance shops, maintenance stores, automotive maintenance, fire trucks and offices for shop and stores supervision. The shops were located side by side along the exterior wall of the building facing the plant. Each had access on the interior side of the building to a "multiple-use" work space which was serviced by a truck aisle running the length of the building. A fire wall divided the building longitudinally into two equal areas. The stores section was on the opposite side of the fire wall from the shops.

Automotive maintenance and repair facilities were located at the south end of the building adjacent to the motor pool. A shipping and receiving dock was provided at the southeast corner of the building which is nearest to the plant entrance. Adjacent to the dock was a decontamination, cleaning and degreasing station. Sampling in the vicinity of Building 408 will be based on the use of many chemicals associated with facility and automotive maintenance. Sampling locations are:

#	Coordinates W	N	Analytical Parameters
23)	49,700	99,550	VOA, SV, PP, IO
24)	49,910	99,830	VOA, SV, PP, IO
25)	49,775	99,975	MTL, VOA, SV, IO, PP

ADMINISTRATION BUILDING - BUILDING 409

The Administration Building (Building 409) was designed and arranged to serve as an administrative and technical headquarters.

Chemical contamination is not expected in the vicinity of building 409 and no sampling will be performed.

SERVICES BUILDING - BUILDING 410

The Services Building (Building 410) housed the following facilities: cafeteria, health department, guard house, gate house and change rooms.

Although Building 410 contained chemicals for first aid and health services, there is no record of routine transport of chemicals in and out of the building nor any record of chemical spills in the vicinity, and sampling will not be performed.

SCRAP CLASSIFICATION AND EQUIPMENT STORAGE FACILITY-AREA 414

The Scrap Classification and Equipment Storage Facility (Area 414) provided for the storage of large pieces of equipment and for the receipt, classification and salvage of usable parts.

The facility consists of a concrete pad and a prefabricated building. The building housed salvage and reclamation operations and provided storage for equipment that could not be stored outdoors. Fenced enclosures are installed for classified scrap. No sampling is planned for this area.

PAINT SHOP - BUILDING 417

The Paint Shop (Building 417) was housed in a separate one-story building divided into two equal sections by a fire wall. One section was used for general storage and the other as work space. Sampling in the vicinity of Building 417 will be based on the routine use of benzene, methylisobutyl ketone, phenoline thinner, various paint solvents, and metals.

Sampling locations are:

#	Coordinates W	N	Analytical Parameters
26)	49,800	99,340	MTL, VOA, SV, IO, TOX
27)	49,870	99,440	VOA, SV, IO
28)	49,830	99,470	MTL, VOA, SV, IO

STORAGE BUILDINGS-BUILDINGS 433, 434, 435, 436, 437 & 438

These buildings fulfilled several functions during the construction of the plant. They were constructed for temporary use as construction warehouses, personnel offices, shops, motor pool including fuel station, garages and general storage. Building 437 is constructed of brick and was previously part of the WSOW. The remaining buildings are Butler-type on concrete slab.

Sampling locations are:

#	Coordinates W	N	Analytical Parameters
29)	50,740	98,250	MTL, VOA, SV, IO
30)	50,710	98,350	MTL, VOA, SV, IO

34)	50,570	98,330	MTL, VOA, SV, PP, IO
35)	50,560	98,440	MTL, VOA, SV, PP, IO

36)	50,670	98,610	MTL, VOA, SV, PP, IO, TOX

REFINERY TANK FARM - AREA 102

The Refinery Tank Farm provided facilities for the unloading, storing, and transferring of liquid process materials required in the refinery operation which were supplied or handled in tank-car or tank-truck quantities. Storage tanks were furnished for hexane, ethyl ether, dilute nitric acid, sulfuric acid, and 50 percent caustic soda solution. Other facilities in this area include unloading docks, transfer pumps and drum filling equipment.

Tank Farm 102A handled all of the above materials except nitric acid, which was handled in Tank Farm 102B.

There are no buildings in the area. All equipment was located in open concrete saddle pedestals. Twelve tanks (19,000 to 26,000 gal) were located in the area but have been removed.

Sampling in the vicinity of the tank farm will be based on the use of hexane, nitric acid, sulfuric acid, ethyl ether and sodium hydroxide. Sampling locations are:

#	Coordinates W	N	Analytical Parameters
37)	50,500	100,140	MTL, VOA, SV, PP, IO, pH
38)	50,500	100,240	MTL, VOA, SV, PP, IO, pH
39)	50,440	100,170	MTL, VOA, SV, PP, IO, pH

40)	50,440	100,380	MTL, VOA, SV, PP, IO, pH
41)	50,440	100,450	MTL, VOA, SV, PP, IO, pH

45)	50,340	100,420	MTL, VOA, SV, PP, IO, pH

NITRIC ACID RECOVERY FACILITY - AREA 108

The Nitric Acid Recovery Plant was designed to recover for re-use the bulk of the nitric acid required for digestion. Accordingly, the facility was equipped to:

- o collect and absorb nitrogen oxides from the Digestion and Denitration Building in water or weak nitric acid; and
- o reconcentrate the recovered weak nitric acid.

The recovery plant was essentially an outdoor installation. Housing was provided for compressors and instrument panels. Sampling in the vicinity of Area 108 will be based on the use of nitric and ferric acids. Sampling location is:

#	Coordinates W	N	Analytical Parameters
46)	50,350	100,350	MTL, TOX, pH, IO

GREEN SALT TANK FARM - AREA 202

The Green Salt Tank Farm (Area 202) provided for tank car unloading and storage of anhydrous hydrofluoric acid (AHF) and anhydrous ammonia, both utilized in the Green Salt Plant (Building 201). In addition, storage and tank car loading facilities were installed for the 70 percent hydrofluoric acid (70% HF) recovered in the green salt process.

The five AHF tanks were located within an insulated enclosure. Five additional tanks were not enclosed, but were located within a diked area. Unloading pumps for AHF and a loading pump for 70% HF acid were installed. A compressor house was provided for the ammonia unloading compressor. Sampling in the vicinity of the Green Salt Tank Farm will be based on the use of hydrofluoric acid, anhydrous ammonia and anhydrous hydrogen fluoride. Sampling locations are:

#	Coordinates W	N	Analytical Parameters
46)	50,370	99,830	MTL, TOX, pH, IO
47)	50,370	99,850	MTL, TOX, pH, IO
48)	50,370	99,110	MTL, TOX, pH, IO
49)	50,300	99,950	MTL, TOX, pH, IO
50)	50,350	99,980	MTL, TOX, pH, IO

ELECTRICAL TRANSFORMER AREAS

Substation No. 412, the main electrical substation on site, contains the electrical equipment (switches and transformers) necessary for the transformation of incoming power at 34.5 KV to plant distribution power of 13.8 KV. Numerous smaller electrical transformers are located in the WSCP and samples will be collected based on the use of PCB and PCB contaminated oil. Sampling locations are:

#	Coordinates W	N	Analytical Parameters
51)	50,790	98,300	PCB
52)	49,940	99,740	PCB
53)	50,200	99,640	PCB, IO
54)	50,250	99,920	PCB, IO
55)	50,680	99,990	PCB
56)	50,440	100,340	PCB
57)	50,480	100,640	PCB, IO
58)	49,700	100,360	PCB
59)	49,780	100,800	PCB

COOLING TOWER - AREA 413

The Cooling Tower is constructed of redwood lumber. It was designed to handle 12,000 gpm and to cool the water from 110^{o}F to 90^{o}F at a wet bulb temperature of 78^{o}F.

A reinforced concrete basin with flume was installed, having a capacity of 80,000 gallons--the minimum amount of water storage required for proper operation of the cooling tower.

A steel frame building with corrugated asbestos siding was constructed adjacent to the cooling tower to house the pumping facilities, the chemical treatment and the electrical equipment necessary for the operation. Sampling in the vicinity of Area 413 will be based on the use of chlorine, chromate phosphate, and sulphuric acid. Sampling location is:

#	Coordinates W	N	Analytical Parameters
60)	50,525	100,525	IO

PROCESS INCINERATOR - AREA 415

The Process Incinerator was a small combustion unit for (1) burning trash or wastes from which uranium was to be recovered from the ashes and (2) burning of classified documents. Chemical contamination is not suspected in this area and no sampling will be performed in this area.

ELEVATED WATER TANK - AREA 426

The Elevated Overhead Storage Tank has a capacity of 350,000 gallons and stands 186 feet above the foundation. It is supported by six tubular steel legs set on a concrete foundation

and is equipped with a steam-heated standpipe. The installation provided a positive means of preventing any possible backflow

from the process system to the potable water system. Chemical contamination is not suspected in this area and no sampling will be performed in this area.

PRIMARY SEWAGE TREATMENT PLANT - AREA 427

A Primary Sewage Treatment Plant was installed near the south site boundary. It was sized to handle sewage wastes for approximately 1,300 persons per day. An Imhoff tank design for sludge settling and digestion was used. Sampling will be based on the spectrum of chemicals used on-site. A single grab sample will be collected and analyzed for metals, semivolatiles, PCBs, pesticides, inorganic anions, and TOX.

PROPANE GAS PLANT - AREA 428

A Propane Gas Plant was installed near the west side of the building area to provide fuel gas to the various plants to satisfy process heating requirements. Two 30,000-gallon storage tanks were provided. No chemical contamination is expected in this area, and samples will not be collected.

RESERVE WATER FACILITIES - AREA 429

The Reserve Water Facilities consist of a large ground storage tank and an auxiliary pump house. No contamination is expected and samples will not be collected.

FIRE TRAINING - AREA 439 & 443

During operations of the plant, the fire protection department maintained fire training facilities on the site. The foundations of these facilities are all that remains. Sampling in this area will be based on the presence of drums of unknown chemicals located during the 1987 chemical inventory. Since oil possibly contaminated with PCB's may have been utilized in the fire training area, the samples will be analyzed for PCB's, PCDF's and dioxins in addition to other parameters. Two grab samples will be collected from the fire training area. Sampling locations are:

#	Coordinates W	N	Analytical Parameters
62)	50,910	100,860	Nitroaromatics, MTL, VOA, SV, PP, PCDP's, dioxins, TOX - Grab from pit
63)	50,810	100,770	MTL, SV, PP, PCDF's, dioxins, TOX - Grab from filter

RAILROADS

A railroad system was installed within the plant site for delivering raw materials to and removing product from the plant.

The trackage is connected at the south boundary line to a railroad spur line that previously served the WSOW. The new railroad system within the plant area consists of double tracks that pass through the building area, and terminate at track bumpers located near the north boundary line. Track turnouts are strategically located to facilitate the movement of loaded or empty cars to and from the various buildings. Limestone ballast at a greater than normal depth was utilized on 190 feet of the track adjacent to the Green Salt Tank Farm, Area 202, in order to neutralize acid spills or drips from hydrofluoric acid tank car unloading. Decontamination of box cars was accomplished using a reinforced concrete basin installed under the east track adjacent to the feed storage pad, Areas 109 and 110. A track hopper is erected under the west track adjacent to the coal storage area for unloading coal from hopper cars to use in Building 401. Sampling will be performed in this area based on an uninvestigated tank area south of Areas 109 and 110. Sampling location is:

#	Coordinates W	N	Analytical Parameters
64)	50,360	100,660	MTL, VOA, SV, IO, PP

UNDERGROUND TANKS

Several underground tanks are present in various areas of the WSCP. These tanks were primarily used to store gasoline, fuel

oil, diesel fuel and other hydrocarbons. Sampling will be performed near each underground tank. Sampling locations are:

#	Coordinates W	N	Building	Analytical Parameters
65)	50,390	100,820	401	VOA
66)	50,750	100,770	439	MTL, SV, PP, TOX
67)	49,740	100,970	101	MTL, VOA, PP, TOX
68)	50,590	98,210	436	VOA
69)	49,870	99,590	408	VOA, PP

MISCELLANEOUS

Included in this category are several filters, isolated tanks and other areas suspected of being chemically contaminated. Analytical parameters were selected based on location, known process and/or suspected contaminants. Samples will be collected at 0 to 6 inch, 24 to 30 inch, and 54 to 60 inch intervals unless noted. Sampling locations are:

#	Coordinates W	N	Area	Analytical Parameters
70)	50,510	99,530	303	MTL, VOA, SV, PP
71)	50,460	99,600	303	MTL, VOA
72)	50,520	99,770	419	MTL, VOA, SV, IO, PP
73)	50,980	100,420	428	MTL, VOA, SV, PP
74)	49,880	100,240	410	MTL, VOA, SV, TOX

75)	49,800	100,620	407	MTL, VOA, SV, IO, PP, TOX, Asbestos
76)	49,730	100,040	404	MTL, SV, PP, TOX - Grab from filter
77)	49,890	100,840	403	MTL, SV, PP
78)	51,970	100,520	Ash Pond	Nitroaromatics, MTL, VOA, SV, IO, PP, TOX, pH

OVERHEAD PIPING SYSTEM

Steam, air, brine and fuel gas were carried in pipe-lines supported overhead on steel pipe racks and bridges. Steam was distributed through a network of asbestos-insulated pipes to the various buildings where it was used for process and heating purposes.

In order to accommodate all the various piping systems, a support system was erected which consisted of steel pipe poles and structural steel and pipe bents, along with several structural steel bridges. The supports were installed on concrete foundation piers.

Utility lines included in the overhead piping systems were as follows:

High pressure air
Instrument air
Ethylene glycol, supply and return
Fuel gas
High pressure steam

Piping for the transfer of the following chemicals was also part of the overhead distribution systems:

Concentrated nitric acid

Dilute nitric acid

Sulfuric acid

Lime slurry

Aluminum nitrate

Ferric nitrate

Caustic

Sodium carbonate

Diethyl ether

Hexane

Deionized water

Additional process lines include:

Digested slurry

"NG" liquor (recycled uranyl nitrate solution)

Aqueous uranyl nitrate

Raffinate

Sump liquor slurry

NO_2 fume headers

Since no documented leaks or spills occurred from overhead piping or railroad systems, samples will not be collected from these areas. However, sample locations selected randomly as discussed in Section 4.5 will provide coverage of affected areas.

SANITARY SEWER

A network of underground sewers was installed to collect and carry sanitary effluent from the various buildings to the primary sewage treatment plant, Area 427.

It was necessary due to the topography of the site to install septic tanks and drainage fields for the steam plant (Building 401) and the pilot plants (Building 403 and 404) since gravity flow to the sanitary sewer system was not possible.

The sanitary sewer system is from 4 to 12 feet deep and consists of 4,780 lineal feet of vitrified clay pipe, 6 in. to 10 in. diameter, and 245 lineal feet of 6 in. cast iron soil pipe.

PROCESS SEWER SYSTEM

A network of underground process sewers was installed to handle large quantities of manufacturing wastes containing chemicals and small amounts of low level radioactive materials. No reported leaks or failures of the process sewer system are known. Minor amounts of leakage would be extremely difficult to detect with borehole sampling. A more rational approach is to observe excavation operations, inspect the sewer lines and collect biased samples during excavation operations.

All WSUFMP Biased Sampling Locations are presented in Table 4-5.

TABLE 4-5

KEY FOR SOIL CHEMICAL ANALYSES

A = Nitroaromatics group (2,4-DNT; 2,6-DNT; 1,3-DNB; 1,3,5-TNB, and 2,4,6-TNT)

B = Nitrite

C = Sulfate

D = Metals

E = Mercury

F = GC/MS volatile fraction

G = GC/MS acid fraction

H = GC/MS BNA fraction

I = Hexavalent chromium

K = Asbestos

L = Inorganics, SO_4, SO_3, NO_3, NO_2, Fl

M = Pesticides/PCBs

N = TOX

O = Soil pH

P = Select metals - aluminum, antimony, barium, iron, lead, magnesium, manganese.

Note: See WSSRAP, RI/FS, QAPP for method description, detection limits, and holding times

4.4 WSOW Biased Sampling Program

4.4.1 Chemical Sources and Source Areas

The TNT and DNT production process that was carried out by Atlas Powder Company during the operation of the WSOW was similar to that used at other TNT and DNT plants.

TNT plants all use the same basic chemical process, i.e., the treatment of liquid toluene with mixed nitric and sulfuric acids followed by removal of undesired isomers and residual dinitrated toluene by conversion to soluble species. The undesired isomers plus residual dinitrated species were removed from the reaction mixture by treatment with aqueous sodium sulfite solution, called "sellite," which reacted with everything except the desired product. The spent sellite solution, containing the extracted sulfonate derivatives, was known as "red water," and constituted a major inherent waste stream.

Red water is a deep red, almost black, aqueous stream containing an extremely complex mixture of nitroaromatics and various inorganic salts. The organic portion is mostly accounted for by the various sulfonated derivatives of the three undesired TNT isomers.

Other organic constituents include smaller fragments, dissolved a-TNT, and complex, unidentified dye bodies formed from the photolysis of a-TNT by sunlight. The inorganic portion consists

mainly of unreacted sulfite plus nitrite and nitrate formed in the extraction reactions. Red water varies somewhat in composition from plant to plant and from run to run, but a typical composition is:

Water

Na_2SO_3-Na_2SO_4

$NaNO_2$-$NaNO_3$

Sulfonated or sellited nitro compounds

Solids

Ash

Figure 4-3 shows the schematic flow diagram of the batch process which was used by WSOW. Numerous buildings at the WSOW have been identified. Table 4-6 relates building number to process description where known. The nitration reactions are carried out in three consecutive batch units referred to as "Mono," "Bi," and "Tri" Houses. The feed chemicals to the Mono House (T-7) are toluene and waste acid from the Bi House (T-12), fortified with 60% HNO_3.

After reaction, the waste acid was transferred to a storage tank for recovery, and the partially nitrated toluene was pumped to the Bi House where further nitration was effected with waste acid from the Tri House (T-9), fortified with 60% HNO_3. The result was a mixture of all possible dinitrated isomers, "Bi Oil." After settling and separation, the Bi Oil was pumped to the Tri House where the feed acid was a mixture of 98% nitric acid and

oleum. The nitrated product from this third nitration stage operation was crude TNT containing a-TNT (2,4,6-trinitrotoluene), which was the desired product, and unsymmetrical TNT isomers, which were the impurities. The crude TNT was fed to the Wash House (T-13) for purification.

The purification of crude TNT involves crystallization in water, free acid neutralization with soda ash and solutilization and removal of undesirable nitrated products by treatment with a solution of sodium sulfite (sellite). The wastewater from the sellite purification stage was transferred to the red water treatment plant for disposal by evaporation-concentration and concentrate incineration.

The TNT slurry was transferred to a filter tank where it was washed and filtered on a screen leaving layers of TNT crystals. The crystals were reslurried with water and pumped to a melt tank where TNT was melted and most of the water was removed by evaporation. The molten product was run into hot air dryers for the removal of residual water. The water-free product was solidified on a water-cooled flaker drum or stainless steel belt, and the resultant film was removed in the form of small flakes by scraping the drum or belt with a beryllium blade. The flaked TNT was boxed and sent to a packing house for transfer to a storage or loading area.

Four waste streams are shown in Figure 4-3: spent acid, waste acid, red water, and yellow water. The spent acid was not

discharged; the nitric acid was distilled off and reused and the residual sulfuric acid was sold for commercial use. The waste acid (mostly spillage, floor drainage and the like) was neutralized with lime or soda ash and discharged to the chemical sewer for treatment and discharge to wastewater lagoons or surface drainage. The yellow water, essentially a dilute nitrator, and the red water were destroyed as previously described.

Dinitrotoluene (DNT), a closely related explosive, can be made in a TNT plant and was produced at the WSOW. No DNT was produced in production lines 1, 2, 3, and 4. Plate 1 shows the location of the process and waste lines as they existed on what is now the WSCP/WSRP. Of the 18 production lines which existed during the peak production period, only lines 1-4 were located in the vicinity of the WSCP/WSRP.

At the time of the closing of the WSOW, all lines, equipment and facilities were reportedly decontaminated to a known condition.

In addition to equipment and building contamination, all earth known to be contaminated around process buildings, catch tanks, and drainage ditches was removed in 1946. The depth of the soil contamination varied from 4 inches to 3 feet, depending on the nature of the soil.

Since the WSOW facilities have been demolished and much process-specific information was destroyed in 1974, a

building-by-building description of the process is not possible. This biased sampling effort is guided by investigations at the WSTA and at other ordnance works facilities (West Virginia, Alabama Army Ammunition Plant).

4.4.2 WSOW Biased Sampling Approach

The biased sampling program for WSOW sources was developed based on WSOW building locations, WSOW topography, current knowledge of WSOW production and waste management practices, and investigations at other ordnance works. Biased sampling locations were targeted towards TNT production areas representing potential source areas. Sampling depths were established using a cut and fill map (Plate 2) to assure that original WSOW topography was sampled. The cut and fill map was prepared by comparing 1954 topography to 1964 topography and contouring the difference in elevation. Cut areas were topographically higher in the WSOW time frame. Fill areas were lower topographically in WSOW days. The accuracy of this map is plus or minus two feet. Sampling locations in fill areas will be sampled to greater depths than cut areas. Analytical parameters were selected based on chemicals used in TNT production which may be present after forty years.

Sampling locations, depths, analytical parameters, and selection rationale for the WSOW biased soil sampling are presented in Table 4-7. Sample locations are shown in Plate 3.

All surface sampling locations are approximate.
Exact locations will be surveyed prior to sampling.

4.4.2.1 Selection and Number of Locations

Soil sampling locations were selected based on WSOW processes, building locations, and topography. For example, areas producing or transporting wastewater have the highest potential for nitroaromatic contamination. Surface drainageways from production areas carried wastewater (USGS, 1944) and should be sampled. Areas of acid usage increase the potential for metals contamination. The areas to be sampled are presented in Table 4-7. The rationale for sampling each area is detailed in the heading above each group of samples and is followed by specific sample locations, borehole depths, number of samples and chemical analyses. Seventy-five boreholes are proposed for the WSOW biased sampling. In addition, 11 surface soil samples will be collected from six areas.

4.4.2.2 Sampling Depths and Intervals

Borehole depths are presented in Table 4-7. Depths were determined by evaluating past and present topography and assuring that each borehole penetrated WSOW topography. Sampling intervals were selected based on the nature of the soils and the suspected contaminants mobility. The primary WSOW contaminants are nitroaromatics and metals, both of which bind to soil particles. Therefore, samples will be collected continuously and composited over two-foot intervals.

4.4.2.3 Analytical Parameters

Analytical parameters for WSOW biased samples include nitroaromatics, select metals, nitrate, nitrite, sulfate, and pH. The exact parameters are listed in Table 4-7. Exact analytical methods are explained in Section 5.0.

4.5 Unbiased Area Sampling

To date, an extremely limited data base has been developed for chemical characterization and contaminant distribution over the 220-acre WSCP/WSRP site. Therefore, in order to meet the sampling objectives to: (1) determine the extent and magnitude of contamination, (2) document uncontaminated areas and (3) provide representative data for risk assessment preparation, it will be necessary to conduct a statistically designed, unbiased sampling effort. The sample design will provide uniform coverage of the site, complementary to the biased sampling programs discussed in Sections 4.3 and 4.4.

The primary objective of the area sampling is to document areas believed to be uncontaminated. The recorded site history indicates probable areas of contamination, and these areas are addressed in the biased sampling program. However, there remains a significant area previously unaddressed as to its status of contamination. While a very large number of samples would be required to document the absence of contamination at specific

locations over the entire site, a statistically designed sampling approach will provide a method for determining areas free of contamination to a known confidence level.

Establishing background metals and inorganic anion concentrations in native soils are also addressed in this section.

4.5.1 Statistical Sampling Approach

The appropriate number of sample locations for achieving data sufficiency and representation is determined using a statistical approach outlined in "Preparation of Soil Sampling Protocol: Techniques and Strategies" (Mason, 1983).

The approach requires the collection of samples on a regular line transect pattern over the investigation area with randomly selected starting locations. The line transect pattern consists of equilateral triangles laid out to form a hexagon. The size of the hexagon and corresponding side lengths of the equilateral triangle are determined using the following formula where L equals the length of a side of a triangle.

$$A = 2.598(L^2)$$

The area is determined by fitting the site into a square area extending 50 feet beyond the site boundary. The total area of the site using this method is 20,250,000 square feet. This area,

when used in the above formula, results in a sample spacing of 558 feet and a hexagonal side length of 279 feet.

Based on a 95% confidence level and 20% acceptable error margin using the following formula:

$$n = (CR)^2 \, t^2/p^2$$

Where: n = number of samples
cr = coefficient of variation
t = two tailed t value
p = allowable margin of error

The total number of sample locations is determined to be 91. Figure 4-4 shows the example locations determined by the Line Transect A system. In order to plot at least 91 sample locations within the site boundary, two hexagonal grids are placed over the site with randomly selected starting locations for orientation. In some cases, the sample points fall in locations currently unaccessible. These sample locations will be moved off the grid in the direction of the shortest distance from the grid node. For example, sample locations which fall in the region of the raffinate pits have been moved out of the pit to the closest accessible area. In this manner, the number of sample locations will remain at 91 in order to achieve a 95% confidence level.

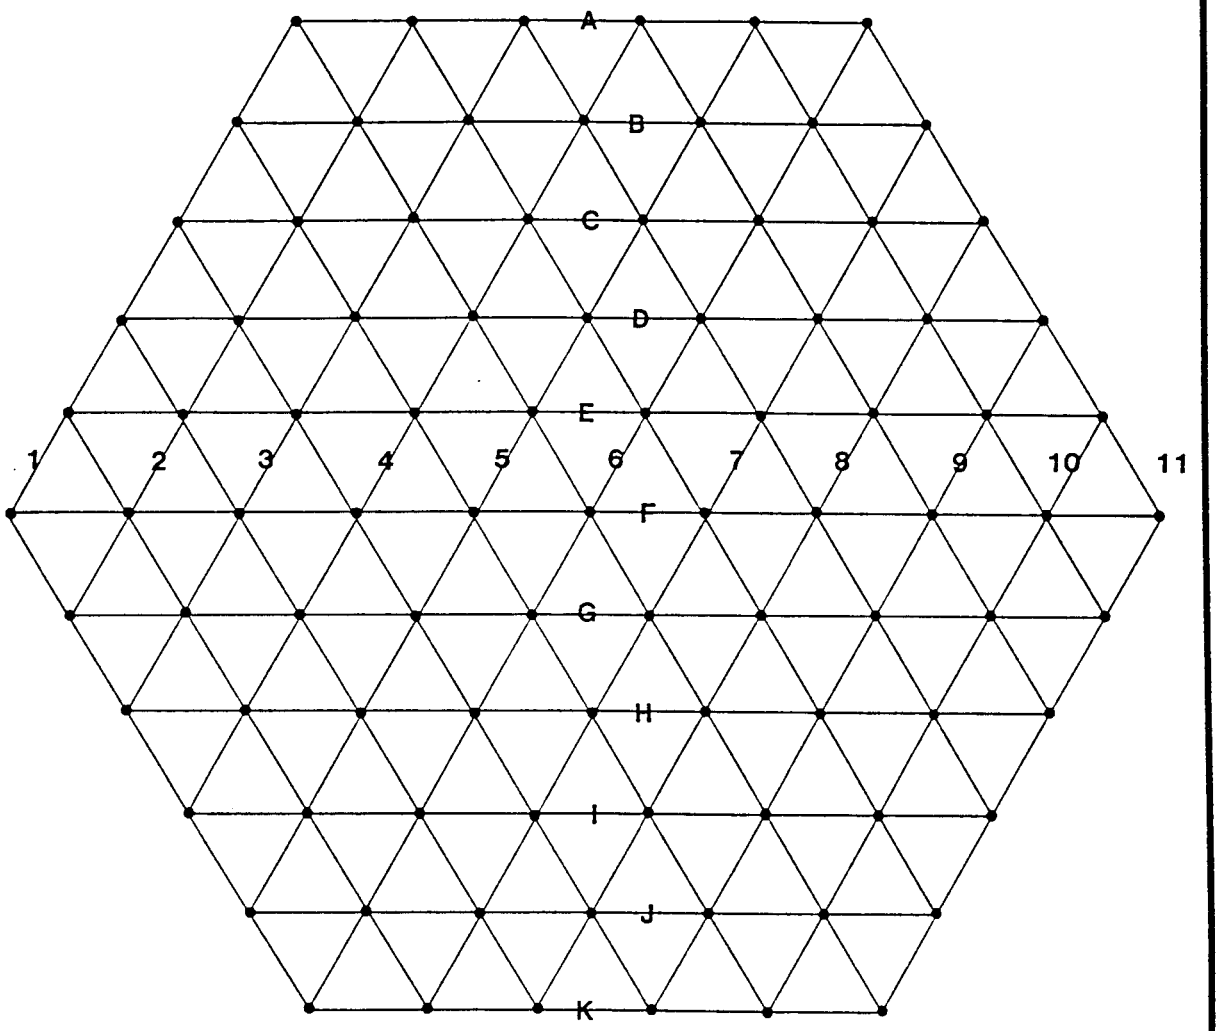

FIGURE 4-4

EXAMPLE LOCATIONS

Figure 4-5 presents an overlay of the two hexagonal grids on the site figure. Figure 4-6 presents the sample locations numbered 1-91.

The overall sampling program, both biased and unbiased, was used to determine the probability of detecting a hotspot of a given size. The formula for determining this probability is:

$p = n A^1/A$

n = # of sample locations

A^1 = Area of target

A = Area of study

p = Probability of detection

The total number of sample locations to be used in contamination assessment is 277. There are 245 samples from this work plan and 32 samples from the Phase I Soil Investigation.

The target was assumed to be elliptical in shape with a semimajor axis of 100 feet and a semiminor axis of 50 feet. This target shape was selected based on a point spill or discharge source with overland dispersion. The target size was selected based on the operational life of the WSOW and WSUFMP. Any spills or discharges are assumed to have occurred with enough frequency to

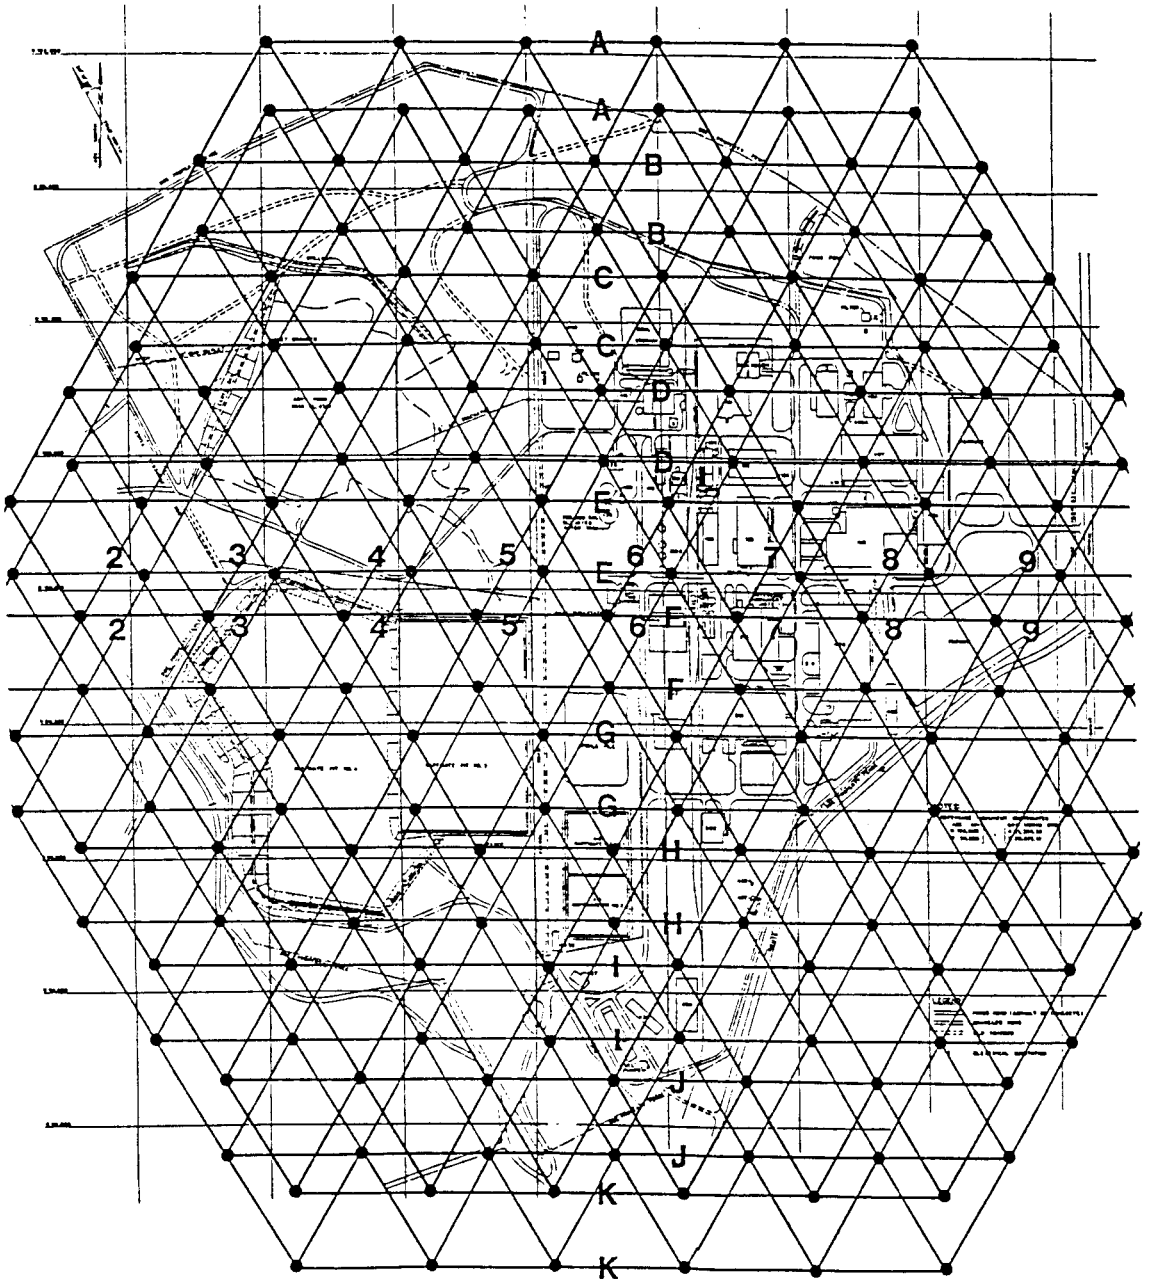

FIGURE 4-5

HEX GRID OVERLAY

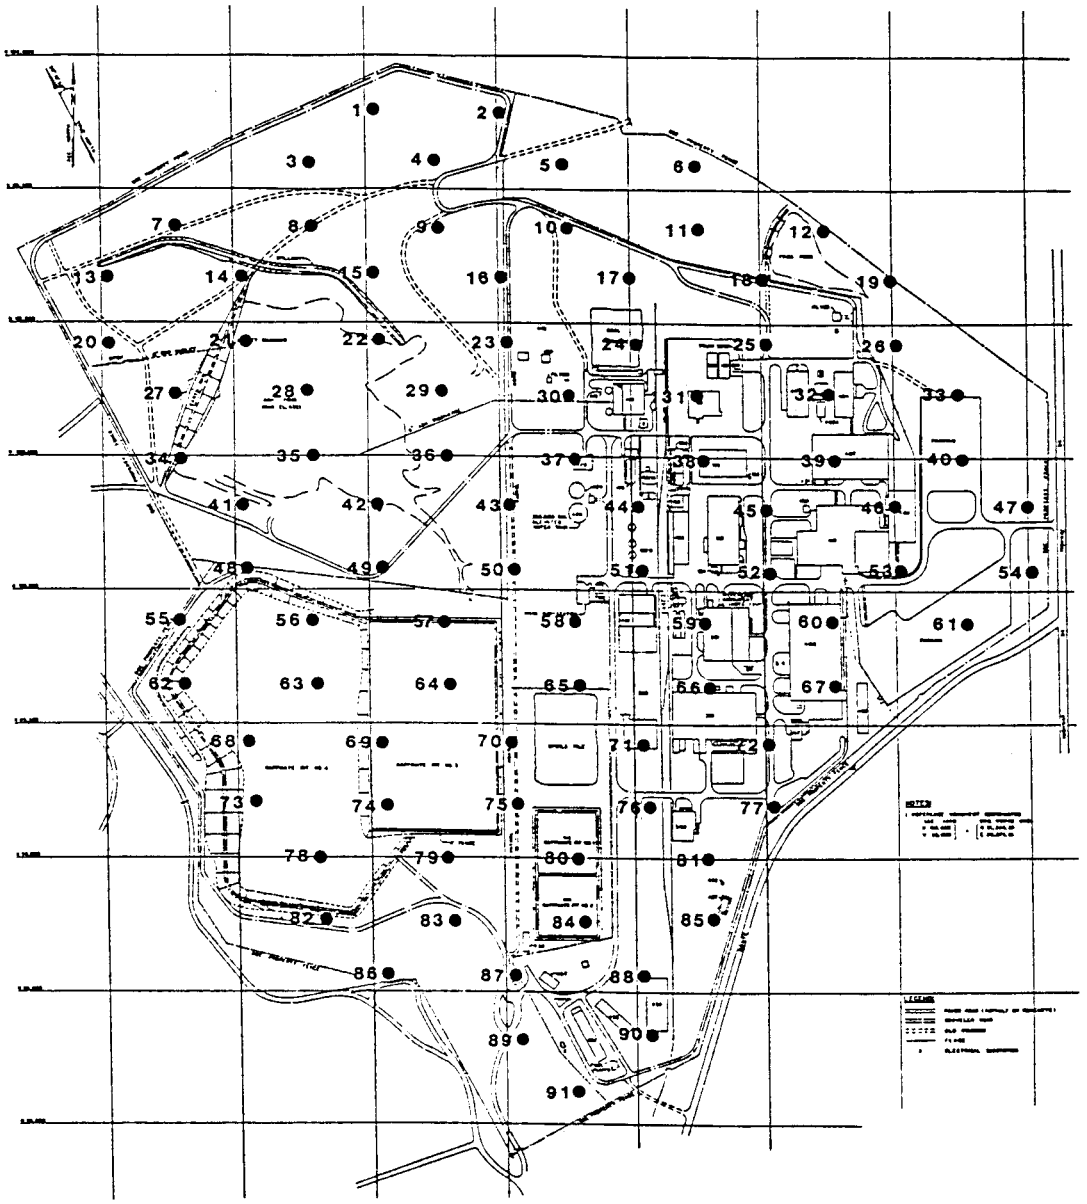

FIGURE 4-6

RANDOM GRID

create an area 200 feet long by 100 feet wide. Using the previously stated equation and assumptions, the probability of detecting elliptical hotspots 200 feet by 100 feet is 45 percent. Changes in target size or shape can affect this probability. However, this target shape and size are realistic, given the known processes and lack of uncontrolled dumping.

4.5.1.1 Sampling Depths and Intervals

Borehole depths were determined by evaluation of the cut and fill topography presented in Plate 2. In order to ensure coverage to the probable extent of vertical migration, borehole depths will be to fifteen feet in cut areas and undisturbed areas. Borehole depths in fill areas will equal the fill depth plus fifteen feet of undisturbed soil. Portions of alternating two-foot intervals will be composited for analyses. For example, the 0-1 interval will be composited with the 2-3, 4-5 and 6-7 foot intervals, and the 8-9 foot interval will be composited with the 10-11, 12-13 and 14-15 foot intervals, resulting in two samples for analysis from 15 feet of sample core. Therefore, a sample will represent 4 one-foot alternating intervals. No more than 4 one-foot intervals will be composited per sample. The composite intervals

were selected to detect large areas of contamination in areas not expected to be contaminated and to keep the number of samples to a manageable number. Detection of contamination under this program may require additional sampling to further define the actual extent. Table 4-8 presents borehole depths, cut and fill depths and sample intervals.

4.5.1.2 Number of Samples

The total number of composite samples is 227. These samples will provide a statistically valid site-wide data base for the contamination assessment.

4.5.1.3 Analytical Parameters

All random samples will be analyzed for a wide range of organic and inorganic constituents in order to provide documentation of previously unsampled areas. The analytical parameters were selected by analyzing and interpreting Phase I soil results (Section 3.1.2) and cut and fill relationships (Plate 2).

The Phase I Soil Investigation established the propensity of nitroaromatics to bind to WSCP/WSRP soil particles as percent

levels of nitroaromatics in the old waste lagoon decreased below detectable levels in approximately eight feet. This tendency may be viewed as "worst case" since the waste lagoon contained water acting as a driving hydraulic head for several years and still retains water. As a result of this analysis, the lowest composite sample from each random sample location will not be analyzed for nitroaromatics. Undisturbed and cut areas will have one composite sample analyzed for nitroaromatics, while fill areas will have at least two (depending on fill thickness) composite samples analyzed for nitroaromatics. Since the processes and potential contaminants from the WSOW and WSUFMP are known, it is not necessary for all random samples to be analyzed for the complete Hazardous Substances List (HSL). Very limited numbers of volatile and semivolatile organic compounds were used in TNT and uranium production. Any organic contamination outside of production areas should be minor in nature. Therefore, only the upper composite samples at each location will be analyzed for the complete HSL. Locations in cut or undisturbed areas will have one sample analyzed for the complete HSL, while fill areas will have at least two (depending on fill thickness) samples submitted for complete HSL analyses, so that one composite sample for HSL compounds will be representative of the original surface material. The Phase I Water Quality Assessment documented the absence of organic compounds in the groundwater, further indicating the lack of significant vertical migration of organic soil contaminants.

All random samples will be analyzed for WSSRAP indicator parameters which include nitrate, nitrite, sulfate, fluoride, soil pH, and percent moisture. These indicator parameters, coupled with the nitroaromatic and HSL analyses, will allow interpretation of all random sample data.

4.5.2 Background Samples

Background samples will be collected from an uncontaminated area within 5 miles of the site, and will be equal to 20% of the number of random samples. The area selected for background samples need not be upwind since significant wind transport is not expected from WSOW or WSUFMP processes. These samples will be analyzed for selected metals (aluminum, antimony, barium, iron, lead, magnesium, manganese, nickel, vanadium, and zinc) and inorganic anions and will be used to establish an environmental baseline data set for contamination assessment. These background samples will allow a valid assessment of calculated background values for on-site metal concentrations. Due to the widespread use of nitric and sulfuric acid in WSOW production, the potential exists for broad areas to be affected by these chemicals. Therefore, background samples for inorganic anions must be collected off-site in an area unaffected by WSOW or WSUFMP processes. Figure 4-7 shows the location of the background samples in relation to the WSCP. Two samples will be collected from each of 25 boreholes spaced according to the previously defined grid. Samples will be composited in the same manner as random samples. According to the St. Charles County Soil

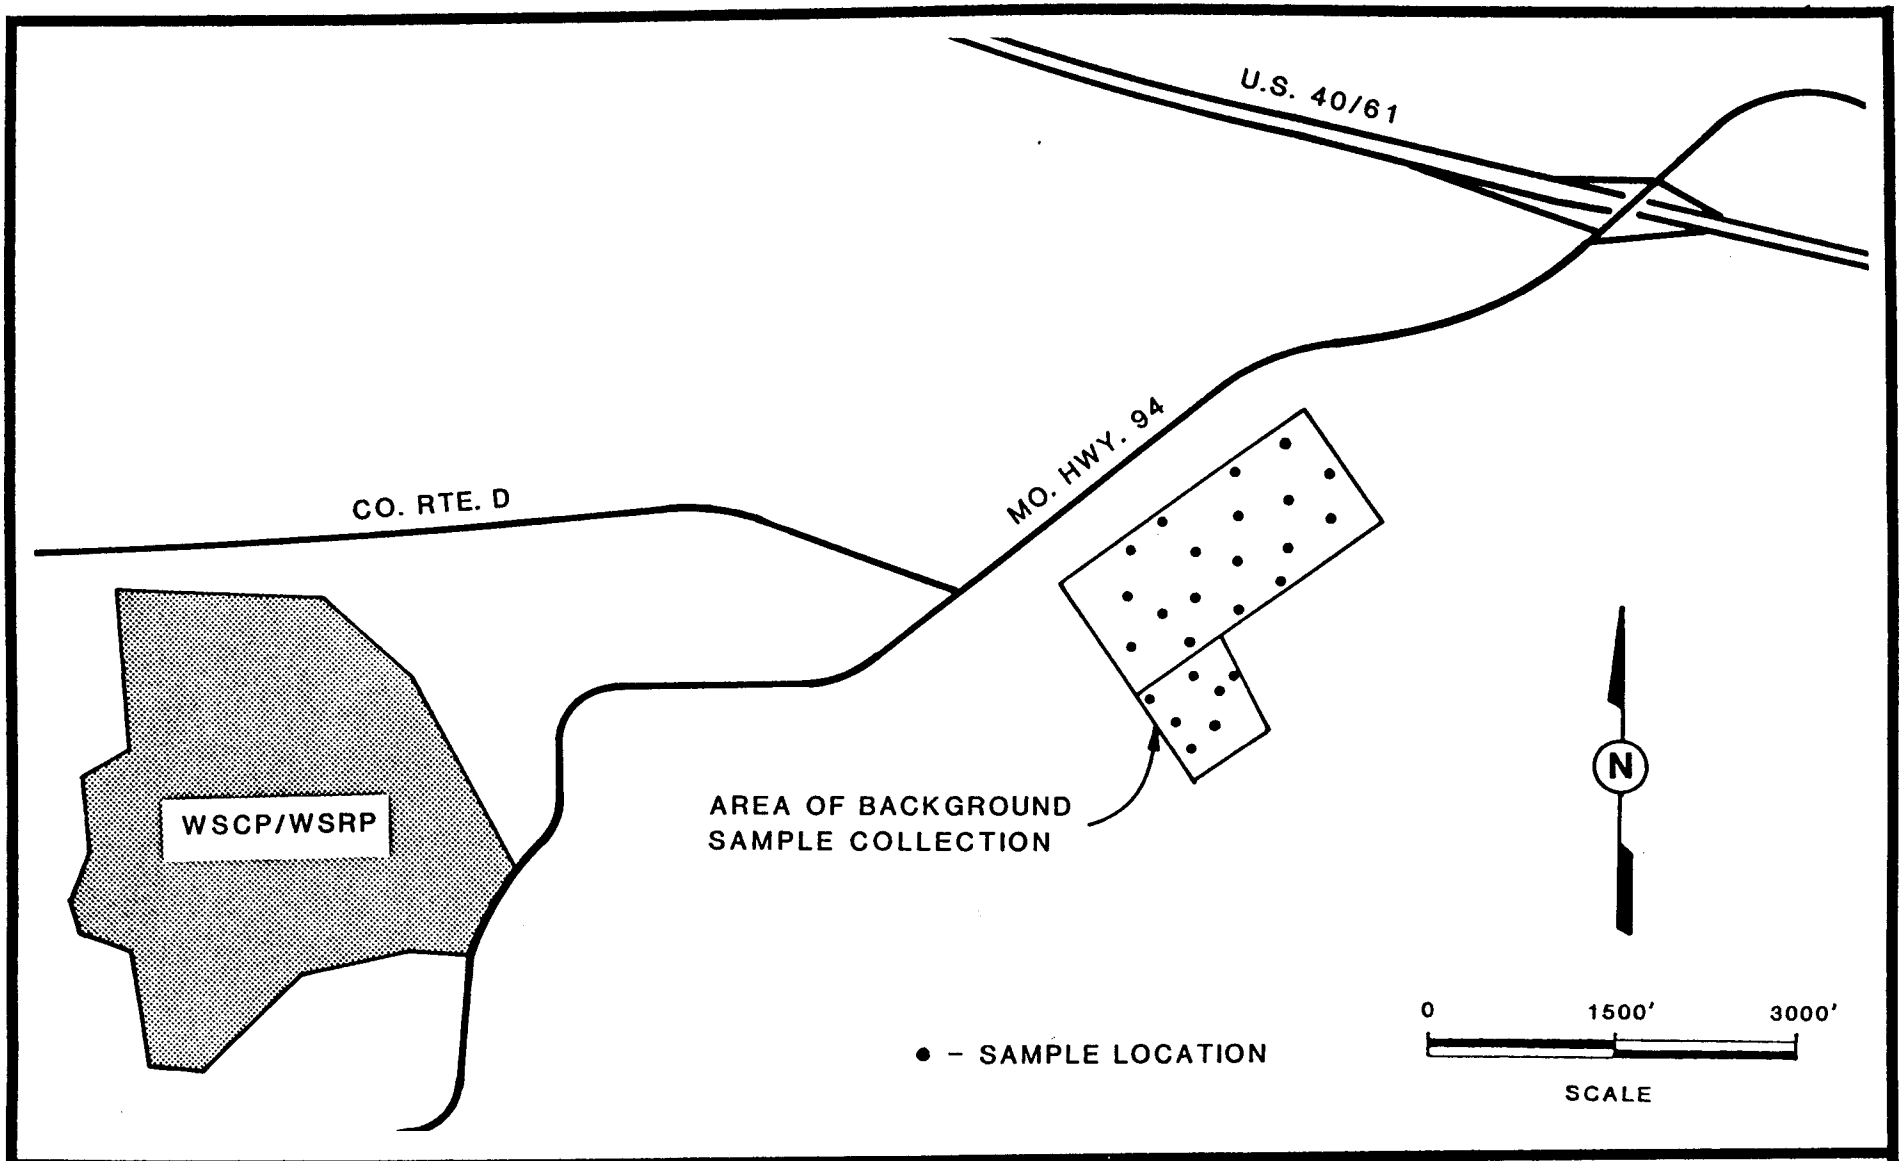

FIGURE 4-7

BACKGROUND SOIL SAMPLE LOCATIONS

Conservation Service Soil Survey, this area exhibits the same soil association (Armster-Mexico-Hatten Assoc.) and vegetative cover native to the WSCP/WSRP area. The area is also located near the Missouri-Mississippi River surface divide and is unaffected by surface drainage from the WSUFMP and WSOW areas.

4.6 Sampling Procedures

4.6.1 Sample Collection

Soil samples will be collected by continuous coring to the desired depth, using hollow stem augers and continuous sampling equipment capable of obtaining a 2 inch diameter by 60 inch long continuous sample. The sampling device will advance with the augers, and is divided longitidinally to facilitate sample removal. This type of sampling equipment has been sucessfully used on WSS soils in previous investigations, and provides sufficient sample for all required analyses and allows thorough geologic logging. Split spoons will be used if samples are not properly retained.

Actual sample collection will be performed using stainless steel spatulas to collect the samples from the desired intervals. Composites will be mixed in a stainless steel pan prior to filling sample containers. Compositing will be performed by mixing visually equal aliquots. All sample collection and compositing will be performed in areas protected from direct

sunlight. All drill cuttings will be collected and stored on-site in the Ash Pond Area.

4.6.2 Radiological Screening of Samples

Continuous monitoring for radiological contamination will be performed during all drilling and sampling activities conducted within areas known or suspected to be radiologically contaminated. A G-M probe will be placed immediately over exposed surface and subsurface samples. Samples which exceed a count rate of 700 cpm will be considered radiologically contaminated and will be handled according to WSSRAP Standard Operating Procedures 2.05.01, Radiation Soil Sampling.

4.6.3 Sample Preservation

Soil samples will be preserved by cooling to $4^{o}C$ as soon as possible after collection and compositing, and will be maintained at $4^{o}C$ during shipment to the laboratory. All samples will be collected in glass jars with polytetrafluorethylene (TFE) lined lids.

Chain-of-custody documentation will be maintained from the time of collection until the samples are delivered to the laboratory according to approved WSSRAP procedures.

4.6.4 Field Equipment Decontamination

The following decontamination efforts will be used to clean sampling equipment and prevent cross-contamination during sample collection and compositing.

All sampling tools will be decontaminated between samples according to the following decontamination procedure:

1. Steam clean
2. Deionized water rinse
3. Toluene Rinse
4. Double Hexane Rinse
5. Air dry

All rinse solvents will be collected and disposed of properly. In addition, where possible, sampling equipment will be stored in plastic containers or precleaned aluminum foil.

Auger flights, drill rigs, drill rods and samplers will be cleaned by steam cleaning on the decontamination pad. This pad allows the whole rig to be cleaned and the wash-water collected for proper management. All augers, samplers and drill rods will be steam cleaned between boreholes. Samplers will be steam cleaned between samples and subjected to the previous described solvent rinse procedure.

All wastewater, waste solvents, and soiled cleaning materials used for decontamination will be collected for proper treatment or disposal.

4.6.5 Borehole Grouting

After completing each borehole and removal of drilling equipment, the boreholes will be completely backfilled with a Bentonite-cement grout which will remain plastic and provide a flexible seal for each boring. This grouting program will maintain the integrity of WSCP/WSRP soils for potential long term disposal. Moisture content of the existing soils will prevent dessication of grout seals. Drill cuttings will be removed from the sampling location and placed in the Ash Pond area. Ultimate disposal must await completion of characterization activities.

5.0 ANALYTICAL PROCEDURES

Appendix B of the WSSRAP Quality Assurance Program Plan (QAPP) outlines all analytical methodologies and detection limits for the analytical parameters addressed in this work plan. A general discussion of the methodologies for organics, inorganics, and nitroaromatics is given in the following sections.

5.1 Organics

Selected soil samples will be analyzed for organic compounds as detailed in "Attachment A, USEPA Contract Laboratory Program Statement of Work for Organic Analysis," October 1986. These analyses include: volatiles, semi-volatiles (including acid and base neutral fractions), pesticides, and PCBs. These analyses will be performed in accordance with the analytical procedures described in the above referenced Scope of Work (SOW). Detection limits are also listed in the above referenced document. Analytical data will be validated as described in the QAPP. Nitroaromatics will be discussed separately.

5.2 Inorganics

Soil samples will be analyzed for several inorganic compounds including metals, nitrate, nitrite, sulfate, chloride, fluoride and pH. Those analyses included in the SOW for inorganic analysis under the USEPA Contract Laboratory Program (CLP) will

be analyzed according to the CLP-required procedures. CLP-required detection limits will also be met. Nitrate, nitrite, sulfate, chloride, and fluoride analyses will be performed according to EPA method 300.0. Soil pH will be determined according to EPA method 9045.

5.3 Nitroaromatics

All nitroaromatic analyses will be performed according to USATHAMA methodology. Analysis will be performed by High Pressure Liquid Chromatography (HPLC). USATHAMA-required standards of precision and accuracy will be met. Approximate detection limits are listed below.

Compound	Approximate Detection Limit
TNT	1 mg/Kg
2,4 -DNT	1 mg/Kg
2,6 -DNT	1 mg/Kg

In the event that high percent-levels of nitroaromatics are detected, soil samples will be submitted for the characteristic of reactivity testing as defined in 40 CFR 261, subpart C to determine explosive stability.

All analytical data will be validated as described in the QAPP.

All primary analyses will be performed by metaTRACE, Inc. of St. Louis, Missouri. Replicate samples will be submitted to JTC Associates of Rockville, Maryland. All sample containers and field blanks will be prepared by the laboratories.

5.4 Sample Containers

Soil samples will be placed in appropriate sample containers. All soil samples, with the exception of volatile organics, will be placed in amber glass jars with TFE-lined caps. Volatile organic samples will be placed in 40-milliliter glass jars with TFE-lined caps.

6.0 QUALITY ASSURANCE

The purpose of the soil sampling quality assurance (QA) procedures is to ensure that the data collected are of known and sufficient quality to assess contamination at the site both qualitatively and quantitatively. Soil sample quality and representativeness will be maintained by the quality assurance measures and samples described in this section. Further description of the overall site characterization quality assurance program is addressed in the QAPP.

QA samples will be collected to assess analytical and sampling variability, to determine the effects of compositing on samples, to demonstrate the effectiveness of decontamination procedures and to assure that samples are not contaminated during shipment to the laboratory. Laboratory data will be validated according to the procedures outlined in the QAPP. Precision, accuracy and representativeness will be determined as outlined in the QAPP.

QA samples will be collected throughout soil investigations at the WSS. Duplicate and replicate samples, field handling blanks and field blanks will be collected to assess sample quality and representativeness during each step of the sampling process. Each QA sample type will be discussed in detail in the following sections.

6.1 Duplicate Samples

Duplicate samples will be collected at the same time, in the same way, and contained, preserved, and transported in the same manner as the original sample. Duplicate samples will be used to verify the reproducibility and precision of the data. All duplicate samples will be submitted as blind duplicates.

All sample locations will require a 1 in 20 duplication for data validation.

6.2 Field Blanks

Field blanks of a known soil composition will be handled in the same manner as the sample and subsequently analyzed to identify possible sources of contamination during collection, preservation, handling and transport. One field blank per sampling team, per day will be prepared in advance of the sampling event. Field blanks will be used to determine analytical accuracy.

6.3 Triplicate Samples

Triplicate samples provide a measure of precision and representativeness of a single sample which tests the homogeneity of the sample. Five percent of all samples will be split into duplicate samples to provide blind duplicates for the analytical laboratory and a third replicate for the referee (JTC) laboratory to determine interlab precision. The use of a referee (JTC) laboratory aids in determining the reliability of the data by detecting bias in the analysis.

6.4 Matrix Spikes, Matrix Spike Duplicates, Spikes and Duplicates

The laboratory is required to perform quality assurance analyses to evaluate analytical method performance. Matrix spikes (MS) and matrix spike duplicates (MSD) are required for organic analyses at a 1 in 20 frequency. Spikes and duplicates are required for all inorganic and nitroaromatic analyses at the same 1 in 20 frequency. These samples will assess laboratory and method performance.

7.0 DATA DOCUMENTATION

This section discusses the documentation procedures to be followed during site sampling and include: log book entry, sample identification, and chain-of-custody procedures.

7.1 Log Books

All field measurements will be recorded in project log books. All data will be recorded directly and legibly in field log books with entries signed and dated. Any entries to be changed will be changed so as to not obscure the original entry. The reason for the change will be stated and the change and explanation will be signed and identified at the time the change is made.

Specific log book entries will be made during soil boring operations.

The log books will be of bound waterproof paper and will be completed using waterproof ink or marker. The book will contain a listing of all personnel at the sampling location and their affiliation, the time of arrival and departure from the site and each sampling location, personnel risiting and/or inspecting and/or auditing the sampling crews, accidents, unusual occurrences or observation, variations from specifications and the contractor's representative authorizing the variations, weather conditions, readings on evironmental monitoring and other

relevant equipment information necessary to allow a re-creation of events. The recorded information will serve as a permanant record of field activities and will serve as a reference resource for evaluating observed data anomalies which may be attributed to weather conditions or field procedures.

In addition to log book entries, specific technical information will be recorded on borehole logging form ENP 7-1. Information to be recorded on the borehole logging form includes:

- Date
- Location number
- Coordinates
- Description of location
- Elevation
- Depth
- Geologic description of soil

Soil descriptions will be done in accordance with the Unified Soil Classification System as described in ASTM D2487-69 (1975), test method for classification of soils for engineering purposes.

The borehole log entries will be made by a geologist with a minimum of a 4 year degree in Geology or Geological Engineering and recent relevant experience in preparing lithologic logs in unconsolidated materials.

7.2 Sample Identification

Field samples will be identified with appropriate sample labels which include: date, time, location number, preservation method, and requested analyses. Sample location numbers will be labeled according to the WSSRAP Standard Operating Procedure (SOP) 4.01.01 (Appendix A - QAPP).

7.3 Chain of Custody

Established Chain-of-Custody (COC) procedures will be followed to document sample possession and to verify that the samples are not tampered with or altered prior to analysis. The WSSRAP COC procedure provides an accurate written record of each sample from the time of collection through analysis and allows the results of the analysis to be used as evidence. COC will be maintained according to WSSRAP SOP Number 4.01.02 (Appendix A - QAPP).

The COC record form (4.01.02) will accompany a sample or group of samples as custody of the sample(s) is transferred from the original custodian to subsequent custodians. Copies of all COC forms will be maintained in project files at the weldon spring site.

7.4 Packaging and Shipping

Samples will be packaged for shipment to the laboratory as specified in WSSRAP SOP 4.01.04 (Appendix A - QAPP).

COC will be maintained throughout shipment to a laboratory or storage. Completed COC forms will be sealed inside transporting containers, a copy of which will be filed in the WSSRAP filing system. Copies of COC forms returned from laboratories will be included in this file. The lab copy will assure that the samples arrived intact.

Laboratories receiving samples will be notified prior to shipping and instructed to notify the shipper in the event that samples are damaged or missing.

All applicable Department of Transportation regulations will be followed during sample shipment.

7.5 Reporting

Completed COC records will be filed in the WSSRAP project filing system and the Environmental Safety and Health (ES&H) files. Copies of the COC forms returned from laboratories will also be filed in the ES&H file. Any problems or variances to the approved COC procedures will be recorded in the file and reported to the Quality Assurance Manager.

8.0 REPORTING REQUIREMENTS

Upon completion of the soil sampling and laboratory analysis program, a comprehensive data review will be performed in preparation of a chemical contaminant preliminary data report. The preliminary data report will present raw data only and will not include a contamination assessment. The data report will compare the data against the field blanks to detect contamination from sampling, compare field sampling replicates, review laboratory quality control, delineate unusable data and attach appropriate qualifiers to usable data. The data report will also explain the limitations of qualified data and summarize detection limits for non-detectable results.

Following the completion of the data report, a contamination assessment report will be prepared in support of the overall site characterization report. Specifically, the report will assess contamination by considering the quantities and types of contaminants at and around the site and transport mechanisms that are allowing or may allow migration of contaminants from the site. The contamination assessment report will include a summary of findings most relevant to the objectives of the site characterization and to the evaluation of remedial action alternatives.

RAFFINATE PIT SAMPLING PLAN

Enclosed is Revision 1 of the "Waste Assessment Raffinate Pit Sampling Plan" for the Weldon Spring Site. This plan has been revised to address comments received from USEPA and the Missouri Department of Natural Resources as indicated in the "Responsiveness Summary," also enclosed.

We trust that this adequately resolves the issues raised during the review of this Plan. We are proceeding with sampling activities as described in the enclosures.

If you have any questions concerning these items, please call.

Sincerely,

R. R. Nelson

1.0 INTRODUCTION

The purpose of this sampling plan is to provide a summary of existing data and to define the rationale for collection of the complement of data necessary to fully characterize the wastes contained in the Weldon Spring Raffinate Pits (WSRP). For complete characterization of the WSRP, combined data from radiological, chemical and physical analyses must be evaluated. The existing data base provides limited characterization analyses to address the radiological and chemical parameters. Additional physical, chemical, and radiological testing of the sludge/sediment in the WSRP must be performed. This additional data is needed for sludge/sediment treatability studies which in turn are necessary for the development/evaluation of remediation alternatives, design of the selected alternative, and verification of remedial effectiveness.

This sampling plan will deal primarily with the sampling and analysis of the sludge/sediments in the WSRP. Section 1.2, Previous Studies, includes sufficient chemical characterization data to evaluate remedial alternatives for the water ponded on the raffinate pits.

1.1 BACKGROUND

1.1.1 Site History

In 1956, the Atomic Energy Commission (AEC) acquired about 89 hectares (ha) (220 acres) of the original Weldon Spring Ordnance Works property from the Department of Army (DA) for use as the Weldon Spring Uranium Feed Materials Plant (WSUFMP). The WSUFMP operated between 1957 and 1966 and during that time processed uranium ore concentrates and recycled scrap to produce pure uranium trioxide, uranium tetrafluoride, and uranium metal. An average of 16,000 tons of uranium materials were processed at this plant per year. Thorium ore concentrates were also processed. These processes generated several chemical and radioactive waste streams, including raffinate streams from the refinery operation and the magnesium fluoride slurry streams (washed slag) from the uranium recovery process. These streams were slurried to the pits where the solids settled out and the supernatant liquids drained to the plant process sewer which drained offsite to a natural drainageway and ultimately to the Missouri River. The solids remaining in the pits consist of silica and other insolubles associated with the yellow cake ore feed materials, along with hydroxides and other precipitates formed from the pH neutralization of the raffinates with lime. Washed slag residues from the uranium metal production operation were also discharged to the pits.

After the plant was closed by the AEC, the DA acquired the facility in 1967 to convert it to herbicide production. The project was cancelled prior to becoming operational.

The 21-ha (52-acre) portion of the site that contains the four raffinate pits was transferred back to AEC in 1971. As the successor agency to AEC, DOE has assumed responsibility for maintenance of the entire site including the WSRP area. The location of the WSRP area is shown in Figure 1-1.

Figure 1-2 is a plan view of the four pits. These pits were constructed by excavating down into the existing clay formation and using the removed clay for constructing the dikes.

1.1.2 Physical Description of Pits

Raffinate Pits 1 and 2 were constructed in 1958, adjacent to each other, on nearly level terrain. Each pit covers an area of about 0.5 ha (1.2 acres) and has a depth of about 4 m (13 ft). The dikes of these two pits are approximately 1 m (3 ft) above the surrounding grade. Pits 1 and 2 each contain approximately 13,300 m^3 (17,400 cy) of low-level radioactive residues from past uranium refining and metal production operations. These waste volumes represent 94 percent of the capacity of each of the two pits (NLO, 1977). Table 1-1 presents the surface area, volume, and content of each of the four pits.

To convert cubic yards to cubic meters, multiply by 0.7646.

To convert tons to kilograms, multiply by 0.9071.

Ref. BNI, 1984

Pit 3 was constructed in 1959 with a design volume of 127,500 m^3 (166,700 cy), a surface area of approximately 3.4 ha (8.4 acres), and a depth of about 3.5 m (11 ft). The natural terrain slopes downward toward the west boundary so that the dikes around Pits 3 and 4, although approximately at the same elevation as those around Pits 1 and 2 are, in fact, much higher with respect to the original grade. A portion of the dike in the northeast corner of Pit 3 was constructed on existing terrain so that the dike is about 7 m (23 ft) above original grade in that area. Pit 3 contains approximately 99,100 m^3 (129,600 cy) of radioactive residues from past uranium refining and metal production operations and is 78 percent filled (NLO, 1977; Weidner and Boback, 1982).

Pit 4 was constructed in 1964 with a design volume of 339,800 m^3 (444,400 cy) and is approximately 12 percent filled. The east dike of Pit 4 is common to the west dike of Pit 3. The west dike of Pit 4 extends to a maximum of about 11 m (35 ft) above the existing grade. Approximately 42,500 m^3 (55,600 cy) of radioactive materials are stored in Pit 4, and the residue fill is irregular across the pit. Pit 3 is designed to overflow into Pit 4 through a connecting pipe 2 m (7 ft) below the top of the common dike.

The sludge material in the pits is covered with water for most of the year. The amount of water in the pits varies depending on the climatic conditions of a given year. During the hot, dry

summer months, the surface water in Pits 1 and 2 often evaporates, leaving the raffinate sludge with a dry and cracked surface. The level of water in Pits 3 and 4 also varies, but past observation has found some surface water always present.

Maintenance, surveillance, and environmental monitoring have been continually conducted at the WSRP site since the former DOE contractor, Bechtel National, Inc., began operation in 1981. The site is fenced, posted, and patrolled by security guards. The grass is mowed, brush is cleared for access to each pit, and the fences are repaired as necessary.

In 1982, a portion of the dike around Pit 4 was repaired to stabilize a shallow, circular arc slide. The slide occurred because of the steep (38-47%) side slopes of sections of the existing dikes. The side slopes of Pit 4 were constructed at undesirably steep slopes in this section because a perimeter road encroached on the space needed for construction.

1.1.3 Process Waste Description

There are three major waste types present at the WSRP site. These are:

1. Neutralized raffinate liquors generated from uranium refining operations, including washed slag residues

from uranium metal production operations and raffinate solids from the processing of thorium recycle materials;

2. Contaminated water ponded on each raffinate pit; and
3. Contaminated rubble.

Each of these waste types is addressed in greater detail in the following text.

1.1.3.1 Neutralized Raffinate Liquors

Neutralized raffinate liquors were generated as follows: the Weldon Spring Uranium Feed Materials Plant (WSUFMP) received yellow cake ore from various uranium mills across the U.S. The yellow cake feed material was ultimately dissolved in a process stream containing nitric acid solution. This solution contained the dissolved uranium along with all the other impurities found in the yellow cake ore. Once the uranium was stripped from the solution, the resulting waste was mixed with lime to produce what is referred to as neutralized raffinates. These neutralized raffinates were discharged directly to the raffinate pits.

In the final stage of the uranium production process, uranium tetrafluoride was reacted with magnesium producing uranium metal and magnesium fluoride. The magnesium fluoride slag was then redissolved with yellow cake feed material to recover unreacted uranium contained in the slag. The remaining magnesium

fluoride, or washed slag, was deposited in the pits. Neutralized raffinates and washed slag were processed out of Building 103, the digestion and denitration building of the WSUFMP.

The residues contained in Pits 1, 2, and 3 consist of the neutralized raffinates and washed slag residues as descirbed above. Thorium is also present in these pits from the uranium feed material and from uranium decay during storage in the pits.

Pit 4 contains the same types of residues that are present in Pits 1, 2, and 3 plus raffinate solids from processing of thorium-232. It also contains recycle materials and copious quantities of drums and rubble dumped during closure of the Feed Materials Plant.

1.1.3.2 Contaminated Water

Approximately 54 million gallons of water is currently ponded on the raffinate pits. Section 1.2.4 of this sampling plan provides a detailed discussion of the analysis performed on these waters.

1.1.3.3 Contaminated Rubble

The contaminated rubble consists of drums and steel scrap dumped during closure of the WSUFMP and when the Army began conversion of a portion of the plant for herbicide production. The main dumping area is in Pit 4. All of the rubble is presumed to be radiologically contaminated since it originated from the WSUFMP. There is no indication that any of this rubble includes containerized chemical wastes. Visual inspection of the rubble has revealed no drums remaining intact. A number of samples of the sludge material will be taken sufficiently close to the rubble area to verify the presence or absence of chemical contamination.

1.1.4 Raffinate Pit Constituents

Radium is present in the raffinate pits due to the decay of uranium to radium and trace amounts of radium in the yellow cake. In addition, some feed materials at the WSUFMP were high-grade uranium ore which would contribute both thorium-230 and radium-226 to the wastes in the raffinate pits.

The majority of the radium (both 226 and 228) was removed at the uranium mill and disposed of with the mill tailings. As for thorium, a significant amount is retained with the uranium when raw uranium ore is processed into yellow cake. Processes at the

Feed Materials Plant separated thorium-230 from the uranium and sent it to the raffinate pits.

The relative solubilities of uranium, thorium and radium determine the radiological composition of the raffinate pit water. Of the three, thorium is the most insoluble in aqueous solutions, while radium is slightly soluble in water with the evolution of hydrogen. However, uranium is attacked by water and several uranium compounds are stable in solution. Therefore, uranium activities should be greater than radium activities and both uranium and radium activities should be greater than thorium activities.

Numerous tanks, drums and other equipment were disposed of in Pit 4 during the 1967-1969 decontamination effort by the Army. Most of the equipment from Buildings 101, 103, and 105 was dismantled and dumped in Pit 4. The equipment in these buildings would have been contaminated with uranium in a soluble form. Near the end of production at the Feed Materials Plant, uranium was used to purge thorium wastes from all steps of the process. Wastes from this purge were disposed of in Pit 4.

1.2 PREVIOUS STUDIES

Three reports have been prepared regarding various properties of the raffinate pit sludges and sediments. Bechtel National, Inc. (BNI) subcontracted with Eberline Instrument Corporation in 1983

to take samples of the waste in the raffinate pits and analyze them for stable metals and radiochemistry. BNI also subcontracted with Environmental Science and Engineering, Inc. (ESE) in 1983 to sample and analyze the raffinate pit wastes in an effort to select equipment best suited to dewater the raffinate pit sludges. In 1986, BNI obtained samples of the raffinate pit sludges and subcontracted Thermo Analytical/Eberline Laboratory to perform radiological analysis and analysis for EP Toxicity, PCBs, reactivity, ignitability, and pH.

One report has also been prepared for characterization of the raffinate pit surface waters. This report was prepared by the current Project Management Contractor (PMC) in 1987.

1.2.1 Bechtel National, Inc. Study, 1983 (with Eberline)

The samples were collected and analyzed by Eberline Instrument Corporation in 1983. The data reported here are analytical results on a single, blended, mixed, composite sample prepared from multiple-location samples taken from each pit. The stable metals (Table 1-2) were analyzed using the method of atomic absorption analysis.

From the referenced study, results of analyses of the chemical components of the raffinate sludge in each pit are presented in Table 1-2 and the radiological components in Table 1-3.

(a) These data do not include lead-210 which would increase total curies, if included. The activity of lead-210 at the WSRP site has not been measured. However, since almost all of the radioactive material brought onto the site was either uranium ore concentrates, uranium scrap, or thorium scrap, only an insignificant amount of lead-210 should be present, and this from radioactive decay of the radium and thorium in the pits. This is due to the long half-lives of radium-226 (1,600 years) and thorium-230 (80,000 years), and the short time (less than 40 years) during which decay has occurred. (Note: only lead-208 (stable) should be present from the thorium-232/thorium-228 chain).

(b) Data presented in this table are based on analysis of sludges obtained from the pits by BNI in May 1983.

Note: The ± values indicate measurement accuracy.

Table 1-2 shows the presence of high concentrations of silicon, zirconium, sodium, nitrates, and fluoride, as well as elevated levels of arsenic, calcium, magnesium, and molybdenum in all four pits.

Table 1-3 presents a preliminary estimate of the radioisotopic content of each of the four raffinate pits at the WSRP site. According to this estimate, the average concentration of radioactive materials in the raffinate sludge is about 3,500 pCi/g. The level of radiation at approximately 0.3 m (1 ft) above the sludge ranges from 0.2 to 1.5 mR/h.

1.2.2 Bechtel National, Inc. Study, 1983 (with Environmental Science & Engineering)

In 1983 Bechtel National, Inc. (BNI) contracted with Environmental Science and Engineering, Inc. (ESE) to sample and test the physical properties of the raffinate pit sludges. Testing was actually performed by Monteagle, Inc., Environmental and Energy Consultants, and Reitz & Jens, Inc.

The initial project intent was to use test results to select the type and size of mechanical dewatering equipment best suited to dewater the raffinate pit sludges. Early test results indicated that the sludges had a considerably higher solids content than expected. For this reason all further tests related to

mechanical dewatering were stopped and replaced with a series of tests useful in developing other treatment options.

Sludges in each of the raffinate pits were sampled by driving a core sampling device into the sludge bed at preselected locations. The sampling was conducted from a polystyrene barge. The sampler was driven with a safety slide hammer and extractor. The sampler itself was constructed of 3-inch PVC tubing with a retaining apparatus and check valve to hold the sample during extraction.

Sludge samples were obtained from eight locations (three each from Pits 3 and 4, one each from Pits 1 and 2). Sample locations are shown in Figure 1-3. A summary of the sampling data is provided in Table 1-4. Samples were obtained from the top, middle and bottom of each core, providing 24 individual sludge samples. Sludge composites were made by homogenizing individual samples from each location within each pit. Preliminary tests were conducted on individual sludge samples; most testing was conducted on the composite samples (Reference ESE, 1983).

Table 1-5 lists percent total solids of each discrete sample. Percent total solids is defined as the weight of the solids in a sample divided by the total weight of the sample times one hundred. The total solids determination is useful in estimating the homogeneity or heterogeneity of the sludge. It can be

interpreted from the solids data in Table 1-5 that the physical density of the sludge appears to be heterogeneous with no discernible trends or patterns. Interpretation of the data, however, is difficult due to the vibratory sampling technique.

Table 1-6 is a summary of physical properties of the composite sludge samples. The liquid and plastic limits are expressed as moisture contents (weight of water divided by the weight of solids for a given sample). Above the liquid limits, the soil-water system is a suspension. Between the liquid limit and the plastic limit the system is said to be in the plastic state. The difference between these two limits is called the plasticity index and is the range over which a soil-water system acts as a plastic material.

The specific gravity of solids is the ratio of the dry density of the solid fraction (weight of solids divided by volume of sample) of a sample to the density of water (62.4 lbs/cf). This parameter can also be an indicator of homogeneity or heterogeneity. Although the specific gravity is shown to vary from pit to pit because the samples from each pit were composited for this particular test, the degree of heterogeneity within each pit is quantitatively indeterminate.

Resistivity is the measure of the resistance of a given material to electric current. This measurement was made in-situ at varying depths in an effort to identify the extent of layering

TABLE 1-6

* Vibration testing performed with equipment conforming to ASTM D-2049.

Ref. Reitz & Jens, Inc. (BNI, 1983, ESE)

or stratification in each pit. The data exhibited on Table 1-6 shows a wide range of resistivities indicating the presence of stratification with depth.

Tests were conducted to determine whether the sludge solids would separate from the water fraction, or whether the sludge would flow in response to vibration, using ASTM D-2049. During the tests very little change in the material was observed after 15 minutes of vibration. The only visible change was that the top surface of the sample developed a smoother appearance. No change was observed when a furrow was struck across the sample and the sample was vibrated for 5 minutes. These results indicate that the material might possibly be excavated with conventional construction equipment (i.e. front end loaders) without recourse to special handling techniques.

The tests showing the percent finer than the #200 screen size indicate that the sludge consists primarily of very fine-grained particle size. Electron micrography photographs revealed that the particles are highly flocculated with some needle-shaped particles. These tests show that the sludge will not easily be dewatered using conventional mechanical methods.

Table 1-7 presents estimates of the sludge permeability range based on consolidation tests using Terzaghis one-dimensional consolidation theory (Reference Holtz and Kovacs, 1981).

TABLE 1-7

WSRP Permeability Results from Composite Samples of Raffinate Sludge

Pit	Natural w%*	Final w%*	Calculated Permeability Range
1	215.6	146.9	7×10^{-7} to 5×10^{-8} cm/sec.
2	196.4	158.6	5.8×10^{-7} to 1.1×10^{-8} cm/sec.
3	174.1	125.6	7.5×10^{-7} to 7.7×10^{-8} cm/sec.
4	171.6	121.1	9.4×10^{-7} to 1.5×10^{-7} cm/sec.

* water content by weight

Ref. Reitz and Jens, Inc. (ESE, 1983)

Permeability is a measure of the rate at which water flows through soil. The range of permeabilities presented in the table is beyond the limit (1 X 10^{-6}cm/s) of any reliable direct measurement using either a constant-head or falling-head permeameter testing apparatus. These test results can be interpreted as relative and imply that the permeability is less than 1 X 10^{-6} cm/s.

Table 1-8 presents additional test results for the composite samples. The use and interpretation of moisture content, total solids, density, and specific gravity have been discussed. An additional parameter, viscosity, is a measure of fluidity. Information on sludge viscosity is used in the selection and sizing of mechanical equipment which might be used for mixing or pumping the sludge. These data will be reviewed and applied as appropriate in conjunction with additional data which are to be collected by the PMC through the execution of this sampling plan.

1.2.3 Bechtel National, Inc., Study, 1986 (with Thermoanalytic/Eberline Laboratory)

BNI conducted an initial Resource Conservation and Recovery Act (RCRA) characteristic sampling program for the Weldon Spring Site (WSS) Raffinate Pits in 1986. The 28 sampling locations are shown on Figure 1-4. These locations were chosen using a random number generator method. At each location, up to three samples were obtained and sent to the Thermoanalytic/Eberline

Laboratory in Albuquerque, New Mexico, for radiological analysis. Each sample was analyzed for uranium 234, 235, and 238, thorium 230 and 232, radium 226 and 228, lead 210, and polonium 210. Maximum, minimum and average concentrations are given in Table 1-9.

Eighteen samples were analyzed by Eberline Analytical Laboratories (EAL) for EP toxicity, reactivity, ignitability, PCBs and pH. All analytical results reported were below regulatory limits and EAL concluded that the material did not exhibit any of the four characteristics of RCRA hazardous waste (Reference BNI, 1986).

1.2.4 WSSRAP Project Management Contractor Study, 1987

Surface water samples were collected from the four raffinate pits as a part of the Phase I Water Quality Assessment conducted in April of 1987 by the PMC. Representative samples for each pit were collected from the shore and composited from at least four locations per pit. These samples were collected using a stainless steel bailer which was slowly lowered to a point just above the sediment. These samples were analyzed for the groundwater parameters listed in Table 1-10.

The analyses in Table 1-10 (Groundwater - Analytical Parameters) were selected based on known or suspected contaminants (nitroaromatics, radionuclides, etc.) and to provide documentation of presence/absence regarding species not expected to be present in the water (organics, Hazardous Substance List (HSL) compounds, PCBs, pesticides, etc.).

Surface water samples from each pit were analyzed for nitroaromatics. A trace level (0.28 ppb) of 2,4 DNT was detected in Raffinate Pit 2. It is possible that some nitroaromatically contaminated soil from across the area of the former Ordnance Works Facility was used in the construction of this pit. No other nitroaromatics were detected in any of the raffinate pit waters, as expected.

Raffinate pit water samples were also tested for four inorganic anions (nitrate, sulfate, chloride, and fluoride) and three water quality indicator parameters (Total Organic Carbon (TOC), Total Dissolved Solids (TDS) and hardness). The results of these analyses are shown in Table 1-11. A comparison of recent data to historical data for the four inorganic anions is presented in Table 1-12.

Due to the nature of the uranium purification process used at the WSUFMP, high levels of nitrates and sulfates were present in the raffinate slurry as it entered the pits. Due to

[a] Source - DOE, DEIS - 1987.

stratification of the sludges and lack of mixing, significant quantities of the inorganic anions would be expected to be bound in the sludge. Much higher levels existed in past pit water samples and in the raffinate sludge (Table 1-12).

Sulfate concentrations in the pit waters are 231, 493, 704 and 136 mg/L in Pits 1 through 4, respectively. This contamination probably originated as wastes from the yellow cake impurities removed by the solvent extraction process. As with nitrates, much higher amounts of sulfates are contained in the raffinate sludge and interstitial water.

Fluoride levels are slightly elevated in raffinate pit waters. The presence of fluoride in the pits is due to the reintroduction of magnesium fluoride into the digestion phase of the process to recover entrapped uranium. A large portion of the raffinate pit sludge is presumed to consist of magnesium fluoride.

Chloride levels were low for all four pits as would be expected, since chlorides were not used in the uranium process.

Total dissolved solids and hardness varied from pit to pit. The highest value was observed in Pit 3 and the lowest in Pit 4. This is as anticipated since Pit 3 contains the largest volume of wastes and Pit 4 was used for only a short time before production ceased.

Total organic carbon concentrations ranged from 6 to 12 mg/L. These values are as expected since no organic chemicals were used in the processing operation. These levels are probably due to natural organic sources such as algae (which is present in all four pits) or decaying organic matter.

Surface water samples collected from the raffinate pits contained varying amounts of metals. The results for each pit are shown in Table 1-13. All but 4 of the 24 CLP metals analyzed were present in at least one of the pits. All of the metals present in the ponded waters are also present, at higher concentrations, in the raffinate sludge (DOE, DEIS 1987). Due to the pH of the water (8.4 to 9.4) and the low solubility of metals in high pH aqueous solutions, most of the metals are expected to exist as solids in the sludge.

In the digestion stage, the magnesium fluoride slag from the final stage of the process was redissolved with yellow cake feed material to recover unreacted uranium; thus substantial quantities of magnesium, as magnesium fluoride, were deposited in the pits. This explains the elevated magnesium levels.

The remaining metals (Table 1-13) probably originated as impurities in the yellow cake concentrate feed material which were removed during the metallurgical purification process.

S - No Drinking Water Standard

** - Contract-Required Detection Limits, US EPA Contract Laboratory Program

U - Undetected at Contract-Required Detection Limits

Surface water samples from all four raffinate pits were also analyzed for volatile and semi-volatile organics, pesticides, and PCBs. No detectable levels of these compounds were observed in the water ponded on the raffinate pits.

Both Ra-226 and Ra-228 isotopes were present in raffinate pit ponded waters at varying activity levels. The highest level of radium-226 was detected in Pit 1 (61 pCi/L). Pit 4 contained the lowest radium-226 activity at 3.4 pCi/L. Radium-228 was observed in Pits 2, 3, and 4 at activities of 6, 32, and 13 pCi/L, respectively.

Thorium-230 was detected only in Pits 2 and 3 at levels of 13 and 16 pCi/L, respectively. Less than 5 pCi/L of thorium-230 was observed in Pit 4. Thorium-230 and thorium-232 activities could not be determined in Pit 1 due to interference. Based on thorium levels in the sludge in Pits 1 and 2, water in Pit 1 is expected to contain approximately 13 pCi/L thorium-230.

Based on the above analysis of surface water samples from the raffinate pits, no further analysis is deemed necessary at this time to characterize the waters ponded on the pits.

1.3 DATA NEEDS/SAMPLING PLAN OBJECTIVES

Radiological and chemical characterization thus far has provided an indication of the types of radiochemicals and chemicals

present in the raffinate pit sludges. From a radiologic standpoint, further testing is necessary to define the radioactive source term present in the raffinate sludge. Further chemical characterization is necessary to identify substances allegedly dumped during operation of the chemical plant and subsequent clean-up activities.

Physical characterization is complete enough to conclude that the sludges exist in a highly heterogeneous state and that the solids content is sufficiently high to preclude the effective use of mechanical dewatering techniques. Further testing is necessary, however, in connection with treatability studies. These studies will explore other stabilization technologies in an effort to achieve the regulatory goals of volume and toxicity reduction. The studies that will require additional sludge testing are: 1) stabilization studies including chemical methods, vitrification, pozzuolanic materials, dewatering techniques, and reprocessing the recoverable radioactive materials; and 2) liner compatibility studies. Section 3 of this sampling plan details all the proposed testing.

2.0 SAMPLING

2.1 SAMPLING RATIONALE

2.1.1 Radiological

The purpose of the radiological characterization of the raffinate pit sludges is to accurately determine the concentrations of radionuclides in the sludges. The importance of accurately determining these concentrations is two-fold. First, the radium-226 source term must be estimated to design an effective radon-222 barrier as part of an engineered cover. The second reason is to help assess the feasibility of recovering constituents (e.g. radionuclides or metals) from the sludges.

The radon barrier of a disposal cell is modeled in relation to a 1000-year design life (40 CFR 192). Significant concentrations of Ra-226 exist in the sludge today and, in 1000 years, 35 percent of the Th-230 will transform into Ra-226. Sixty-five percent of the original Ra-226 will also still be present. It is important, then, to estimate as accurately as possible the concentrations of these two radionuclides in the raffinate pit sludges in order to maximize the accuracy of subsequent radon barrier thickness calculations.

In 1984, the raffinate pit sludges were sampled by Bechtel National, Inc., (BNI). This is the most recent, most

comprehensive sampling effort of the sludges performed to date. This effort showed that there is great pit-to-pit variability for all radiologic species.

The BNI data was used to determine the number of samples per pit necessary to characterize the average radionuclide concentrations of each pit at a given level of statistical confidence. The accuracy determined to be adequate for this characterization was 90 percent confidence intervals about the mean with a relative error of the mean of 30 percent. The BNI data for Th-230 and Ra-226 was tabulated and the averages and standard deviations calculated. Only Th-230 was evaluated further because this radionuclide controls (for the 1000-year design-life of the disposal cell) the Ra-226 source term. Additionally, the statistical variability of the Ra-226 concentration was less than the statistical variability of the Th-230 concentration. The statistical variability of the uranium species concentrations is also less than the Th-230 concentration variability.

The derived sample requirements were then scaled volumetrically relative to Pit 3. Considering that Pit 3 contains nearly one-half the total sludge volume, the number of samples needed for the other pits could be scaled relative to Pit 3 without significant increases in error but with significant cost savings. This caused the number of samples to be reduced for Pits 1 and 2 and slightly increased for Pit 4. Then

approximately 85 percent of the sludge will be characterized with at least the desired level of accuracy.

It should be noted that the sludge is being characterized volumetrically and without regard to any vertical or horizontal stratification characteristics. It is not feasible to develop layer averages since there is no way to estimate how the sludge will be excavated and its subsequent disposal. The placement of the samples required to complete the sludge characterization will be made with regard to the previous sampling so as to provide uniform coverage of sludge area and depth.

2.1.2 Chemical

The purpose of the chemical characterization of the sludge/sediment material within the pits is to define the degree of contamination and to help quantify the magnitude of the effort that will be required to ultimately dispose of the wastes. The variability of contaminant types within the sludges will determine the disposal alternatives to be evaluated. Knowledge of these contaminants is required to develop the rationale behind liner engineering and compatibility testing.

The chemical characteristics of the raffinate sludge materials can be predicted to a limited extent from the history of the processes performed during the plant's operation, and from knowledge of the process sewers which drained to the pit.

However, because of alleged indiscriminate dumping of other chemicals into the pits, a scan for Hazardous Substance List (HSL) compounds will be conducted on samples acquired across each of the pits. This will determine the actual concentration of suspected wastes, as well as verify the presence or absence of other chemicals which may have been deposited in the pits.

The sludges will be analyzed for chemical products and by-products of process chemicals used on site, as well as their degradation products. These compounds include: metals, nitroaromatics and inorganic anions such as chloride, fluoride, nitrates, and sulfates. It is expected that no organic chemical contamination from volatile or semi-volatile fractions are present in the sludge; however, scans for likely compounds within these groups will be performed to confirm their absence. The sampling for the chemical parameters will be accomplished with the sampling efforts for radiologic characteristics. A list of the individual compounds and elements within each group is included as Attachment B.

Since these data will be applied primarily toward evaluation of disposal alternatives, a 90 percent confidence limit and one standard deviation about the mean were chosen as adequate for devising the sampling strategy.

The approach utilizes the formula

$$n=(cv)^2(t)^2/(p)^2$$

where n = the number of samples

cv = the coefficient of variation in percent

t = the student's t value for 90% confidence and 30 degrees of freedom

p = the acceptable error in percent

In the absence of usable data to determine actual variations in concentrations across the pits some assumptions must be made for the values of cv and p. Assumptions which were made for the raffinate sludge sampling were that the Coefficient of Variation equals 65% and the acceptable error will be chosen at 20%. The t-value for 90% confidence level and 30 degrees of freedom was obtained from the student's t table as 1.66. Calculating the minimum necessary number of samples (n) from these numbers:

$$n = (65)^2(1.66)^2/(20)^2$$

$$n = 29.10$$

Rounding up, n = 30

Approximately 30 samples would deliver a 90% confidence level with two standard deviations about the mean.

Since each of the pits contains, in effect, a different statistical population, a coverage of 30 samples per pit will be necessary to achieve the desired confidence. Consideration was given to combining the sampling efforts for Pits 1 and 2, since the pits are immediately adjacent to one another and the wastes were deposited in both pits in a relatively short span of time. However, review of existing data has shown some large variations in the concentrations of radiologic characters between the two pits. Therefore, these pits will be treated as separate statistical populations, with at least 30 samples taken in each of the four pits. Figure 2-1 exhibits the sample location layout.

A complete column of sample will be collected at each location to assess the degree of stratification of the waste materials. Of greatest concern with respect to high degrees of variation are the semi-volatile organic compounds and their impacts on liner compatibility. To date, no data have been collected on the semi-volatile fraction from the raffinate pit sludges. A breakdown of the numbers of samples and analyses to be performed, by pit, is given in Tables 3-2 through 3-6 (in Section 3.1).

Other parameters being investigated include CLP metals (plus lithium, molybdenum and zirconium), volatile organics, nitroaromatics, PCBs/pesticides, and inorganic anions (including chloride, fluoride, nitrate and sulfate). Previous studies have investigated, to a very limited extent, the sludge's content of

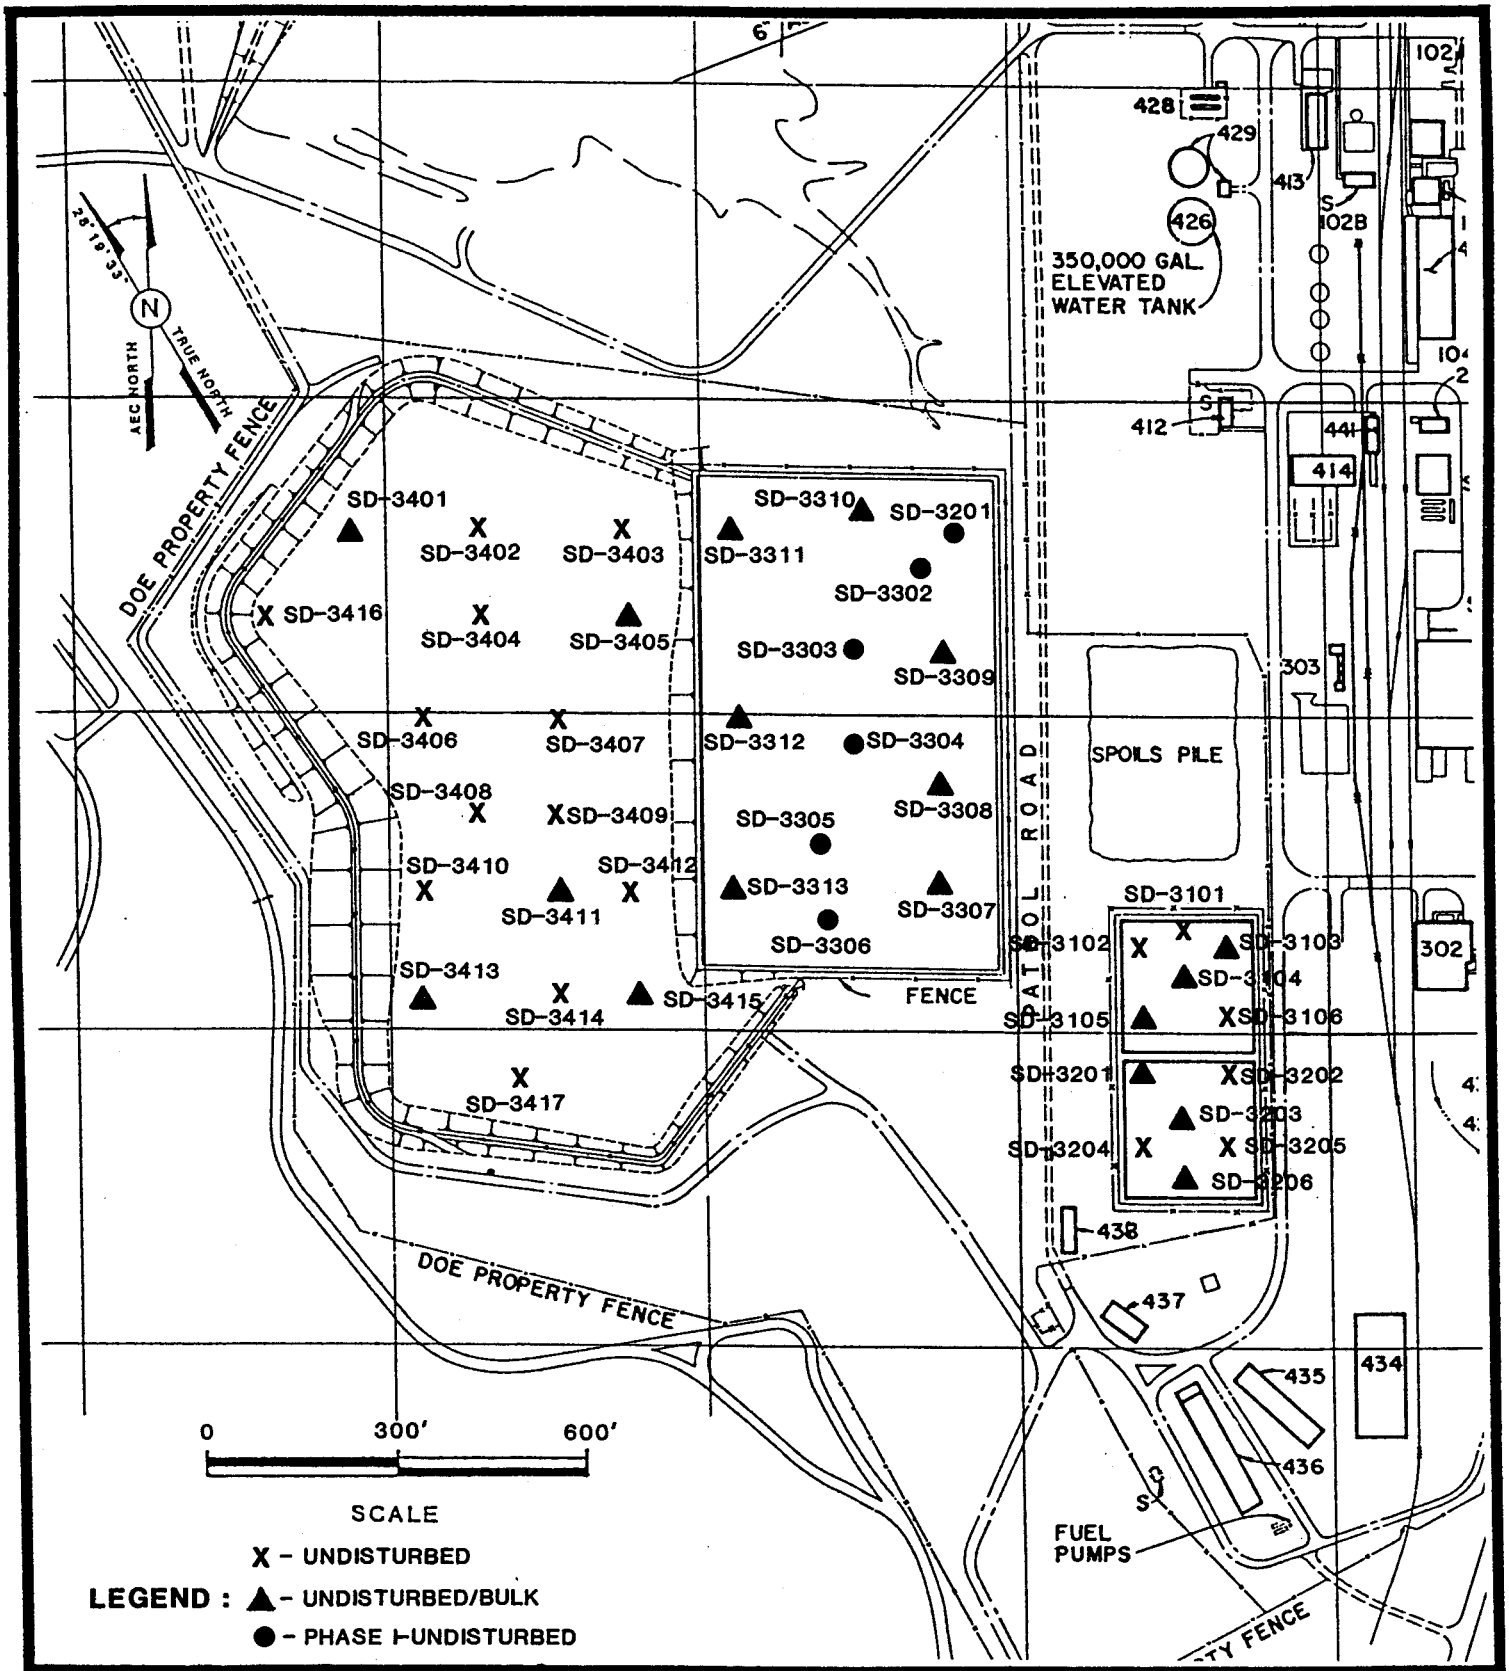

FIGURE 2-1

SAMPLING LOCATIONS FOR THE WSS RAFFINATE PITS CHARACTERIZATION

metals (minus lithium, molybdenum and zirconium), PCBs/pesticides, as well as the presence of nitroaromatics and inorganic anions in the supernatant waters. These studies revealed occasional areas across the pits where concentrations of metals (As, Ba, Cd, Pb, Hg, Ag) slightly exceeded detection limits (as determined through EP Toxicity tests). No evidence of PCB/pesticide contamination was found in the sludge. In the supernatant water of the raffinate pits, nitroaromatics were detected only in Pit 2. The inorganic anions were detected in waters from all four of the pits at varying concentrations.

Thirty samples will be collected from each pit, although the number of analyses for some parameters will be scaled down from thirty. Table 3-6 (Section 3.1) provides a breakdown of the analytical parameters in the investigation and the number of samples per pit for each parameter.

In an attempt to reduce the costs of the raffinate sludge characterization effort, yet maintain data reliability and statistical utility, factors such as pit size and previous data were considered when determining data quantity needs for volatile organics. Because of the relatively small size of Pits 1 and 2 (200 feet per side), the volatile nature of the compounds, and the age of the wastes in the pits (20-plus years) it is likely that variations in concentrations will be smaller than those for metals or semi-volatiles, if volatiles are present at all.

The number of analyses for PCBs/pesticides has been scaled back since some analyses previously performed on the sludges for these compounds indicated no presence above detection limits. Also, the number of analyses for nitroaromatics has been slightly decreased based on historical information and preliminary sampling of the supernatant waters which showed no evidence of these compounds in Pits 1, 3, and 4, and 0.28 ppb of 2,4 DNT in Pit 2. Should significant variability be encountered with the Phase 1 samples from Pit 3, then the analyses will be expanded.

Sampling, by a PMC subcontractor, will be accomplished in a single phase for Pits 1, 2, and 4 and in two phases for Pit 3. Pit 3 sampling will be expanded due to its considerably greater volume of sludge material.

Sampling will commence at Pit 3 with the collection of composite samples from six locations along a curved line (see Figure 2-1) from the southwest corner of the pit and moving towards the northeast corner (the corner from which the raffinate wastes were discharged). These samples will be submitted immediately for analysis, from which data will be used as a rough measure of the variability of concentrations across Pit 3. While awaiting analytical results (approximately 7 to 10 days) from Pit 3 samples, the sampling barge will be transferred to the other pits and complete sampling will be conducted at Pits 1, 2, and 4. The sample layout presented for Pit 3 in Figure 2-1 was devised assuming some reasonably limited analytical variation across the

pit area. If instead the pit shows a coefficient of variation near 100 percent or greater, alternative strategies may be considered prior to the Phase II sampling in Pit 3. Upon review and evaluation of Pit 3 Phase I data (concurrent with completion of sampling Pits 1, 2 and 4), a decision will be made on correct sample location layout, and the sampling equipment will be returned to Pit 3 to execute the appropriate sampling strategy.

2.1.3 Physical

The purpose of the physical characterization is to determine the degree of heterogeneity of the sludge both horizontally and vertically within each pit. In addition, selected physical parameters are indicative of the feasibility of various methods of stabilization. Since previous studies indicate a random distribution of physical parameters, sample locations are based on an even areal distribution across each pit. Samples at intervals of two feet will be taken continuously through the sludge.

The range of variation of physical parameters within each pit may have significant influence on in-situ stabilization techniques. A five-gallon grab sample from each discrete sample interval will be utilized in treatability studies.

Compositing of discrete samples for stabilization testing will be performed off-site and will be based on the parameters determined

in the physical characterization testing. Also, the stabilization technique under consideration will affect the extent of compositing. Composited samples from each pit will be used for vitrification, dewatering and reprocessing treatability studies. Compositing samples for in-situ stabilization techniques will be based on the effective depth range of the in-situ technique. Any remaining portion of sample will be stored for use in future bench scale studies, if required. If further testing is not necessary, the samples will be returned to the raffinate pits.

2.2 SAMPLING PROCEDURES

Characterization of the sludge material from the raffinate pits is necessary in order to define and evaluate the disposal alternatives. Representative samples of the sludge will be collected and evaluated for chemical, radiological, and physical parameters and the data used to support technical decisions and, if necessary, to demonstrate regulatory compliance.

The sample collection effort will be performed by a PMC subcontractor selected through a competitive bidding process. The precise sampling methodology will be determined by the subcontractor with approval of the DOE.

2.2.1 Description of the Sludge Material

Previous studies on the physical properties of the sludge indicate that the materials are very fine grained (nearly 95% passing the No. 200 sieve). The water content ranges from 70 to 75 percent with some stratification of solids apparent. The material has been described as having the consistency of pudding. Preliminary data indicates that wet bulk densities range from 73.9 lb/cf to 76.1 lb/cf. Depth estimates of the sludge range from an average of four feet in Pit 4 to approximately sixteen feet in Pit 3. The sludge is underlain by a stiff saturated clay.

2.2.2 Sample Location Access

The samples will be collected using a barge-mounted drilling rig. The barge rig will be maneuvered to specific sample locations through the use of ropes or cables. Samples will be located by line-of-sight cross-reference between survey grid stakes on each bank of the pits.

The individual samples will be acquired by driving an outer casing into the sludge in order to isolate a column of material. Drilling and sampling will take place within the casing.

2.2.3 Sample Collection

2.2.3.1 Method of Collection

Samples will be collected from the barge-mounted drilling rig as described above. It is anticipated that the material will be of such a consistency as to require casing of the entire column and sampling through the casing. Undisturbed samples will be collected with a piston sampler, consisting of an outer tube and a coaxial piston that creates a suction pressure within the tube. This method has been used successfully to retrieve high moisture content, fine-grained sludge material (see Reference 9). Bulk samples will be obtained by cleaning out an 8-10 inch casing. Different procedures will be attempted in order to optimize recovery, including augering, bailing or fabricating a large diameter piston sampler.

2.2.3.2 Quantity/Containers/Preservation

Analysis of sludge materials will require that some minimum quantities be properly packaged to maintain sample integrity. Table 2-1 details the container types and volumes to be used and the parameters to be tested on aliquots from each container. Finally, the table also lists the method by which the samples will be preserved.

Table 2-1
Sample Containers for Radiological and Chemical Analysis

Parameters	Containers	Preservatives
Volatile Organics	2-40ml vials	Refrigeration
Organics--Semi-Volatile, Pesticides, PCBs, Nitroaromatics	2-250ml wide-mouth amber glass jars	Refrigeration
Inorganics--Metals, Radiologic, Ionic Species	2-250ml wide-mouth amber glass jars	Refrigeration

2.2.3.3. Decontamination of Sampling Equipment

Equipment that could possibly influence the chemical or radiologic character (either concentration or substance) of the samples through direct or indirect contact will be decontaminated between uses, as necessary. Each discrete undisturbed sample will be collected with a sampler that has been decontaminated with pressure steam followed by a triple rinse with distilled water. Other sampling equipment that will potentially contact the sample material (casing, augers etc.) will be decontaminated with pressure steam between sampling locations. The flotation device and drilling rig will be decontaminated with pressure steam following sampling in each pit.

The decontamination procedures will consist of pressure steam cleaning (and abrasive brushing, if necessary) followed by a triple rinse with distilled water, where indicated. This method has been shown to be effective during previous investigations at the WSS. The effectiveness of the decontamination will be verified by the following methods: 1) visual inspection of the sampling components; 2) radiologic scan through the use of an alpha probe or GM probe (as appropriate); and 3) occasional collection of rinsate samples from the down-hole sampler.

2.2.4 Sample Container Labeling

All samples will be assigned specific numbers consistent with the WSSRAP Standard Operating Procedure's (SOP's) Environmental Numbering System for sediment. Information included on the labels will be site name and address, sample number, percent recovered, sampling personnel, date, time and comments. Following completion of each label with the specific sample data, the labels will be taped to protect the information and ensure that it remains legible.

3.0 SAMPLE ANALYSIS

All sample analysis will be performed according to industry standard testing protocols. The criteria to be met for each type of analysis are detailed in the following sections. Specific testing criteria are listed in Table 3-1 according to the parameters of interest in this study. Tables 3-2, 3-3, 3-4 and 3-5 show the number of analyses anticipated from the sampling effort in each pit. Table 3-6 provides a summary of sampling parameters and tests. These numbers are based on the sludge depths reported in Table 1-4 (Reference ESE, 1983).

3.1 RADIOLOGICAL

3.1.1 Uranium

In general the raffinate pit samples will be analyzed for total uranium with results reported as ppm-U. The analytical method used will follow EPA 600/4-80-032 "Prescribed Procedures for Measurement of Radiation in Drinking Water" August 1986. A small portion (2-10%) of the samples will be analyzed for isotopic uranium; U-234, U-235, U-238. The results will be reported as activity per unit volume and will be used to indicate the isotopic distribution of uranium in the sampled media. The

TABLE 3-1

Sample Analysis Criteria

Parameter	Standard Method of Analysis

Sludge Surface Charge	Zeta Meter
Atterberg Limits	ASTM 4318
Sludge Centrifuge Moisture Yield	ASTM D425
Sludge Consolidation	ASTM D2435
Sludge Phase Separation	See Note 2

Note 1: Viscosity and Gel Strength

Viscosity shall be measured according to ASTM D4016. To measure gel strength, the viscometer is turned off and the grout or sludge allowed to stand for ten (10) minutes. The viscometer is then turned on at a low rate of shear (5 s^{-1} for a Fann viscometer) and the gel strength is read directly as the maximum deflection on the scale.

Note 2: Phase Separation

Phase separation, a measurement of drainable water, is determined by a settling test in a 250-ml graduate cylinder. A sludge sample (200 ml) is poured into the graduate and allowed to stand. Phase separation is calculated as the volume of clear, drainable surface water divided by the total initial volume X 100.

Field Duplicates	2	2	3	3	10

analytical method used for the isotopic uranium analyses will follow EPA 520/5-84-006 "Eastern Environmental Radiation Facility Radiochemistry Procedures Manual" August 1984.

The results of these analyses will be used to estimate the uranium source term for the sampled media. The source term will then be used in various pathway analysis calculations, in risk assessments for total uranium, and in the final-disposal-cell design.

3.1.2 Thorium

The raffinate pit samples will be analyzed for isotopic thorium; Th-232, Th-230, and Th-228. The results will be reported as activity per unit volume and will be used to indicate the isotopic distribution of thorium in the sampled media. The analytical method used will follow EPA 520/5-84-006 "Eastern Environmental Radiation Facility Radiochemistry Procedures Manual" August 1984.

The results of these analyses will be used to estimate the thorium source term for the sampled media. The source term will then be used in various pathway analysis calculations for thorium (mainly Th-230), in the final-disposal-cell design, and in estimating thoron (radon-220) flux from the final disposal cell.

3.1.3 Radium

The raffinate pit samples will be analyzed for radium-226 and radium-228. The results will be reported as activity per unit volume. The analytical method used will follow EPA 600/4-80-032 "Prescribed Procedures for Measurement of Radiation in Drinking Water" August 1986.

The results of these analyses will be used to estimate the radium-226 and radium-228 source terms independently. The source terms will then be used in various pathway analysis calculations for radium, in the final-disposal-cell design, and in estimating radon (radon-222) flux from the final disposal cell.

3.2 CHEMICAL

3.2.1 HSL Compounds

Analyses for those volatile organics, semi-volatile organics, PCBs/pesticides and metals contained within the Hazardous Substance List (see Table 3-1) will be performed following the CLP methodologies. A detailed list of these analyses are presented in Appendix B of the WSSRAP Quality Assurance Program Plan.

3.2.2 Nitroaromatics

Analyses for nitroaromatics including 2,4 DNT, nitrobenzene and isophorone will be performed through EPA Method 609. 2,4,6 TNT will be quantified through performance of the United State Army Toxic and Hazardous Materials Agency (USATHAMA) methodology for that compound by a USATHAMA registered laboratory.

3.3 PHYSICAL

The number of physical tests required to adequately characterize the sludge waste is currently estimated as shown on Table 3-6. These numbers represent the minimum number of tests to be performed. Specific parameter testing may be expanded based on data variability. Samples representative of the top and bottom of each bulk sampling location in Pits 1, 2 and 4 and samples representative of the top, middle and bottom of bulk sampling locations in Pit 3 will be tested for moisture content, specific gravity, phase separation, viscosity and Atterberg limits. Particle size distributions will be performed on samples from multiple locations within each pit as shown on Table 3-6. The remaining physical testing parameters will be determined using a single composite sample.

Physical sample analysis will be required to evaluate the feasibility of the selected stabilization technologies. The indicative parameters for chemical stabilization and dewatering

methods other than mechanical are presented in Table 3-7. These parameters will be used in the feasibility evaluations. Vitrification tests will be accomplished by providing a composite sample to Pacific Northwest Laboratories where they will vitrify the material and analyze the off-gasses. This analysis will provide input for the evaluation of the feasibility and, if necessary, the design of the off-gas treatment system. These special studies are discussed in detail in the special study on sludge stabilization.

3.4 LABORATORY FUNCTIONS AND RESPONSIBILITIES

The analytical laboratory will be required to furnish standard operating procedures, equipment calibration and maintenance procedures, and personnel qualifications required to perform all analytical procedures. The laboratory will also report, for each method, the detection limit, sensitivity, interferences or bias, and analysis time. The laboratory must follow prescribed QA/QC protocol as mandated by the CLP/USATHAMA methodologies or internal QA plans. Written documentation of the results of that QA/QC testing prescribed in the laboratory QA/QC plan and described in the QAPP must be furnished. Any variance from those procedures will be reported and noted for data qualification.

TABLE 3-7

Indicative Parameters for Treatability Studies

Parameter	Stabilization Method
Sludge Moisture Content	Chemical stabilization; in-situ stabilization techniques
Sludge Specific Gravity	Chemical stabilization
Sludge Capillary Moisture	Dewatering
Sludge Particle Size Analysis	Confirm % passing #200 sieve
Sludge Viscosity	Handling techniques (pumpability and mixing)
Sludge Solids Specific Gravity	Chemical stabilization
Sludge Phase Separation	Chemical stabilization
Sludge Solids Surface Charge	Dewatering
Centrifuge Moisture Yield	Dewatering - decant water will be analyzed as worst case for liner compatibility study
Consolidation	Dewatering
Atterberg Limits	Handleability

4.0 QUALITY ASSURANCE MEASURES

All aspects of the site characterization, field investigations and data collection will conform to and adopt the required practices of the WSSRAP Quality Assurance Project Plan (QAPP). The QAPP presents the policies, organizations, objectives, functional activities and specific quality assurance (QA) and quality control (QC) activities designed to achieve the data quality goals of WSSRAP. Detailed below are the specific practices to be employed as quality assurance measures during characterization of the wastes in the raffinate pits.

The general QA objectives for analytical data are that data of known and acceptable quality be provided. To provide a check of the quality of the laboratory analytical data, a number of blank, duplicate, and spiked samples will be submitted to the analytical laboratory as per standard protocol for the CLP. Blank samples will be analyzed to check for container contamination and the adequacy of the field decontamination procedures. Duplicate samples provide a check for sampling and analytical error. Spiked samples will be analyzed for recovery determination. The frequency of submittal is detailed in the following sections.

4.1 FIELD BLANKS

One sample per each twenty samples collected will be acquired as field blanks by filling a sample container with distilled, deionized water, exposed to the sampling environment to detect accidental or incidental contamination.

4.2 DECONTAMINATION (RINSATE) BLANKS

One rinsate blank sample will be prepared per every twenty sludge samples collected. Following decontamination, the sample will be prepared by rinsing the sampling apparatus with distilled water and collecting the rinsate to check for residual contamination on the sampling tools.

4.3 BLIND FIELD DUPLICATES

One sample per every twenty samples collected for chemical/radiological analysis will be split and both samples analyzed by the same laboratory to determine data reproducibility. These samples will be labelled with different sample numbers to disguise their relationship.

5.0 DATA DOCUMENTATION

5.1 SAMPLE TRANSFER/CHAIN-OF-CUSTODY RECORDS

All raffinate pit samples leaving the Weldon Spring Site shall be in Department of Transportation regulated and approved containers. All sludge samples shall be handled and shipped according to Standard Operating Procedure (SOP) ENP-11.

5.2 FIELD REPORTS

The construction engineer responsible for monitoring field activities will, as outlined in Standard Operating Procedure numbers ENP-12 and ENP-18 (see Attachment A), fill out a field activity report and make appropriate entries into the field daily diary. Appropriate entries include date, time, sample number, location sketch, physical description, analyses requested, recovery and any problems encountered in obtaining the sample. Logs of stratification breaks, color, texture, etc. will also be recorded for the undisturbed samples.

5.3 PHOTOGRAPHS

Following extrusion from the sampling tool, all sludge samples shall be photographed. A legible sample identification card will be in each frame to identify the sample in the picture.

6.0 REPORTING REQUIREMENTS

Appropriate data obtained from this sampling plan will be reported in the Remedial Investigation Report. Original data forms and reports will be placed in the site document control files.

SET I.D. _____

APPROVAL SHEET FOR

PROCEDURES FOR HANDLING AND
SHIPPING OF GEOTECHNICAL SAMPLES

	Signature	Date
PROJECT MANAGER	D Hammond	2/8/88
ENGINEERING MANAGER	D K Lewis	2/8/88
CONSTRUCTION/OPERATION MANAGER	L J Stewart	2/8/88
E. S. & H. MANAGER	Boyd A Wilson	2/8/88
QUALITY ASSURANCE MANAGER	J. J. Hairston	2/8/88

PROCEDURE TITLE: PROCEDURES FOR HANDLING AND SHIPPING OF GEOTECHNICAL SAMPLES

1.0 OBJECTIVE

1.1 To provide instruction to the Field Technical Representative (FTR) for packaging, marking, and shipping soil and rock samples collected in the field.

2.0 APPLICABILITY

2.1 This procedure outlines the minimum requirements for handling and shipping soil and rock samples collected in the process of site characterization. Figures 1 through 3 show completed examples of the required forms.

- Soil Sample Inventory
- Soil Sample Inventory Summary
- Diffusion Coefficient/Radon Emanation Sample Inventory

Figures 4 through 7 show the proper labeling procedures for the appropriate samples collected.

2.2 Soil samples from field sampling programs consist of large and small bulk samples, Standard Penetration Test (SPT) samples, Shelby Tube samples and large diameter (2 or 3 inch) ring or tube samples.

2.3 In conjunction with this Engineering Procedure and when shipping any soil or rock sample thought to possess low levels of radioactivity, ES&H Procedure 2.03.10 "Packaging and Shipping Radioactive Materials" is applicable and must be strictly followed.

3.0 EQUIPMENT

- 5-gallon plastic buckets with lids
- Large plastic bags - 3 mil thick
- Small plastic bags - 2 mil thick
- Shelby tube shipping boxes
- Twist ties

PROCEDURE TITLE: PROCEDURES FOR HANDLING AND SHIPPING OF GEOTECHNICAL SAMPLES

4.0 PROCEDURE

4.1 Sample ID

A sample identification number will be assigned to each discrete sample to ensure that data collected retains uniqueness from other data collected when ambiguity is possible. The final number assignment for all samples will be made in accordance with the Environmental Numbering System, ES&H Procedure number 4.01.01, where practical.

4.2 Large Bulk Samples

Large bulk samples shall be placed into a 5-gallon bucket which has been lined with a large plastic bag. A twist tie shall be used to securely fasten the top of the plastic bag. The top of the plastic bag shall have a complete sticky-back sample tag placed on it. The lid shall be securely fastened onto the top of the bucket. Complete sticky-back sample tags shall be placed on the top and on the side of the plastic bucket and covered with clear tape.

4.3 Small Bulk and Standard Penetration (SPT) Samples

Small bulk and SPT samples shall be placed inside small sample bags and shall be double-bagged. A complete sticky-back sample tag shall be placed on the outside of the inner bag prior to insertion into second bag. A twist tie shall be used to securely fasten the top of each plastic bag.

If several small bulk samples or SPT samples are collected from one or more test pit or borehole locations, they should be placed into a 5-gallon bucket with Soil Sample Inventory forms placed inside the bucket showing what location ID and sample ID's are contained within this 5-gallon bucket. The outside of the bucket should then be labelled on the lid and side or on a blank sticky label, with an indelible pen. Requisite label information shall be the site name and sample ID of the samples contained therein. In any case, a complete sticky-back label should be placed on the side of the bucket and covered with clear tape.

PROCEDURE TITLE: PROCEDURES FOR HANDLING AND SHIPPING OF GEOTECHNICAL SAMPLES

4.4 Large Diameter Ring Samples

Ring samples shall have the top and bottom capped with a plastic cap. The drilling subcontractor shall provide the rings as well as plastic caps. Caps shall be sealed to the ring or tube with plastic tape.

Labeling ring samples shall consist of placing a completed stick-back sample label on the side of the ring. Once this has been done the ring shall be placed inside a single, small plastic bag and securely fastened with a twist tie.

If several ring samples are collected from one or more borehole locations, they shall be placed into a 5-gallon bucket with Soil Sample Inventory forms placed inside the bucket that shows what sample ID's are contained within this 5-gallon bucket. The outside of the bucket should then be labelled on the lid and side, with an indelible pen, as to the site name and ID's of the samples contained therein.

In no instance shall the ring samples be allowed to freeze during handling and shipping operations.

4.5 Shelby Tube Samples

Shelby tube samples, once recovered, shall have the top and bottom of the tube sealed with paraffin. If insufficient space remains at the bottom of the tube for sealing, trim away 3/4-inch of soil and seal the tube. Once the wax has hardened, a plastic cap shall be placed over both ends. Seal the caps to the Shelby tube with strapping tape. The drilling subcontractor shall provide the Shelby tubes, paraffin, plastic caps, and the means to melt the paraffin.

Labeling of Shelby tube samples shall include placing a completed stick-back sample label on the side and near the top of the Shelby tube, and one sticky-back sample label on the plastic cap covering the top of the tube. The Shelby tube shall then be placed inside an adequately constructed shipping crate in preparation for shipment.

In no instance shall Shelby tube samples be allowed to freeze or be placed in any position different from the orientation in the bore hole. Vibration and movement of Shelby tubes should be minimized.

4.6 Post-collection/Pre-shipping Instruction

Prior to shipping soil samples, and preferably as they are collected, the Soil Sample Inventory Summary form shall be complete with the appropriate sample ID, sample type (large or small disturbed bulk sample, SPT, ring, Shelby tube or drill cuttings), material type (Unified Soil Classification, ASTM D2487 and D2488), depth sample taken from, if sample was taken from a borehole or test pit, where the sample was shipped and any comments. It is the Field Technical Representative's responsibility to retain a copy of the Soil Sample Inventory Summary form.

Additionally, the Diffusion Coefficient/Radon Emanation Sample Inventory Log must also be complete and returned to the Radiation Protection Manager or his designee within approximately 5 days.

PROCEDURE TITLE: COMPLETING THE DAILY FIELD ACTIVITY REPORT

SET I.B. _____

APPROVAL SHEET FOR

COMPLETING THE DAILY FIELD

ACTIVITY REPORT

	Signature	Date
PROJECT MANAGER	J. Hammond	2/5/88
ENGINEERING MANAGER	D R Lewis	2/8/88
CONSTRUCTION/OPERATIONS MGR.	C. J. Stewart	2/5/88
E. S. & H. MANAGER	Roger A Miles	2/8/88
QUALITY ASSURANCE MANAGER	J. J. Hairston	2/8/88

PROCEDURE TITLE: COMPLETING THE DAILY FIELD ACTIVITY REPORT

1.0 OBJECTIVE

1.1 This Standard Operating Procedure describes the procedures to be followed in completing the Daily Field Activity Report (DFAR). The need for completing a DFAR for a subcontract shall be determined by the Technical Representative (TR) and shall be requested either in the technical specifications or as instructions to the Field Technical Representative (FTR). The DFAR permits tracking of all billable items and serves as a basis of payment at the completion of the subcontract. Proper completion is vital to the successful execution of the contract. Adherence to the provisions of this procedure will ensure proper completion of the DFAR.

1.2 Figure 1 shows an example of a completed DFAR. Variations in the specification line items prevents using common line items on the form. A blank form is shown as Figure 2. As an alternative a specific DFAR may be developed for specific subcontracts. This DFAR form should be included in the Technical Specifications for the subcontract. Alternative DFAR forms should have line items with identifiable units and quantities and spaces for signatures or initials of Contractor's and Subcontractor's representatives.

1.3 Each DFAR shall be prepared with the item number description. The item and unit of payment shall be recorded as it appears in the Subcontract Pricing Schedule. A sample DFAR should be inserted in the Request For Proposal so that the bidder is fully aware of its existence. The items listed on the DFAR should be prepared by the FTR in cooperation with the Subcontract Administrator (SA). The FTR shall daily record the total material and/or labor quantities on the appropriate line. Then the FTR and the Subcontractor's Representative shall initial the indicated space for the day's activities.

PROCEDURE TITLE: COMPLETING THE DAILY FIELD ACTIVITY REPORT

2.0 PROCEDURE

2.1 Preparation of the Daily Field Activity Report.

2.1.1 In the blanks provided, enter the site name, Subcontract number, the full name of the FTR, and the week. The week should be shown as Monday's date to Sunday's date. Write in each date to correspond to the day of the week.

2.1.2 Enter the appropriate billable work items for which records must be kept. Lump sum items such as Mob/Demob are not necessary. If additional space is needed, use a second sheet clearly labeling these as sheets 1 of 2 and 2 of 2. A breakdown of items not in the pricing schedule should go into the FTR's Diary, not on the DFAR.

2.2 Daily entries for labor and/or material quantities.

2.2.1 Enter the totals of work done for each day in each category. The FTR shall total the items and ensure that units of measurement are in agreement with the pricing schedule. Some costs can be in "hours" or by "volume" or by "each". For example, casing installation may be in units of hours or by lineal feet. Tensiometer installations are by "each". The same type of work, under different conditions may be priced differently and thus require separate entries. For example, drilling an 8-inch borehole may or may not be at the same cost per foot, or per hour, as a 6-inch borehole. Be aware that certain single labor entries could be a group of tasks rather than a single task; for example, well installation and development includes labor for casing installation, gravel pack, bentonite seal, grouting, and well development.

2.2.2 Enter the unit quantity for materials used each day. Verify that units agree with the pricing schedule. Refer to the item number to ensure that materials are not lumped in with labor costs for these tasks.

2.2.3 Discuss the entries with the Subcontractor's representative and have that person initial the column for each day's entry. No other entries shall be made after the column is initialed. Show a dash in each unused item. Details are given on the example, Figure 1. The FTR shall indicate on the DFAR if the Subcontractor's representative refuses to initial the day's entry.

2.2.4 Changes made on the DFAR entries shall be initialed by both the FTR and the Subcontractor.

2.3 After completing each sheet, the FTR should total all items. This total provides the FTR with a weekly progress summary that can be reported to the SA.

2.4 The DFAR is the basis of payment for each subcontract line item. The Subcontractor shall receive a copy of this document to prepare the billing. This will reinforce the instructions of the Subcontract on structuring the invoice so that it is consistent with the subcontract, i.e., on a daily basis for each line item and not on a hole by hole basis.

PROCEDURE TITLE: FIELD DAILY DIARY

APPROVAL SHEET FOR

FIELD DAILY DIARY

	Signature	Date
PROJECT MANAGER		2/8/88
ENGINEERING MANAGER		2/8/88
CONSTRUCTION/OPERATIONS MGR.		2/8/88
E. S. & H. MANAGER		2/8/88
QUALITY ASSURANCE MANAGER		2/8/88

PROCEDURE TITLE: FIELD DAILY DIARY

1.0 OBJECTIVE

1.1 This procedure provides guidelines for the minimum entries made by the Field Technical Representative (FTR) in the Bound Daily Diary while at a work site.

1.2 This procedure assigns responsibility and accountability to the FTR to maintain a bound daily diary. The diary shall contain the minimum entries described below and any other entries that the FTR's professional judgement dictates to completely document the conditions and events that affect the assignment.

1.3 This diary is assumed to be the only record of activity which can protect the Project Management Contractor (PMC) in case of litigation or dispute by the Subcontractor. Incidents and conditions are readily forgotten and those personnel who could provide any facts about the activities may have left the project.

2.0 PROCEDURE

2.1 At the start-up of each field assignment, the FTR should record (as a minimum) the following information in the diary:

- The diary shall be a permanently bound waterproof notebook. All entries should be made in waterproof ink or a pencil of at least 3-H hardness.
- A description of all significant equipment on the work site;
- The names and position of each crew member;
- A full inventory of all materials brought to the work site and a comparison with contractual quantities required;
- Any reference literature or special equipment provided by the PMC.

2.2 The FTR shall record the following information on a daily basis:

- Copies of "Daily Field Activity Report" or FTR diary provided to the Subcontractor.
- Active and inactive crews and equipment;
- Start and stop times of activities including arrivals and departures of individuals from the job site;
- Weather or surface conditions which may effect the activities (wind, rain, mud, heavy brush, etc);
- All conversations with and instructions given to the Subcontractor;
- All agreements or disagreements recorded on "Daily Field Activity Reports" affecting pay items or procedures;
- The names and purpose of any visitor entering the work area;
- A periodic summary of work accomplished (number of holes, footage, casing used, samples collected, etc.);
- Any additional material ordered or purchased for the project;
- Any information about conditions or procedures which appear to be unsafe and corrective actions taken.

2.3 At completion of the project, the following data shall be recorded:

- A complete inventory of all unused materials remaining plus any waste to be disposed of;
- Any work left undone (e.g., site restoration);
- A description of cleanup procedures;

- The final cumulative totals of materials used and work accomplished.

[e]Medium Water Contract Required Detection Limits (CRDL) for Pesticide HSL Compounds are 100 times the individual Low Water CRDL.

[f]Medium Soil/Sediment Contract Required Detection Limits (CRDL) for Pesticide HSL compounds are 15 times the individual Low Soil/Sediment CRDL.

*Detection limits listed for soil/sediment are based on wet weight. The detection limits calculated by the laboratory for soil/sediment, calculated on dry weight basis, as required by the contract, will be higher.

** Specific detection limits are highly matrix dependent. The detection limits listed herein are provided for guidance and may not always be achievable.

Table 1. Elements Determined by Inductively Coupled Plasma Emission or Atomic Absorption Spectroscopy

Element	Contract Required Detection Level[1,2] (ug/L)
Aluminum	200
Antimony	60
Arsenic	10
Barium	200
Beryllium	5
Cadmium	5
Calcium	5000
Chromium	10
Cobalt	50
Copper	25
Iron	100
Lead	5
Magnesium	5000
Manganese	15
Mercury	0.2
Nickel	40
Potassium	5000
Selenium	5
Silver	10
Sodium	5000
Thallium	10
Vanadium	50
Zinc	20

Table 2. Cyanide Determination

Element	Contract Required Detection Level[1], [2] (ug/L)
Cyanide	10

1: Any analytical method specified in SOW Exhibit D may be utilized as long as the documented instrument or method detection limits meet the Contract Required Detection Level (CRDL) requirements. Higher detection levels may only be used in the following circumstance:

If the sample concentration exceeds two times the detection limit of the instrument or method in use, the value may be reported even though the instrument or method detection limit may not equal the contract required detection level. This is illustrated in the example below:

For lead:
Method in use = ICP
Instrument Detection Limit (IDL) = 40
Sample concentration = 85
Contract Required Detection Level (CRDL) = 5

The value of 85 may be reported even though instrument detection limit is greater than required detection level. The instrument or method detection limit must be documented as described in Exhibit E.

2: These CRDL are the instrument detection limits obtained in pure water that must be met using the procedure in Exhibit E. The detection limits for samples may be considerably higher depending on the sample matrix.

SET I.D. _____

Weldon Spring Site Remedial Action Project (WSSRAP)
ENVIRONMENTAL SAFETY AND HEALTH PROCEDURE MANUAL SOP No.: 2.03.10
Rev.: 1
2.03.10 PACKAGING & SHIPPING PROCEDURES FOR RADIOACTIVE MATERILAS Date: 05-13-88
Page: 1 of 9

APPROVED: ES&H MGR. _____ QUALITY MGR. _____

OBJECTIVE:

To provide guidance for packaging, marking, labeling, and shipping radioactive materials so as to ensure compliance with U.S. Department of Transportation (DOT) regulations.

APPLICABILITY:

During the course of remedial action at the WSS, radioactive materials will be shipped off-site for laboratory analysis. This procedure applies to the shipment off-site of any material of which the combined activity of all radionuclides in the material exceeds 2000 picocuries per gram (pCi/g). Failure to comply with this procedure could result in liabilities and fines levied against the shipper.

REFERENCE:

Code of Federal Regulations, Title 49, Parts 100-178 (Revision June, 1986)

EQUIPMENT AND MATERIALS:

1. Type A sample container(s) (5-gallon steel bucket, lid, and gasket, enclosure ring, locking nut and bolt).

2. Plastic liners with closures.

3. "Radioactive material" markings and labels:

   - Appropriate Radioactive White-1 or Radioactive Yellow-11 label as determined by this procedure.

   - Stencil(s) of "USA DOT 7-A Type A Radioactive Material LSA n.o.s. UN2912"; for liquid samples "This end up".

- o Calibrated G-M Probe (located with ES&H radiological equipment)
- o Exposure rate meter

PROCEDURE:

A. Method for estimating the total activity of all radionuclides in a 5-gallon steel container.

1. This section of the procedure describes a quick and conservative means of determining whether the material of concern must be classified as radioactive material. If the material is suspected to contain Th-230 then part A.1, A.2. and B.1 of this procedure does not apply.

   a. After the material has been placed in the container and before the lid has been fastened on, place the G-M Probe very near the surface of the material and obtain a one-minute count. (Note: Here, "container" refers to the primary vessel holding the material.)

   b. Fill out Part 1 of Form 2.03.10.01

   c. If the count rate of the G-M probe reads less than 700 counts per minute the material is assumed to contain less than 2000 pCi/g total activity. (The basis of this assumption is a calculation on file with the Radiation Protection Manager (RPM).) Continue with Part B of this procedure. | 1

2. If the activity of the material is known from previous characterization studies or sample analysis this information may be used instead of method A.1 above with the RPM's approval. (49 CFR 172.402) | 1

   a. Fill out Part 1 of Form 2.03.10.01, "Comments" section only, explaining where this data may be found.

B. Materials (excluding instruments, equipment, and articles) shipped off-site will conform to one of the two following classifications (see also Section A of this procedure):

1. Should the total activity of all radionuclides be less than 2000 picocuries per gram (pCi/g)(based on either A.1 or A.2 above), the material is then classified as non-radioactive and is therefore exempt from any shipping requirements concerning radioactivity. (49 CFR 173.403) | 1

NOTE: Frequently WSSRAP samples will contain more than one radionuclide. The 2000 pCi/g limit applies to the sum of the activities of all of the radionuclides present in the material being shipped.

Radioactive materials or materials that could potentially contain radioactivity cannot be shipped off-site without signed approval (Form 2.03.10.01) from the RPM or his designee. | 1

2. Should the total activity of all radionuclides be greater than 2000 pCi/g (based on A.1 or A.2 above), the material may be shipped either as limited quantity or as low specific activity (LSA). Materials from the WSS determined to be radioactive material will be shipped as "Radioactive material LSA n.o.s." for reasons of conservatism and ease of repetitive application of this shipping procedure. | 1

a. Place a plastic liner in a Type A container (5-gallon steel bucket) and fill the container with material as appropriate.

b. Pull the ends of the liner together and seal it closed.

c. Place lid and gasket on container. Install the lock-ring around the edge of the lid. Secure the lock-ring with a bolt and nut such that the accidental removal of the lid and content spillage is prevented. (Approximately 40 foot pounds).

d. Wipe any loose material from the outside of the container. Ensure that any removable contamination is less than 22 dpm/cm^2 (see WSSRAP Procedure No. 2.03.08). Include Form 2.03.03.01 with Form 2.03.10.01. Fill out only the smear survey section of Form 2.03.03.01. (49 CFR 173.443)

e. Measure the gamma levels at four locations on the surface of the 5-gallon steel bucket. Record these values on Form 2.03.10.01.

f. Determine the maximum radiation level in millirem per hour at one meter (3.3 feet) from the external surface of the container. Round up to the first decimal place. This is the transportation index to be applied to this container. Record this value on Form 2.03.10.01. (49 CFR 173.403)

g. Items e) and f) above and Table 1 will be used to determine the appropriate category of label to be applied to the container. The label to be applied shall be the highest category required for any of the two determining conditions for the package. (49 CFR 172.403)

Table 1: Category of label to be applied to radioactive materials containers.

TRANSPORT INDEX (TI)	RADIATION LEVEL AT PACKAGE SURFACE (RL)	LABEL CATEGORY
N/A	RL $\leq$0.5 mrem/hr	White-1
TI <1.0	0.5mrem/hr <RL <50 mrem/hr	Yellow-11
1.0 <TI	50 mrem/hr <R	Yellow-111

The following applicable items of information must be entered in the blank spaces on the "radioactive" label by legible printing using a durable weather resistant means of marking:

i. "Contents". The name of the radionuclides. For mixtures of radionuclides, the most restrictive radionuclides on the basis of radiotoxicity must be listed as space on the label allows.

ii. "Activity". Units shall be expressed in appropriate curie units.

iii. "Transportation index" as applicable.

A label must be placed on two opposite sides of the container.

h. The outside of each container must be marked as follows (in letters of at least one-half inch): (49 CFR 172.301, 172.310, 178.350)

USA DOT - 7A Type A
Radioactive material, LSA, n.o.s. UN2912

Liquid samples must be labeled "This end up".

The ES&H RPM has a stencil for this purpose.

Any internal packages or containers must be packed with closures upwards. (49 CFR 172.312)

i. Attach a label listing the shipper's name, address, and telephone number to each container. (49 CFR 172.306)

1

j. Another shipping consideration for material shipped as "Radioactive material LSA n.o.s." is the average concentration of the contents. Table 2 lists the average concentration limits for the radionuclides of concern at the WSS.

Table 2 Average concentration limits for Type A containers shipping material as radioactive LSA.

NUCLIDE	CONCENTRATION LIMIT (uCi/g)
U-238	unlimited
U-nat	unlimited
Th-nat	unlimited
Th-232	unlimited
Th-230	0.1
Ra-224	5
Ra-226	0.1
Ra-228	0.1
Pb-210	5
Ac-228	0.1

This will ensure that the material meets the definition of low-specific activity and meets the requirements of activity limits for Type A packages. (49 CFR 173.403, 173.431)

Record the average concentration of each radionuclide in the comments section of Part 2 of Form 2.03.10.01 or on an attached sheet (note attached page in comments section). This implies that the sample must be radiologically characterized by the WSSRAP radiological laboratory or WSSRAP RPM before shipment. (See Section A.2) | 1

3. The RPM or his designee will authorize a container to be shipped only after a completed Part 1 of Form 2.03.10.01 has been filled out by the originator. If the RPM or designee determines that the container can be shipped as non-radioactive material, no further effort is required by the originator and the container may be shipped. | 1

   If the RPM or designee determines that the container must be shipped as radioactive material then the originator must complete Part 2 of Form 2.03.10.01 and comply with Section B.2 of this procedure. Additionally, the originator must complete the carrier's shipping papers as follows: | 1

   a. All description(s) must be printed in English and shall not contain any code or abbreviation except to specify the type of package and weight or volume. (49 CFR 172.201)

   b. The container(s) must be described on the shipping papers exactly as follows (descriptions in parentheses require determination by shipper) (49 CFR 172.203):

      "Radioactive Material, LSA, n.o.s. UN2912, (weight or volume) (limiting radionuclide(s) present), (form e.g. soil, liquid, gas, solid...) (total activity), (label category) (Transportation index)".

   c. Included on the shipping paper must be the shippers' certification worded exactly as follows in either (i) or (ii) (49 CFR 172.204):

      i. "This is to certify that the above-named materials are properly classified, described, packaged, marked and labeled, and are in proper condition for transportation according to the applicable regulations of the Department of Transportation".

NOTE: The words "herein-named" may be substituted for the words "above-named".

ii. "I hereby declare that the contents of this consignment are fully and accurately described above by proper shipping name and are classified, packed, marked, and labeled, and are in all respect in proper condition for transport by (*) according to applicable international and national governmental regulations."

d. No radioactive material from the WSS shall be transported by passenger aircraft. (49 CFR 172.204)

e. When a hazardous material and a material not subject to the requirements of 49 CFR Parts 170-178 are described on the same shipping paper the hazardous material shipping entries: 1

i Must be entered first, or
ii Must be entered or highlighted in a color that clearly contrasts with any description on the shipping paper of a non-hazardous material,
iii Must be identified by the entry of an "X" placed before the proper shipping name in a column captioned "HM".

4. Complete WSSRAP Chain of Custody requirements per ES&H SOP 4.01.02

* Additional language indicating the modes of transportation to be used may be inserted at this point. All modes of transportation may be indicated provided that any mode not applicable to a specific shipment is deleted.

GEOPHYSICAL/GEOTECHNICAL INVESTIGATION SAMPLING PLAN

Enclosed is a final copy(s) of the Geophysical/Geotechnical Investigation Sampling Plan for the Weldon Spring Chemical Plant. This investigation will gather the additional data necessary to derive required geotechnical design parameters and evaluate the suitability of the site for constructing a long term storage facility.

The final copy includes a responsiveness summary for USEPA & MDNR review comments.

Mr. Rodney R. Nelson
U.S. Department of Energy
Weldon Spring Site Remedial
Action Project
Route 2, Highway 94, South
St. Charles, Missouri 63303

Dear Mr. Nelson:

We have completed our review of the "Geophysical/Geotechnical Investigation Sampling Plan." Our general comments on earlier partial work plan submittals are adequately addressed in this submittal. Specifically, sections describing the sufficiency and validity of the available field and laboratory data have been incorporated, and additional testing is shown to be justified. Also, technical approaches for the proposed investigations appear to be sound. However, a general review of the document points out the following:

The work plan does not attempt to link this study with related studies necessary prior to design of the containment structure, such as sampling and testing to determine the suitability of proposed borrow soils. Presumably, the forthcomming RI/FS work plan will accomplish this.

The work plan presents the geophysical studies in a very positive manner with regard to their application to the problem of defining bedrock fracture zones, cavities, and channels. While these techniques are applicable and should provide useful information, the reliability of the techniques may be overstated. It is important for all parties to understand that these procedures may fail to detect the identified bedrock features even though proper equipment and procedures are used.

The work plan consists of three principal parts: 1. An introduction and review of the site history and previous studies; 2. A proposed scope of work; and 3. Appendices specifying the work to be performed by the subcontractor. The Appendices (specifications) are difficult to follow due to the various addendums and modifications. However, as stated in previous review comments on the partial submittals, the specifications do not appear to be consistent with the scope of work outlined in

JU261C
5-16-88

the body of the work plan. This problem should be reconciled prior to soliciting bids.

Thank you for the opportunity to comment on this work plan. Our specific comments are contained in the enclosure to this letter. We are expecting comments on this work plan from the Missouri Department of Natural Resources within the next few days, and they will be forwarded to you at that time. Please call if you have any questions.

Sincerely yours,

Katie Biggs

SPECIFIC COMMENTS

The following comments relate to specific sections of the Geophysical/Geotechnical Investigation Sampling Plan. The comments are presented according to the section and page within the text.

1. Section 1.4.2, p. 49, Seismicity of the area should also be investigated and considered in this assessment.

2. Section 1.4.3, p. 52, If present in significant thickness, engineering properties of the residuum may be important to design and should probably be defined to the extent possible.

3. Section 1.4.3, p. 57, Appropriate Number of Samples and Tests - Several assumptions are involved in making the indicated statistical analysis. It does not appear that five tests for each engineering parameter per geologic unit are adequate to allow for vertical and horizontal variations, weathering profiles, etc.

It is suggested that moisture content, dry unit weight (if possible) and field strength tests (pocket penetrometer and/or vane shear) be run on all samples, and sufficient classification tests (Atterberg limits and gradation) be run on representative samples to facilitate the horizontal and vertical characterization of the soil profile. These data, when analyzed, will allow the selection of representative soil samples from each geologic unit for use in strength, permeability, and consolidation tests.

4. Section 2.1.2, p. 67, The sequencing of events is not clear. Will geophysical surveys be performed and interpreted before the drilling program begins or the other way around? In any case, engineering and geologic personnel should also have input in determining the depth and location of boreholes.

5. Section 2.1.2, p. 67, The geophysical logging program for the two deep holes needs to be discussed in more detail, including the type of down hole surveys to be run.

6. Section 2.1.2, p. 69, The procedure should state the criteria for taking more than one undisturbed sample every five feet, i.e., every five feet or at more frequent intervals if changes in soil type occur.

7. Section 2.1.4, p. 71, The supervising geologist should estimate the shear strength of all cohesive soil samples at the time the sample is retrieved, using a pocket penetrometer and/or vane shear device.

8. Section 2.2.3, p. 74, The geophysical methods selected include seismic, electrical resistivity and electromagnetic conductivity. The plan should include a detailed survey grid for each method, supported with documentation explaining the survey grid and the expected results, i.e., depth of investigation, resolution with depth, etc. As previously pointed out, the plan must identify what surveys will be performed and how.

9. Section 3.1.2, p. 79, As indicated in comment no. 2, we believe the residuum should also be tested if present in sufficient thickness.

10. Section 3.1.2, p. 79, Samples for engineering properties tests (strength, consolidation, and permeability) should be selected subsequent to completion and evaluation of moisture content, dry unit weight, classification (Atterberg limits and gradation) and undrained strength tests (field and laboratory) to assure that the samples are representative of the geologic unit.

11. Section 3.1.2, Table 3-1, Moisture contents should be determined on all samples to provide a continuous profile at each boring location. Dry unit weight should be determined on all undisturbed and on other samples if possible. The number of uu triaxial shear tests should be increased to assist in the characterization of lateral and vertical variations in strength and compressibility. Table 1-7 indicates a need for more cu triaxial shear strength tests than shown.

12. Section 3.1.2, p. 84, In-situ field permeability tests may provide useful design information.

13. Section 4.3, p. 91, Geophysical Surveys - This section indicates that approved written procedures and work instructions will be issued prior to commencement of the work. We would appreciate the opportunity to review these prior to their implementation.

Ms. B. Katherine Biggs, Chief
Environmental Review Branch
U.S. EPA, Region VII
726 Minnesota Ave.
Kansas City, KS 66101

Dear Ms. Katie Biggs:

DNR COMMENTS ON DRAFT GEOPHYSICAL/GEOTECHNICAL INVESTIGATION SAMPLING PLAN - WELDON SPRING SITE (APRIL 1988)

The Missouri Department of Natural Resources (MDNR) has reviewed the draft "Geophysical/Geotechnical Investigation Sampling Plan" prepared by the U.S. Department of Energy for the Weldon Spring Site. The plan is generally well thought out, accurate and informative. Our comments follow:

Most of the geophysics related to cavity detection is aimed at detecting cavities in bedrock. The downhole camera work that has been done to date, as well as other drillhole data, suggest that voids likely to be encountered in the bedrock will have no significant impact on the structural integrity of the facility.

Voids in the overburden are a greater concern because of 1) reduced strength of overburden in comparison to bedrock, and 2) potential size and increase in size with normal subsurface weathering, stoping, moisture changes, etc. The overwhelming majority of sinkhole collapses in Missouri are not caused by catastrophic failure of cavernous bedrock. They are caused by slumping of soil materials into openings in the overburden usually developed in the interval of the weathered bedrock-overburden contact zone. The soil that falls into the bedrock openings in the interval of overburden-bedrock contact zone is carried away be seasonal surges of water flow through these openings. The soil void stopes upward to the surface.

JU2609
5-16-88

The chance of a surface collapse by upward stoping at the Weldon Spring facility is not significant. The low permeability cohesive soils that overlie the residual soils and bedrock are not prone to such collapse conditions. The near-surface soils inhibit infiltration of water which reduces water velocity in the residuum and shallow bedrock. Nevertheless, the geophysical efforts should concentrate on detecting cavities in overburden, especially in the overburden-weathered bedrock zone as these are the ones which could potentially affect the structural integrity of the facility.

Another serious concern is that the plan apparently does not include determining geotechnical characteristics of residual soils which are present under the majority of the site. This material could certainly affect the design of the facility. In fact, voids in overburden (if present) would most likely be found in the residual soils. Residual soils with low dry unit weights (below 90 to 95 pounds per cubic foot) would be those with the highest collapse potential and leakage potential. Residual soils are separate and distinct from the bedrock itself. The two units should not be lumped together as they are on Page 52 of this document.

A related error appears in Appendix A where dry unit weights of basal till are listed to range from 104.8 pcf to 86.5 pcf. Possibly, the lower number represents either a typographical error or analysis of a residuum sample.

MDNR appreciates the opportunity to comment on this sampling plan. If you have any questions on these comments please call me at (314) 751-4533 or Mr. William Duley of the Division of Geology and Land Survey at (314) 364-1752.

Sincerely,

INTRODUCTION

1.0 INTRODUCTION

1.1 Purpose and Scope of Plan

This sampling plan presents a rationale and procedures for further geotechnical and geophysical investigations of the Weldon Spring Site (WSS). The proposed investigation will gather the additional data necessary to derive required geotechnical design parameters and evaluate suitability of the WSS for constructing a long-term waste disposal facility.

This document reviews data from the previous geotechnical and geophysical investigations for adequacy and sufficiency. The plan then describes additional geotechnical and geophysical investigations required to fully characterize the proposed disposal facility site.

The proposed investigation categories are:

- Surface geophysical surveys
- Geotechnical drilling and sampling
- Geotechnical laboratory testing

The surface geophysical surveys will integrate various techniques to characterize soil and bedrock units. Geotechnical drilling and sampling will provide information to correlate geophysical measurements with known subsurface conditions. The disturbed and

undisturbed samples collected during geotechnical drilling will be tested for a broad range of engineering parameters. These data will be used for engineering design of the disposal facility and to demonstrate suitability of the site.

1.2 Relevant Site History

The Weldon Spring Site is located about 30 miles west of St. Louis and 14 miles southwest of St. Charles, Missouri. From 1941 to 1944 the Department of the Army operated the Weldon Spring Ordnance Works for the production of trinitrotoluene (TNT) and dinitrotoluene (DNT).

In 1956, the Atomic Energy Commission acquired approximately 205 acres of the original Weldon Spring Ordnance Works for use as a uranium feed materials plant. During plant operation (until 1966), four pits were excavated for storage of raffinate sludge from the plant.

In 1984, Bechtel National, Inc. (BNI) performed a detailed geological investigation for a long-term residual radioactive materials storage area (BNI, 1984). This investigation found that the raffinate pit area was suitable for long-term storage.

In 1986, BNI performed a hydrogeological investigation to provide information for siting a disposal facility on the 217-acre site of the former uranium feed materials plant (BNI, 1987), which

appeared to be acceptable for the long-term storage of low-level radioactive and hazardous wastes. Favorable site features included:

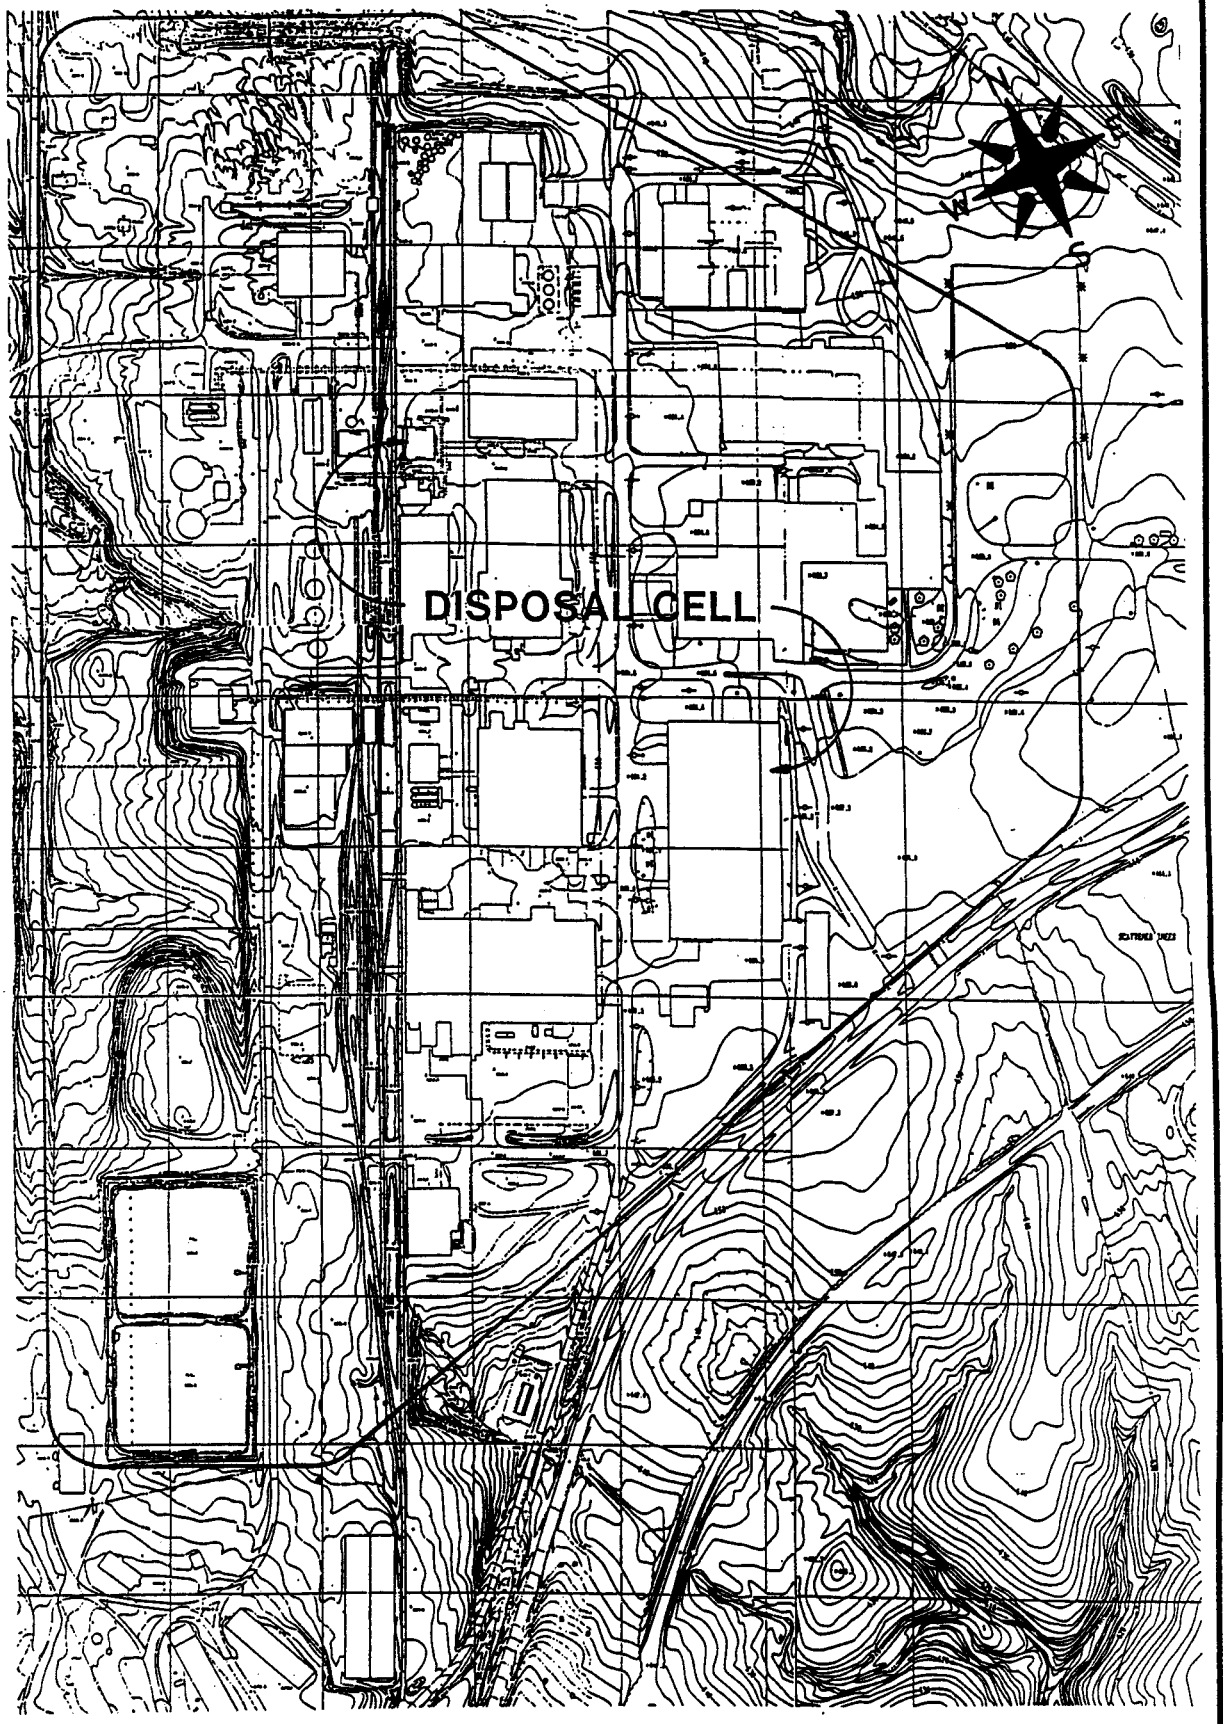
- Thick overburden
- Strong, cohesive soils
- No well developed surface drainage
- Good sorbtive soil characteristics for radionuclides
- Native soils that are stable for engineered slopes
- Proximity to wastes
- Situated on surface drainage divide

Seventy-five acres (Figure 1-1) have been selected for more detailed investigation as a disposal facility site. This area has been selected based largely on the thickness and quality of overburden soils. The 75-acre area is the subject of this plan.

1.3 Evaluation of Previous Studies

1.3.1 Background

Several investigations and geotechnical testing programs have been performed at the site. These studies included drilling, trenching, geotechnical laboratory testing, and surface geophysical surveys. These investigations were designed for purposes other than locating a disposal facility within the



REFERENCE : SURDEX CORP., 1987

FIGURE 1-1

AREA TO BE EVALUATED FOR PROPOSED DISPOSAL CELL

75-acre area and, therefore, lack sufficient detail to characterize the proposed disposal facility site.

During previous investigations, over 75 borings were drilled in the chemical plant and raffinate pit areas. These borings include test borings for construction of buildings and borings for installation of monitoring wells. In addition to borings, 21 trenches were excavated into the undisturbed soils of the raffinate pits and chemical plant areas. Soil samples were obtained and some geotechnical laboratory testing was performed. Seismic refraction, electrical resistivity, electromagnetic, and magnetometer surveys were also performed. The following sections describe these previous studies, the quality of data generated, and applicability to the current study.

1.3.2 Geotechnical Investigations

The completed geotechnical sampling studies are discussed individually. Reports evaluated include:

- U.S. Army Corps of Engineers (1955)
- Henry M. Reitz (1964)
- Bechtel National, Inc. (1984)
- Bechtel National, Inc. (1987)

1.3.2.1 U.S. Army Corps of Engineers (1955)

Investigation Purpose

Subsurface explorations were initiated by the St. Louis District, U.S. Army Corps of Engineers (COE), at Weldon Spring, Missouri under the direction of the United States Atomic Energy Commission in November 1954. The field investigation took place during November and December 1954. The final report was completed in February 1955. The purpose of the investigation was to gather geotechnical data for general foundation design work.

Drilling and Sampling Scope

A total of eight boreholes were advanced into limestone bedrock using "standard truck-mounted rotary drilling equipment." However, no depths were recorded on the boring logs, so no depth information is available. Four- or eight-inch augers were used to advance the boreholes to bedrock. It is not known whether hollow-stem or solid augers were used. Fractured rock was penetrated with a 4.75-inch roller bit.

Undisturbed soil samples were taken at two boreholes by driving 4.75-inch thin-walled Shelby tubes. At one borehole, disturbed samples were taken using a Standard Penetration Test (SPT) with a

split-spoon sampler. Rock cores were obtained with NX diamond bits.

Sampling Adequacy

Standard drilling and sampling methods were used by the COE during this investigation. Augering is an acceptable means for advancing a borehole in shallow clays. Shelby tubes and split-spoons are standard equipment for taking undisturbed and disturbed samples respectively.

No information is available on the drilling or sampling procedures. Augering is a simple operation unless it is affected by adverse soil conditions such as flowing sands or caving. Since boring logs generally indicated clays and silts, the drilling method and procedures are assumed to be appropriate.

Since no information on sample recovery or sample characteristics is given in the boring logs, other sampling validity estimates must be used. Based on laboratory test results, some disturbance in the Shelby tube samples is apparent. There is no way to determine whether the disturbance resulted from sampling, sample handling, or testing procedures. Therefore, no conclusions can be drawn regarding sampling validity.

The COE boring logs were valid for the investigation though they are inadequate in content. Individual soil descriptions, sample

recovery rates, intermediate and total borehole depths, and groundwater data are not reported. This incomplete record prevents a direct comparison of the COE data with subsequent site investigations.

Sampling Sufficiency

Eight boreholes were sufficient for the scope and extent of the COE foundation investigation. Each borehole was appropriately advanced to bedrock. Continuous Shelby tube sampling was done in two boreholes, and split-spoon sampling was done in one borehole.

Scope of Lab Testing

The following geotechnical laboratory tests were run on the COE samples:

LABORATORY TEST	NO. OF TESTS
Moisture content	83 (a)
Atterberg limits	15
Proctor compaction	1 (b)
Consolidation	2
Unconfined compression (undisturbed)	11
Unconfined compression (remolded)	5
Direct shear	
(CU) (consolidated-undrained)	1
(CD) (consolidated-drained)	2
(UU) (unconsolidated-undrained)	2

(a) Includes moisture tests apparently made on auger cuttings

(b) Assumed to be Standard Proctor

Data Validity

The laboratory soil tests were valid for their purpose. These results must be considered invalid for disposal cell siting, however, since results cannot be correlated with sufficient confidence to specific soil types. The Proctor compaction is the only test considered valid.

1.3.2.2 Henry M. Reitz (1964)

Investigation Purpose

In 1963, Henry M. Reitz Consulting Engineers performed investigations to determine geotechnical characteristics of soils underlying the proposed new raffinate pit. The final report for this investigation was completed in January 1964.

Drilling and Sampling Scope

A total of 12 boreholes were advanced using "mechanical" and "hand" augering equipment. Five mechanical auger borings extended to rock with borehole depths ranging from approximately 19 to 33 feet. Seven hand auger borings, with depths ranging from approximately 5 to 20 feet, were terminated within the soil overburden. No information is provided in the report on whether

hollow-stem or solid augers were used. No information on sampling procedures is given.

Undisturbed soil samples were taken at three boreholes at a depth of approximately 10 feet. Disturbed samples were also taken at one of these boreholes.

Sampling Adequacy

The drilling and sampling methods were valid for the raffinate pit sludge. Their validity to disposal cell siting cannot be determined however, since no information was provided on sampling methods, sample recovery or soil characteristics.

The Reitz boring logs appear to be reasonable for their purpose, but are inadequate for current disposal cell siting needs. Sample recovery rates, depths to soil changes, and groundwater data are not reported. Also, based on limited correlation with Atterberg limits testing, it appears that some soil descriptions on the boring logs may not correspond to the Unified Soil Classification System (USCS). However, the logs do provide some useful overburden depth information.

Sampling Sufficiency

Twelve boreholes were generally adequate for the limited scope and extent of this raffinate pit investigation. The extent of

sampling is not sufficient for present needs. From laboratory test data, it appears that only three undisturbed samples were retrieved. The method by which these samples were taken is not known. In addition, it cannot be determined if sufficient disturbed samples were retrieved, since no information can be found regarding this aspect of the sampling program.

Scope of Lab Testing

The following geotechnical laboratory tests were conducted on collected samples:

LABORATORY TEST	NO. OF TESTS
Moisture content	70
Atterberg limits	2
Compaction	2 (a)
Permeability	3
Vane shear strength (peak)	29 (b)
Vane shear strength (continuous)	27 (b)
Triaxial shear strength (UU-remolded)	5

(a) ASTM-D698 (Standard Proctor)

(b) Vane type, method and test procedure unknown

Data Validity

As with the 1955 Corps of Engineers investigation, test results cannot be correlated to specific soil type due to inadequate depth information reported on the boring logs. Therefore, test results must be considered invalid for disposal cell siting except for the Atterberg limit and compaction tests.

1.3.2.3 Bechtel National, Inc. (1984)

Investigation Purpose

Bechtel National, Inc. (BNI) conducted a geologic site characterization study of the raffinate pits area between December 1982 and November 1984 to:

- Define the site stratigraphy
- Describe the lithology and general conditions of each geologic unit
- Determine the existence of groundwater and how it relates to the geology

Field work was performed between December 1982 and April 1983. Laboratory soil sample testing was completed by McClelland Engineers in July 1983 and the final report was issued by BNI in November 1984.

Drilling and Sampling Scope

A total of 26 holes, with depths ranging from approximately 15 to 150 feet (average depth of about 30 feet), and 15 test pits, with depths ranging from approximately 15 to 27 feet (average depth of about 22 feet), were advanced into the overburden in the raffinate pits area. Eight-inch hollow-stem augers and NX core

drilling equipment were used for the holes. A backhoe with a 3-cubic-yard bucket was used for excavating test pits.

Undisturbed Shelby tube soil samples were taken from four boreholes on the dikes that contain raffinate pits nos. 3 and 4. All other borehole soil samples were taken using split-spoon samplers. No samples were obtained from any of the test pits.

Sampling Adequacy

The drilling and sampling methods used were appropriate for the BNI site investigation. Hollow-stem augering and NX core drilling are preferred methods of drilling on a contaminated site. Shelby tubes were used to acquire undisturbed samples. The procedures used for drilling and sampling are well documented in the investigation report.

The Bechtel boring and trenching logs appear to be generally complete and adequately documented. However, descriptions of the soil in the boring logs lack detail. A "generic" soil description is used for each soil type; the identical description is repeated in all borehole logs whenever a certain soil type is encountered. Thus, localized differences were not noted giving the impression that each of the soil types is uniform throughout the area investigated. Specific and distinct descriptions are given for each soil type in the test pit logs.

Sampling Sufficiency

Borehole depths are insufficient for present needs. Only eight of the 26 boreholes extended to competent bedrock. This is inadequate to define bedrock contours or to determine overburden thickness in the area of the site to be investigated. More boreholes located at greater distances from the raffinate pits are needed to help define overall geologic structure.

The extent of sampling is not sufficient for the present requirement. Four boreholes were sampled using Shelby tubes. All of these borings were located on raffinate pit dikes. Additional Shelby tube samples are needed from boreholes situated entirely within the natural soils. Disturbed sample coverage was sufficient for the BNI investigation. Current requirements include undisturbed sample testing in addition to disturbed sample testing.

Scope of Lab Testing

The following geotechnical laboratory tests were conducted on samples collected for this investigation:

LABORATORY TEST	NO. OF TESTS
Moisture content	75 (a)
Dry unit weight	59 (a)
Specific gravity	20
Atterberg limits	22
Gradation	22
Triaxial shear strength	
(CD multistage)	8
(CD multi-specimen)	3
(CU multistage)	5
(CU multi-specimen)	4
Permeability	5 (b)

(a) Includes data from triaxial shear strength tests

(b) Results from consolidation phase of triaxial shear strength tests

Data Validity

The documentation of soil samples, soil types, and laboratory testing is adequate for purposes of design. The test results are valid for disposal cell siting unless otherwise stated.

Dry unit weight, specific gravity, moisture content, Atterberg limits, and gradation tests are basic soil identification tests that are relatively simple to perform. These test values are valid and useful.

Triaxial shear strength tests were performed on laboratory consolidated soil samples under both drained and undrained conditions. Consolidated-drained tests (CD) and consolidated-undrained tests (CU) with pore-pressure measurements were conducted using both one-specimen multistage test procedures

procedures and three-specimen multi-specimen test procedures. CD tests provided data on effective (long-term or drained) soil shearing strengths, and CU tests with pore-pressure measurements provided data on both effective and total (short-term or undrained) soil shearing strengths.

Only six of the 20 triaxial strength test results reflect natural in-situ soils, while the remaining 14 tests were carried out on remolded dike fill materials. Of the six tests run on the natural soils, four triaxial test results applied to the Ferrelview Clay (three CD multistage tests and one CU multi-specimen test) and two triaxial test results applied to the Clay Till (one CD multistage test and one CD multi-specimen test).

Only two of the six applicable triaxial test results appear accurate. Both of these tests were carried out on Ferrelview Clay soils. For the remaining four tests, effective strength friction angles are reported to vary from 0 to 10 degrees, which is not typical for soils tested under drained loading conditions. The two "acceptable" triaxial test results report more reasonable effective strength friction angles of approximately 30 degrees.

There are a number of reasons why most of the strength test results may be inaccurate and, therefore, inadequate for purposes of design. These reasons are detailed below based on the laboratory test data presented by McClelland Engineers (1983).

- There appears to be a lack of consistent failure criteria for the first and second stages of multistage triaxial strength tests. Typically, the maximum deviator stress, principal stress ratio, or some predetermined maximum strain value is chosen to define sample failure (Bowles, 1982; Lambe and Whitman, 1969; Terzaghi and Peck, 1967; U.S. Dept. of the Navy, 1982; Wroth, 1984). However, it is not readily apparent what failure criteria have been chosen for these tests. As a result, it is possible that during the first stages of the test, the samples may have failed and been sheared to such an extent that a failure plane could have developed and remained despite subsequent consolidation during the next stage. This would weaken the specimen, and test results would significantly underestimate effective friction angles and overestimate cohesion for a drained test.

- Many samples were not sufficiently back-saturated before testing took place. Approximately one-half of the soil samples were back-saturated to a pore-pressure "B" parameter of less than 0.90, and some samples were back-saturated only to B = 0.65. The parameter B expresses the ratio of the change in pore-pressure to the change in total stress, and can be thought of as the portion of the total stress which is being carried by the pore water (Lambe and Whitman, 1969; U.S. Dept.

of the Navy, 1982). For testing clayey soils, "B" parameters should be as close to 1.0 as possible in order to fully saturate the sample (Lambe and Whitman, 1969; Mitchell, 1976).

- Some samples were reported to lengthen slightly after initial consolidation was completed. This tends to discredit either the validity of the data reporting or the manner in which the samples were consolidated. Regardless of the source of this error, the test results for these samples are not valid.

- The length to diameter ratio (L/D) for some samples appears to be too low when compared to accepted triaxial test procedures. Generally, L/D for triaxial shear strength specimens should fall between 2.2 and 2.7; however, L/D values as low as 1.7 were reported for some samples in this study. The effect of this procedural error again causes some doubt on the usefulness of these test results.

Consolidation data from the triaxial strength tests were recorded in the form of time curves. However, no void ratio or vertical strain versus log-pressure curves were presented, so no direct determination of compression characteristics and preconsolidation pressures is possible. There may be some means of determining desired consolidation characteristics from the basic test data,

but the means are not readily apparent from existing laboratory data. The consolidation data cannot be considered useful for design purposes because of the triaxial strength test data concerns and, in particular, the reported sample lengthening after laboratory consolidation.

Some qualitative consolidation information can be obtained from the triaxial strength test data. Stress paths from the two "reasonable" triaxial test results show dilative behavior and induced negative pore-pressures, which suggest that the Ferrelview Clay may be overconsolidated (Bowles, 1982; Lambe and Whitman, 1969; Mitchell, 1976). This should be verified through additional consolidation testing as part of this program.

Permeability data resulting from the consolidation phase of triaxial strength testing appear to be inconsistent. Therefore, values associated with these tests are suspect, and the permeability data are not considered useful for design purposes.

1.3.2.4 Bechtel National, Inc. (1987)

Investigation Purpose

Bechtel National, Inc. (BNI) performed a hydrogeological

characterization study to:

- Provide a groundwater monitoring system to determine if contaminants from the site have degraded groundwater quality
- Evaluate the site geology and hydrogeology for utilization of the site as a waste disposal facility

Field work was conducted between January 1986 and August 1986. The final report was completed by BNI in July 1987.

Drilling and Sampling Scope

A total of 35 boreholes with depths ranging from 54 to 94 feet and five test pits with a consistent depth of about 15 feet were located around the chemical plant area and north of the raffinate pits. Six-inch OD hollow-stem augers and both NQ and NXB wireline core drilling equipment were used. A backhoe was used to excavate the test pits.

Generally, boreholes were sampled at 5-foot intervals with split-spoon samplers. One or two undisturbed samples per borehole were obtained from 24 of the borings. Undisturbed sampling was accomplished using 3-inch OD Shelby tubes. Samples were not obtained from the test pits.

Sampling Adequacy

The drilling and sampling methods were appropriate for this hydrogeological study. Hollow-stem augering and NQ or NXB core drilling are preferred drilling methods in contaminated soils and rock. Casing was not installed in boreholes to seal possible contamination pathways prior to rock coring. Shelby tubes were used for reliable geotechnical testing.

The boring and test pit logs appear valid, generally complete, and adequately documented. Specific and distinct descriptions are given for each soil type within each borehole documenting localized variations in soil characteristics.

Sampling Sufficiency

For the scope of this hydrogeological study, the extent of the borehole and trenching plan was sufficient since this study incorporated data from boreholes previously drilled by BNI in 1984. Each borehole extended into reasonably competent limestone bedrock.

The extent of sampling is not sufficient for present design needs. Only one or two Shelby tube samples were taken in each borehole. Undisturbed sampling was not done in about one-third of the borings. Undisturbed sampling apparently was not a priority for this study, as indicated by the minimal number of

laboratory tests requiring undisturbed samples. Disturbed samples were obtained at approximately 5-foot intervals.

Scope of Lab Testing

The following geotechnical laboratory tests were run on samples collected for this investigation:

Laboratory Test	No. of Tests
Moisture content	25
Dry unit weight	33
Specific gravity	32
Atterberg limits	30
Gradation	40
Centrifuge moisture equivalent	20
Cation exchange capacity	5
Distribution ratio	5

Data Validity

Documentation of soil samples, soil types, and laboratory testing were adequate. It is assumed that the tests were properly performed and that the results are valid unless otherwise stated.

Dry unit weight, specific gravity, moisture content, Atterberg limits and gradation test results are basic soil identification tests that are relatively simple to perform. These test values are valid and useful.

Results from the centrifuge moisture equivalent tests appear to be reasonable, although there is a fairly wide variation in test

Results from the centrifuge moisture equivalent tests appear to be reasonable, although there is a fairly wide variation in test values. As expected, the Ferrelview Clay shows the highest test value, while the Basal Till exhibits the lowest. This is consistent with the types of materials involved. The fine-grained Ferrelview Clay should retain more moisture than either the sandy Clay Till or the gravelly Basal Till.

Both cation exchange capacity and distribution ratio measure chemical characteristics of the soil and pore water interactions. The test results appear to be reasonable although there is a wide variation in values. An insufficient number of test results is available for each soil type. Therefore, the test results are inadequate for design purposes.

1.3.3 Geophysical Surveying

Three geophysical investigations were carried out at the Weldon Spring Site (WSS) between 1982 and 1987 by Weston Geophysical Corporation (WGC) and Detection Sciences, Inc. (DSI) under contract to Bechtel National, Inc. (WGC, 1983; WGC, 1984; DSI, 1986). The studies utilized a total of five different geophysical techniques. Table 1-1 lists the geophysical techniques used, survey dates, and the survey subcontractors.

T A B L E 1-1

GEOPHYSICAL SURVEYS PERFORMED AT WSS

SURVEY METHOD	DATE	COMPANY
Seismic Refraction	Feb/March 1986	Detection Sciences, Inc.
Electromagnetic	February 1986	"
Seismic Refraction	March/April 1984	Weston Geophysical Corp.
Electrical Resistivity	March/April 1984	"
Seismic Refraction	December 1982	"
Electrical Resistivity	December 1982	"
Self Potential	December 1982	"
Magnetometer	December 1982	"

1.3.3.1 Scope and Purpose of Surveys

Each of the three investigations utilized multiple geophysical techniques. The combination of several survey methods and subsequent correlation of results can be used to corroborate and enhance the findings of a single method and provide more detailed information on the subsurface. However, in some instances, a particular survey was employed to investigate a specific parameter. Table 1-2 lists the general purpose of each geophysical survey method performed at WSS.

Most of the geophysical surveys performed by Weston Geophysical Corp. in 1982-84 were carried out in the vicinity of the raffinate pits area (Figure 1-2 and 1-3). Magnetometry and some electrical resistivity surveys were performed at five tentative monitoring well locations denoted as A through E on Figure 1-4. The seismic refraction and electromagnetic studies performed by Detection Sciences, Inc. were performed in the area north of Raffinate Pit 4 and east of raffinate pits 1 and 2 as shown on Figures 1-5 and 1-6. Results of these studies and their applicability to the current investigation are discussed in the following sections.

T A B L E 1-2

PURPOSE OF GEOPHYSICAL STUDIES AT WSS

METHOD	PURPOSE
Seismic Refraction	Provide subsurface information regarding the overburden thickness and depth to rock, seismic velocities, and characteristics of bedrock.
Electromagnetic	Identify contaminant plumes in the groundwater and provide a basis for selecting monitoring well locations.
Electrical Resistivity	Provide information on subsurface layering and depths including depth to groundwater.
Self Potential	Detect background potentials from fluid streaming, bioelectric activity or variations in the electrolytic concentration in water.
Magnetometry	Detect buried metal objects (e.g. abandoned process lines) in the overburden at proposed monitoring well locations.

GENERAL NOTES

1. GEOPHYSICAL SURVEYS SHALL BE PER SPECIFICATION 201-23-C-01.
2. LOCATIONS SHOWN FOR GEOPHYSICAL SURVEYS ARE APPROXIMATE. EXACT LOCATIONS WILL BE DETERMINED IN THE FIELD BY BECHTEL.
3. THE GREATEST DEPTH OF OVERBURDEN IS APPROXIMATELY (C5) FEET.
4. GEOPHYSICAL SURVEYS SHALL BE DISCONTINUED AT FENCE LINES AND RESUMED AT OPPOSITE SIDE OF FENCE. FENCE SHALL NOT BE DISTURBED
5. GEOPHYSICAL SURVEYS WILL NOT BE REQUIRED IN AREAS OF STANDING WATER
6. EM SURVEY WAS PERFORMED WITH A GEONICS EM 34-3 INSTRUMENT.
7. EM SURVEY WAS PERFORMED USING HORIZONTAL COPLANAR DIPOLE CONFIGURATION WITH A 20 METER INTERCOIL SPACING.
8. FOR AS-BUILT INFORMATION ON THE SHALLOW SEISMIC REFRACTION SURVEY, SEE THE SUBCONTRACTOR'S REPORT.

1.3.3.2 Data Validity

Weston Geophysical Corp., 1982

The seismic refraction, electrical resistivity, and self potential survey results are summarized on Figure 1-7. The study area is characterized by a near-surface low velocity layer (1,200 to 1,800 ft/sec), underlain by a more consolidated layer (2,000 to 5,400 ft/sec), which in turn is underlain by bedrock (11,000 to 13,000 ft/sec). The depth to bedrock varies between 30 and 60 feet (DSI, 1986). Survey lines closest to the proposed disposal cell area were compared with drillhole information to test the accuracy of the surveys. Survey results from lines 1, 2, 3, 10, 11, and 12 are shown on Figures 1-8 and 1-9. Data from drillholes B19A, B17, B21, and G15, located in the vicinity of these lines and penetrating bedrock, correlate well with the seismic survey results.

One discrepancy is that the weathered bedrock surface was characterized as overburden because of its relatively low velocity. The bedrock depths determined by seismic refraction apparently delineate the less fractured, more competent limestone and not the actual top of bedrock. From an engineering standpoint, this competent rock boundary is probably more significant than the top of weathered rock. This fractured bedrock layer has an average thickness of 10 feet in

FIGURE 1-9

SEISMIC PROFILES LINES 10, 11 & 12

most drillholes, but is 19 feet thick in hole G15 as indicated by low rock quality designation (RQD) values. A second discrepancy between borehole and geophysical information results from the similar seismic velocities of various overburden layers. This causes layers with similar velocities (densities) to be grouped into a single unit.

The electrical resistivity values indicate a three-layer subsurface condition which correlates well with seismic refraction data. Results range from 60 to 150 ohm-feet for the uppermost layer, 30 to 50 ohm-feet for the thick intermediate layer, and over 1,000 ohm-feet for bedrock. These values appear to be consistent with expected resistivity. Correlation of the seismic refraction results with electrical resistivity surveys is shown on Figures 1-8 and 1-9. Results obtained by these methods appear consistent. Although original field data was not included in the reports, the data appears to be accurate and the results valid.

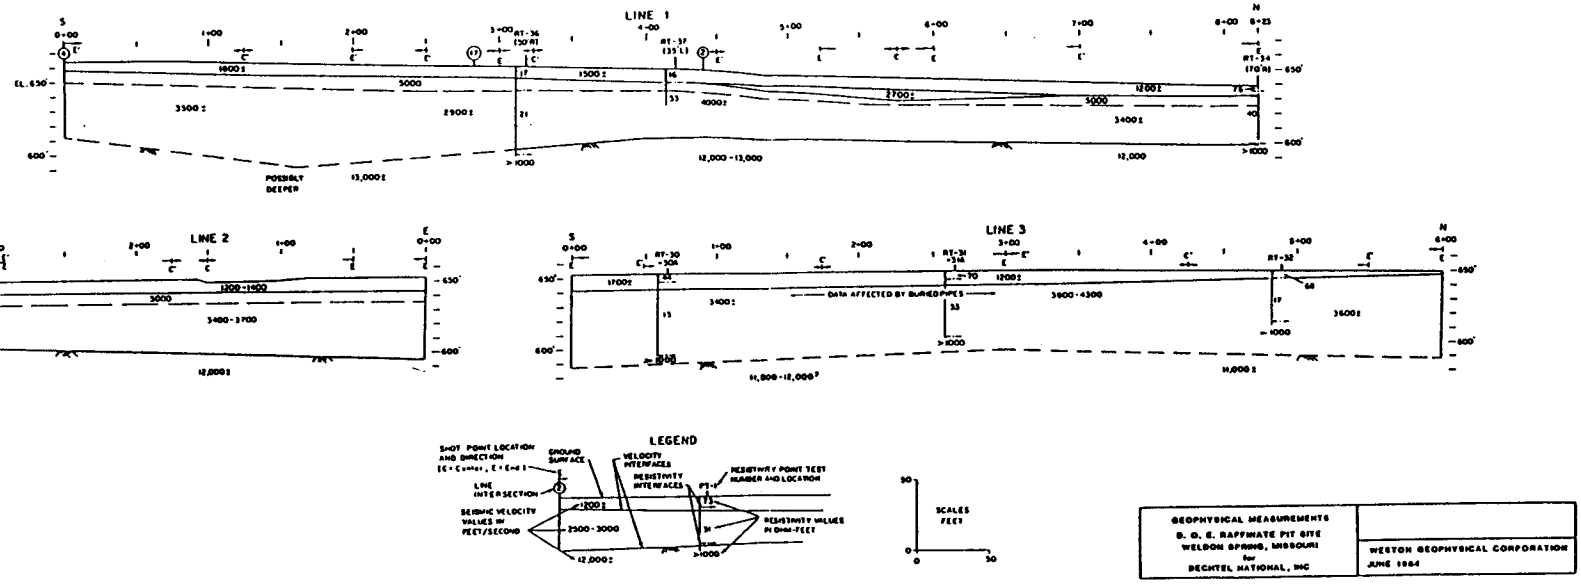
The self potential data appear to be accurate. The results are plotted on Figure 1-7. Only lines SP-1 and SP-2 reveal anomalies indicated by potential reversals. These negative anomalies were identified as a characteristic of fluid streaming, a condition that is typical of permeable materials. However, the soils in the area consist of impermeable clays, clayey silts, and silty clays as demonstrated by the boring logs and supported by low

resistivity values. Therefore, the correlation of the SP anomalies with existing groundwater conditions is questionable. Magnetometric and electrical resistivity survey data appear accurate and results seem to have valid and reasonable interpretations.

Weston Geophysical Corp., 1983-1984

Seismic refraction surveys conducted in and around raffinate pits 3 and 4 revealed a rather complicated overburden structure (Figure 1-10). Seismic velocities under the ponds suggest the presence of four layers. This may be explained by an increase in moisture content. The seismic velocity of the overburden increases with moisture content to approximately 5,000 ft/sec when saturated. Lower velocity materials may be present beneath the ponds, but were not detected due to higher velocity, saturated surface material. The seismic refraction interpretation is based on the assumption that seismic velocity increases with depth.

A comparison of interpreted seismic data with borehole logs indicated that the bedrock depth determined from the seismic survey is not the top of rock but the depth to competent, less-fractured rock. The bedrock surface was characterized as overburden because of its relatively low velocity due to its weathered and fractured condition.



SOURCE : WESTON GEOPHYSICAL CORP., 1984

FIGURE 1-10

SEISMIC PROFILES OF RAFFINATE PIT NO. 3, LINES 1,2 & 3

Electrical resistivity results generally correlate well with the seismic refraction interpretation. In some instances, the depth to top of bedrock was less than the seismic results as shown on Figure 1-10. The geophysical results from the investigations in the raffinate pit area have characterized the subsurface as shown on Table 1-3.

Detection Sciences, Inc., 1986

Seismic refraction survey results (Figures 1-5 and 1-11) indicate four layers in the subsurface. These are described in Table 1-4. Borehole logs, however, indicate eight or more layers in the subsurface. This can be explained by the similarity in seismic velocities of various overburden layers resulting in layers with similar velocities (densities) grouped into a single unit. A further complication in interpretation results from groundwater within unconsolidated soils which increases the apparent velocity of the material and may mask the presence of underlying lower velocity material.

Results from the DSI investigation appear to be reasonable and consistent with the borehole logs. The seismic results also generally agree with previous investigations performed near the raffinate pits.

The electromagnetic (EM) surveys (Figure 1-6) were affected by buried metallic debris, pipes, and power lines. Most of the

observed terrain conductivities were interpreted based on the known geology and hydrology of the area. In the Ash Pond area, results indicated southwest to northeast groundwater flow. North of the chemical plant, a high conductivity (50 mmhos/m) may indicate degraded groundwater quality. East of the chemical plant, the high conductivities were interpreted as a possible expression of a solution feature. These interpretations cannot be verified at present due to the lack of drillhole information.

1.3.3.3 Validity of Methods

The geophysical methods used in the investigations were acceptable techniques and fulfilled the program objectives. Magnetometry was used only to detect magnetic anomalies at proposed monitoring well locations. The method was appropriate and the results suggested changes in proposed well locations at some sites. The accompanying electrical resistivity surveys provided additional support in characterizing the subsurface materials.

Seismic refraction surveys were most useful for determining depth to competent bedrock. Accuracy increased considerably once drillhole logs were correlated with seismic profiles. Seismic survey limitations were recognized and subsequent interpretations were more accurate.

Electrical resistivity surveys support the results of the refraction studies by providing independent data that could be correlated with the seismic studies. Interpretations were similar and usually did not differ by more than 5%, except in some instances where interpretations varied by 15% to 20%. The Wenner electrode configuration was used. It is a common and acceptable technique. Computer programs such as INVERSE were used to interpret the data and model the subsurface. This method is more accurate than manual matching of resistivity curves.

Electromagnetic traverses generally provided valid data. The presence of cultural features (power lines, subsurface pipes, and metallic structures) precluded surveys from being carried out near the chemical plant site.

The self potential technique is basically used to investigate shallow contaminant plumes. It provides qualitative information on the extent and degree of contamination. The negative anomalies detected in some areas at WSS could be interpreted as either fluid streaming or variations in the water chemistry of overburden material.

1.3.3.4 Data Sufficiency

The data obtained from previous geophysical investigations at WSS were applicable for interpretations of the subsurface in and around the raffinate pits. The data obtained were sufficient for

the scope of the BNI investigations. The coverage extended only slightly into the proposed disposal facility area. Based on the existing data, subsurface interpretations in the disposal facility area must be extrapolated from the raffinate pit area and correlated to borehole logs. Insufficient coverage in the disposal facility area needs to be augmented by additional geophysical studies.

1.3.4 Summary

Previous site investigations have been thoroughly reviewed and evaluated to determine applicability of the results for present disposal facility design requirements. Table 1-5 summarizes the findings of sections 1.3.2 and 1.3.3 regarding adequacy and sufficiency of data and investigative methods. In general, there is a lack of coherence among the studies because they were conducted for different objectives. None of the previous investigations are considered to be directly applicable and sufficient for current needs. Much of the data is useful but incomplete. As described in the previous sections, much more detail is required to obtain the engineering parameters necessary for the engineering design. The additional data requirements are discussed in Section 1.4.

1.4 Justification for Further Investigations

1.4.1 Rationale

This sampling plan proposes further site investigations necessary to demonstrate suitability of the site as a satisfactory disposal facility. Data analyses and interpretation will yield engineering characteristics of soil and bedrock affecting disposal facility performance. The following sections provide a rationale for the proposed investigations including:

- Siting decisions concerning the disposal facility
- Sufficiency and validity of the proposed data gathering
- Data requirements to establish disposal facility design criteria
- Objectives of the specific data collection methods
- Methods of data analysis and possible need for additional studies

1.4.2 Disposal Facility Siting

Siting a waste disposal facility requires a foundation that will remain stable for the facility design life. Surface stability processes such as erosion and settlement can be observed and measured. Subsurface conditions that may affect stability can be observed directly only by trenching or drilling. Remote sensing

by geophysical methods gives an indirect indication of subsurface conditions that usually require corroboration by drillholes.

The proposed investigation must demonstrate that the selected site is currently stable and has a high probability of remaining stable for at least 1,000 years. The results from the investigation described in this plan together with knowledge of the site geology will aid in assessing whether these criteria can be met.

1.4.3 Data Sufficiency/Validity

To characterize a disposal facility site, data must be collected. This data must be representative and accurate and the results must be reproducible. The following sections describe the methods that will be followed to obtain sufficient and valid data.

1.4.3.1 Geotechnical Drilling

To adequately characterize an area such as the proposed disposal facility locale, preliminary boreholes should be placed approximately 200 to 500 feet apart, with additional borings used to investigate critical locations or anomalous conditions (Bowles, 1982; U.S. Dept. of the Navy, 1982). All borings should be drilled into competent bedrock, so that sufficient overburden thickness and bedrock elevation data can be collected (U.S. EPA,

1987). The location of some of the boreholes should coincide with proposed geophysical survey line locations so that the boring results can confirm the geophysical data. Such a baseline of corroborated data can then be used to more accurately interpret the geophysical results over the entire site. The proposed drilling program is discussed in Section 2.1.

Because the site may be contaminated, wash type borings which could spread contaminants from upper to lower soils, or to bedrock, are inappropriate (U.S. EPA, 1975; U.S. EPA, 1987). Percussion drilling is not appropriate since water is required within the borehole to slurry the cuttings for removal and since it is not recommended for undisturbed sampling (U.S. Dept. of the Navy, 1982). Auger boring is the preferred method of soil drilling and particularly hollow-stem augers which serve as a casing to keep the borehole open during drilling. Since water is not required to flush the soil cuttings to the surface in auger drilling, the potential for downhole contamination is minimized.

1.4.3.2 Geotechnical Lab Testing

The sampling plan objectives relative to the geotechnical laboratory testing program are to determine the quality of the reported data and verify that it is acceptable for its intended end use. The EPA (U.S. EPA, 1976; U.S. EPA, 1982) indicates that the data quality considered to be acceptable must be defined as quantitatively as possible. Because of the inherent variability

of soils and rocks and the requirement for a quantitative acceptability standard, a statistical sampling and testing plan has been developed to address the adequacy and representativeness of the sampling and testing effort.

The overall approach of the statistical sampling and testing plan is:

1. Determine the number and types of geotechnical samples and the associated geotechnical parameters that will be considered in the disposal facility design.

2. Identify the end use of each engineering parameter.

3. Determine and summarize the valid data from existing geotechnical testing.

4. Compute sample means, standard deviation, and coefficients of variation.

5. Compute the number of samples and tests required for a desirable confidence level and a predefined confidence interval for each parameter and material type.

6. Determine the adequacy and representativeness of the collected data.

The approach presented by EPA (1976, 1982) and Barth and Mason will be used to calculate the number of required samples and tests. A confidence level of 90% will be used. If the existing number of valid data points is less than that for meeting the minimum criterion in Step 5, additional sampling and testing will be performed to meet the requirements.

Material Types and Engineering Parameters

The foundation materials of interest in the disposal facility design consist of:

Ferrelview Clay
Clay Till
Basal Till

Material of interest will also include the residuum (weathered rock/residual soil) if sufficient thickness is encountered. Other overburden material, with the exception of loess, is not expected to be present but will be tested if encountered. Loess will be excavated and spoiled when encountered. Bedrock is not included in the above list since its quantitative engineering properties are not required for design.

The bedrock will be described and classified during drilling. Rock data that might affect disposal facility design (e.g. RQD and percent of core recovery) will be presented in the drill

logs. Also, the geophysical exploration will provide information on the integrity of the bedrock foundation and possibly the presence of solution features and fractures. Laboratory tests of bedrock cores are therefore not planned as part of the characterization program.

Data From Previous Studies

The previous studies on geotechnical sampling and testing are documented in the following reports:

- U.S. Army Corps of Engineers Report (1955)
- Henry M. Reitz (1964)
- Bechtel National, Inc. (1984) (laboratory test by McClelland Engineers)
- Bechtel National, Inc. (1987)

The reports contain laboratory test data for the foundation materials in the Weldon Spring chemical plant and raffinate pits sites.

Table 1-6 summarizes the quantity and types of valid geotechnical test data contained in these reports for the three major soil types in the disposal facility area including Ferrelview Clay, Clay Till, and Basal Till. The table shows that most of the previous tests were performed on samples of Ferrelview Clay and Clay Till. There is a lack of comparable data for the Basal Till, and insufficient analyses for strength, consolidation, and

permeability parameters for all soil and rock materials. Each valid test identified in Table 1-6 is documented in Appendix A. Documentation includes laboratory test, soil type, boring number, sample number, and test results.

Appropriate Number of Samples and Tests

As discussed previously, the appropriate number of samples and tests for achieving data sufficiency and representativeness can be determined using a statistical approach. Assuming that an engineering parameter is normally distributed, the number of samples and tests required to maintain a confidence level for that parameter to lie within a certain confidence interval can be computed. Using this approach, five tests are required for each engineering parameter of each soil type. However, as described in the following paragraph the number of tests performed will generally exceed the minimum required number calculated statistically. Standard engineering practices and professional judgement will be applied in selecting samples for testing.

Data Sufficiency

The sufficiency of the existing geotechnical test data can be evaluated based on the number of tests required as determined above. The difference between the number of existing valid test results (determined as described in Section 1.3.2) and the required number of results (5) is the number of tests that should

required number of results (5) is the number of tests that should be carried out in the testing program shown in Table 1-7. The quantities presented in Table 1-7 are the minimum that should be performed. Most physical and index property tests are relatively quick and inexpensive. These tests should be performed both for additional quality assurance checks and for obtaining basic data required for strength, compressibility, consolidation, and permeability. The index properties are frequently used in empirical correlations for estimating strengths, compression indices, preconsolidation pressures, and permeability. These estimates can provide another check on the reliability of the values of these parameters obtained by direct testing methods.

1.4.3.3 Geophysical Surveys

The objectives of the previous investigations were different from those contemplated for the disposal facility area. Previous studies were performed primarily to determine the depth to bedrock and the characteristics of the overburden. The proposed survey is designed to both define the thickness and characteristics of the overburden and determine limestone bedrock parameters. The degree of fracturing in the bedrock and the presence of voids or other solution features that may affect the disposal facility foundation are of particular interest.

(a) Basal Till soils are not expected to require compaction

The previous geophysical surveys were located primarily outside the present area of interest. Although geophysical data acquired in the raffinate pits are valuable in understanding the general site characteristics, current program objectives require specific information on the subsurface within the boundaries of the proposed disposal facility.

Only two seismic refraction lines from previous investigations are located within the proposed disposal facility area (Figures 1-5 and 1-11). The north-south line passing east of raffinate pits 1 and 2 is relevant because it extends along the western boundary of the disposal facility. Seismic data obtained along this line will be useful in characterizing the subsurface. The east-west seismic profile extends only 500 feet into the disposal facility area and consequently only the eastern 500 feet of the profile is relevant.

Three EM survey lines by Detection Sciences, Inc. (1987) are located within the study area. The resulting terrain conductivity contour map (Figure 1-6) covers only the northern and eastern portion of the disposal cell. These data will be useful once additional EM surveys are performed within the central area of the proposed disposal cell.

The geophysical testing program proposed for the disposal cell area is discussed in Section 2.2. Methods of investigation include various geophysical techniques, correlation with

previously acquired data, and ground-truth information provided by boreholes.

The existence of borehole logs and additional drilling will assist in the geophysical interpretation. Boreholes corroborate geophysical results and provide non-interpretive, ground-truth information used to derive more accurate interpretations.

1.4.4 Data Requirements

To site a disposal facility, an area must be screened to show that certain engineering requirements are met. These requirements are that the foundation of the disposal facility:

- Has sufficient strength to withstand horizontal and vertical forces induced by the disposal facility
- Maintains integrity for the design life of the disposal facility

To meet these criteria, soil samples must be collected and tested. Standard engineering models are then developed using the collected data. The model results will demonstrate whether or not the selected site is stable under design loads.

1.4.5 Data Collection Methods

The geotechnical and geophysical testing will use standard methods. The sampling and testing procedures are defined in the following sections.

1.4.5.1 Geotechnical Drilling and Sampling

Geotechnical samples can be either disturbed or undisturbed. Completely undisturbed soil samples are impossible to obtain, and the quality of an undisturbed sample is related to how much disturbance the sample was subjected to during sampling procedures. Disturbed samples are collected with samplers which significantly alter the structure of the in-situ soil during sampling procedures.

Disturbed samples are generally obtained using some type of split-spoon sampler. Because these samplers are usually hammer driven, vibration affects the soil within the sampler. Also, the driving shoe at the tip of the sampler has a relatively large volume displacement which disturbs the soil as it enters the sampler (U.S. EPA, 1987; U.S. Dept. of the Navy, 1982). For these reasons, disturbed sampling techniques cannot be used in obtaining soil samples for permeability, consolidation, or shear strength testing as these tests require samples with a minimum of disturbance.

Disturbed soil samples can be used for physical property and index testing such as gradation, compaction, or Atterberg limits. In addition, the standard penetration test (SPT) has been correlated with geotechnical properties such as relative density and undrained shear strength (Bowles, 1982; Lambe and Whitman, 1969; Mitchell, 1976; Terzaghi and Peck, 1967). Therefore, disturbed sampling is most useful when SPT equipment and procedures are used.

Undisturbed borehole samples are retrieved using thin-wall seamless brass or steel tubing pushed into the soil under hydraulic or pneumatic pressure. Some disturbance occurs along the outside of the sample due to friction with the inside wall of the tube; however, this disturbed area is usually trimmed off prior to laboratory testing.

In general, as the diameter of the tube increases, the quality of the soil samples increases since wall friction tends to disturb the same amount of soil regardless of the tube diameter. However, sampling costs escalate rapidly as larger tubes are used so that a compromise must be reached between sampling and testing requirements. An additional constraint is that the sampler must fit within the hollow inner stem of the augers. Three inch diameter tube samples are most common and provide adequate samples for strength, permeability, and consolidation testing of nominally undisturbed soils.

Boring logs are required to provide a record of the soil and rock types encountered during drilling. Logs also show where samples were taken within the borehole and provide sample identification and sampling method documentation.

1.4.5.2 Geotechnical Lab Testing

The following standards will be used when performing geotechnical laboratory tests:

- American Society of Testing and Materials
- Army Corps of Engineers

Specific standard methods which apply to individual laboratory tests are given in Table 3.1.

1.4.5.3 Geophysical Surveys

Various geophysical methods may be applied to meet current objectives. Data is generally obtained using signals from electronic sensors recorded in the field on a data logger and later transferred to a computer for storage and processing. Although a variety of techniques are used to obtain data by any individual method, the basic geophysical principles are followed. These techniques vary among companies involved in geophysical studies and are too numerous and complex to describe. In electrical resistivity (ER) surveys, for example,

the electrode configuration may be Wenner, Schlumberger, modified Schlumberger, monopole, dipole-dipole, or modifications of these with the first two configurations the most commonly used. Seismic refraction and reflection lines may vary in length of spread, overlap, geophone separation, energy applied, location of shot points, and minor modifications of arrays.

There are also variations in techniques applicable to electromagnetic (EM), induced polorization (IP), and self potential (SP) surveys. Microgravity and magnetometry surveys are less complex with the separation between stations and type of instrument being the basic variations. The applicability and objective of each geophysical method proposed at WSS is further discussed in Section 2.2.

SECTION 2

PROPOSED SCOPE OF WORK

2.0 PROPOSED SCOPE OF WORK

The proposed geotechnical and geophysical work tasks are necessary to demonstrate that radioactive and hazardous wastes can be safely encapsulated at the Weldon Spring Site. The combined geotechnical and geophysical studies will characterize the soil and bedrock horizons beneath the proposed disposal facility site and provide engineering parameters for design.

The "Contractor" referred to in the following sections is the Project Management Contractor responsible for overseeing the work tasks. The "Subcontractor" is the party actually performing the specific task.

2.1 Geotechnical Drilling

2.1.1 Purpose and Scope

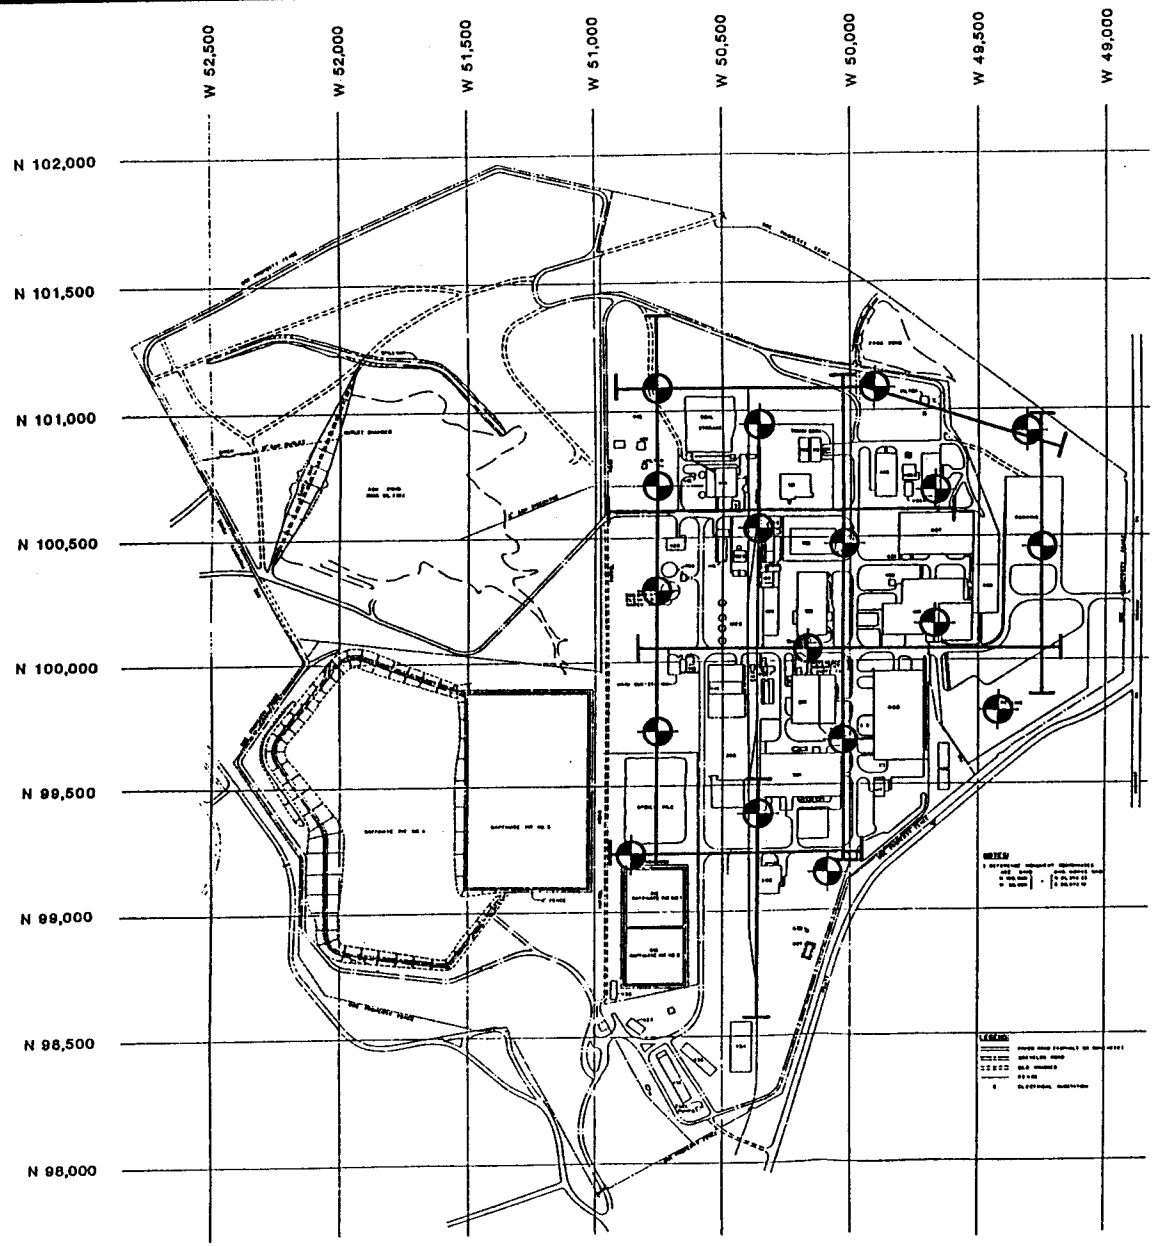
The drilling program will be used to obtain samples required for design of the disposal facility and to obtain direct visual information on soil and rock parameters and thickness of overburden. Twelve boreholes will be drilled beneath geophysical survey lines and six additional boreholes will be placed within the disposal facility area to provide additional soil and bedrock data away from the geophysical survey lines.

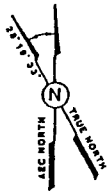
Drill holes provide noninterpretive, ground-truth information on soil and bedrock conditions. The 18 boreholes will be used to correlate geophysical measurements to subsurface conditions. Laboratory tests of samples will be performed to obtain geotechnical design data (Section 3.1.2). Additional borings into the bedrock may later be required if geophysical data reveals solution features.

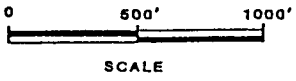
2.1.2 Drilling Locations

Approximate borehole locations are shown on Figure 2-1 on a tentative geophysical survey grid that encompasses the proposed disposal facility area. Most of the borings will be located within the chemical plant area and thus may require coring through or breaking concrete foundations to reach overburden soils.

Boreholes will generally be 50 to 70 feet deep. A minimum of two boreholes will be drilled to approximately 200 feet below the ground surface. These deep holes will be geophysically logged. All boreholes will penetrate at least 20 feet into competent bedrock. The depth and location of all boreholes will be determined by the Contractor's technical representatives including geophysicist, geologist, and engineer.







– APPROXIMATE LOCATION OF PROPOSED BORINGS

– APPROXIMATE LOCATION OF PROPOSED GEOPHYSICAL LINES

FIGURE 2-1 PLAN MAP

TENTATIVE BORING LOCATIONS AND GEOPHYSICAL LINES

Samples in the overburden will be collected at 2 1/2 foot intervals or continuously as determined by the field geologist. After a hole is advanced five feet below the ground surface, at least one undisturbed sample will be taken every five feet or at every change of material type until refusal.

Disturbed split-spoon samples will be collected between undisturbed samples. Rock samples will be obtained by coring below auger or sampler refusal.

2.1.3 Drilling Equipment and Methods

Standard drilling equipment will be used. The equipment will be capable of undisturbed and disturbed sampling above and below the groundwater table. Drilling equipment will be sufficient for coring and recovering rock core to a depth of 300 feet. The drilling Subcontractor will advance an 8-inch or 10-inch OD hollow-stem auger to refusal depth, and a 3-inch OD NQ wireline core barrel below auger refusal.

Undisturbed soil samples will be collected with new and previously cleaned 30-inch or 36-inch Shelby tubes (3-inch OD) pushed with smooth hydraulic or pneumatic pressure to the full usable length. Usable length is defined as 24 inches for a 30-inch long tube and 30 inches for a 36-inch long tube. The

Contractor may redefine usable length if sample recovery is inadequate or sample disturbance is too great.

The loaded Shelby tube shall be detached from the sampler head and then capped and wax-sealed upon removal from the borehole. After capping and sealing, Shelby tubes will be stored vertically in an environment protected from temperature extremes. Sampling techniques and equipment shall be in accordance with ASTM D1587 (Shelby Tube Sampling).

Disturbed soil samples will be recovered from clean and uncontaminated split-spoon samplers. Split-spoon soil samples will be sealed in airtight 8-ounce (or larger) glass jars and stored in a protected environment. Techniques and equipment used for split-spoon sampling shall be in accordance with ASTM D1586 (Standard Penetration Test).

Rock cores will be obtained using clean and uncontaminated 3-inch OD NQ wireline core barrels. Recovered cores will be placed in standard core boxes. Boxes will be labelled, and stored in a protected dry location to prevent mishandling and damage to the rock samples. Rock coring shall employ techniques and equipment as called for in ASTM D2113-83.

Coring shall be performed through the hollow stem of the auger. If this method proves to be unsatisfactory for any reason, a 6-inch diameter casing (schedule 40 PVC pipe) will be installed

to the depth of auger refusal and grouted in place before coring operations begin. The PVC casing will have flush threaded joints. No adhesives or solvents shall be used to cement the pipe lengths together. The borehole will be reamed to a diameter of at least 10 inches prior to casing installation to create sufficient annular space for grouting the casing into the borehole. A cement-bentonite grout mix will be used and will completely fill the annular space between the outside of the conductor casing and the natural soils of the open borehole. Grout will be tremmied from the bottom of the hole. The grout mix and the curing time will follow the Manual of Water Well Construction Practices (U.S. EPA, 1975). The casing will prevent potential leakage and cross-contamination between overburden soils and the limestone bedrock. All boreholes will be plugged after sampling has been completed and in accordance with established WSSRAP procedures.

2.1.4 Drilling and Sampling Procedures

Drilling and sampling will be performed in accordance with accepted procedures as discussed in the U.S. EPA RCRA Technical Enforcement Guidance Document (U.S. EPA, 1986). Standard operating procedures (SOPs) have been developed for WSSRAP based on EPA guidance. A supervising geologist will be present to document all drilling and sampling activities. The geologist will perform pocket penetrometer or vane shear testing on all cohesive soil samples immediately after the sample is retrieved.

Results will be recorded on the core logs. Samples will be handled, tested, and shipped in accordance with approved WSS procedures for potentially contaminated materials.

2.1.5 Decontamination

All sampling equipment, augers, drill rods, drill bits, and other equipment which has been in contact with the site soils or rock shall be decontaminated by high pressure hot water or steam before each borehole is drilled. The entire drilling rig will be decontaminated upon arrival on-site and upon completion of drilling activities. Interior portions of equipment such as pumps and hoses which are not accessible for cleaning with a pressure or steam cleaner shall be thoroughly cleaned and flushed with potable water. Decontamination will be performed at the established site decontamination pad. Split-spoon samplers shall be washed with a dispersant (such as Calgon or tri-sodium phosphate) and water, rinsed with potable water, rinsed with de-ionized water, and reassembled prior to further sampling. Solid waste from the drilling program shall be placed in barrels. The contents of each barrel will be identified. The barrels will be stored in a secure area on site.

2.2 Geophysical Surveys

2.2.1 Purpose

The primary emphasis of the geophysical program will be to try to determine if solution features are present in the bedrock below the proposed disposal facility area. These features could adversely affect the integrity of a disposal facility. The geophysical survey will also attempt to obtain other parameters that might impact the design or integrity of the disposal facility. Characteristics to be detected and delineated include, but are not limited to:

- Bedrock channel, cavity, joint, and fracture distribution
- Overburden types, thicknesses, extents, and characteristics
- Depth to top of bedrock
- Bedrock layer condition and extent
- Depth to top of saturated overburden
- Perched water tables
- Overburden and bedrock velocities and densities

2.2.2 Survey Layout

The proposed disposal facility site is located on 75 acres and includes portions of the chemical plant and raffinate pit area. Numerous buildings, concrete paving, buried pipes and other hindrances must be considered when planning the layout of geophysical survey lines. The proposed area will be crossed by north-south and east-west survey lines varying in length from 500 to 2500 feet. Approximate geophysical survey line locations are shown on Figure 2-1. These locations are only tentative and precise locations will have to be determined based on careful consideration of the many obstructions and sources of interference on the site. The location of the lines will be determined by the Subcontractor in consultation with the Contractor's geophysicist. Required depth of investigation is approximately 200 feet below top of bedrock. Both long and short survey lines will be used to investigate deep and shallow conditions/layers respectively.

Elevation and position of survey lines and stations will generally be located to an accuracy of 0.1 feet. Higher precision may be required for some surveys. Precise elevations and required positions will be determined by a licensed surveyor.

2.2.3 Geophysical Methods

The following geophysical methods are potentially applicable in this study:

- Seismic refraction
- Seismic reflection
- DC electrical resistivity (ER)
- Electromagnetic induction (EM)
- Induced polarization (IP)
- Self potential (SP)
- Microgravity
- Magnetometry

Seismics, ER, and EM are the primary methods for the current program. The accuracy of geophysical interpretations will be increased by combining and correlating data from more than one method. The primary methods will be employed for data acquisition; secondary methods may be used to support the data obtained. A description of how these methods and results address the program objectives follows.

Seismic refraction surveys yield overburden and bedrock seismic velocities. Velocities are then used to identify the top and general condition of bedrock, thickness and general consistency of overburden materials, and location of the water table in

overburden. When correlated with other geophysical methods, seismic refraction surveys could identify possible anomalous areas where solution features may be present.

Seismic reflection surveys also yield data on soil and bedrock seismic velocities. This information shows variations within the bedrock horizons. Deep penetration to 200 feet below top of bedrock may be possible through high resolution survey techniques, but shallow and irregular bedrock surfaces may disperse the reflected waves. This method may therefore be used as a secondary technique to complement the refraction surveys.

DC electrical resistivity (ER) surveys detect resistivity contrasts in subsurface materials. ER can identify overburden and bedrock layers, lateral variations in composition, and hidden lower density layers not detected by seismic methods. ER may also detect the overburden/bedrock contact and large subsurface fracture zones, cavities, or channels. This technique complements seismic methods and correlates with the electromagnetic induction data to derive more accurate interpretations or locations of fractured or cavernous areas. Both lateral profiling and vertical sounding surveys are applicable to the present investigation.

Electromagnetic induction (EM) survey data will be integrated with the ER surveys to locate anomalous areas that may contain fractures, voids, or cavities. Various exploration depths up to

250 feet may be investigated with this technique using vertical soundings as well as lateral profiling. The combination of EM and ER survey data with borehole information results in a better understanding of specific subsurface features.

Induced polarization (IP) surveys detect polarization phenomena caused by water-borne ions in clays that fill voids primarily in the overburden and above the water table. If the polarizations can be differentiated, they may identify anomalous subsurface features such as cavities. The IP survey is a secondary method that provides additional information to corroborate EM and ER data.

Self potential (SP) surveys measure the natural electric potentials in the subsurface caused by electrochemical activity such as a contaminant plume interaction with groundwater. This method can detect "streaming potentials" caused by fluid movement through fractures, joints, or cavities in the shallow subsurface.

Microgravity surveys detect density contrasts in the subsurface such as large solution features within the bedrock. With appropriate computer modeling programs, the density contrasts are identified and interpreted. To compensate for the inadequate depth control, other geophysical results and drilling are used to enhance microgravity.

Magnetic surveys are not applicable to current program objectives at WSS. Their only use would be to identify magnetic anomalies caused by buried pipes, structures or other metallic debris (cultural interference) which would impact other survey measurements.

2.2.4 Survey Techniques

The geophysical methods described in the previous section employ a variety of techniques to obtain data. Although the general principle of each method is described in the literature, the data may be obtained and processed by a variety of procedures. Differing methodologies may all be valid. Subcontractors rely on a particular combination of techniques, corresponding reduction procedures, computer programs and experience. The selection of techniques is left to the Subcontractor's discretion subject to review and concurrence by the Contractor's technical staff. Selected techniques must use proven methodologies and geophysical principles and be responsive to the primary objective of locating solution features.

SECTION 3

ANALYTICAL REQUIREMENTS

3.0 ANALYTICAL REQUIREMENTS

3.1 Geotechnical Laboratory Testing

3.1.1 Site Soils

Geotechnical laboratory testing is necessary to provide valid and sufficient data for each soil type within the Weldon Spring Site. Section 1.4.3.2 describes the statistical evaluation used to determine the minimum number of valid test results necessary to achieve data sufficiency.

Site soils relevant to design of the disposal facility are generally divided into three types. In order of increasing depth below ground surface they are:

- Ferrelview Clay
- Clay Till
- Basal Till

In addition, the residuum (weathered rock/residual soil) will be included for testing if sufficient thickness is encountered and if good quality representative samples can be obtained.

3.1.2 Laboratory Tests

The proposed laboratory testing program will be combined with results determined to be valid from the previous investigations to provide complete geotechnical design data. Assigning specific soil samples to each laboratory test will take place after the boring logs have been thoroughly reviewed and analyzed.

Testing will be performed in different phases so that representative samples can be selected for the more sophisticated tests such as shear strength and permeability. Geotechnical laboratory tests suggested for the proposed drilling and sampling program described in Section 2.1 are shown in Table 3-1 and are followed by a brief test description. For some of the detailed tests required for data adequacy such as triaxial shear strength, additional basic tests such as moisture content are recommended as a check on data consistency and reliability.

Moisture content, a physical soil property, is the ratio of the weight of the free water within the soil voids to the weight of the soil solids expressed as a percentage. The results of this test are used to help define soil horizons and to determine volume-weight relationships of the in-situ soils (U.S. EPA, 1983; U.S. Dept. of the Navy, 1982). When used with the Atterberg limits, moisture content can indicate whether a soil is preconsolidated. One moisture content test will be run on each

Table 3-1

SUGGESTED MINIMUM
NUMBER OF GEOTECHNICAL
LABORATORY TESTS

LABORATORY TEST	FERRELVIEW CLAY	CLAY TILL	BASAL TILL
Moisture Content (ASTM D2216)	18	18	18
Dry Unit Weight	18	18	1
Specific Gravity (ASTM D854)	3	3	5
Capillary Moisture (ASTM D3152 & ASTM D2325)	5	5	5
Gradation (ASTM D422)	5	5	5
Atterberg Limits (ASTM D4318)	12	12	12
Triaxial Shear Strength: Consolidated Undrained (CU), pore-pressure measurements, 3-point test (EM-1110-2-1906)	$_3$(a)	$_3$(a)	$_3$(a)
Unconsolidated Undrained UU (EM-1110-2-1906)	5	5	5
Falling Head Permeability (EM-1110-2-1906)	5	5	5
Consolidation (ASTM D2435)	5	5	5
Compaction (ASTM D698)	2	5	0

(a) Each "test" consists of one (1) specimen subjected to three (3) CU test cycles, with increasing confining (consolidation) pressures, in order to obtain three (3) data points for each "test" performed.

of the triaxial shear strength (CU and UU), permeability, and consolidation test soil samples.

Dry unit weight is another physical property of the soil, and measures the weight of the soil solids within a given volume. This test must be run on undisturbed samples, and helps to define soil horizons and determine volume-weight relationships of the soils (U.S. EPA, 1983; U.S. Dept. of the Navy, 1982). As with moisture content, one dry unit weight test will be performed on each of the triaxial shear strength (CU and UU), permeability, and consolidation soil samples.

Specific gravity measures the ratio between the unit weight of soil solids and the unit weight of water. The primary uses of the soil specific gravity are in determining volume-weight relationships and in helping to classify soils and soil types (U.S. EPA, 1983; U.S. Dept. of the Navy, 1982). Because of existing test data, only three tests will be performed on Ferrelview Clay and Clay Till samples. Five tests will be run on the Basal Till.

Capillary moisture measures the moisture content of a soil subjected to an external suction pressure. Typically, suction values ranging from -0.1 bars to -15 bars are used. Capillary moisture values are used to determine long-term moisture contents for radon attenuation studies and also for correlating unsaturated hydraulic conductivities with soil saturation

(Mitchell, 1976). Five capillary moisture tests will be run on each soil type.

Gradation tests are used to measure the relative percentages of gravel, sand, silt, and clay-size portions of a soil. Test results are used to help classify soils and to aid in defining soil horizons. Five additional gradation tests are specified for each soil type in this investigation.

Atterberg limits, in the form of plastic and liquid limits, are used to classify and characterize fine-grained soils. The plastic limit is defined as the moisture content at which a soil just begins to exhibit plastic behavior, and the liquid limit is defined as the moisture content at which a soil first begins to flow. These limits are highly correlated with shear strength, consolidation, and shrink/swell characteristics of fine-grained soils (Bowles, 1982; Lambe and Whitman, 1969; Mitchell, 1976; Terzaghi and Peck, 1967; U.S. EPA, 1975; Wroth, 1984). Three Atterberg limit tests will be performed for each of the following: triaxial shear strength (CU and UU), permeability, and consolidation for a total of twelve Atterberg limit tests per soil type.

Triaxial shear strength tests determine soil shearing strength under varying drainage and loading conditions. Consolidated-undrained (CU) tests with pore-pressure measurements provide both effective and total strength parameters for a

laboratory consolidated soil sample. Unconsolidated-undrained (UU) tests measure the undrained shear strength of soil samples which have not undergone laboratory consolidation. In general, effective strength applies to long-term or drained loading conditions, while total strength approximates actual soil strength during short-term or undrained loading conditions (Lambe and Whitman, 1969; Wroth, 1984). The undrained shear strength represents a more accurate soil strength during short-term undrained loading conditions. Three 3-point CU tests with pore-pressure measurements and five UU tests will be performed on each soil type.

Falling head permeability tests measure the flow rate of water through a given soil sample under a decreasing hydraulic gradient. Test results are given in terms of coefficients of permeability which are then used to classify the relative soil permeability. Five falling head tests will be run on undisturbed samples of each soil type. Field permeability tests may be performed if the soil encountered is below the groundwater table.

One-dimensional consolidation tests analyze time-dependent settlement behavior of fine-grained soils. Total settlement, secondary settlement, and time rates of settlement are calculated from test results. In addition, maximum past pressures and overconsolidation rates can be determined (Bowles, 1982; Lambe and Whitman, 1969; Terzaghi and Peck, 1967; Wroth, 1984). Test data from these consolidation tests will be correlated with

undrained shear strength (Wroth, 1984). Five consolidation tests will be run on each soil type.

Compaction tests determine the maximum dry density and optimum water content for a soil compacted at a specified energy level. These tests are used to determine the required compactive effort and methods of compaction. Two additional compaction tests will supplement existing data for the Ferrelview Clay. Five tests will be run on the Clay Till. The Basal Till will not be compacted during construction and thus will not be tested.

3.2 Geophysical Surveys

3.2.1 Data Reduction Methods

Data reduction translates the raw data into useful results and consists of a sequential process consisting of data retrieval, input, calculation, and output. Computer programs enhance and simplify geophysical data reduction by eliminating tedious and lengthy calculations of manual data processing. Preliminary data reduction will be done as field measurements are collected. Survey techniques can be modified and instruments can be adjusted to optimize data acquisition methods and data reliability.

Because of variable subsurface characteristics including numerous subsurface layers, irregular bedrock surface, saturated soils, perched water tables, and the water table in the bedrock,

computer data reduction procedures at WSS may require modification by manual data reduction methods. Some manual data reduction may also be required to verify computer results. Reduction processes are described in numerous geophysical publications (Breiner, 1973; Keller and Frischnecht, 1960; Telford, 1976). References and computer codes will be documented by the Subcontractor once the specific geophysical techniques are clearly identified. Independent verification of reduction methods by multiple checks, cross checks (with other results), and spot checks, especially of lengthy calculations, will be performed.

3.2.2 Data Analysis

Results of the data reduction process are used to derive subsurface interpretations. This process includes:

- Correlating data with parameters documented in the literature
- Correlating data with ground-truth information from boreholes
- Correlating data with a stored reference data base included in the computer codes
- Independent analysis of results and interpretations
- Verifying compatibility of results by correlating data obtained from different geophysical methods

The objective of the analyses is subsurface characterization. This is generally shown by means of pseudo-sections along the geophysical survey lines depicting the subsurface configuration, location of water tables, anomalous zones, and values of the soil and rock properties (e.g. resistivity or seismic velocity). Preliminary interpretations are drawn from the original data. Subsequent modifications or additions are based on further detailed correlations, additional ground-truth information, or refinements to computer models. The survey results will be presented as tables, cross-sections, and contour maps.

3.2.3 Models

Geophysical models of the WSS would be generally confined to microgravity surveys, if performed. The other survey methods yield results that directly portray the subsurface pseudo-sections. Microgravity survey models compare observed anomalies with conceptual density variations in the subsurface.

SECTION 4

QUALITY ASSURANCE

4.0 QUALITY ASSURANCE

Geotechnical drilling and sampling, geotechnical lab analysis, and geophysical surveys will be designed, performed and reviewed in accordance with the following quality assurance (QA) procedures. The QA plan includes all applicable WSSRAP procedures established in the Weldon Spring Quality Assurance Program Plan (QAPP) in accordance with EPA guidelines. The following QA requirements provide assurance that methods and techniques used to collect, analyze, and report data shall produce scientifically sound results consistent with the program objectives. Work will be carried out in accordance with WSSRAP Engineering Procedures (ENPs) and Standard Operating Procedures (SOPs). Forms required for the Geophysical/Geotechnical programs include:

- Chain of custody forms (Appendix I)
- Sample seals and tags
- Field data sheets

The required QA elements are generally described in the QAPP and in the relevant SOPs and ENPs. Task-specific aspects of the elements directly applicable to the Geophysical/Geotechnical Sampling Plan are presented in this document.

4.1 Geotechnical Drilling and Sampling

Quality assurance during drilling and sampling operations will consist of surveillance and audits of the drilling Subcontractor. Drilling and sampling procedures will be inspected. Samples will be stored in containers that will prevent sample contamination or cross-contamination.

All drilling and sampling activities shall be continuously inspected by qualified, experienced personnel. A PMC geologist or soils engineer with experience in geotechnical drilling, sampling, rock coring, and core recovery procedures will log each borehole.

4.2 Geotechnical Lab Analysis

All soil samples and rock cores will be labeled immediately after removal from the sampler. Labeling will correspond with identification provided on the borehole logs for each sample taken. All soil samples and rock cores will be stored in an environment safe from mishandling or temperature extremes.

Sample disturbance will be minimized during transport to the testing facility. Correlating sample identification to assigned laboratory tests will be verified at the laboratory upon receipt of the sample. Thorough sample tracking and documentation will be initiated and maintained throughout the testing program.

Laboratory test results will be cross-checked and approved by different personnel before being sent from the laboratory. Adherence to proper ASTM and COE standards will be verified by the Contractor prior to the start of laboratory testing.

4.3 Geophysical Surveys

Quality assurance during geophysical testing will consist of:

- Written procedures and work instructions defining the methods and sequence for performing the tests

- Approved written procedures and work instructions issued to the appropriate personnel prior to the commencement of the work and used during the performance of the tests

- Test performance by qualified personnel

- The presence of at least two persons (Subcontractor and Contractor technical representatives) for all geophysical work

- Mutual on-site verification by the Subcontractor and Contractor representatives of data acquisition, data storage, documentation of inconsistencies, problem

resolution, and adherence to all Contractor and DOE guidelines and QA/QC procedures

- Recording test results by the personnel performing the tests

- Photographing field procedures and survey locations

- Auditing all elements of the geophysical investigation and taking corrective action as required

SECTION 5

DATA DOCUMENTATION

Appendix D

Specification WP028, Geotechnical Investigation

5.0 DATA DOCUMENTATION

All field activities performed by WSSRAP staff and subcontractors will be thoroughly documented by a combination of chronological field notes encompassing all field activities, photographs of field activities, and data forms for specific sampling activities and field measurements. During the course of the geotechnical and geophysical sampling and testing, a qualified field geologist, geophysicist, or engineer will record daily activities in a permanently bound, waterproof, and paginated notebook. Entries in this notebook shall include:

- Date
- Weather conditions
- All on-site personnel involved
- Chronological record of the day's activities (a description of the activity and the time will be included)
- Any measurements or other information not recorded on designated field forms

5.1 Geotechnical Samples

5.1.1 Sample Transfer/Chain-of-Custody Records

The presence of contaminated soils requires careful handling of samples and detailed documentation. Since the extent of

subsurface contamination has not been completely delineated, all samples taken within the boundary of WSS will be considered as potentially contaminated and treated accordingly. The principal component of the quality control procedures lies in the accuracy of documentation and chain-of-custody records. Procedural requirements are:

- Strict adherence to the proposed sampling techniques as described in ASTM procedure
- Prepared labels showing project, hole location, sample identification number, date, and type of sampler
- Standardized field tracking report forms to establish sample custody in the field
- Documentation of preservation methods, if required

5.1.2 Test Records

Appropriate forms for reporting raw data and test results will be used. These forms will address all pertinent factors. In addition to the standard information required, these forms will also include the continuation of chain-of-custody by showing the hole and sample number, sample type, date, and name of the sampler. The form will also include a section where the reviewer will initial and date the form after the data and/or results have been checked. All tables and headings will be clearly identified and the appropriate units will be shown.

5.1.3 Borehole Logs

Borehole logs will be kept on-site and updated as drilling progresses. Information contained in these logs will provide an accurate characterization of the soil/rock encountered, drilling conditions, well completion (if appropriate), and any other related data pertinent to understanding borehole conditions. These logs will be prepared by a qualified geologist and reviewed for accuracy by the Contractor. The following data will be included on each borehole log (additional information may be required):

- Hole identification
- Hole location (coordinates and elevation)
- Drilling method(s) and equipment
- Drilling contractor, driller, and logger's names
- Date of drilling commencement and completion
- Total borehole depth
- Depth to water table and bedrock
- Hole diameter
- Casing diameters and quantities
- Type of casing and method of installation
- Grouted interval
- Accurate advance penetration control
- Lithologic description of materials and soil classification
- Sample numbers, depth of sample, and sample interval

- Length of sample recovered
- Description of sampling method; number of blows for Standard Penetration Tests (SPTs)
- Drilling rate and any unusual drilling problems, especially any drop of drill rods or rapid penetration
- Description of completion operations

For core logs, the appropriate information listed above will be recorded in addition to the following:

- Core length
- Coring rate
- Fluid gain or loss
- Core logs
- Percentage of recovery
- Discontinuities
- Rock quality designation
- Rock classification and lithology

5.1.4 Photographs

Photographs will be taken of soil samples prior to placement in storage containers. Opened split-spoon samples will be photographed using an adequate scale and label depicting the sampled interval, hole number, date and soil type. Rock samples may be photographed in the core boxes and must depict similar information as the soil samples. Additional photographs of

important sections of samples or drilling processes may be taken if these are relevant to the accurate documentation of the drilling/logging operation. Upon completion of the investigations, the photographs will be labeled and compiled to provide clear documentation.

5.1.5 Calculations

All calculations required for the geotechnical sampling program will follow standard quality control procedures of verification by independent checking. The reviewer will place his/her initials and date on each calculation page after appropriate verification of calculations, assumptions, data, and results. Any corrections or additions will be written without erasing or eliminating previous figures and initialed by the reviewer.

5.2 Geophysical Surveys

5.2.1 Test Records

Data record labeling shall show date, time, survey type, methodology, equipment operator, length and number of the survey lines, coordinates, instrument settings, orientation, spacings (if required), and any other inferred or required information that impacts data acquisition.

5.2.2 Equipment Calibration

All geophysical equipment will be calibrated to the manufacturer's specifications prior to commencement of any field activities and again after testing is completed. For systems with internal calibration, calibration will be performed daily prior to the start of work. Accurate documentation of all calibration will be maintained. All specifications for calibration shall be traceable to nationally recognized standards. Should no nationally recognized standards exist, the basis for calibration shall be documented.

5.2.3 Assumption Documentation

Geophysical data acquisition, reduction and interpretation generally follow standard physical and mathematical principles documented in the literature (Breiner, 1973; Keller and Frischnecht, 1966; Telford, 1976). However, certain assumptions are usually required for the data reduction process. For example, in seismic refraction investigations assumptions are required for the number of subsurface layers present and the homogeneity of the individual layers. Similar assumptions may apply to the other geophysical methods.

There also may be basic assumptions inherent in the data reduction methods themselves. For example, seismic refraction interpretation assumes that seismic velocity increases with

depth. The interpretation of other geophysical parameters may also be based on similar types of assumptions. The validity of these assumptions can be verified by correlating interpretations obtained from the various geophysical methods as well as utilizing ground-truth information from boreholes. The data reduction and analysis procedures (Section 5.2.4 and 5.2.5) will document assumptions made in the interpretation process.

5.2.4 Computer Runs

Various computer programs will be used during the data reduction procedure. The number of computer runs will be determined once the quality and quantity of data is evaluated. Computer programs will be verified and documented prior to reducing the data.

5.2.5 Data Reduction and Analysis

Proper documentation (labeling and filing) of data will be maintained throughout the reduction process. This involves clear identification of field data and final product as well as all assumptions made in the data reduction and analysis process.

All independent checks will be documented. Inconsistencies in both raw data and final results will be documented. These include inconsistencies noted in correlations of data with previous results, correlations of data among the various

geophysical methods, correlations with borehole information, and apparent inconsistencies in the data itself.

5.3 Daily Logs

The events of the day shall be maintained in a daily log by the subcontractors. These logs will include, but not be limited to, the activities performed, locations where the activity was performed, the time, the weather conditions, problems encountered and actions taken to solve them, personnel working on-site, and equipment used. These logs will become part of the permanent project record.

ADDENDUM NO. 01

TO

REQUEST FOR PROPOSAL NO. RFP-3589-WP028

GEOPHYSICAL INVESTIGATION

This Addendum No. 01 is issued in accordance with the Request For Proposal documents. Exact copies of this addendum have been sent to all subcontractors on the "Prospective Proposer's List".

The following modifications and/or clarifications are hereby incorporated into RFP-3589-WP028:

I. Delete in its entirety Specifications WP028, dated June 10, 1987. In its place incorporate Specifications WP028, dated August 7, 1987. The revised Specification WP028, dated August 7, 1987 reflects minor changes to Specification WP028, dated June 10, 1987. Revised sections of the Specification indicated by a vertical line in the right margin.

II. Delete in its entirety Technical Instructions to Proposers 3589-SC-WP028 dated July 7, 1987. In its place incorporate Technical Instructions to Proposers 3589-SC-WP028, dated August 7, 1987.

III. Attachment No. 1, enclosed herewith, provides additional information on the hydrogeological characteristics of the Weldon Spring Chemical Plant.

GEOTECHNICAL DRILLING AND SAMPLING CHARACTERIZATION

MK-FERGUSON COMPANY

WELDON SPRING REMEDIAL ACTION PROJECT

ST. CHARLES, MISSOURI

06/10/87

SPECIFICATION 3589-SC-WP024
SECTION NO. 01
WELDON SPRING SITE

GEOTECHNICAL DRILLING
AND
SAMPLING CHARACTERIZATION PROJECT

1.0 SCOPE AND OBJECTIVES

The purpose of the work is to determine the geotechnical characteristics of the soils by drilling and standard soils sampling.

This project is conducted by MK-Ferguson company (MK-F), to collect soils data at Weldon Spring Site Remedial Action Project.

2.0 LOCATION

The site is in St. Charles County, Missouri approximately 30 miles west of St. Louis, Missouri, as shown on Figures 1 and 2.

3.0 PROJECT SUPERVISION

All technical activities shall be under the supervision of the MK-Ferguson Co. (MK-F) Construction Engineer (CE). No work shall commence without the Contractor's approval.

4.0 DRILLING AND SAMPLING

4.1 General

Drilling for this subcontract is subject to the specification clauses contained in Section No. 02 of this Subcontract.

4.2 Site Conditions

4.2.1 Surface

The surface conditions on the site and in the area immediately west of the building area is relatively flat and vegetated with grasses. These areas are readily accessible by existing, improved dirt roads and paved roads and thus access problems should be minimal in the area. However, there may be areas of soft soils which will require working pads (see Section No. 02, Paragraph 6.0). Every effort will be made by MK-F to avoid drilling in locations with poor access.

4.2.2 Subsurface

Based on the best available information for the project area, the natural soils consist of 30 to 50 feet of silts and clays which overlie limestone bedrock.

4.3 Hole Location and Depths

This project is exploratory in nature. Test pit and boring locations may be anywhere within the area shown in Figure 2 of Section 02., other than areas covered by structures or paving. A total of ten (10) borings shall be drilled to an approximate depth of 50 feet (50') but shall not penetrate competent bedrock.

4.4 Sampling

Borings shall be advanced with conventional geotechnical exploratory equipment as outlined in Section No. 02. Soil sampling shall be continuous as outlined in Section No. 02.

The Sampling intervals in the overburden will be at two and one half feet (2-1/2') on center and then every five feet (5') on center past a depth of forty feet (40'). Sampling shall consist of Standard Penetration Tests (SPT), and at the discretion of the Contractor, Shelby tube or Ring Lined Split Barrel samples will be substituted for SPT sampling at certain sample intervals.

4.5 Test Pits

The Subcontractor shall supply a track or tractor mounted backhoe with a two foot (2') wide bucket capable of excavating to depths of twelve feet (12'). During the excavation of the test pits, the subcontractor shall segregate the top one foot (1') of topsoil from other excavated soils while minimizing the area of disturbance. The Subcontractor shall carefully replace excavated soils following completion of sampling in the test pits and replace the topsoil as the topmost layer of the backfill.

4.6 Soils Logging and Supervision

Soils logging, sampling, and drilling monitoring will be performed by the Contractor.

4.7 Health Physics

The Contractor shall provide industrial hygiene and/or health physics support, as appropriate, during all field operations in areas of radiological and/or chemical contamination.

The Subcontractor shall comply with all applicable Federal, State, and local health and safety regulations and requirements, including, but not limited to, those established pursuant to the Occupational Safety and Health Act (OSHA) and the WSSRA Project Safety and Health Plan.

4.8 Quality Assurance

The Contractor shall direct all fieldwork. Periodic Quality Assurance Surveillance will be performed by the Contractor to verify compliance with specification requirements.

4.9 Permits

The Subcontractor shall abide by the requirements contained in any required permits, letters of authorization, and environmental laws which are applicable to the data collection project. Copies of the applicable documents shall be transmitted to the Subcontractor by the Contractor prior to the start of fieldwork.

4.10 Site Restoration

The Subcontractor shall reclaim areas disturbed by drilling and test pitting activities performed under this subcontract.

4.10.1 All disturbed areas shall be recontoured to approximate original contours.

4.10.2 The Subcontractor shall purchase an appropriate seed mixture, spread this seed mixture over the disturbed areas, and lightly rake the seed into the surface.

GEOTECHNICAL DRILLING SPECIFICATIONS

1.0 DRILL RIG EQUIPMENT AND CAPABILITIES

A drilling rig used for soil sampling shall be capable of drilling in clayey or granular soil, above or below the water table. It shall be able to conduct standard penetration tests (SPT) and push Shelby tubes. A hollow stem auger rig equipped for rotary/mud drilling satisfies the requirements of this Specification. Any change in the proposed drilling rig capabilities or other equipment must be approved in writing by the Contractor.

The Subcontractor must supply the three inch (3") outside diameter (O.D.), two and one half inch (2-1/2") inside diameter (I.D.), and twenty-four inch (24") long tube, ring lined split barrel samplers. This sampler shall be designed to accepting a 2.5" O.D. by 6" long brass tube having a 0.042 wall thickness.

2.0 SOIL SAMPLING STANDARDS, METHODS AND MATERIALS

2.1 Standards

The subcontractor's equipment must be capable of performing soil sampling using all sampling techniques and equipment in accordance with the latest American Society for Testing and Materials (ASTM) Standard. Copies of these standards are available from MK-F upon request. These include:

- ASTM D1586 - Standard Penetration Test (SPT).
- ASTM D1587 - Shelby tube sampling.
- ASTM D3550 - Ring-lined barrel sampling.

2.2 Methods

2.2.1 Standard Penetration Tests (SPT)

These tests shall be performed according to the ASTM D1586 method. The recovered SPT samples shall be sealed in airtight "olive sized" (8 ounce or larger) plastic jars, immediately on removal from the drill hole.

2.2.2 Shelby Tube Samples

Samples shall be obtained by pushing a new three (3") inch O.D. x thirty-six (36") inch long Shelby tube beneath the lead hollow-stem auger, into undisturbed ground, to its usable length or to a point of refusal. A constant smooth hydraulic pressure shall be applied as necessary to penetrate the material being sampled. Upon removal from the hole, the loaded Shelby tube shall be removed from sampler head and sealed with wax and end caps or as directed by the Contractor.

2.2.3 Ring Lined Split Barrel Samples

Samplers shall be pushed in the manner similar to that used in Shelby tube sampling, where possible. Immediately upon removal from the hole, the split barrel samplers shall be capped and taped. All brass tubes for each sample shall be retained in this manner.

2.3 Sample Handling

The Subcontractor shall place all contained samples (Shelby Tubes), neatly and carefully, in the immediate vicinity of the drill site, as directed by the Contractor. The Contractor will be responsible for labeling and shipping all samples. The Subcontractor shall assist the Contractor in handling and opening split spoons and hand samples to the Contractor for packaging and labeling.

2.4 Materials

2.4.1 Subcontractor Furnished Material

The following items will be provided by the Subcontractor for the Weldon Spring Site drilling and sampling program.

Item	Quantity	Description
1	160	Plastic jars for SPT samples, 8 ounces or larger, olive size.
2	25	Shelby tubes, three inch (3") outside diameter (O.D.) by thirty-six inches (36") long, with wax and end caps.
3	140	Brass tubes (liner), two and one half (2 1/2") inches O.D. by six (6") inches long, 0.042" wall thickness, with caps, tape and storage boxes.
4	230'	PVC, two inch (2") Schedule 40, flush-jointed, threaded, slotted 0.010" screen.
5	50'	PVC, two inch (2"), Schedule 40, flush-jointed, threaded riser
6	6	PVC slip caps
7	6	PVC Bottom plugs for piezometers
8	1000 lbs.	Bentonite pellets, 1/4" to 1/2" diameter, minimum 90% montmorillonite.
9	6	Filter pack, clean coarse silica sand. (20 to 40 mesh)

3.0 DRILLING FLUIDS AND ADDITIVES

All drilling fluids and additives must be approved by the Contractor prior to their use. Where the potential exists for drilling fluids and/or additives to contaminate existing surface or ground water, such fluids/additives shall be contained at each drill site and disposed of as directed by the Contractor.

4.0 INSTALLATION OF PIEZOMETERS

The Subcontractor shall, upon reaching bedrock, install a two inch (2") diameter piezometer according to the following specifications.

The hole shall be backfilled with bentonite pellets - 1/4 to 1/2 inch diameter having a minimum purity of 90% montmorillonite as specified by the American Colloid Company or equivalent from the top of competent bedrock to five feet (5') above the bottom of the glacial till. These pellets shall be placed through the augers in five foot (5') lifts (maximum) and hydrated with Contractor approved water.

After the final lift of bentonite pellets has hydrated, the Subcontractor shall install a 2 inch (2") inside diameter piezometer. This piezometer shall be constructed of 2 inch (2") Schedule 40 PVC, flush-threaded, factory slotted (0.010") screen and riser. The screen shall extend from the top of the bentonite plug to within five feet (5') of the surface. All screen and riser shall be placed through the augers. After the screen and riser are in place, the Subcontractor shall install a sand pack as the augers are removed. This sand pack shall extend from the bottom of the screen to one foot (1') above the top of the screen. The filter pack shall consist of a clean coarse silica sand (WB-40 or equivalent). After the filter pack is in place, the remainder of the annular space shall be sealed using the previously specified bentonite pellets. The riser pipe shall extend between 2 and 3 feet above the grade and be covered with a PVC slip cap.

5.0 WORKING PADS

It is anticipated that the surface soils may be soft in certain areas. In these areas, working pads shall be supplied and constructed by the Subcontractor from portable loading mats. The dimensions of the pads shall be limited to those required to support the drill rig and provide working space in order to limit displacement of soft soils.

6.0 FIELD DOCUMENTATION

The CE shall maintain a "Daily Field Activity Report" (a sample copy is attached to Section 02 as Figure 3) detailing billable drilling work. The Subcontractor is required to initial this report on a daily basis and note any differences that cannot be resolved. Any differences shall be documented for future reviews and resolution between the Subcontract Administrator and Subcontractor.

7.0 DECONTAMINATION EQUIPMENT AND PROCEDURES

Augers and downhole tools shall be thoroughly washed/cleaned before moving to a new hole or demobilizing from the site by the Subcontractor. These augers and tools will then be inspected by MK-F personnel before being returned to service or demobilization by the Subcontractor. MK-F shall be responsible for furnishing all potable water and cleaning equipment to decontaminate drilling equipment. Any necessary decontamination work shall be performed at the stipulated standby time (hourly rate).

8.0 PERMITS

The Subcontractor shall abide by the requirements contained in any required permits, letters of authorization, and environmental laws which are applicable to the data collection project.

9.0 LEGAL ACCESS

The Contractor will be responsible for and provide legal access Agreements and permits (if applicable) for the drilling locations. It will be the Subcontractor's responsibility to comply with the terms of the access agreements and permits which the Contractor will provide to the Subcontractor prior to commencement of work.

GEOTECHNICAL DRILLING AND SAMPLING OF PIT 4 DIKE

MK-FERGUSON COMPANY

WELDON SPRING REMEDIAL ACTION PROJECT

ST. CHARLES, MISSOURI

06/10/87

SPECIFICATION 3589-SC-WP024-02
SECTION NO. 01
WELDON SPRING SITE

GEOTECHNICAL DRILLING AND SAMPLING OF PIT 4 DIKE

1.0 SCOPE AND OBJECTIVES

The purpose of the work is to determine the geotechnical characteristics of the soils by drilling and standard soils sampling. Piezometer installation will provide a means to monitor the phreatic surface through the dike.

This project is conducted for MK-Ferguson Company (MK-F), to collect soils data at Weldon Spring Site Remedial Action Project.

2.0 LOCATION

The site is in St. Charles County, Missouri approximately 30 miles west of St. Louis, Missouri, as shown on Figures 1 and 2.

3.0 PROJECT SUPERVISION

All technical activities shall be under the supervision of the MK-Ferguson Co. (MK-F) Construction Engineer (CE). No work shall commence without the Contractor's approval.

4.0 DRILLING AND SAMPLING

4.1 General

Drilling for this subcontract is subject to the specification clauses contained in Section No. 02 of this Subcontract.

4.2 Site Conditions

4.2.1 Surface

The surface conditions on and at the toe of the dike of pit 4 varies from gravel packed to vegetated with grasses. The crest of the dike ranges in width from eight (8) to twenty feet (20'). The outer slope of the embankment is 2:1. The inner slope is fenced and the pit contains radiologically contaminated water. The area is readily accessible by improved dirt roads and paved roads and thus access problems should be minimal.

However, there may be areas of soft soils which will require working pads (see Section No. 02, Paragraph 6.0). Every effort will be made by MK-F to avoid drilling in locations with poor access.

4.2.2 Subsurface

Based on the best available information for the project area, the natural soils consist of 25 to 30 feet of silts and clays which overlie limestone bedrock. The dike rises approximately 25' above the surrounding terrain.

4.3 Hole Location and Depths

This project is exploratory in nature. Boring locations are shown in Figure 2 of Section 02. A total of six (6) borings shall be drilled; two (2) at the toe and four (4) on the crest of the dike, to an approximate depth of 30 to 60 feet but shall not penetrate competent bedrock.

4.4 Sampling

Borings shall be advanced with conventional geotechnical exploratory equipment as outlined in Section No. 02. Soil sampling shall be continuous as outlined in Section No. 02.

The Sampling intervals in the dike will be continuous and through the foundation soils at five feet (5') on center. Sampling shall consist of Standard Penetration Tests (SPT), and at the discretion of the Contractor, Shelby tube or Ring Lined Split Barrel samples will be substituted for SPT sampling at certain sample intervals.

4.5 Soils Logging and Supervision

Soils logging, sampling, and drilling monitoring be performed by the CE.

4.6 Health Physics

The Contractor shall provide industrial hygiene and/or health physics support, as appropriate, during all field operations in areas of radiological and/or chemical contamination.

The Subcontractor shall comply with all applicable Federal, State, and local health and safety regulations and requirements, including, but not limited to, those established pursuant to the Occupational Safety and Health Act (OSHA) and the WSSRA Project Safety and Health Plan.

4.7 Quality Assurance

The CE shall direct all fieldwork. Periodic Quality Assurance Surveillance will be performed by the Contractor to verify compliance with specification requirements.

4.8 Permits

The Subcontractor shall abide by the requirements contained in any required permits, letters of authorization, and environmental laws which are applicable to the data collection project. Copies of the applicable documents shall be transmitted to the Subcontractor by the Contractor prior to the start of fieldwork.

4.9 Site Restoration

The Subcontractor shall reclaim areas disturbed by drilling activities performed under this subcontract. All disturbed areas shall be recontoured to approximate original contours. Seeding is specified as follows.

4.9.1 All disturbed areas shall be recontoured to approximate original contours.

4.9.2 The Subcontractor shall purchase and apply an appropriate seed mixture, and rake into disturbed areas.

GEOTECHNICAL DRILLING SPECIFICATIONS

1.0 DRILL RIG EQUIPMENT AND CAPABILITIES

A drilling rig used for soil sampling shall be capable of drilling in clayey or granular soil, above or below the water table. It shall be able to conduct standard penetration tests (SPT) and push Shelby tubes. A hollow stem auger rig equipped for rotary/mud drilling satisfies the requirements of this Specification. Any change in the proposed drilling rig capabilities or other equipment must be approved in writing by the Contractor.

The Subcontractor must supply the three inch (3") outside diameter (O.D.), two and one half inch (2-1/2") inside diameter (I.D.), and twenty-four inch (24") long tube, ring lined split barrel samplers. This sampler shall be designed to accepting a 2.5" O.D. by 6" long brass tube having a 0.042 wall thickness.

2.0 SOIL SAMPLING STANDARDS, METHODS AND MATERIALS

2.1 Standards

The subcontractor's equipment must be capable of performing soil sampling using all sampling techniques and equipment in accordance with the latest American Society for Testing and Materials (ASTM) Standard. Copies of these standards are available from MK-F upon request. These include:

- ASTM D1586 - Standard Penetration Test (SPT).
- ASTM D1587 - Shelby tube sampling.
- ASTM D3550 - Ring-lined barrel sampling.

2.2 Methods

2.2.1 Standard Penetration Tests (SPT)

These tests shall be performed according to the ASTM D1586 method. The recovered SPT samples shall be sealed in airtight "olive sized" (8 ounce or larger) plastic jars, immediately on removal from the drill hole.

2.2.2 Shelby Tube Samples

Samples shall be obtained by pushing a new three (3") inch O.D. x thirty-six (36") inch long Shelby tube beneath the lead hollow-stem auger, into undisturbed ground, to its usable length or to a point of refusal. A constant smooth hydraulic pressure shall be applied as necessary to penetrate the material being sampled. Upon removal from the hole, the loaded Shelby tube shall be removed from sampler head and sealed with wax and end caps or as directed by the Contractor.

2.2.3 Ring Lined Split Barrel Samples

Samplers shall be pushed in the manner similar to that used in Shelby tube sampling, where possible. Immediately upon removal from the hole, the split barrel samplers shall be capped and taped. All brass tubes for each sample shall be retained in this manner.

2.3 Sample Handling

The Subcontractor shall place all contained samples (Shelby Tubes), neatly and carefully, in the immediate vicinity of the drill site, as directed by the Contractor. The Contractor will be responsible for labeling and shipping all samples. The Subcontractor shall assist the Contractor in handling and opening split spoons and hand samples to the Contractor for packaging and labeling.

2.4 Materials

2.4.1 Subcontractor Furnished Material

The following items will be provided by the Subcontractor for the Weldon Spring Site drilling and sampling program.

Item	Quantity	Description
1	160	Plastic jars for SPT samples, 8 ounces or larger, olive size.
2	25	Shelby tubes, three inch (3") outside diameter (O.D.) by thirty-six inches (36") long, with wax and end caps.
3	140	Brass tubes (liner), two and one half (2 1/2") inches O.D. by six (6") inches long, 0.042" wall thickness, with caps, tape and storage boxes.
4	230′	PVC, two inch (2") Schedule 40, flush-jointed, threaded, slotted 0.010" screen.
5	50′	PVC, two inch (2"), Schedule 40, flush-jointed, threaded riser
6	6	PVC slip caps
7	6	PVC Bottom plugs for piezometers
8	1000 lbs.	Bentonite pellets, 1/4" to 1/2" diameter, minimum 90% montmorillonite.
9	6	Filter pack, clean coarse silica sand. (20 to 40 mesh)

3.0 DRILLING FLUIDS AND ADDITIVES

All drilling fluids and additives must be approved by the Contractor prior to their use. Where the potential exists for drilling fluids and/or additives to contaminate existing surface or ground water, such fluids/additives shall be contained at each drill site and disposed of as directed by the Contractor.

4.0 INSTALLATION OF PIEZOMETERS

The Subcontractor shall, upon reaching bedrock, install a two inch (2") diameter piezometer according to the following specifications.

The hole shall be backfilled with bentonite pellets - 1/4 to 1/2 inch diameter having a minimum purity of 90% montmorillonite as specified by the American Colloid Company or equivalent from the top of competent bedrock to five feet (5') above the bottom of the glacial till. These pellets shall be placed through the augers in five foot (5') lifts (maximum) and hydrated with Contractor approved water.

After the final lift of bentonite pellets has hydrated, the Subcontractor shall install a 2 inch (2") inside diameter piezometer. This piezometer shall be constructed of 2 inch (2") Schedule 40 PVC, flush-threaded, factory slotted (0.010") screen and riser. The screen shall extend from the top of the bentonite plug to within five feet (5') of the surface. All screen and riser shall be placed through the augers. After the screen and riser are in place, the Subcontractor shall install a sand pack as the augers are removed. This sand pack shall extend from the bottom of the screen to one foot (1') above the top of the screen. The filter pack shall consist of a clean coarse silica sand (WB-40 or equivalent). After the filter pack is in place, the remainder of the annular space shall be sealed using the previously specified bentonite pellets. The riser pipe shall extend between 2 and 3 feet above the grade and be covered with a PVC slip cap.

5.0 WORKING PADS

It is anticipated that the surface soils may be soft in certain areas. In these areas, working pads shall be supplied and constructed by the Subcontractor from portable loading mats. The dimensions of the pads shall be limited to those required to support the drill rig and provide working space in order to limit displacement of soft soils.

6.0 FIELD DOCUMENTATION

The CE shall maintain a "Daily Field Activity Report" (a sample copy is attached to Section 02 as Figure 3) detailing billable drilling work. The Subcontractor is required to initial this report on a daily basis and note any differences that cannot be resolved. Any differences shall be documented for future reviews and resolution between the Subcontract Administrator and Subcontractor.

7.0 DECONTAMINATION EQUIPMENT AND PROCEDURES

Augers and downhole tools shall be thoroughly washed/cleaned before moving to a new hole or demobilizing from the site by the Subcontractor. These augers and tools will then be inspected by MK-F personnel before being returned to service or demobilization by the Subcontractor. MK-F shall be responsible for furnishing all potable water and cleaning equipment to decontaminate drilling equipment. Any necessary decontamination work shall be performed at the stipulated standby time (hourly rate).

8.0 PERMITS

The Subcontractor shall abide by the requirements contained in any required permits, letters of authorization, and environmental laws which are applicable to the data collection project.

9.0 LEGAL ACCESS

The Contractor will be responsible for and provide legal access Agreements and permits (if applicable) for the drilling locations. It will be the Subcontractor's responsibility to comply with the terms of the access agreements and permits which the Contractor will provide to the Subcontractor prior to commencement of work.

ADDENDUM NO. 01

TO

REQUEST FOR PROPOSAL NO. RFP-3589-WP024

GEOTECHNICAL DRILLING AND SAMPLING CHARACTERIZATION

This Addendum No. 01 is issued in accordance with the Request For Proposal documents. Exact copies of this addendum have been sent to all subcontractors on the "Prospective Proposer's List".

The following modifications and/or clarifications are hereby incorporated into RFP-3589-WP024:

I. Add to Specification WP024-01 Section 4.5 Test Pits:

No individuals are to be in any of the test pits, therefore, no shoring is required.

II. Revision to Specifiction WP024-01 Section 2.2 Methods:

Did read:
3.2.1 Standard Penetration Tests (SPT)

Shall now read:
2.2.1 Standard Penetration Test (SPT)

III. Clarification to Specification WP024-01. Section 2.2.1 does state the required method. Tests shall be performed according to the ASTM D1586 method.

IV. Clarification to Specification WP024-01.
Section 2.2.2 does state the required method.

Samples shall be obtained by pushing a new three (3") inch O.D. x thirty-six (36") inch long Shelby tube beneath the lead hollow-stem auger, into undisturbed ground, to its usable length or to a point of refusal.

V. Revision to Specification WP024-01 Section 4.3 Hole Location and Depths.

4.3 Did read:
This project is exploratory in nature. Test pit and boring locations may be anywhere within the area shown in Figure 2 of Section 02, other than areas covered by structures or paving. A total of ten (10) borings shall be drilled to an approximate depth of 50 feet (50') but shall not penetrate competent bedrock.

4.3 Shall now read:
This project is exploratory in nature. Test pit and boring locations may be anywhere within the area shown in Figure 2 of Section 02, other than areas covered by structures. Approximately six inches (6") of concrete covers only one (1) of the boring locations. A total of ten (1) borings shall be drilled to an approximate depth of 50 feet (50') but shall not penetrate competent bedrock.

The due date and hour for proposals under this Request for Proposal remains scheduled for Wednesday, July 29, 1987 at 3:00 p.m. local time. Proposals may be hand-delivered to the cognizant Subcontract Administrator, S. A. Mager, during the 15-minute time period immediately prior to this deadline, or mailed to reach MK-F prior to bid due date/time.

You are reminded that each addenda to this RFP must be acknowledged on the first sheet of the proposal sheet of the

proposal form by inserting the NUMBER (i.e. 01) in the space provided.

Sincerely,

S. A. Mager

SPECIFICATIONS WP028

SUBCONTRACT NO. 3589-SC-WP028

GEOPHYSICAL INVESTIGATION

MK-FERGUSON COMPANY

WELDON SPRING REMEDIAL ACTION PROJECT

ST. CHARLES, MISSOURI

AUGUST 7, 1987

SPECIFICATION 3589-SC-WP028

WELDON SPRING SITE

GEOPHYSICAL INVESTIGATION

1.0 OBJECTIVE & SCOPE

1.1 OBJECTIVE

The objective of the geophysical investigation is to provide a geological model of the subsurface below the proposed area for the disposal cell. The geological model shall address, in adequate detail for design, the characteristics of the overburden and the bedrock, with particular attention to the configuration of the bedrock surface, and the distribution, orientation, dimensions, and condition of cavities, channelways, and fracture systems within the bedrock.

1.2 SCOPE

The geophysical investigation shall consist of acquisition survey(s), data processing, interpretation, modelling and reporting to provide the Contractor with continuous subsurface information across the disposal cell area.

The investigation shall be limited in geographical extent to an area of about 44 acres: 30 acres within the perimeter of the proposed disposal cell area, plus 14 acres within a 100-foot-wide area surrounding the perimeter (see Exhibit 2). The depth of investigation shall be not less than 200 feet below the top of bedrock.

1.3 The Subcontractor shall submit a report fulfilling the requirements of this Specification. A draft version of the report shall be submitted for review and comment by the Contractor prior to issuance of the final report.

2.0 PROJECT SUPERVISION

2.1 The geophysical surveys shall be designed and conducted by the Subcontractor in close coordination with the Contractor to ensure that the data needs will be fulfilled.

3.0 SITE CONDITIONS

3.1 As shown on Exhibit 2, improved dirt roads and paved roads form an east-west, north-south grid across the area of investigation. However, there may be areas of soft soils which may require working pads should the Subcontractor wish to occupy them with geophysical equipment, instruments, or vehicles.

3.2 Numerous buildings, as well as raffinate pits, coal storage and spoils piles, and other features shown on Exhibit 2, exist on the site, and may influence the physical layout, equipment and types of surveys for a geophysical investigation. The Subcontractor shall be aware of the potential for utilities within or immediately adjacent to the area to be investigated. Power lines, overhead and underground metallic pipelines, and metallic structures are all present.

3.3 Topographically, the area of investigation is one of relatively flat terrain with surface elevations generally between about 640 and 665 feet above sea level. Exhibit 3 shows the topography across the site area.

3.4 The best information available to the Contractor at this time shows that in general, unconsolidated overburden overlies bedrock across the area of investigation. Generally, the overburden, with an average thickness of about 30 feet, consists of topsoil, modified loess, clay (Ferrelview Formation), clay till, basal till, and cherty clay in descending order from the ground surface. The continuity of each of these overburden units across the entire area is suspect.

3.5 Bedrock is comprised of the cherty limestone of the Burlington/Keokuk Formation. The upper surface of the bedrock unit is highly irregular and has been referred to as being "pinnacled." This irregularity, and the variability of the rock mass within its upper 40 feet, has been attributed to dissolution and other weathering phenomena. Underlying the weathered zone of the bedrock, the limestone is competent, fine-to coarse-grained locally fractured and contains solution features.

3.6 The best information available at this time shows a subsurface structure of four layers. The velocity, thickness or depth, and geologic interpretation of each layer are summarized below:

3.6.1 Layer 1 - 950 to 1200 feet per second (fps); up to 15 feet thick; topsoil and possibly other loose overburden such as the modified loess unit.

3.6.2 Layer 2 - 1800 to 5000 fps, averaging about 3000 fps, but with anomalously high and low velocities detected; 10 to 43 feet thick;

predominantly overburden, but may include weathered bedrock.

3.6.3 Layer 3 - 4000 to 7650 fps, averaging 6000 fps; depth to top of layer ranges between 15 and 45 feet; predominantly weathered bedrock, but may include compacted and/or saturated overburden.

3.6.4 Layer 4 - 8000 to 25,500 fps, averaging 17,000 fps; depth to top of layer is 43 to 110 feet, averaging 70 to 75 feet; harder, more competent, and less weathered bedrock.

4.0 PERSONNEL

4.1 The geophysical investigation shall be performed by personnel qualified on the basis of education, experience, and training. The professional geophysicists, other degreed professionals, as well as non-degreed technicians that perform the field and central office tasks shall have actual and verifiable experience in geophysical surveying, data processing, interpretation and modelling procedures proposed by the Subcontractor. The Subcontractor shall, prior to starting work, satisfy the Contractor that the Subcontractor's personnel are the same as those proposed. The Subcontractor shall notify and receive approval from the Contractor for any personnel changes.

5.0 PERFORMANCE DOCUMENTATION

5.1 The documentation of the results of the geophysical investigation shall demonstrate satisfactory completion of the investigation and form the basis for the Subcontractor's interpretations, judgements, and decisions. The documentation shall be complete,

including as appropriate, the following minimum requirements:

- o Field data forms, logs, and notebooks
- o Land survey data
- o Final computer output
- o Verification of assumptions
- o Photographs
- o Peer review reports
- o Calculations
- o Results and interpretation of the geophysical investigation

All such documentation generated by the Subcontractor shall become a part of the project records.

5.2 The Subcontractor shall provide access at any time to all of the project documentation (field notes, calculations, etc.) necessary to produce the final report.

6.0 EQUIPMENT REQUIREMENTS

6.1 The geophysical survey techniques and equipment proposed by the Subcontractor for the site investigation shall be selected on the basis of the following factors:

- o Site conditions

- o Type of information required
- o Extent of information required
- o Results of previous geological and geophysical investigations
- o Suitability of geophysical survey techniques and equipment for fulfilling the data needs and satisfying the stated objective
- o Speed, economy and accuracy with which the investigation can be performed and completed.

6.2 Geophysical survey techniques and equipment employed in the site investigation shall be limited to surface methods to ensure that the following data be provided with a high degree of confidence:

- o Total thickness of overburden
- o Lateral and vertical extent/dimensions of each overburden layer
- o Material types, characteristics and variation of each overburden layer, including velocities/densities
- o Depth to bedrock
- o Distribution, orientation and dimensions of solution channels and other anomalous features or irregularities in the bedrock surface

- Distribution, orientation, dimensions and depth below bedrock surface of solution cavities, channelways and their interconnections

- Distribution, dimensions and orientation of joints, solution-widened joints and of other fracture systems

- Lateral and vertical extent of bedrock layers, including weathered zone

- Material types, characteristics and variation of bedrock layers, including velocities/densities

- Nature of cavity, channel or joint infilling material (air, water, clay, other geologic material, or combination)

- Location of top of saturated overburden/perched water tables

- Location of water table within the bedrock

6.3 The Subcontractor's proposed techniques, equipment and instrumentation shall ensure that the time at the job-site and the central office is minimized.

6.4 The Subcontractor shall provide all of the personnel, geophysical equipment and instrumentation, and any ancillary equipment necessary to perform and complete the geophysical investigation.

7.0 CALIBRATION OF EQUIPMENT

7.1 The Subcontractor shall assure that the geophysical survey equipment used to obtain field measurements during the site investigation is calibrated and maintained in accordance with documented procedures at prescribed intervals and/or prior to use. The Subcontractor shall calibrate equipment to National Bureau of Standards (NBS) criteria. If NBS standards have not been established, the Subcontractor shall calibrate equipment to the appropriate manufacturer's standard.

7.2 The Subcontractor shall furnish the Contractor with a signed and dated copy of the documented calibration procedures at the time of award and thereafter. The procedures shall be based on the type of equipment, effect of error on the quantities measured, stability characteristics of the equipment, required precision and accuracy, or other conditions affecting measurement control. Procedure content should include, as appropriate:

- Identification of equipment.
- Documented or reference calibration methods.
- Acceptance limits.
- Frequency of calibration.
- Tagging of the equipment to indicate calibration status.

- o Identification and traceability of calibration standards.

- o Segregation and identification of equipment failing calibration to prevent inadvertent usage.

- o Required documentation.

7.3 The Subcontractor shall furnish the Contractor with records prepared and maintained for each piece of equipment subject to calibration to indicate that the Subcontractor's established calibration procedures and schedules have been followed. The records should contain a history of calibration, acceptance/failure, and repair. Each file should include, as appropriate:

- o Name and identification number of the equipment.

- o Calibration frequency.

- o Names of individual(s) performing the calibration.

- o Acceptance limits.

- o Most recent calibration data and results of equipment evaluation.

- o Identification of calibration standard and/or test equipment used.

- o Certificates or statements of calibration provided by manufacturers or external organizations.

- o Schedule of due dates for recalibration.

7.4 The geophysical survey equipment and instrumentation used by the Subcontractor during the site investigation shall be uniquely identified by the manufacturer's serial number or an assigned identification number. Whenever possible, the assigned number shall be indicated by a label or tag attached to the equipment. Calibration status shall be indicated by a label or tag attached to the equipment and showing date of last calibration and due date of recalibration.

7.5 Should the latter be impractical, records traceable to the equipment shall be readily retrievable for reference with the recalibration due date clearly indicated.

8.0 PERFORMANCE

8.1 The Subcontractor shall, at a minimum, design the geophysical investigation to ensure that all personnel and equipment are on-site at the proper time, conduct the field data acquisition and preliminary processing for quality control, process all data acquired during the field surveys, interpret the data, model the results, and prepare and submit the data and final reports of the investigation to the Contractor.

8.2 The Subcontractor, at a minimum, shall design the surveys to provide continuous subsurface coverage across the area of investigation and ensure that the data needs will be fulfilled. During the conduct of the surveys, the Subcontractor shall verbally keep the Contractor informed of the status of the data acquisition process and the outlook for successful and timely completion of the work. The final report shall include a geological model representative of the

subsurface at the proposed disposal cell site, with appropriate descriptive and explanatory narrative, as well as appropriate graphical data and interpretation representations.

9.0 SITE CLEANUP AND RESTORATION

9.1 The Subcontractor shall be responsible for site cleanup and restoration required as a result of the geophysical surveys. This shall include:

1. Removing any survey stakes and flagging.

2. Repairing fences or damaged structures.

3. Retrieving detonator leads, backfilling shot holes and inspecting area for remaining explosives, if explosive charges are used for seismic sources.

10.0 DATA PROCESSING

10.1 Processed data shall be legible and in a form suitable for reproduction, filing and retrieval. Calculations shall include assumptions, methods of computation, parameters and physical units so that a qualified individual can review and understand the processing and verify the results. Data processing shall be identified by project name and number, activity or survey type and location, originator and data collected, and reviewer and date reviewed.

10.2 Assumptions shall be documented; assumptions which cannot be verified shall be identified. The methods used for reducing and processing the field data shall be identified. Associated computer output shall be identified by run number or other unique means.

10.3 The results and conclusions of processing large quantities of data shall be summarized. The results and conclusion can be presented in, or form the bases for drawings, graphs and tables.

11.0 DECONTAMINATION

11.1 If the Subcontractor is directed by the Contractor to decontaminate any equipment, he shall be reimbursed at the standby hourly rate.

Appendix E

Addenda Nos. 01 and 02 to WP028

IV. Incorporate the drawings identified on the enclosed Index of Drawings. Drawings are sent as a separate package.

V. Delete in its entirety the Pricing Proposal for RFP WP028. In its place incorporate 3589-SC-WP028 Pricing Proposal Rev. 1.

The due date and hour for proposals under this Request for Proposal remains scheduled for Friday, September 4, 1987 at 3:30 p.m. local time. Proposals may be hand-delivered to the cognizant Subcontract Administrator, Mr. S. A. Mager, during the 15-minute time period immediately prior to this deadline, or mailed to reach MK-F prior to bid due date/time.

You are reminded that each addenda to this RFP must be acknowledged on the first sheet of the proposal sheet of the proposal form by inserting the NUMBER (i.e. 01) in the space provided.

Specification WP029, Geotechnical Laboratory Testing

MK-FERGUSON COMPANY
A MORRISON KNUDSEN COMPANY

SPECIFICATIONS WP029

SUBCONTRACT NO. 3589-SC-WP029

GEOTECHNICAL LABORATORY TESTING

MK-FERGUSON COMPANY

WELDON SPRING REMEDIAL ACTION PROJECT

ST. CHARLES, MISSOURI

Dated: 07-09-87

SPECIFICATION 3589-SC-WP029

SECTION A

DATED 07/09/87

SCOPE OF WORK

GEOTECHNICAL LABORATORY TESTING

1.0 Scope and Objectives

The Subcontractor shall provide the services and supplies required for geotechnical laboratory testing of radiologically and chemically contaminated and uncontaminated soils, rock, sludges, and stabilized sludge in support of MK-F's prime Contract to the U.S. Department of Energy under the Weldon Spring Site Remedial Action Project (WSSRAP).

The objective of this Subcontract is to provide a detailed geotechnical evaluation of the soils at a potential disposal site and the Raffinate pit sludges. Sludge stabilization testing is intended to provide a range of mix designs that will meet workability, absorption, and strength criteria. Mix design will be phased work, closely coordinated and directed by a designated Contractor representative.

The following outlines the proposed scope of services that will be required to obtain geotechnical information of the proposed materials.

2.0 Soil, Rock, and Sludge Sample Containers and Labeling

Sample collection and delivery will be the responsibility of the Contractor. Soil samples will be contained in large and small plastic bags, jars, Shelby tubes, and 2 to 3 inch diameter tube (ring) samples. Bulk samples will be contained in 5 gallon buckets with lids. The samples will be independently labeled by the Contractor for adequate identification as to site, location, sample number, depth, etc. All undisturbed samples (Shelby tubes) as indicated by the Contractor shall be stored in the vertical position.

3.0 On-Site Laboratory Requirements

The Subcontractor may choose to provide a mobile laboratory, to be parked at a designated location on the Weldon Spring Site for approximately four (4) months. The Subcontractor shall direct all wash water and any other water resulting from laboratory operations to the existing sump located at the mobile laboratory site and operate the existing pump in that sump to ensure that the sump does not overflow. An on-site laboratory used by the Subcontractor shall be equipped in accordance with the applicable health and safety regulations.

4.0 Laboratory Testing

Laboratory testing, (as defined below), of retained soil, rock, sludge, and stabilized sludge samples will be required. All testing shall be performed in conformance with the latest edition of the appropriate ASTM Standard or other specified standard. Tests required, but for which no standard exists, will require the Subcontractor to present, in writing, proposed test procedures. These methods will then be approved, disapproved, or approved with modification to the satisfaction of the Contractor and the Subcontractor prior to performing any testing. Tests which may be necessary include, but are not limited to, the following:

Sieve analysis without hydrometer (ASTM ~~C136~~ D422)
Sieve analysis with hydrometer (ASTM D422)
Atterberg limits (ASTM D4318)
Moisture content (ASTM D2216)
Moisture density (ASTM D698)
Capillary moisture relationships (ASTM D3152 and ASTM D2325)
Specific gravity (ASTM D854)
Triaxial permeability (Army Corps of Engineers EM 1110-2-1906)
Three point sets Triaxial (R) (Army Corps of Engineers EM1110-2-1906)
Three point sets Triaxial (Q) (Army Corps of Engineers EM-1110-2-1906)
One-dimensional consolidation (ASTM D2435)
Crumb tests (ASTM Proceedings STP623)
Pinhole (ASTM ~~D422~~ STP 623)
Remolding of samples per test sample
Leaching tests (EP Toxicity)
Partially saturated hydraulic conductivity
Aggregate specific gravity and absorption (ASTM-C127)
Aggregate soundness (ASTM C88-course aggregate only) (Sodium)

Los Angeles abrasion (ASTM C535)

Rock crushing in preparation of samples per bulk samples

Petrographic analysis of rock samples (ASTM C295)

Resistance of rock material to freezing and thawing (ASTM C666 Procedure A)

5.0. Testing Procedures

The following are some specific requirements relating to the testing to be done under the terms of this Subcontract.

1) Compacting Samples of Cohesive Soil and Stabilized Sludge

Samples of compacted soil shall be prepared in a split mold having inside dimensions equal to the dimensions of the desired sample. The soil shall be compacted into the mold in 6 equal layers using a pressing or kneading action of a tamper having a contact area with the soil of less than one-sixth the area of the mold. The surface of the layer shall be thoroughly scarified before placing the next layer. Under no circumstances shall standard impact types of compaction be acceptable.

The sample shall be prepared according to the ASTM D-698 test procedure using an appropriate amount of water to produce the desired water content.

The desired density shall be produced by either kneading or tamping each layer until the accumulated weight of the soil placed in the mold is compacted to a known volume or by adjusting the number of tamps per layer and the force per tamp. For the latter method of

control, special constant force tampers are necessary. After each sample has been compacted to finished dimensions and removed from the mold, the appropriate laboratory test may be performed. Input parameters such as moisture content at compaction, etc., will be provided by the Contractor.

Preparation of compacted granular soils shall be performed as outlined in the U.S. Army Corps of Engineers' "Laboratory Soil Testing," publication EM 1110-2-1906.

2) Consolidation Testing

Consolidation tests must include time-rate of settlement plots of all load increments. These plots will be both log-time or square root of time plots, whichever best defines the end of primary consolidation. An on-site laboratory, if used, shall be equipped with a minimum of three (3) consolidation machines.

3) Triaxial Testing

Triaxial testing of select undisturbed or compacted samples shall include one or more of the following: permeability test, unconsolidated undrained tests (Q), and consolidated undrained tests with pore pressure measurements (R). All testing shall be conducted according to procedures outlined in EM 1110-2-1960. A "B" parameter of 0.97 or higher is required on all test samples prior to shearing, unless otherwise indicated. Input parameters such as confining pressures, etc., will be provided by the Contractor. Photographs showing an external view(s) and a cross section view of each sample, at failure, shall be included in the test data.

4) Capillary Moisture Relationships

Capillary Moisture relationships shall be determined for a specific soil sample using a combination of ASTM D3152 and ASTM D2325 test methods to produce a series of moisture contents at tension values ranging from minus 0.1 to 15 bars. The increments used shall be 0.1, 0.3, 0.5, 1.0, 2.0, 4.0, 7.0, 10.0 and 15.0 bars.

Partially saturated hydraulic conductivity tests shall use pressure chamber apparatus and/or suction apparatus as described by Klute and Dirksen.[1] Equipment must be capable of maintaining pressure heads of -7000 cm of water.

Procedures used to determine the main wetting and drying curves of individual samples shall be similar to those used by Klute and Heermann.[2]

5) Partially Saturated Hydraulic Conductivity Tests

Partially saturated hydraulic conductivity tests shall use pressure chamber apparatus and/or suction apparatus as described by Klute and Dirksen.[1] Equipment must be capable of maintaining pressure heads of -7000 cms of water.

Procedures used to determine the main wetting and drying curves of individual samples shall be similar to those used by Klute and Heermann.[2]

[1]Klute, A., and C. Dirksen, "Methods of Soil Analysis, Part I. Physical and Mineralogical Methods, Chapter 29," 1985 Second Edition.

[2]Klute, A., and D.F. Heermann, "Water Movement in Uranium Mill Tailings Profiles", 1978, Fort Collins, Colorado.

6) Leaching Tests

Leachability test procedures will be conducted in accordance with EP Toxicity Test Procedures as described in 40 CFR Part 261 Appendix II. The leachate produced from the first extraction of a series of extractions shall be retained for use as leachant in the subsequent samples. The Contractor will provide the sequencing of samples to be tested.

The Subcontractor shall perform water quality analysis on the leachate produced from the last sample in a series. Analysis will be for uranium and the metals listed in the EP Toxicity Procedures only.

7) Sludge and Stabilized Sludge Testing

A research by design sludge stabilization program is being developed by the Contractor. The Subcontractor will be responsible for mixing (remolding) and testing the stabilized sludge samples. Tests will consist of in-situ moisture content and density for sludge samples and density, moisture content, and unconfined compression for stabilized sludge samples. EP Toxicity tests will be performed on select stabilized sludge samples.

A Contractors Representative will be present during sample preparation and testing to direct and observe the work. The Contractor will provide all dry materials necessary for mix designs. Dry materials will likely be cement, fly ash, and/or other pozzolans.

6.0. Project Schedule

A specific Delivery Order (DO) (Attachment 14) will be given to the Subcontractor with each batch of samples to be tested. All analyses for each phase must be completed no later than four (4) weeks after receipt of the samples unless otherwise specified in the DO as issued. For selected specific gravity, moisture density, gradation, and Atterberg Limits tests a two (2) week completion will be required. Stabilized sludge tests will be performed in coordination with a designated Contractor Representative.

7.0. Quality Assurance

All laboratory testing shall be performed by experienced and qualified personnel in conformance with the applicable ASTM or other required test procedures as indicated in the Laboratory Testing Section. Any deviation from these procedures or any analytical procedures that are not available from ASTM or Army Corps of Engineers shall be submitted in writing to the Contractor for review and approval of required changes of any such procedure, prior to performing the test. These deviations shall be carefully documented and included on the typed laboratory report to be submitted with the effected test results. The laboratory, including equipment, shall be available to the Contractor's Representative prior to and during the testing for inspection.

The laboratory must have a Contractor's approved Quality Assurance (QA) Program in affect to assure that the data transmitted is correct and that the laboratory tests are run according to the required standard. The Subcontractor shall provide a designated person as the primary contact person should any questions arise as to the reliability of transmitted data.

8.0. Subcontract Performance

All testing is subject to review and acceptance by the Contractor. Acceptance or non-acceptance of a deliverable, will be made by the Contractor within 14 days after receipt of test data. Tests improperly or inadequately performed, will be retested at no cost to the Contractor.

All testing must be performed by the Subcontractor. No tests are to be further subcontracted without prior approval by the Contractor. If tests are to be run at a subcontractor owned off-site laboratory, the laboratory used must be specified on Attachments to Section C. Shipment of samples will be paid by the Contractor only to the Subcontractors off-site lab nearest to Weldon Spring, Missouri.

Any discrepancies in data must be identified and explained on the "Comments" section of the forms attached under Section C of this specification; as to the unusual nature or reason for apparent invalid test results.

9.0. Deliverable Quality Assurance

Results of all analyses shall be submitted on the specified reporting forms (Section C) and accompanied by legible copies of all associated laboratory work sheets. Reporting forms shall be typewritten with all lines on the form being completed. The letter designation "N/A" for not applicable or "N/K" for not known will be used in all blank spaces. If some steps or procedures were not performed as specified by delivery order requirements, the reasons must be stated on the appropriate reporting form or submitted as an attachment thereto. All laboratory worksheets shall provide objective evidence that the data has been checked by appropriate personnel other than those performing the tests.

10.0 Sample Storage and Shipment

The Subcontractor must return WSSRAP samples to the Weldon Spring Site. The Subcontractor must certify in writing that the samples being returned are only those received from WSSRAP and are not samples from other sources. Samples must be returned with their original containers, labeled and packaged in accordance with all applicable DOT regulations.

11.0 Health and Safety Requirements

Some of the samples received will be radiologically contaminated. The Contractor will provide personnel to screen and mark contaminated samples. These samples shall be handled in accordance with Special Conditions 10 and 11 of this Subcontract. The Subcontractor shall submit, two (2) weeks after award, a detailed description of the measures to be taken to conform with the applicable health and safety requirements.

SPECIFICATION 3589-SC-WP029

SECTION B
DATED 07/09/87

DELIVERY REQUIREMENTS

GEOTECHNICAL LABORATORY TESTING

The Subcontractor shall provide the testing and analysis as set forth in the individual Delivery Orders (DO) (work plans) and deliver the following items on or before the date indicated therein.

Deliverables	No. of Copies	Contract Delivery Date
1a. Soil laboratory results for selected specific gravity, moisture-density (proctor), gradation, and Atterberg Limits tests reported in accordance with Attachment 1, Attachment 2, Attachment 3, and Attachment 13 of Section C.	2	Two weeks after Work/Plan Delivery Order & samples are received by the Subcontractor
b. Soil laboratory results for the balance of tests not identified in 1a above, reported in accordance with Attachments 2 through 13 of Section C.	2	Four weeks after Work test Plan/Delivery Order and samples are received by the Subcontractor
c. Description of health and safety measures.	1	Two weeks after award

Two copies of the results are required. One copy shall consist of the original data containing both laboratory worksheets, handwritten and edited results using copies of the Attachment 1 through 13 above depending upon the test performed. Also describe condition of samples prior to testing, evidence of disturbance, damage to containers, and any other pertinent information regarding the samples.

	14	Delivery Order Form

* Note: Instruction for completing Attachment No. 13, Form MKF-AL-C-1 are as follows:

Check appropriate box: If all analyses required by the Delivery Order are being transmitted, check "Total"; if the delivery is partial, check "Partial" and insert date. The balance will be sent to MK-F.

Add any description, comment, etc., in section provided under "Title/Description of Documents."

Sign and date form under section "Approved By:".

ATTENTION: Should the Subcontractor be required to reanalyze/resubmit analyses, the box "Revision" must be checked and the revision designator assigned to Attachment 1 entered in the blank provided next to the box.

Appendix G

Proposed Modification to Specification WP029

PROPOSED MODIFICATION TO SPECIFICATION WP029

Section II, Health and Safety Requirements, will be modified. Presently, the section states that some samples will be radiologically contaminated. Since this specification was prepared , chemical contaminants have been detected on the Weldon Spring Site. This information will be included in the modified section. The Subcontractor will still be required to submit a health and safety plan to protect workers from contaminated samples.

Specification WP091, Geotechnical Coring and Sampling

SPECIFICATIONS WP091

GEOTECHNICAL CORING AND SAMPLING

MK-FERGUSON COMPANY

WELDON SPRING REMEDIAL ACTION PROJECT

ST. CHARLES, MISSOURI

3/1/88

SPECIFICATION WP091

WELDON SPRING SITE
GEOTECHNICAL CORING
AND
SAMPLING

1.0 SCOPE AND OBJECTIVES

The purpose of the work is to procure bedrock core samples.

This project is conducted by MK-Ferguson Company (MK-F), to collect geotechnical data at Weldon Spring Site Remedial Action Project.

2.0 LOCATION

The site is in St. Charles County, Missouri approximately 30 miles west of St. Louis, Missouri.

3.0 PROJECT SUPERVISION

All technical activities shall be under the supervision of the MK-Ferguson Company construction engineer (CE). No work shall commence without the Contractor's approval.

4.0 DRILLING AND SAMPLING

4.1 General

Drilling for this subcontract shall be performed in accordance with "Standard Practice Diamond Core Drilling For Site Investigation" (ASTM D2113-83) except as noted in this specification.

4.2 Surface

The surface conditions on the Site and in the area immediately west of the building area is relatively flat and vegetated with grasses. These areas are readily accessible by existing, improved dirt roads and paved roads and thus access problems should be minimal in the area. However, there may be areas of soft soils which will require working pads. Every effort will be made by MK-F to avoid drilling in locations with poor access.

4.3 Boring Location and Depths

Bedrock coring shall be an extension of borings made under the authority of Specification WP024-01. Coring through the uppermost twenty (20) feet of competent bedrock shall be performed in sixteen (16) of the original borings. Coring through the uppermost two hundred (200) feet of competent bedrock shall be performed in two (2) of the original borings. The selection of borings to advance the two hundred (200) foot corings shall be at the discretion of the Construction Engineer.

4.6 Coring Rods and Bits

The Subcontractor shall use NQ wireline rods and NQ wireline bits for this coring program.

4.5 Soils Logging and Supervision

The Subcontractor shall not be responsible for preparing the boring log as described in Section 7 of ASTM D2113-83 (Boring Log). Bore logging and drilling monitoring will be performed by the Contractor.

4.6 Cross-Contamination Prevention Measures

The Subcontractor shall at all times prevent the contamination or cross-contamination of all borings. Prevention measures include appropriate drilling procedures and decontamination of drilling equipment. A designated representative of the Contractor will observe decontamination activities to assure that no contamination or cross-contamination occurs. Potential contaminants include, but are not limited to oil, greases, hydraulic fluids, fuels, and contaminated soils.

To reduce the potential of contamination occurring, the drilling rig, tools, drilling stem, and all other pertinent equipment shall upon entering the site, be steam cleaned or hot high pressure washed under the direct supervision of the Contractor. All decontamination shall be performed at the decontamination facility located near the south end of the site. The Contractor shall supply a hot high pressure washer.

Cleaning of the entire rig and tools shall be accomplished on a one-time basis before work begins. Decontamination of the entire rig will not be required again, unless the equipment becomes contaminated. If the rig or any other equipment becomes contaminated due to equipment breakdown or the Subcontractor's negligence, decontamination shall be at the Subcontractors' expense. Drill bits, drilling rod, other downhole tools, and hand tools shall be decontaminated between boreholes. Only potable water from the Contractor's source shall be used to supply the hot high pressure washer.

Interior portions of equipment, such as pumps and hoses, which are not accessible for cleaning with a pressure washer shall be thoroughly cleaned and flushed with potable water from the Contractor's source. Oils, greases, or pipe dope shall not be used on pipe threads or drilling rods. Non-hydrocarbon based lubricants, such as silicon or teflon are acceptable.

Drilling equipment used in known or suspected contaminated areas shall be handled with special precautions to prevent the introduction of any contaminants into the well or boring. No hand tools, drill bits, drill stem, or any other equipment other than that in use in the borehole shall be allowed to contact the ground surface at any time. New, clean plastic sheeting shall be required for the temporary storage of such items. If any equipment or supplies come into contact with the ground, or are otherwise contaminated, they shall be thoroughly cleaned by hot high pressure washing.

Cross-contamination shall be minimized by thoroughly cleaning all external and internal surfaces of all drilling equipment, tools, drill bits, drilling stem, mud tubs, pumps, hoses, and all other appurtenant equipment after each hole is completed and before moving to the next drilling location. Cleaning shall be accomplished by completely removing all soil from the equipment and thorough hot high pressure washing.

During drilling operations, the Subcontractor shall prevent soils and liquids other than approved drilling fluids from entering the borehole. Steel surface casing of the appropriate diameter and at least five feet (5') in length shall be used when liquids are present on the surface at a drilling location. The surface casing shall be thoroughly decontaminated by hot high pressure washing prior to use at another drilling location.

4.7 Drilling Fluids

Uncontaminated, potable water shall be used as a drilling fluid for rock coring. The water source shall be provided by the Contractor. The Subcontractor shall be responsible for providing hoses, tanks, and other equipment and transporting water to drilling locations. All tanks, hoses, and other water-handling equipment shall be decontaminated by hot high pressure washing prior to commencing work. Hoses, valves, and other fittings shall be cleaned between drilling locations.

No other drilling fluid or additives other than water shall be used. Absolutely no toxic and/or contaminating substances shall be added to the drilling fluids, nor be permitted to enter boring as a result of the Subcontractor's operations.

4.8 Sampling During Coring

The Subcontractor shall attempt to attain a core run with a minimum of five feet and maximum of 10 feet in length. The Subcontractor will supply pre-manufactured and treated cardboard core boxes capable of holding at least 10 feet of rock core. The cores will be delivered to the Contractor for logging and storage. The Subcontractor will be required to use a 10 foot long core barrel and use his workman-like "best" techniques to obtain full runs.

Competent core will be stored in the cardboard core boxes. Unconsolidated, very friable, or clayey sections of core will be placed in clear, plastic-sheeting core tubing or bags, sealed, and stored along with the competent core in the core boxes. Some sections of core chosen by the Contractor may also be sealed in the core tubing for subsequent chemical analysis. The Subcontractor will assist the Contractor in collecting, sealing, and storing samples.

4.9 Lost Equipment, Lost Boreholes, and Borehole Abandonment

A hole shall be termed "lost" if the Contractor determines that the condition of the hole will prevent its successful completion, or if for any reason it is impractical to continue operations. The term "abandonment" shall mean abandonment to suit the convenience of the Contractor.

A hole which is determined to be lost shall be grouted from its total depth to land surface using a high solids bentonite clay grout. The grout mix shall consist of 50 pounds of grout solids mixed with not more than 23 gallons of water. If the Contractor determines that a hole has been lost for reasons within the control of the Subcontractor, or because of negligence, incompetence, or malpractice on the part of the Subcontractor or Subcontractor's personnel, or because of the use of defective or unsuitable equipment, the Subcontractor shall not be paid for any drilling, demobilization, or other services performed in the lost hole. The Subcontractor will not be paid for equipment lost in the hole. This includes boreholes lost in the event drill bits, drill rod, or other downhole tools are lost in the borehole and cannot be recovered by the Subcontractor's efforts.

In addition, the Subcontractor shall be required to grout the hole from its bottom to land surface, and then move over and drill a new hole in the proper manner to replace the abandoned one. The Subcontractor shall be notified in writing of the decision.

4.10 Standby Time

Standby time shall be defined as time during which the Subcontractor has been instructed by the Contractor to cease working pending further instructions.

Decontamination time shall be defined as time spent decontaminating drilling equipment, well screens, and casing as specified in Section 3.3 and is not considered standby time.

Time spent for clean-up and restoration of drilling locations or for other routine housekeeping or equipment maintenance is not considered standby time.

All standby time shall be recorded on the Daily Field Activity Report discussed below.

4.11 Field Documentation

The Contractor will maintain a "Daily Field Activity Report" (a sample copy is attached as Figure 1) detailing Subcontractor activities. The subcontractor is required to initial this report on a daily basis and note any differences that cannot be resolved. Any differences shall be documented for future reviews and resolution between the Contractor and Subcontractor. This is the only form that will serve to document quantities of work.

A designated Contractor representative will be assigned to each drilling rig to document the activities. The Contractor representative will assure that work is performed in accordance with specifications.

5.0 Health Physics

The Contractor shall provide industrial hygiene and/or health physics support, as appropriate, during all field operations in areas of radiological and/or chemical contamination.

The Subcontractor shall comply with all applicable Federal, State, and local health and safety regulations and requirements, including, but not limited to, those established pursuant to the Occupational Safety and Health Act (OSHA) and the WSSRAP Construction Safety and Health Management Program.

6.0 Quality Assurance

The Contractor shall direct all fieldwork. Periodic Quality Assurance surveillance will be performed by the Contractor to verify compliance with specification requirements.

Gentlemen:

Enclosed are three (3) copies of "Work Plan, Geophysical Investigation, Specification 3589-SC-WP028, Weldon Spring Site" for your review and approval. We understand that a meeting has been scheduled for May 31, 1988 at your office to discuss the details of this work plan prior to commencing the field operations.

We look forward to working with MK-Ferguson personnel on this project. If you have any questions regarding the contents of this work plan, please do not hesitate to contact me.

Sincerely,

GEOTECHNOLOGY SERVICES, INC.

1.0 INTRODUCTION

Geotechnology Services, Inc. has been retained by MK-Ferguson Company to perform a geophysical investigation at the proposed disposal cell at the Weldon Spring Site. The geophysical investigation consists of an integrated program of multiple geophysical data acquisition surveys, data processing, interpretation and modelling to develop subsurface information across the disposal cell area.

The Scope of work is outlined in Specification 3489-SC-WP028, dated July 7, 1987 and amended on August 7, 1987, and August 28, 1987 included as Appendix A. As a minimum, surface seismic refraction, DC resistivity, EM induction conductivity, and self potential (SP) surveys are required by the specifications. The area of investigation includes approximately 75 acres, with the depth of investigation ranging up to 200 feet below the top of bedrock.

This work plan provides the details of a geophysical investigation proposed by Geotechnology, consistent with our proposal dated September 15, 1987. Briefly, the work plan includes a discussion of the project requirements, purpose, geophysical systems, application of integrated systems and clarification of specification requirements; detailed discussion of our technical plan, including instrumentation, field procedures and calibration requirements; project schedule; and project team.

2.0 PROJECT REQUIREMENTS

2.1 Purpose of Project

The purpose of this geophysical investigation is to provide a geological model of the subsurface conditions below the proposed disposal cell at the Weldon Spring Site.

2.2 Geophysical Systems

Surface geophysical survey systems will be employed to investigate the specific subsurface, overburden, bedrock and groundwater conditions stated in Specification 3589-SC-WP028, for the Weldon Spring Site. These systems will include:

- Gradient magnetometry
- Engineering seismic refraction
- High resolution shallow seismic reflection
- Vertical D.C. electrical resistivity (VES)
- Spontaneous potential (SP)
- Shallow Electromagnetic induction (EM)
- Deeper Electromagnetic induction (EM)
- Very Low Frequency EM (VLF/EM) (Optional)

2.3 Application of Integrated Systems

All the geophysical data acquired during this project, as well as the previously supplied geotechnical information, will be subject to cross-reference and correlation in order to develop a subsurface model. Based on previous investigations (Bechtel, 1987), it is apparent that any geophysical investigation without external correlation could be misleading for this site. Subsurface data collected by means of borings is usually the prime ground truthing cross-reference data utilized to correlate geophysical interpretations. In order to offset this

possibility, all data from an area or zone that yields contradictory results will be thoroughly reviewed before including such data into the final interpreted subsurface model.

2.4 Clarification of Specification

Employment of an integrated geophysical investigation to determine an appropriate subsurface model requires that several requirements of Specification 3489-SC-WP028 be clarified, including:

- Utilizing the geophysical results for "design" (1.1 Objective, line 4, page 1) should require that the interpreted model be confirmed to an acceptable probability level by ground truthing. Such final ground truthing is often acquired long after the acquisition of geophysical data which itself it usually utilized to target the ground truthing program. Therefore, before any parameters for "design purpose" are based upon these geophysical results, the interpreted geophysical model should be subject to revisions (feedback) incorporating all such ground truthing data.

- Although the overall target depth of investigation of the integrated survey is 200 feet below the top of bedrock, some of the proposed geophysical techniques are used to penetrate specific depth horizons or zones.

- The term "continuous subsurface information" usually refers to continuity of information of a 2-dimensional profile presentation based upon data acquired at some meaningful grid or data point spacing. The Weldon Spring site contains several surface and buried obstacles, buildings, utilities, etc., which will inhibit or prevent the overall acquisition of such data. For 3-dimensional coverage, it may be necessary to acquire scattered point data that would enhance a 3-dimensional model but would be disjointed and not continuous information if presented on a 2-dimensional profile without extrapolation between data points.

- An integrated geophysical survey conducted for design purposes which is limited to surface methods only is required to provide with a high degree of confidence (pages 6 & 7, section 6.2) such information as: material types of overburden and rock and their densities; the nature of joints and solution features in overburden and rock, the nature of the infilling material, and water levels. Such identifications may require correlation with core data, geophysical logging, and single-hole and

cross-hole compressional and shear wave velocity data. Material types are more accurately described by directly observed geological data. Without subsurface geophysical data, the accuracy of the classifications of material types is reduced to an inference of the character of the material present based on the survey data, particularly in the case of a difficult data site. Therefore, the surface geophysical data should not be utilized for "design" without correlation with other information.

3.0 TECHNICAL APPROACH

3.1 Location of Geophysical Surveys

Specified geophysical techniques will be performed to acquire data in the vicinity of the 8 traverses shown in Plate 1. The traverses are tentatively designated as Lines 1 through 8, and together are comprised of approximately 12,000 lineal feet. The locations of the lines were selected based on the following factors:

- providing sufficient areal coverage;
- utilizing existing subsurface data;
- avoiding surface cover which prohibits or significantly hinders geophysical data acquisition such as buildings, paved roads and parking areas, railroad tracks, shallow underground utilities and raffinate pits;
- aligning electrical and magnetic "noise" such as underground utilities, overhead pipes, railroad tracks, and metal fences, such that they be perpendicular to the survey line or-in a possibly usable but less satisfactory alignment-parallel to the survey line;
- accommodating tentative boring locations and geophysical lines suggested by MK-Ferguson, provided the locations satisfy the above requirements.

Information used to locate survey lines are based solely upon site plans provided by MK-Ferguson Company. Positions of the survey lines may be subject to modifications after the site is physically reviewed. The lines will be surveyed in the field with respect to control points provided by MK-Ferguson by staking at 100-foot intervals.

3.2 Geophysical Data Acquisition

The following data acquisition plan assumes that each technique produces acceptable results. In some areas, particular methods may not provide adequate information due to geologic or manmade conditions that are not conducive to that

particular technique. In these instances we may request to adjust the work plan such that a non-informative technique be replaced with additional data acquisition using a technique currently in the work plan.

The geophysical data acquisition will be performed in three phases as follows:

- Phase I - EM induction and gradient magnetometry
- Phase II - Seismic refraction and reflection
- Phase III - SP and DC resistivity

For continuity, the data analysis and interpretation methods are presented within the data acquisition program. Detailed data interpretation and consolidation will take place after all the data have been acquired, however, some preliminary interpretation may be necessary in order to proceed from one method to another. Due to the shortened daily working hours, it may be necessary for the phases to be lengthened or to overlap in time. Additionally, Phase II and Phase III may be interchanged depending upon the quality of data collected in Phase I.

3.3 Phase I Geophysical Survey

3.3.1 Scope of Work

A combination of electromagnetic (EM) and magnetic survey techniques will be used to provide data from which an interpreted layer-conductivity model may be derived. Electrical "noise" due to power lines, overhead and underground pipes, and metallic structures does exist at the site. The effects of electrical noise may be identified and possibly minimized by integrating specific electromagnetic and magnetic procedures. Even though the locations of many utilities, metallic fences and structures are known, several fast-track surveying methods are proposed to evaluate the presence of shallow buried (and surface) conductors from deeper geologic conductors.

3.3.2 Instrumentation

The following instruments, or their equivalent, will be obtained by Geotechnology for use in Phase I:

- SHALLOW EM INDUCTION
  - Geonics EM31-DL terrain conductivity meter
  - Data logger
- DEEP EM INDUCTION
  - Geonics EM34-3XL/DL or EM34-3 terrain conductivity system
  - Data logger
- MAGNETICS
  - EDA OMNI PLUS Magnetic Gradiometer (self-contained data logger)
- VLF/EM (optional)
  - ABEM VLF/EM WADI (self-contained data logger)

Most of the data acquired in Phase I will be downloaded from a data logger (external or internal) onto storage disks via a Zenith 181 portable lap-top computer. A Geonics IBM PC forward modeling program will be used for layered conductivity analysis.

3.3.3 Field Procedures

Initially, a base station area will be surveyed with the EM31, EM34, and magnetic gradiometer for calibration purposes. The area should be free of electrical "noise" from near surface conductors, have relatively constant conductivity (lower than 30 mmhos/meter), and preferably be accessible from outside the control area. A single base station will be selected within this area for calibrating all three instruments. The instruments will be operated at the base station before and after each survey.

The Geonics EM34-3 or EM34-3XL/DL system will be used first at a constant coil spacing and constant dipole attitude in order to quickly generalize the site conductivities and identify areas exhibiting possible noise due to near-surface conductors. The EM34 system is capable of measuring conductivities at coil spacings of 10, 20 and 40 meters for both horizontal and vertical dipoles providing information from depths ranging from approximately 7.5 to 60 meters.

Once areas prone to conductive interference are generally located, shallow EM induction and magnetic methods may be used to assist in delineating the noisy areas. Thus, the shallow methods may be employed predominately in areas where they are most needed.

A Geonics EM31-DL with data logger will be used primarily to depict the non-magnetic conductors, and an EDA OMNI PLUS magnetic gradiometer with self-contained data logger would be used to depict magnetic targets. Both of these systems may be pulsed at short intervals for continuous recording which can be conducted at a slow walking pace. The data stored in the data loggers may be downloaded onto a portable Zenith 181 lap-top computer. These two methods will be run concurrently.

Deep EM induction data will be acquired in areas least susceptible to electric noise due to near-surface conductors, as determined from the previously acquired data. The EM34-3XL/DL or EM34-3 will be used and conductivities for 3 different coil spacings and 2 different dipole attitudes (a total of six readings) recorded at each station. The coverage is anticipated to require 40 stations. A data logger may be used and downloaded onto the Zenith 181. The data would be used later for modeling vertical changes in conductivity.

A VLF/EM (Very Low Frequency EM) system (optional) may be used in addition to the above techniques. This system will be used to locate and delineate the vertical orientations of conductive zones in the overburden and bedrock, as well as to evaluate the relative overburden thickness. VLF/EM relates to the magnetic component of the electromagnetic field (radio waves) generated by long distance very low frequency radio transmitters. Radio waves are distorted by variations in ground conductivity and the perturbations can be measured accordingly.

The proposed VLF system is the ABEM VLF/EM WADI. The ABEM WADI is an automatic, digital system that can be operated by one man at a walking pace. WADI data is stored in the unit, is automatically interpreted and displayed directly on a built-in LCD. The recorded data up to several thousand data points (plotted curves, station values and coordinates, interpreted conductor dips and depths) can be directly downloaded to a standard serial printer.

If the VLF/EM system proves to be very informative, its survey locations would be extended to fill-in and tie-in the seismic refraction and reflection and other geophysical data.

3.4 Phase II Geophysical Survey

3.4.1 Scope of Work

Seismic refraction and reflection data will be acquired in order to detect velocity contrasts present within the overburden, at the surface of the limestone bedrock, and at depths of at least 200 feet beneath the bedrock surface. The refraction and reflection data are intended to complement each other, therefore, a total of 12,000 lineal feet along survey

lines 1 through 8 are proposed for each seismic method. Seismic data acquisition should begin immediately after the completion of Phase I.

3.4.2 Instrumentation

Geotechnology plans to obtain the following equipment or their equivalent for the seismic method used in Phase II:

- SEISMIC REFRACTION AND REFLECTION
  - Geometrics ES 1225, 12-channel engineering seismograph
  - Seismic cable, 440 feet (maximum geophone spread length) with 12 geophone takeouts
  - Mark 8 Hz vertical geophones (refraction)
  - Mark 100 Hz vertical geophones (reflection)
  - BETSY downhole electric firing capsules with 8-gauge cartridges (50 to 500 grains of Pyrodex each)
  - Geometrics HVB-1 electric blaster
  - Hammer, strike plate, and trigger switch

Information recorded on the ES 1225 will be transferred to storage disks via a Zenith 181 portable lap-top computer. The Interpex program GREMIX, based on the generalized reciprocal method, will be used to interpret the refraction data. The Geometrics GEOFLEX high-resolution shallow-seismic reflection program will be used to process and interpret the reflection data.

3.4.3 Field Procedures

Initially, refraction data will be acquired along the survey lines located in the southeast portion of the study area. Based on existing subsurface data, the limestone bedrock of this area is apparently shallower than elsewhere on the site occurring at depths ranging from less than 20 feet to 35 feet. Initially, the geophone spacing will be about 20 feet (possibly greater in the central portion of the spread) in order to identify thin

overburden layers, diminish hidden layer possibilities, and help to better-define pinnacles. This information, particularly that pertaining to the surface of the bedrock, if detectable, may be helpful throughout the remainder of the subject area. Approximately five shots will be taken for each geophone spread: one at each end of the spread; one near the center of the spread; and a shot off each end of the spread at up to a spread length distance.

In order to avoid interference between charges and geophones, all shots will be taken approximately 2 to 3 feet perpendicularly away from the line that is coincident with the geophone spread. The 8-gauge cartridge charges will be placed in 1.5 to 3 foot deep holes, backfilled and tamped to prevent venting. The charge size may vary from 50 grains to 500 grains of Pyrodex, depending on the source offset, source coupling and subsurface conditions. Water and/or a mat cover may be applied to each shot hole in order to promote source coupling and control airborn dust and debris. Each cartridge requires 50 volts for ignition to take place. The Geometrics HVB-1 blaster produces a 200-volt signal, therefore, two cartridges may be connected in parallel if a larger charge is required, specifically for off-end shots. Open shot holes will be filled and all cap wires will be gathered.

The presence of asphalt pavement along a survey line may require the removal of small portions of the asphalt and underlying base course, if present, at the locations of shot holes and geophones.

The field data recorded on the ES 1225 seismograph will be transferred to a Zenith 181 computer and stored on disk. First breaks will be picked and time-distance graphs will be plotted and analyzed to check for data accuracy and to establish layers and layer velocities. All seismic data will be hand-reduced by phantoming, parallelism, and end-time analysis before applying

computer modeling techniques. The computer analysis may require several cycles of manual changes and correlation with external data before the computer program can be used to refine the model and produce a final interpretation.

Soil identification by examination of shot hole material and surface trawling material would be used to help evaluate the overburden horizon on which the seismic spread lies. If possible, each spread would be laid out over the same surface material for continuity so that the interpretive techniques used would deal with more narrow velocity values and not average of a wide span of values. Horizontal changes in layering sequences would be interpreted by split-spread analysis rather than averaging velocities across the spread.

To complement the seismic refraction data and to extend the depth of seismic data acquisition to at least 300 feet, a high-resolution seismic reflection survey is proposed. Water table horizons and variations within bedrock may be detected by reflection, though it is probable that the overburden layering, and possibly the top of bedrock, may be too shallow to resolve adequately. It is possible to reach penetration to 300 feet by seismic refraction, however, a spread length of at least 1000 feet would be required, as well as the use of large quantities of explosives.

The shallow high-resolution seismic reflection method proposed is referred to as "common offset" and is based on test shooting off the end of a geophone spread to establish an optimum distance between the source and the receiver. Once established, this distance remains a fixed parameter up to the next test spread.

Reflected and refracted events are digitally recorded on the ES 1225 seismograph which contains high-pass reflection filters. A short cable with geophone spacings of 10 to 20 feet is utilized with high-frequency 100 Hz reflection geophones. A sledge hammer source may be used in place of the 8-gauge cartridges provided that sufficient energy is produced to give information from at least 200 feet beneath the surface of the limestone bedrock.

The field data is transferred to a storage disk via a Zenith 181 computer. The common offset records are then reviewed on the monitor for picking first break "static" data. The static-corrected common offset records are sequentially printed out and then inspected for character of the seismic signals and presence of weak and strong reflectors. Different processing and filtering techniques are applied to the data to enhance definition of the stratigraphic horizons. The processed data is stored and the final seismic pseudo-sections are produced. Velocity analyses are then conducted and the selected velocities utilized to calculate depth intervals.

3.5 Phase III Geophysical Survey

3.5.1 Scope of Work

Self-potential (SP) data and vertical electrical soundings (VES) D.C. resistivity will be acquired in Phase III geophysical surveys.

The SP would be useful in analyzing telluric current flow between the alkaline groundwater fluids and any oxides above the water table. Current flow through conductors or disseminated conductors (contaminants) and channeling through porous zones such as fractures and solution channels, may generate a Streaming Potential.

A standard 4-electrode (Schlumberger or Wenner) VES D.C. resistivity would be used to detect different overburden and bedrock layers based upon their electrical characteristics. The locations of the soundings will be selected depending on the need to resolve the seismic problems of hidden layers, velocity inversions, and velocity overlaps. Additionally, areas containing large amounts of electrical interference due to surface conductors, as noted by the EM induction and magnetic data, will be avoided.

3.5.2 Instrumentation

Geotechnology plans to obtain the following equipment or their equivalent for the SP and D.C. resistivity methods:

- SP AND D.C. RESISTIVITY
  - ABEM Terrameter 300B with current and potential electrodes
  - ABEM Terrameter Booster 2000 (optional D.C. resistivity only)
  - Cables and reels
  - Gossen Geohm - 3 Earth Resistivity meta (optional - D.C. resistivity only)

The forward and reverse modeling program RESIX, by Interpex, will be used for layered resistivity analyses of the VES data.

3.5.3 Field Procedures

The SP method will require only 2 potential electrodes, cable and the receiver within the Terrameter 300B. One electrode, designated as the base electrode, will be placed at the beginning of a survey line; the other electrode will be placed at successively greater distances along the survey line away from the base electrode and the natural potential between the electrodes will be measured at every separation.

VES is conducted by measuring the voltage that is generated between the two potential electrodes when the transmitter induces current into the ground through the two current electrodes. To define 300 feet of penetration requires an electrode spacing to at least 1,000 feet. It is anticipated that the Terrameter 300B will provide sufficient current out to the desired spacings. However, the Terrameter Booster 2000 will be used if more voltage is necessary due to highly resistive near-surface conditions.

The shallow portion of the VES configuration is proposed to supplement the seismic refraction data. Five-foot linear electrode spacing will be used for the upper 50 feet and the normal logarithmic electrode spacings used for the deeper penetration. The linear data will be manually analyzed and the logarithmic data will be computer analyzed for multi-layering (up to 10 layers) and inverse modeling.

3.6 Instrument Calibration and Data References

All instruments will be calibrated to the manufacturers specifications traceable to the National Bureau of Standards (NBS). All data except for VES, SP, and deeper EM data, will be digitally recorded and entered into data loggers, or directly into computers or printed out in hard copy. Additionally, data summary sheets will be maintained for all geophysical techniques and will be referenced to time, date, site, traverse line, station number or coordinate, instrument operator, methodology, and with pertinent remarks and logs. Elevation control and positioning will be referenced to the supplied topographic map. All data, data sheets, notebooks, calculations, publications, photographs, time sheets, work schedules, instrument logs, work logs, computer plots and derivations, pertinent documentation and project records generated for this project will be filed as project material.

4.0 PROJECT SCHEDULE

The schedule shown in Plate 2 gives the order and duration of field work required for each geophysical method. Without contingency and barring delays due to mobilization/demobilization, weather, instrument downtime, holidays, etc., the field work should be completed in 38 working days. Additional time has been allotted for preliminary interpretation during the data acquisition portion. Approximately 4.5 weeks will be required to process and interpret the data after the field work is complete. Though some computer programs provide selection of velocity horizons as an option, because of the complexity of this site, this approach is likely to be unreliable. As a result most of the initial data reduction must be done manually, which accounts for the additional time required to process the data. The final report should be available 6.5 weeks after the completion of field work. Preliminary information will be available during the progress of data processing and interpretation.

5.0 PROJECT TEAM

The Project Team is organized as shown on Plate 3 and consists of the following individuals:

Project Manager - Sal M. Gazioglu, P.E.

Principal Geophysicist - Marvin Ehrlich, R.Gp., P.E.

On-site Superintendent - Lawrence C. Rosen, M.S.

Field Technicians - Douglas W. Lambert, M.S.
David Cisiewski
Alan K. Renner

RI/FS-EIS WORK PLAN

Enclosed, we are pleased to provide the RI/FS-EIS Work Plan for your review and comment. This document summarizes existing information about the site; provides an overall picture of the environmental compliance requirements for this project; and includes other pertinent information.

The work plan also serves as the implementation plan as required under NEPA (Ref. Appendix A).

We would appreciate your input by June 21, 1988, at which time we will agree on timing for a public meeting.

Sincerely,

R. R. Nelson

1 INTRODUCTION

1.1 SUMMARY AND BRIEF HISTORY OF THE WELDON SPRING SITE REMEDIAL ACTION PROJECT

The Weldon Spring Site Remedial Action Project is being conducted as a Major System Acquisition under the Surplus Facilities Management Program (SFMP) of the U.S. Department of Energy (DOE). The major goals of the SFMP are to eliminate potential hazards to the public and the environment that are associated with contamination at SFMP sites and to make surplus real property available for other uses to the extent possible.

The Weldon Spring site is located near Weldon Spring, Missouri, about 48 km (30 mi) west of St. Louis (Figure 1). It is surrounded by large tracts of land owned by the federal government and the state of Missouri. The site consists of four raffinate pits, an inactive chemical plant, and a contaminated quarry. The raffinate pits and chemical plant are on adjoining land about 3.2 km (2 mi) southwest of the junction of Missouri (State) Route 94 and U.S. Route 40/61, with access from Route 94. The quarry is located in a comparatively remote area about 6.4 km (4 mi) south-southwest of the raffinate pits and chemical plant area; the quarry can also be accessed from Route 94. These areas are fenced and closed to the public.

From 1941 to 1944, the U.S. Department of the Army operated the Weldon Spring Ordnance Works, constructed on the land that is now the Weldon Spring site, for production of trinitrotoluene (TNT) and dinitrotoluene (DNT). The Army used the quarry for disposal of rubble contaminated with TNT. In the mid 1950s, 83 ha (205 acres) of the ordnance works property was transferred to the U.S. Atomic Energy Commission (AEC); this is now the raffinate pits and chemical plant area. An additional 6 ha (15 acres) was later transferred to the AEC for expansion of waste storage capacity. From 1957 to 1966, the AEC operated a uranium-processing facility at the Weldon Spring uranium feed materials plant, which subsequently became the Weldon Spring chemical plant. Ore concentrates and some scrap metal were processed at the plant, and products that included uranium metal were then shipped to other sites. Thorium-containing materials were processed on an intermittent basis. Radioactive raffinates from the processing were placed in four on-site pits. Other radioactive wastes were disposed of in the quarry.

After closure by the AEC, the chemical plant was reacquired by the Army in 1967. The Army partially decontaminated several buildings, dismantled some of the equipment, and began converting the facilities to produce herbicides. In 1969, prior to becoming operational, the herbicide project was canceled. In 1971, the Army returned the 21-ha (51-acre) portion of the site containing the raffinate pits to the AEC. As successor to the AEC, DOE assumed responsibility for the raffinate pits. In 1984, the Army repaired several of the buildings at the chemical plant; decontaminated some of the floors, walls, and ceilings; and isolated some contaminated equipment.

Several areas in the vicinity of the raffinate pits and chemical plant area and the quarry, but outside of current fenced boundaries, are radioactively and chemically

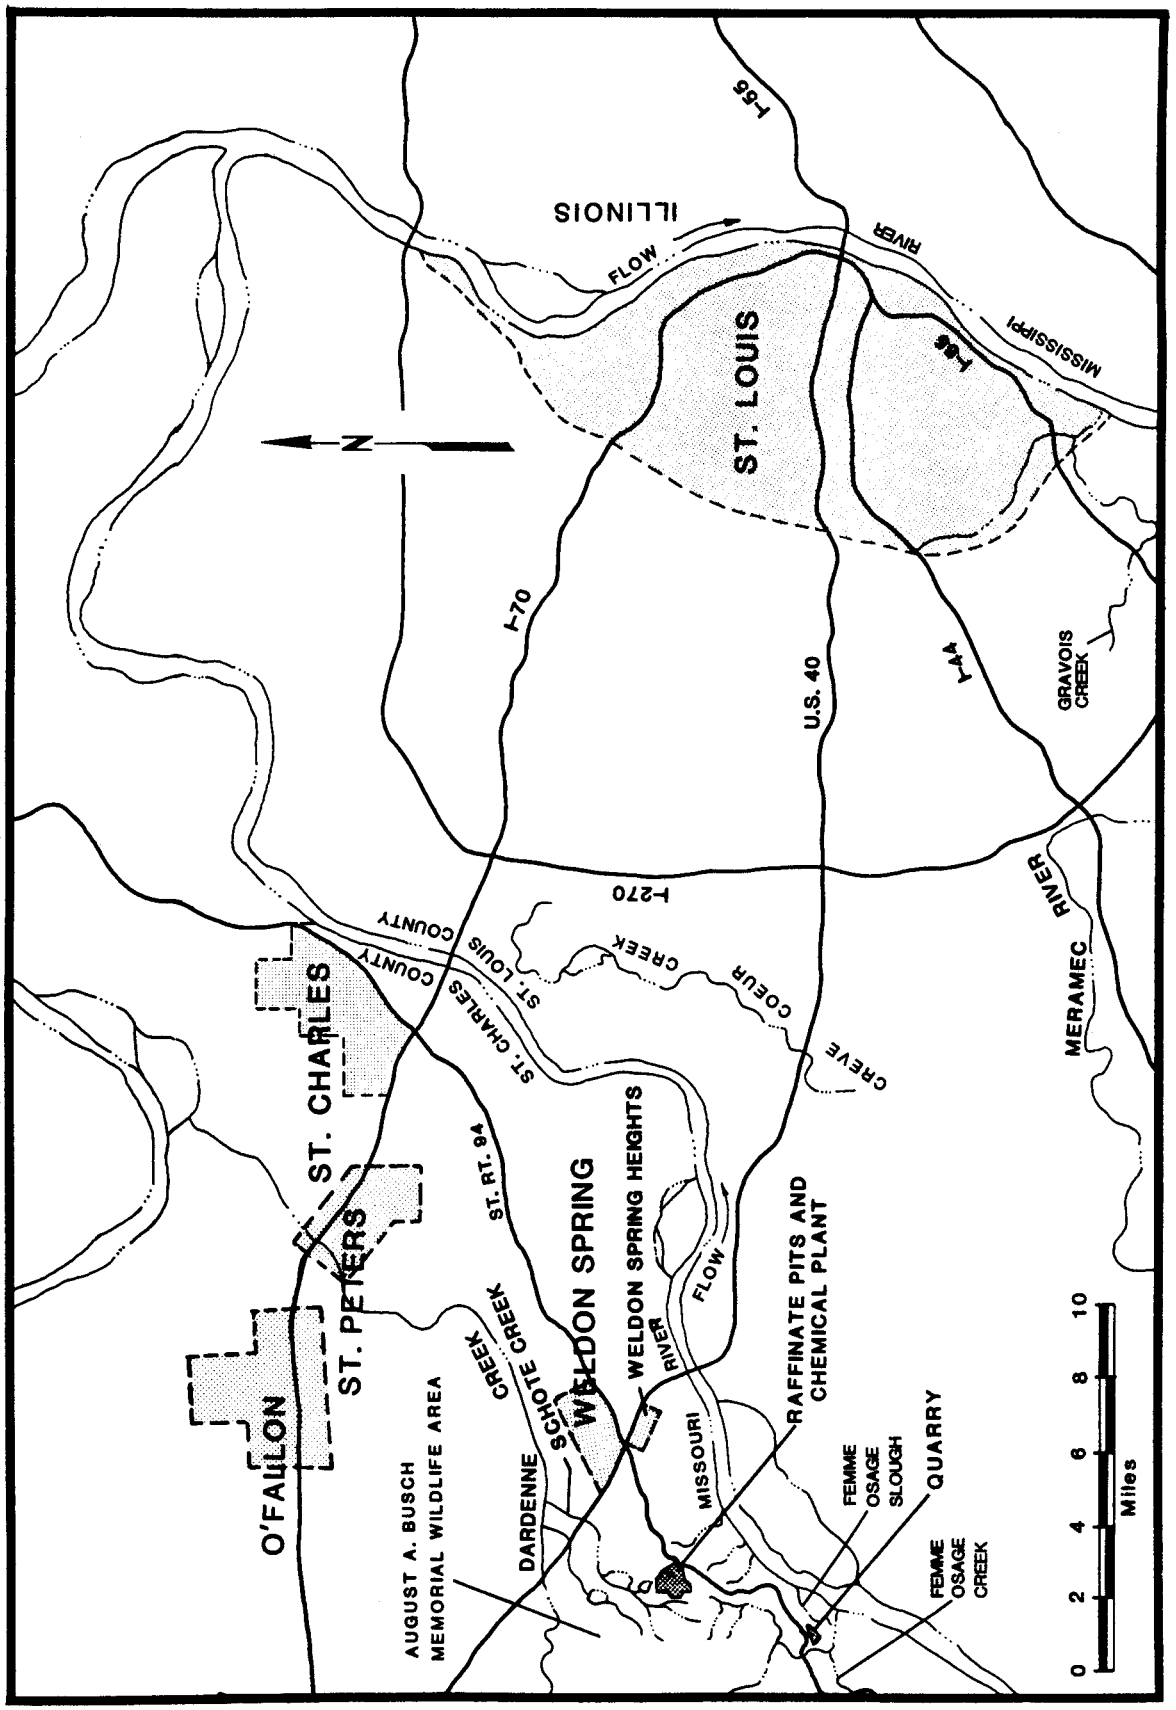

FIGURE 1 Area and Vicinity Map of the Weldon Spring Site, Weldon Spring, Missouri

contaminated as a result of activities previously carried out at the Weldon Spring site. These contaminated areas are termed vicinity properties. The DOE is responsible for the contaminated vicinity properties associated with previous uranium-processing activities conducted at the site. This contamination consists of radioactive constituents (i.e., uranium, thorium, and radium) and any chemicals associated with the processing of these materials. The DOE is also responsible for any chemical contamination that is mixed with radioactive contamination. The U.S. Department of the Army is responsible for contamination on vicinity properties resulting from previous ordnance production activities. The DOE is continuing to work with the Army in identifying off-site areas contaminated as a result of Army activities. To minimize disturbance of the environment, DOE will coordinate the cleanup of vicinity properties with the Army.

In May 1985, DOE designated the control and decontamination of the Weldon Spring site as a Major Project (this project has since been designated as a Major System Acquisition). In October 1985, custody of the chemical plant was transferred to DOE. A project management contractor for the Weldon Spring Site Remedial Action Project was selected in February 1986, and a DOE project office was established on the site in July 1986. The project management contractor, MK-Ferguson Company, assumed control of the Weldon Spring site on October 1, 1986.

On October 15, 1985, the U.S. Environmental Protection Agency (EPA) proposed to include the quarry on the National Priorities List (NPL). This listing occurred on July 30, 1987. On June 24, 1988, EPA proposed to expand this designation to include the raffinate pits and chemical plant area.

1.2 OVERVIEW OF THE ENVIRONMENTAL COMPLIANCE PROCESS

In February 1987, DOE issued a draft environmental impact statement (EIS) to assess the environmental impacts of alternatives for long-term management of contaminated materials associated with remedial action at the Weldon Spring site (U.S. Dept. Energy 1987a). The draft EIS was prepared in accordance with the National Environmental Policy Act (NEPA), as implemented by regulations promulgated by the Council on Environmental Quality (CEQ) and DOE's implementing guidelines. A Notice of Intent to prepare this draft EIS was issued March 2, 1984, in the *Federal Register*, and a public scoping process was conducted. The draft EIS was prepared taking into account the comments received during the scoping process.

The response actions, i.e., removal actions and remedial actions, to be carried out by DOE at the Weldon Spring site are subject to EPA oversight under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), as amended by the Superfund Amendments and Reauthorization Act (SARA). For this project, the oversight function is being carried out by EPA Region VII. Because preparation of the draft EIS was already in progress when EPA's role in the project was identified, DOE and EPA entered into a Federal Facility Agreement (FFA) in August 1986 whereby the respective responsibilities of these two agencies were defined. By this agreement, DOE intended to meet EPA's remedial investigation/feasibility study (RI/FS) requirements under CERCLA with the EIS and supporting documentation.

Since publication of the draft EIS in February 1987, the Phase I water quality assessment (U.S. Dept. Energy 1987c) has provided significant new information relevant to environmental concerns at the Weldon Spring site. In response to this new information (i.e., high concentrations of nitrates and sulfates and significant quantities of nitroaromatics in the groundwater at the site), DOE announced in June 1987 its intent to issue for public comment a revised draft EIS on remedial action at the Weldon Spring site. Since that time, EPA Region VII has formally requested that DOE prepare an RI/FS for this project, pursuant to the requirements of CERCLA. The DOE and EPA have agreed that the appropriate environmental review required by an RI/FS and an EIS can be more expeditiously accomplished by incorporating those elements required by an EIS into the format of an RI/FS (herein referred to as an RI/FS-EIS). The purpose of this work plan is to describe the integrated process by which DOE intends to implement the Weldon Spring Site Remedial Action Project.

This document consists of three parts. The first part is an RI/FS-EIS work plan (essentially an RI/FS work plan prepared in accordance with EPA guidance), which (1) is typically prepared prior to detailed site characterization activities, (2) summarizes existing information regarding the site, and (3) serves to integrate the site characterization and analysis of alternatives phases of the remedial action process. The second part of this document (Appendix A) augments the information given in the body of the RI/FS-EIS work plan and contains information necessary to ensure compliance with DOE procedures for preparation of an EIS. This appendix was prepared in accordance with DOE guidance for an EIS implementation plan. The third part of the document (Appendix B) consists of responses to the major issues raised during public review of the draft EIS.

For purposes of investigation and evaluation relevant to the Weldon Spring Site Remedial Action Project, the Weldon Spring site has been divided into two separate areas: (1) the raffinate pits and chemical plant area and (2) the quarry. These two areas are considered to be one site for purposes of NEPA and CERCLA compliance. However, because the areas are geographically separate and have very distinct physical characteristics, it is reasonable to treat them separately for purposes of environmental analysis. The seven environmental compliance components associated with these two areas are shown in Figure 2. The relationship of these environmental compliance components to the RI/FS-EIS are shown in Figure 3.

Several distinct response actions may be needed at each of these two areas. The three major actions currently envisioned for the raffinate pits and chemical plant area are (1) management of the contaminated surface structures, raffinate pit wastes, surface water, and soils; (2) assessment of the need to restore contaminated groundwater; and (3) cleanup of contaminated vicinity properties. These three actions will be addressed in the RI/FS-EIS and supported by a single response decision. This decision will also include disposition of the bulk wastes currently in the quarry (Figure 3). It is possible that the groundwater restoration issue will be ready for a decision at a different time than the waste disposal issue. If this is the case, DOE may handle groundwater restoration as a separate operable unit to satisfy the requirements of NEPA and CERCLA for this decision.

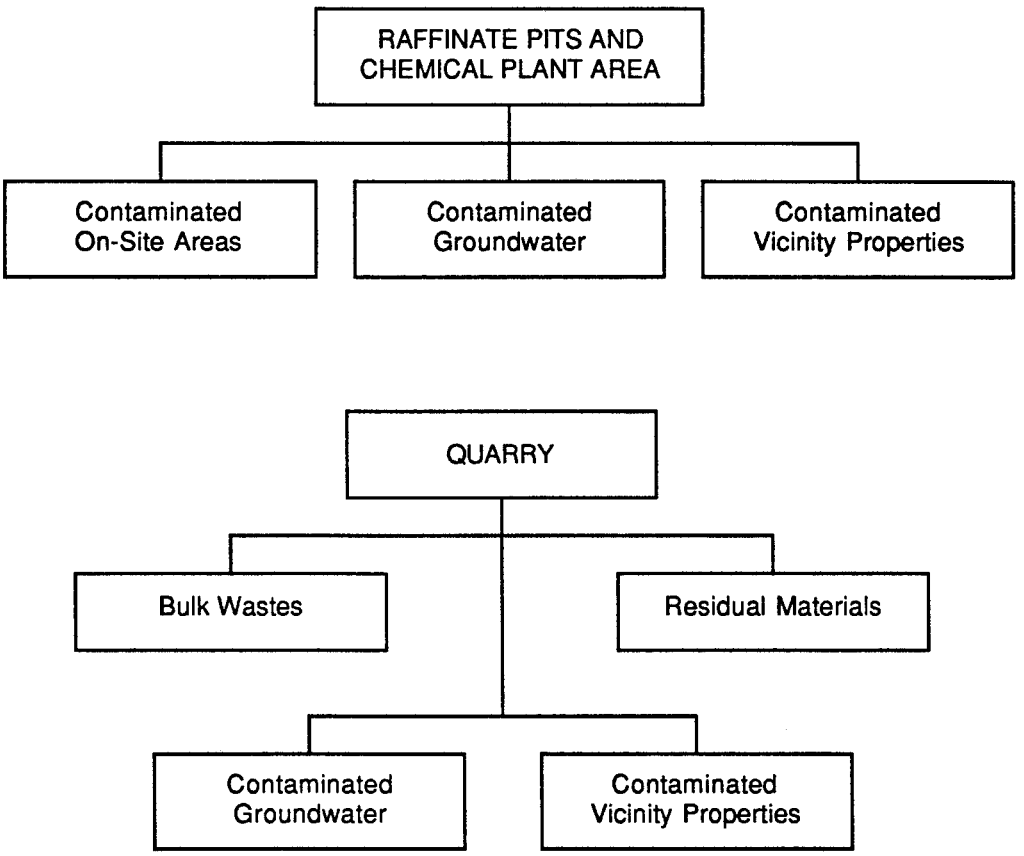

FIGURE 2 Environmental Compliance Components for the Weldon Spring Site Remedial Action Project

Four distinct response actions may be required at the quarry: bulk waste removal, removal of any residual materials following bulk waste removal, groundwater restoration, and cleanup of contaminated vicinity properties. The DOE is proposing to address bulk waste removal as a separate operable unit and will prepare a separate RI/FS and environmental assessment (EA) to support this decision (see additional discussion in Section 3.11 of this work plan). The need to remove any residual materials following bulk waste removal and the need to restore groundwater at the quarry cannot be determined until the bulk wastes have been removed and the remaining conditions evaluated. The DOE will address this issue following bulk waste removal and will involve EPA Region VII and the state of Missouri in its determination. Although removal of residual materials and groundwater restoration are shown as two separate compliance components (or operable units) in Figures 2 and 3, these may be addressed as one operable unit pending the results of environmental investigations at the quarry following bulk waste removal.

Of the vicinity properties for which it is responsible, DOE is planning to clean up those that pose an unacceptable risk to public health and the environment. Management

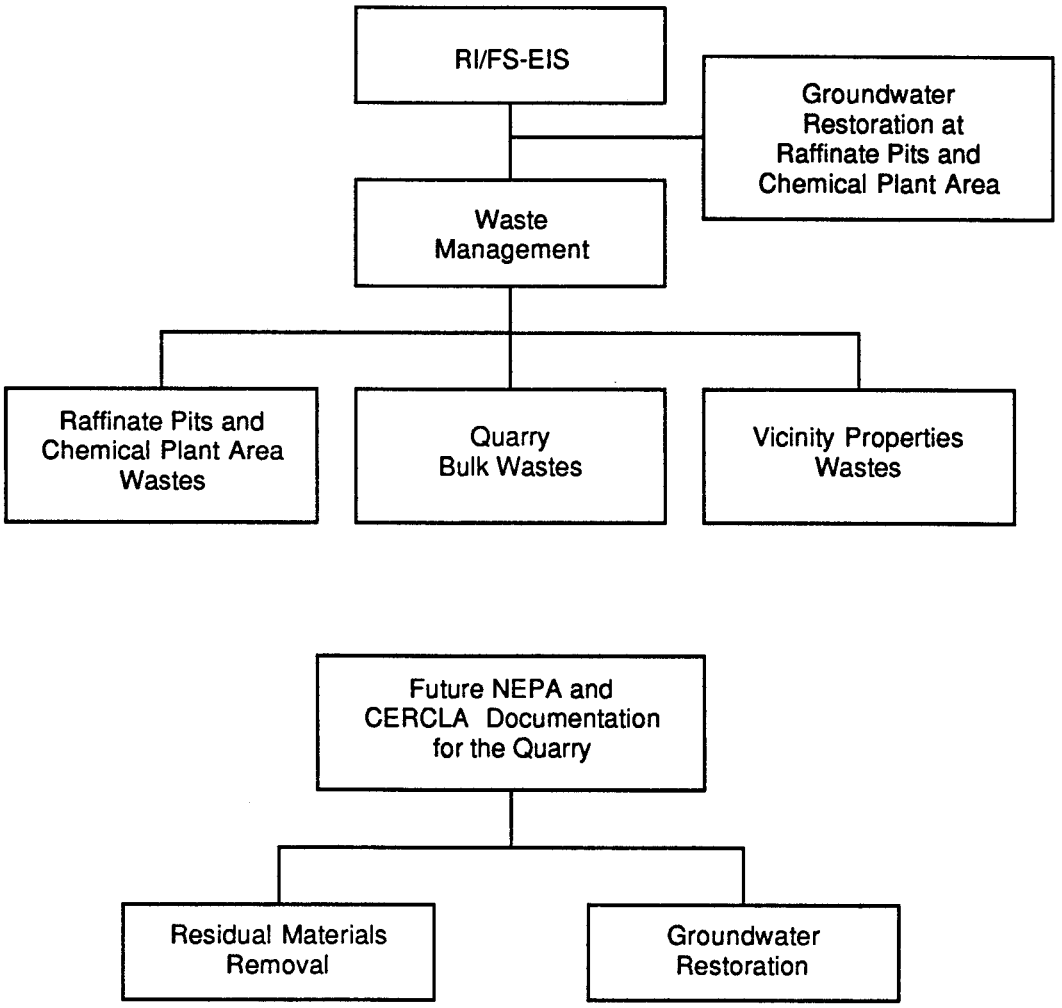

FIGURE 3 Environmental Compliance Documentation for the Weldon Spring Site Remedial Action Project

of the resulting contaminated materials will be included in the record of decision (ROD) for disposition of the raffinate pits and chemical plant area (including the bulk quarry wastes). Appropriate NEPA and CERCLA compliance documentation will be prepared prior to cleanup of the vicinity properties. Those vicinity properties cleaned up prior to the ROD will be addressed per the modified engineering evaluation/cost analysis (EE/CA) process discussed in Section 3.10.1. The cleanup of any remaining vicinity properties at the raffinate pits and chemical plant area will be included in the RI/FS-EIS. A thorough study of the need for additional cleanup of vicinity properties in the quarry area will be part of the NEPA and CERCLA processes for the residual materials and groundwater restoration operable units at the quarry.

1.3 SUMMARY OF PROPOSED APPROACH

The DOE proposes to implement a multifaceted approach at the Weldon Spring site, consisting of the following elements:

- A thorough site characterization program will be completed prior to issuance of the RI/FS-EIS for public review. The results of this characterization program will be documented in an RI report that will provide the level of environmental information required to support decisions under both NEPA and CERCLA.

- Concurrent with site characterization, a baseline risk assessment will be prepared to determine the potential threats to public health and the environment in the absence of any remedial action at the site. The results of this assessment will be included as the near-term impacts for the no-action alternative in the FS-EIS.

- The RI/FS-EIS will be prepared to analyze various alternatives for conducting remedial action at the Weldon Spring site consistent with the requirements of NEPA and CERCLA.

- Prior to issuance of the ROD for this project, various interim response actions (IRAs) will be performed to mitigate actual or potential uncontrolled releases of radioactively or chemically hazardous substances to the environment. The scope of the IRAs will be limited to those actions that can be performed under CERCLA and within the constraints of CEQ regulations for NEPA (i.e., actions will be limited to those that do not have adverse environmental impacts or limit the choice of reasonable alternatives for the ultimate disposition of the site).

- Also prior to issuance of this ROD, DOE is planning to remove the bulk wastes from the quarry and transport them to the raffinate pits and chemical plant area for temporary storage; this will be accomplished as a separate operable unit. This action will be documented in an RI/FS and EA and will be conducted within the same constraints of CEQ regulations for NEPA as the IRAs.

Several actions will occur prior to the ROD for waste disposal. The quarry bulk wastes are proposed to be removed and placed in temporary storage at the raffinate pits and chemical plant area. In addition, various IRAs will be performed, including decontamination of certain vicinity properties, as well as other actions that will alter the environmental conditions at the raffinate pits and chemical plant area. The baseline risk assessment will be prepared using current site conditions. If appropriate, this assessment will be updated at the time the RI/FS-EIS is issued to accurately reflect site conditions at that time.

This multifaceted approach has several advantages:

- Because the RI/FS-EIS will be in a format providing the level of detail required by both NEPA and CERCLA, separate documentation for NEPA and CERCLA will not be required. The DOE, in cooperation with EPA Region VII and the state of Missouri, will ensure that all NEPA and CERCLA requirements are contained within the RI/FS-EIS.

- This approach is intended to result in a single ROD by both DOE and EPA.

- This approach provides for the appropriate degree of public participation required under NEPA and CERCLA.

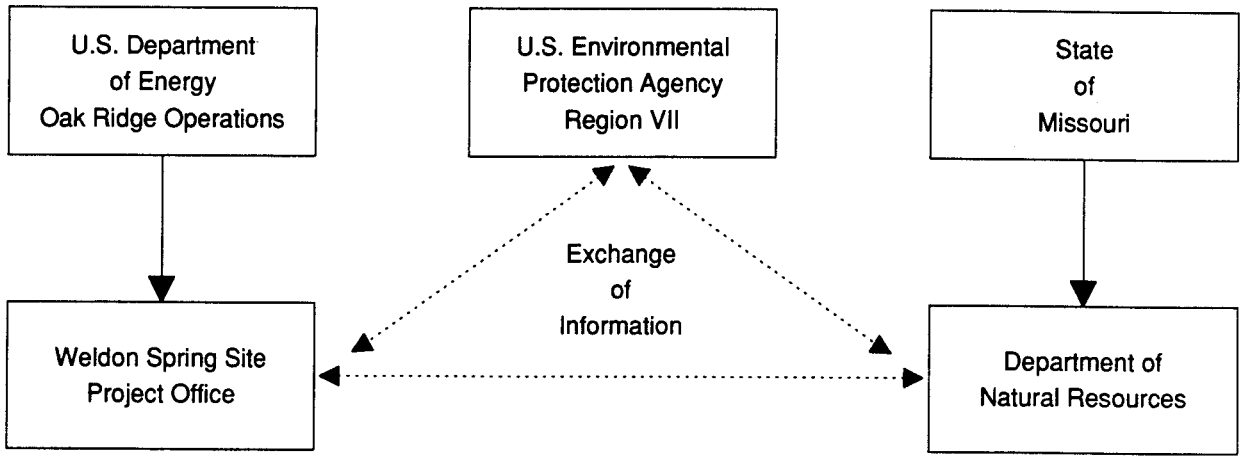
- Limited actions can be initiated via the IRAs to ensure the health and safety of on-site personnel and to minimize or preclude off-site releases of contamination.

- Removal of the bulk wastes from the quarry will reduce the risk to public health and the environment by eliminating the primary source of contamination in this area and reducing the potential for migration.

This approach will allow DOE to meet the requirements of NEPA and CERCLA and to initiate response action activities expeditiously.

The FFA signed in August 1986 provides for an exchange of information and expertise between EPA Region VII and DOE, and it establishes a basis for delisting the Weldon Spring site from the NPL upon completion of the Weldon Spring Site Remedial Action Project. This agreement, which was signed prior to the promulgation of SARA in October 1986, may need to be revised to incorporate new requirements mandated by SARA. The need for such revisions is being discussed with EPA. The DOE will also consult with the state of Missouri on this project. The DOE will interface directly with the Missouri Department of Natural Resources (DNR), the agency designated by the state of Missouri to coordinate state involvement. The relationship between DOE, EPA, and the Missouri DNR and the major responsibilities of each are shown in Figure 4. Through its community relations plan, DOE will also exchange information with the St. Charles County Commission, federal and state legislators from Missouri, local citizens, and public interest groups.

Two additional agencies that are directly involved in this project are the U.S. Geological Survey (USGS) and the University of Missouri. These agencies are funded by DOE and perform specific geological and hydrological studies based on their expertise and experience in these areas.



U.S. Department of Energy	U.S. Environmental Protection Agency	Missouri Department of Natural Resources
Perform environmental analyses and prepare NEPA and CERCLA documentation in accordance with existing requirements and guidance.	Ensure compliance with NEPA and CERCLA requirements.	Ensure compliance with state environmental review requirements. Coordinate review and response of other appropriate state agencies.
Prepare engineering and characterization plans and reports.	Review engineering and characterization plans and reports.	Review engineering and characterization plans and reports.
Monitor the environment before, during, and after response action activities to ensure a safe environment for the nearby population.	Ensure a safe environment for the workers and nearby population.	Ensure a safe environment for the workers and nearby population. Conduct independent environmental monitoring, as appropriate.
Perform response action activities.	Oversee response action activities.	Oversee response action activities. Perform special studies, as appropriate.

FIGURE 4 Relationship between the U.S. Department of Energy, U.S. Environmental Protection Agency Region VII, and State of Missouri for the Weldon Spring Site Remedial Action Project

This work plan presents a description of the Weldon Spring site, its history, and the existing environmental setting. In addition, the document includes an initial evaluation of site contamination, environmental transport mechanisms, and potentially exposed individuals. It also presents the procedures that will be followed to obtain data that, with evaluation, will allow the RI/FS-EIS process to be completed and documented. As a component of the overall program of project management, quality assurance, and quality control, this work plan also includes a description of the organization, project controls, and task schedules that will be employed to fulfill the requirements of the proposed studies.

2 SITE BACKGROUND AND SETTING

2.1 SITE DESCRIPTION

The 21-ha (51-acre) raffinate pits area at the Weldon Spring site contains four surface impoundments (raffinate pits) covering approximately 11 ha (26 acres). These pits were constructed by excavating the existing clay formation and using the removed clay to construct the dikes. The raffinate pits contain the residues from uranium and thorium processing operations previously conducted at the chemical plant (U.S. Dept. Energy 1987a). These residues are generally covered with water during the entire year. Ash Pond and Frog Pond are two additional surface water bodies in the chemical plant area. The 67-ha (166-acre) chemical plant consists of 13 major buildings and approximately 30 support structures, as shown in Figure 5 (U.S. Dept. Energy 1987c).

The quarry is located in limestone and covers about 3.6 ha (9 acres). The deepest part is filled with water covering about 0.2 ha (0.5 acres) and is the only surface water body within this controlled area. The layout of the quarry is shown in Figure 6. The quarry was used for disposal of a variety of wastes at different times during the Weldon Spring site's operational period. A major source of potable groundwater in this area is the county well field located about 1.6 km (1 mi) southeast of the quarry in the Missouri River alluvium (U.S. Dept. Energy 1987a). The nearest well is located about 0.8 km (0.5 mi) from the quarry.

The Weldon Spring site is located within the St. Louis metropolitan area in St. Charles County. The St. Louis metropolitan area has a population in excess of 2.5 million. The communities of Weldon Spring and Weldon Spring Heights are located approximately 3.2 km (2 mi) from the chemical plant and raffinate pits area and have a combined population of about 800. The Francis Howell High School is located about 1 km (0.6 mi) east of the raffinate pits and chemical plant area on State Route 94. An estimated 2,300 persons are on campus daily during the school year (U.S. Dept. Energy 1987a). The largest city in St. Charles County is the city of St. Charles, which is located about 24 km (15 mi) northeast of the raffinate pits and chemical plant area and has a population of about 40,000. St. Charles County has been experiencing a rapid population growth in the last few decades. The 1980 population of 144,000 represented a 55% increase over the 1970 population.

2.2 SITE HISTORY

In 1941, the U.S. Department of the Army acquired about 7,000 ha (17,000 acres) of land in St. Charles County, Missouri. The Weldon Spring Ordnance Works was constructed on this land and was operated for the Army as a TNT and DNT explosives production facility from November 1941 through January 1944 by Atlas Powder Company. The ordnance works was closed and declared surplus to Army needs in April 1946. By 1949, all but about 810 ha (2,000 acres) had been transferred to the state of Missouri (August A. Busch Memorial Wildlife Area) and the University of Missouri (agricultural research land). A large portion of the land transferred to the University of Missouri is now included in the Weldon Spring Wildlife Area. Except for several small parcels

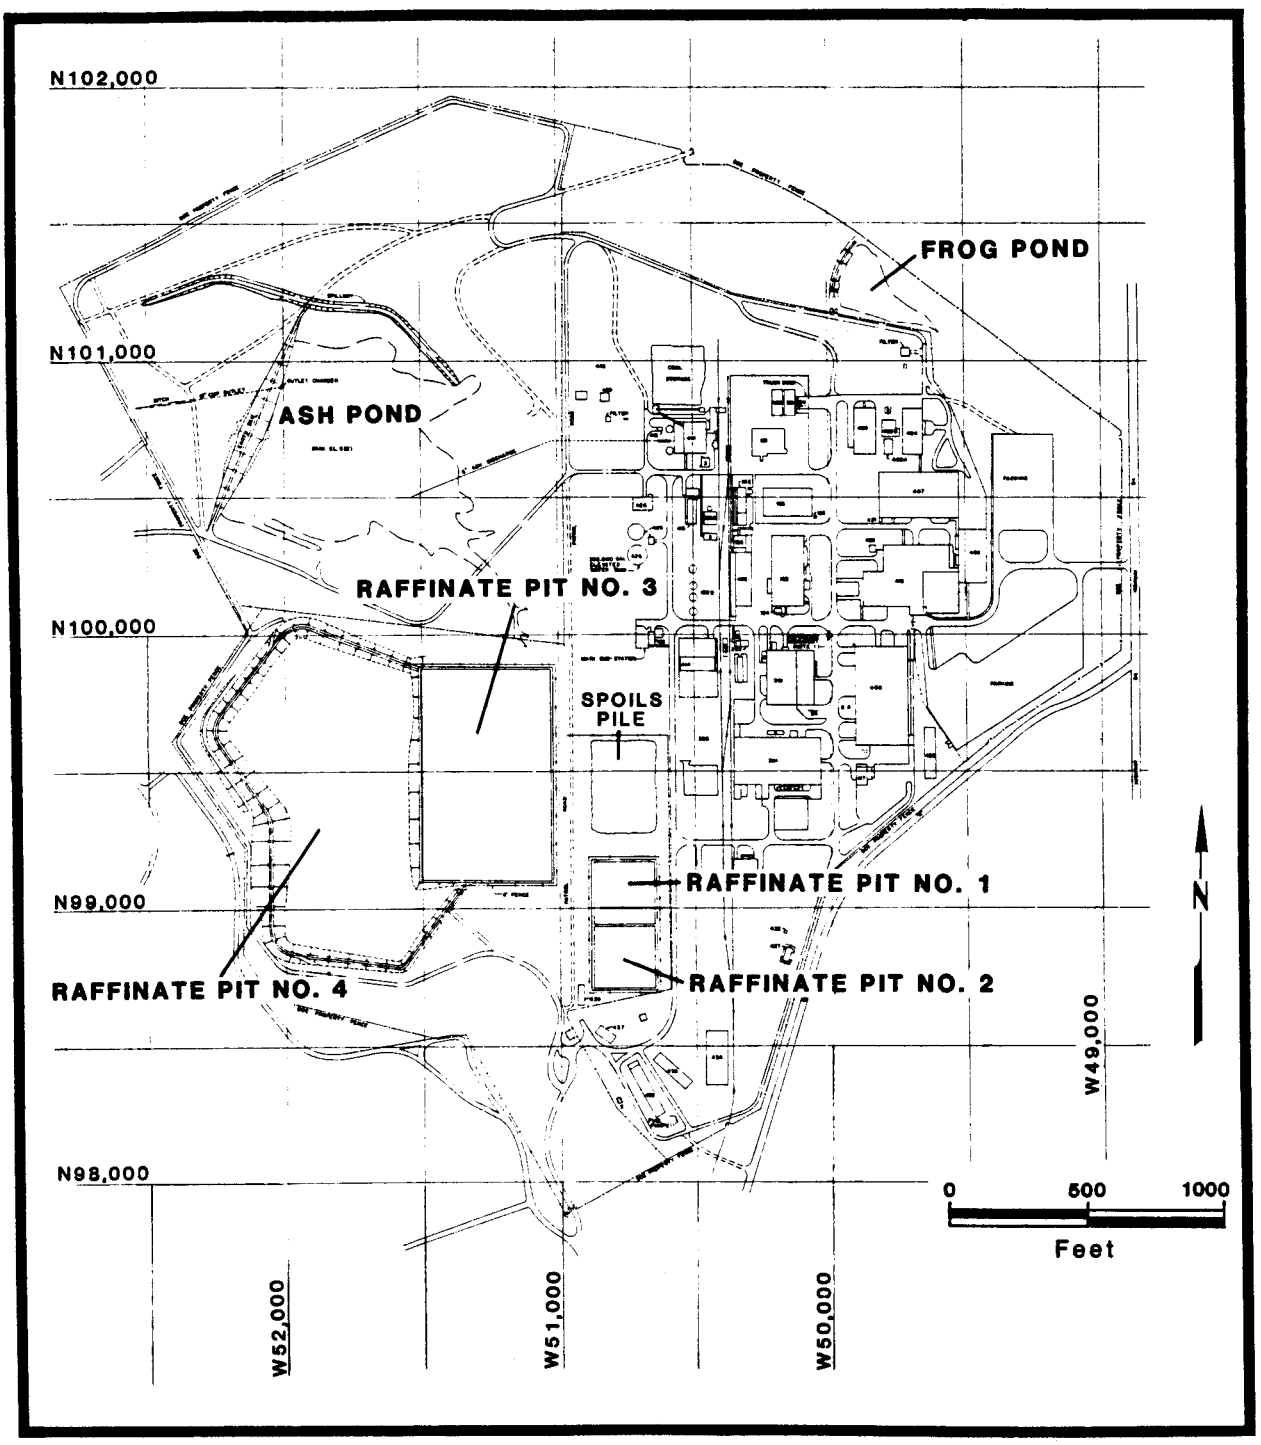


FIGURE 5 Layout of the Weldon Spring Raffinate Pits and Chemical Plant Area

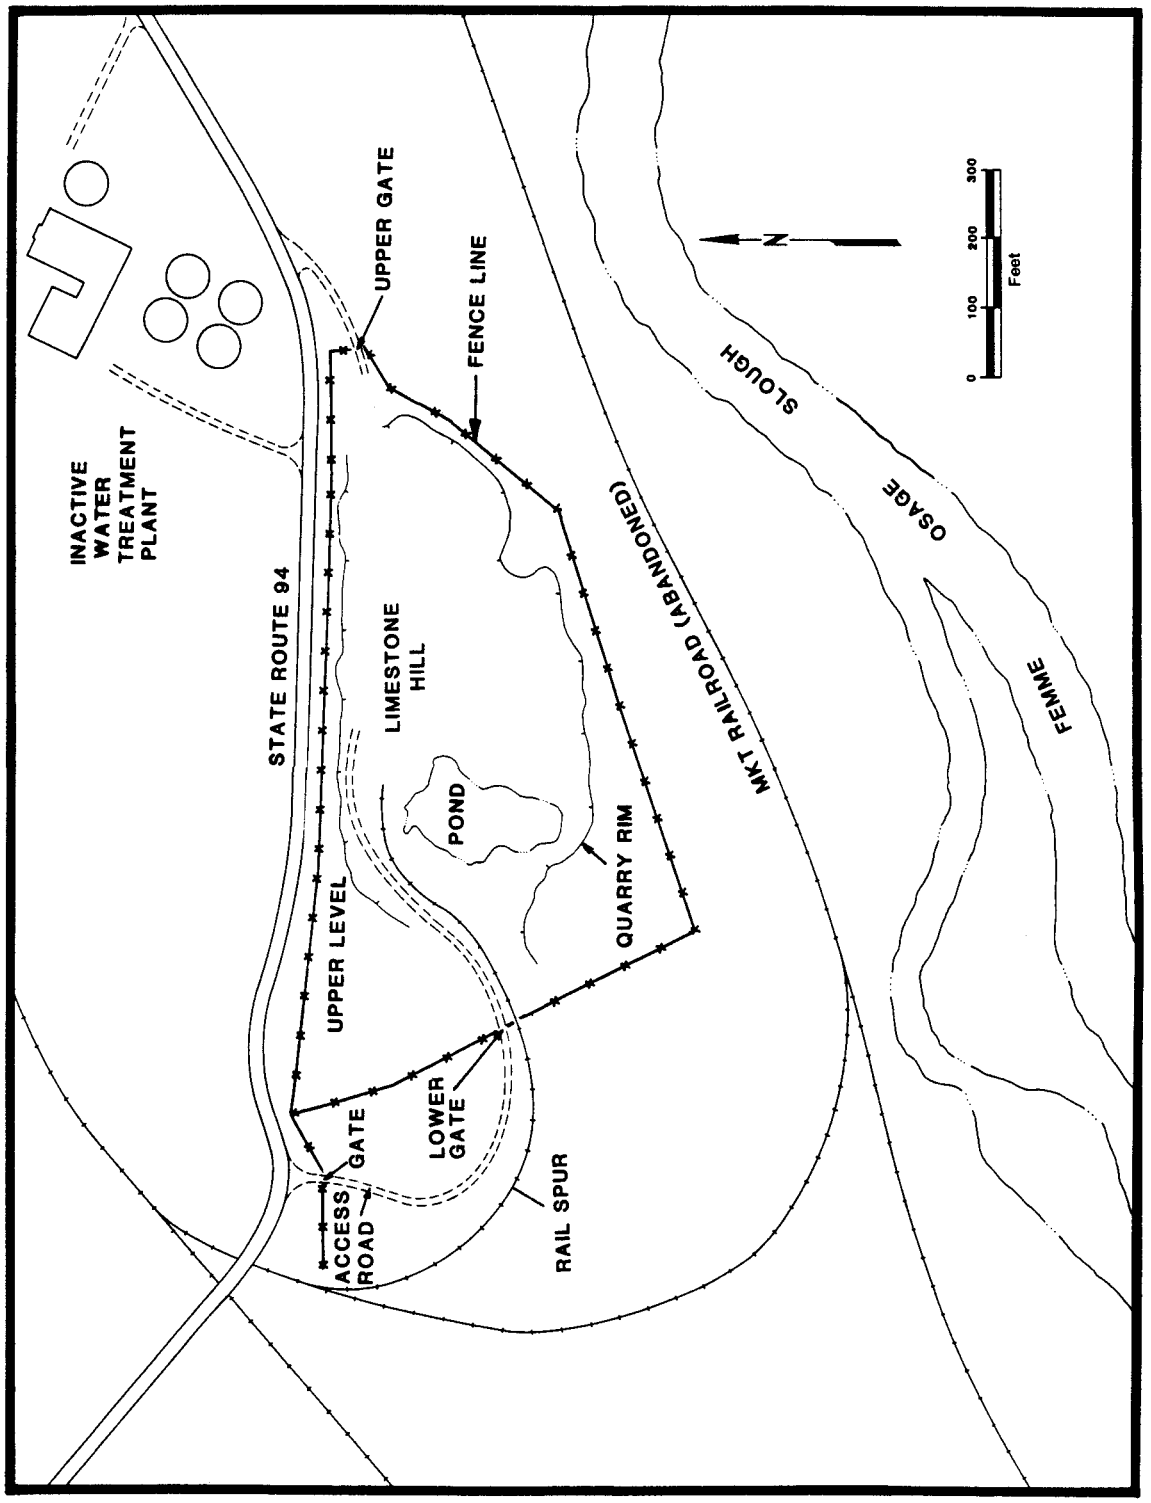

FIGURE 6 Layout of the Weldon Spring Quarry

transferred to St. Charles County, the remaining property became the current Weldon Spring site and the adjacent U.S. Army Reserve and National Guard Training Area.

Through a memorandum of understanding between the Secretary of the Army and the General Manager for the AEC in May 1955, 83 ha (205 acres) of the former ordnance works was transferred to the AEC for construction and operation of the Weldon Spring Uranium Feed Materials Plant. Considerable explosives decontamination was performed prior to construction of the plant. The feed materials plant processed uranium and thorium ore concentrates from 1957 to 1966, with the Uranium Division of Mallinckrodt Chemical Works acting as the AEC operating contractor.

During plant operations, uranium ore concentrates and recycled scrap were processed to produce uranium trioxide, uranium tetrafluoride, and uranium metal; an average of 14,000 t (16,000 tons) of uranium materials was processed per year. In addition, a limited amount of thorium ore concentrates was processed at the plant. These processes generated several chemical and radioactive waste streams, including raffinates from the refinery operation and magnesium fluoride slurry (washed slag) from the uranium recovery process. These streams were slurried to the raffinate pits where the solids settled out and the supernatant liquids were decanted to the plant process sewer; this sewer drained off-site to the Missouri River. The solids remaining in the pits consist of silica and other insoluble metals and oxides associated with the uranium ore feed materials, hydroxides and other precipitates formed from lime neutralization of the raffinates, and washed slag residues from uranium metal production.

The AEC closed the feed materials plant in December 1966; however, in August 1967, the plant was selected as the site for an herbicide production facility. The AEC granted a license to the Army for the radioactive source material that was present as contamination throughout the site. On December 31, 1967, the feed materials plant was transferred to the Kansas City District of the U.S. Army Corps of Engineers for the design and construction of the herbicide facility. Excluded from the transfer were custody and control of the source and special nuclear material stored in the four raffinate pits. Because the AEC did not elect to remove the source and special nuclear material, the 21 ha (51 acres) on which the raffinate pits are located was transferred back to the AEC in December 1971.

Decontamination and dismantling operations at the feed materials plant, now referred to as the chemical plant, were initiated for the Army in January 1968 by Thompson-Stearns-Roger Corporation to allow for construction of the herbicide facility. However, the extensive decontamination effort and associated costs required to meet radiological contamination limits imposed on the facility, combined with a reduction in the military's requirements for herbicides, resulted in cancellation of the project on February 4, 1969. The cancellation occurred before any processing activities were initiated. The Army retained responsibility for the land and facilities at the chemical plant.

The National Lead Company of Ohio (NLO) was contracted by the AEC to perform environmental monitoring and maintenance of the raffinate pits and quarry. Bechtel National, Inc. -- under contract to DOE -- assumed management responsibility for the raffinate pits and quarry from NLO in October 1981. In November 1984, DOE

was directed by the Office of Management and Budget to assume custody and accountability for the chemical plant from the Army. This transfer occurred on October 1, 1985. The site is currently under control of DOE and its project management contractor, MK-Ferguson Company.

2.3 ENVIRONMENTAL SETTING

2.3.1 Physical Setting

The Weldon Spring site is located in two distinct physiographic regions. The raffinate pits and chemical plant area is situated at the southern edge of the dissected till plains of the Central Lowlands Physiographic Province. The quarry is located about 6.4 km (4 mi) south-southwest of the raffinate pits and chemical plant area on the northern flank of the Salem Plateau of the Ozark Plateaus Physiographic Province. Parts of the raffinate pits and chemical plant area are covered with buildings and ponds, and the remainder is covered with vegetation (predominately grasses, shrubs, and small trees), gravel, or paved surfaces. The August A. Busch Memorial Wildlife Area is located to the north, the Weldon Spring Wildlife Area to the south and east, and the U.S. Army Reserve and National Guard Training Area to the west of the raffinate pits and chemical plant area. At the quarry, which is surrounded by the Weldon Spring Wildlife Area, vegetation consists largely of grasses, shrubs, and small trees. The deepest portion of the quarry is filled with water.

The Missouri River is located approximately 2.4 km (1.5 mi) southeast of the raffinate pits and chemical plant area and 1.6 km (1 mi) east of the quarry. At its closest point to the Weldon Spring site, the Mississippi River lies about 23 km (14 mi) north of the raffinate pits and chemical plant area and about 29 km (18 mi) north of the quarry. Surface hydrological features in the vicinity of the Weldon Spring site are shown in Figure 7.

2.3.2 Topography and Site Drainage

The Weldon Spring site is located in the southwest portion of St. Charles County. The county, roughly triangular in shape, is bounded by the Mississippi River on the north and east and the Missouri River on the south. Approximately half of the county land is floodplain and half is uplands characterized by gently rolling topography. The southwest uplands, which contain the site, are dissected by small stream valleys.

The raffinate pits and chemical plant area straddles the watershed divide that separates the Mississippi and Missouri river valleys. Gently rolling topography characterizes areas to the north and west whereas the terrain to the south and east is heavily wooded, rugged, and ravined (Figure 8). Elevations range from approximately 190 m (610 ft) mean sea level (MSL) near the northern edge of the raffinate pits and chemical plant area to approximately 200 m (670 ft) MSL near the southern edge.

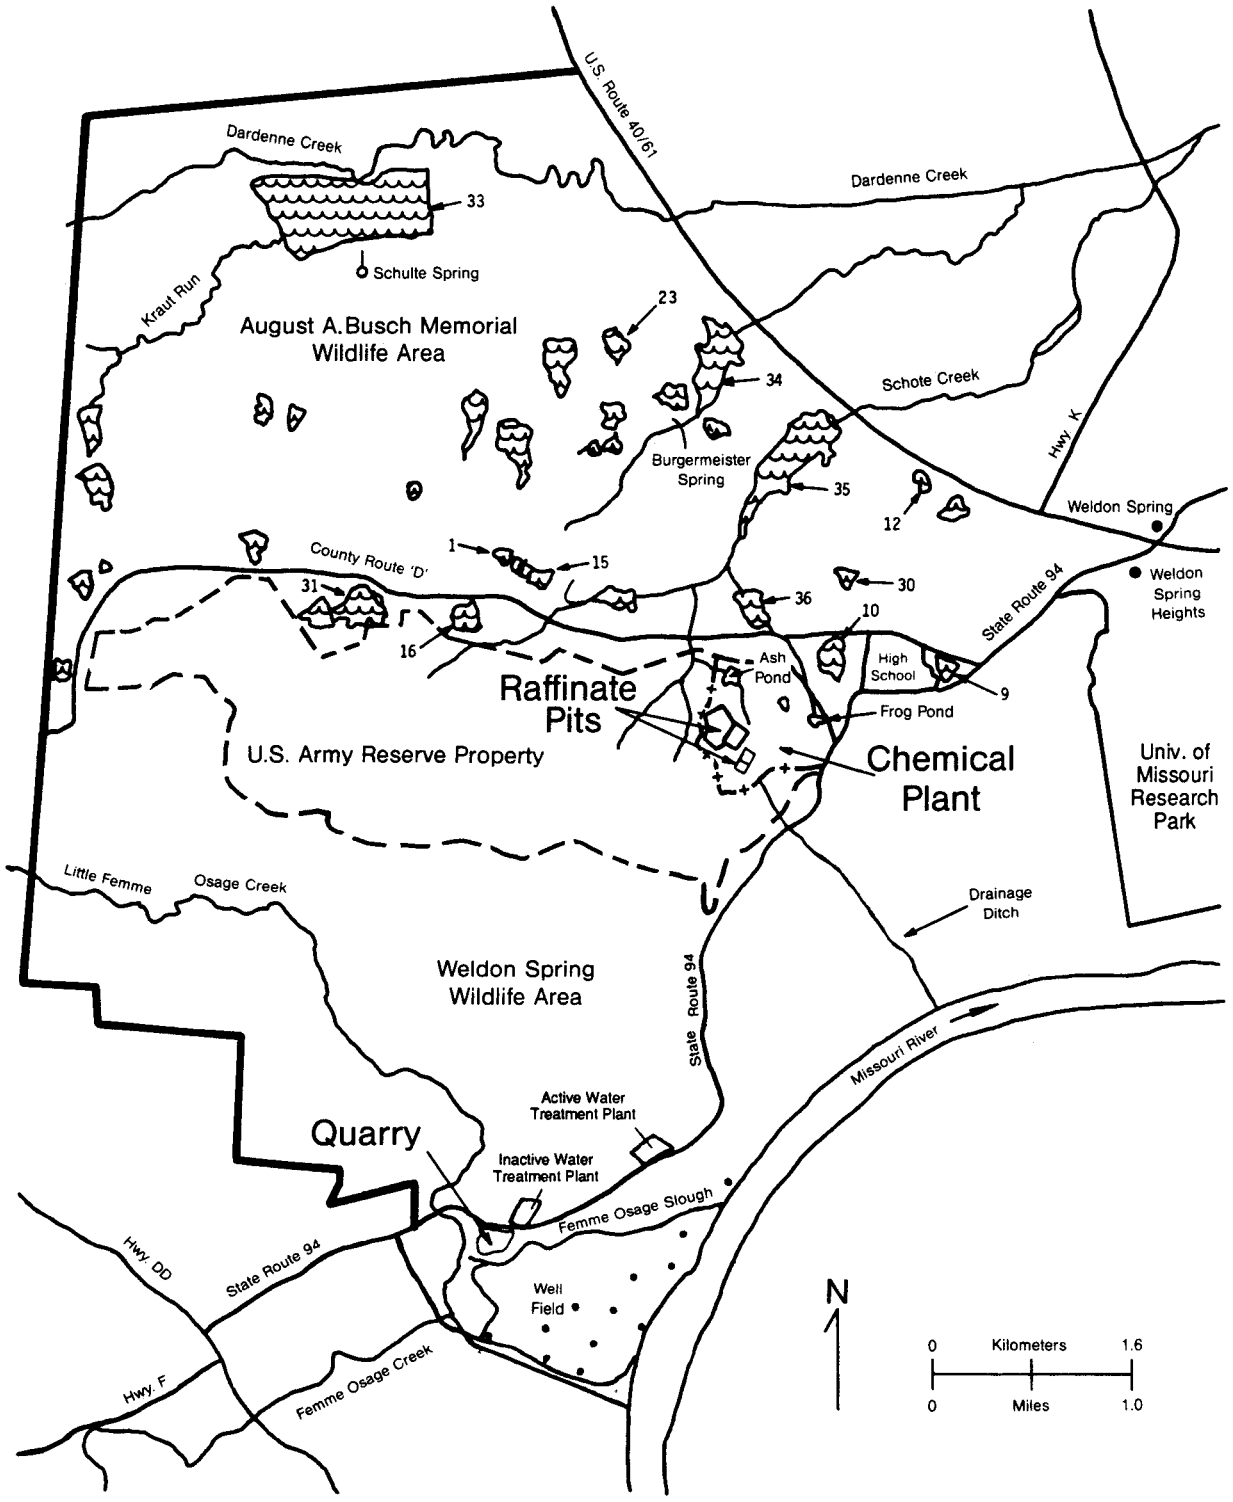

FIGURE 7 Surface Hydrological Features in the Vicinity of the Weldon Spring Site (the numbers refer to lakes in the Busch Wildlife Area) (Source: Modified from U.S. Department of Energy 1987a)

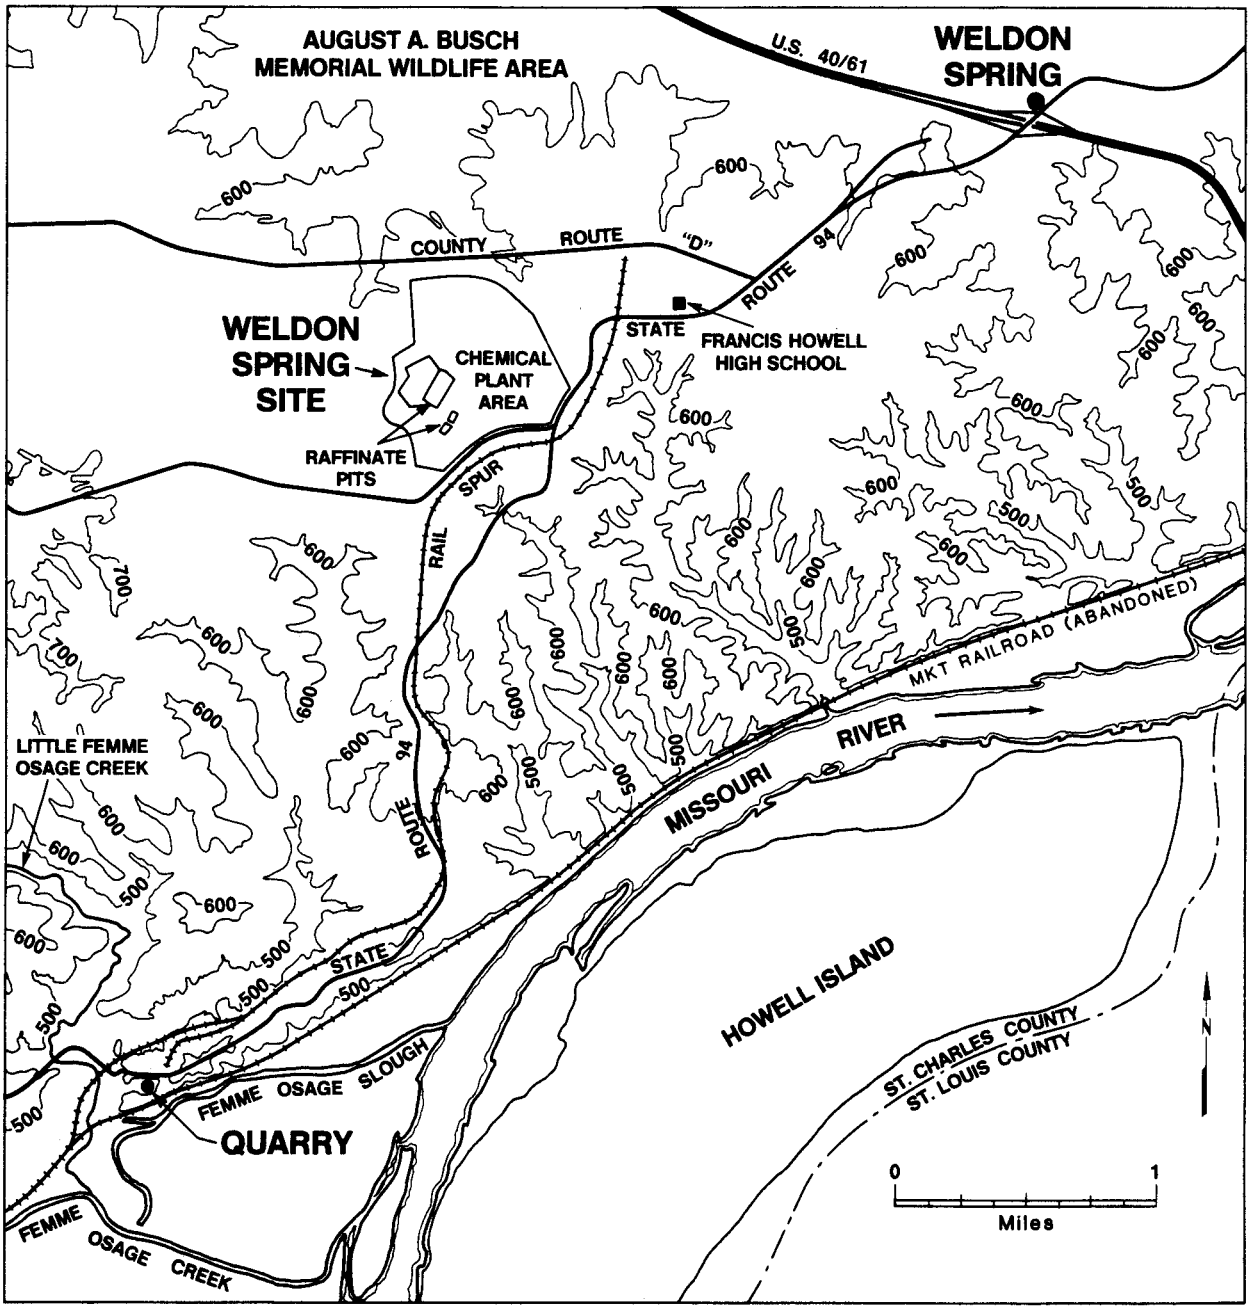

FIGURE 8 Topographic Map of the Weldon Spring Area (Elevations in Feet above MSL) (Source: Modified from U.S. Department of Energy 1987a)

Drainage and the migration of contaminants are influenced by pits, buildings, drainage ditches, and other man-made features -- as well as by ponds and other surface features, including remnants of a channel through the Ash Pond area. Surface hydrological features near the raffinate pits and chemical plant area are shown in Figure 9.

Most surface drainage from the raffinate pits area discharges either via intermittent streams in the Army Reserve training area to the west or into Ash Pond on the chemical plant area. Discharges from the intermittent streams and Ash Pond combine near County Route "D" and flow northward into Schote Creek; from there they enter Dardenne Creek, which discharges into the Mississippi River. An additional surface drainage system reaching the Mississippi River exits the chemical plant area from Frog Pond. Frog Pond drains stormwater events from most of the chemical plant area (via the stormwater sewer). Surface water flow from the northeastern edge of the chemical plant also drains to Frog Pond.

Drainage from the southern portion of the chemical plant area flows southeast to the Missouri River. As flows occur, a portion enters the subsurface; this flow reemerges farther downstream in springs or the stream channel. The drainage originates from two sources. The first is the sanitary sewer system for the chemical plant. Although this system was taken out of service in 1986, it does receive some flow from the stormwater runoff system. The sanitary system drain pipe merges with the chemical plant process sewer, which is also unused. The second source of southeast drainage flow is the overland flow from the southern portion of the chemical plant area during precipitation events.

The limestone quarry is southwest of the raffinate pits and chemical plant area and borders the Missouri River alluvial floodplain. The surrounding topography, except the floodplain area to the south, is rugged and heavily wooded and is characterized by deep ravines. The quarry floor and rim are at an elevation of about 140 and 170 m (450 and 550 ft) MSL, respectively.

Drainage in the quarry area occurs primarily through the subsurface, with limited surface drainage on the southern rim. The quarry drainage flows to the Missouri River, 1.6 km (1 mi) to the east, through Femme Osage Creek and Little Femme Osage Creek. About 210 m (700 ft) south of the quarry is a 2.4-km (1.5-mi) section of the original Femme Osage Creek that was dammed at both ends by the University of Missouri between 1960 and 1963. This section is now called the Femme Osage Slough. The water level of the slough is affected by the levels of the Missouri River and the groundwater, and the average water level is about 140 m (450 ft) MSL (U.S. Dept. Energy 1988a). The St. Charles County well field is located between the Femme Osage Slough and the Missouri River. The location of production wells in the well field is shown in Figure 10.

2.3.3 Geology

The following general description of the geology of the raffinate pits and chemical plant area highlights the major geologic characteristics of the area. More detail is provided in a recently completed hydrogeological characterization report for the chemical plant (Bechtel Natl. 1987).

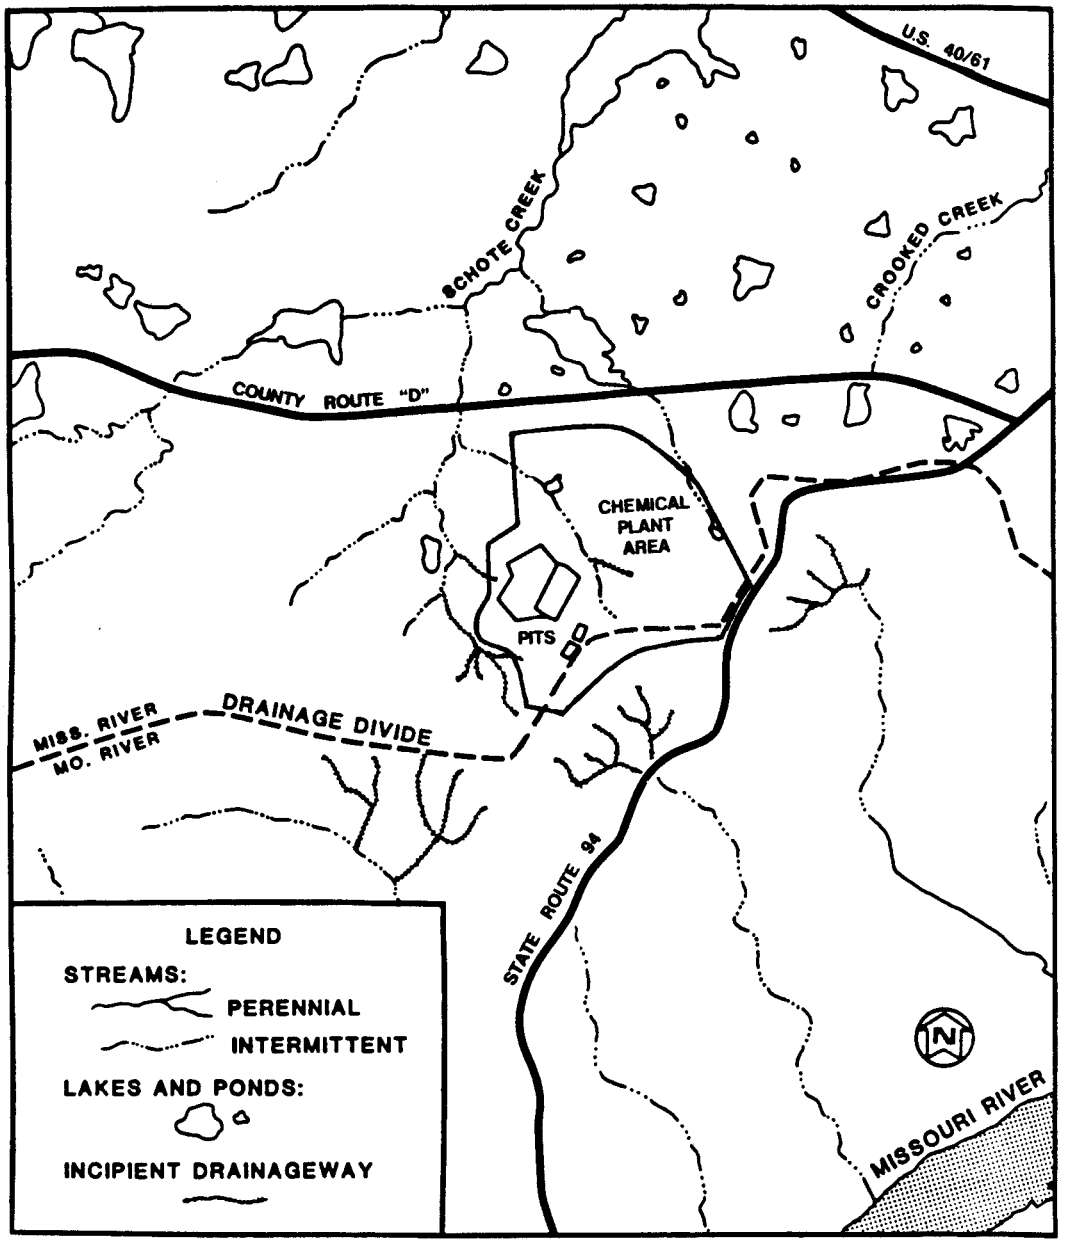

FIGURE 9 Surface Hydrological Features in the Vicinity of the Raffinate Pits and Chemical Plant Area (Source: Modified from U.S. Department of Energy 1987a)

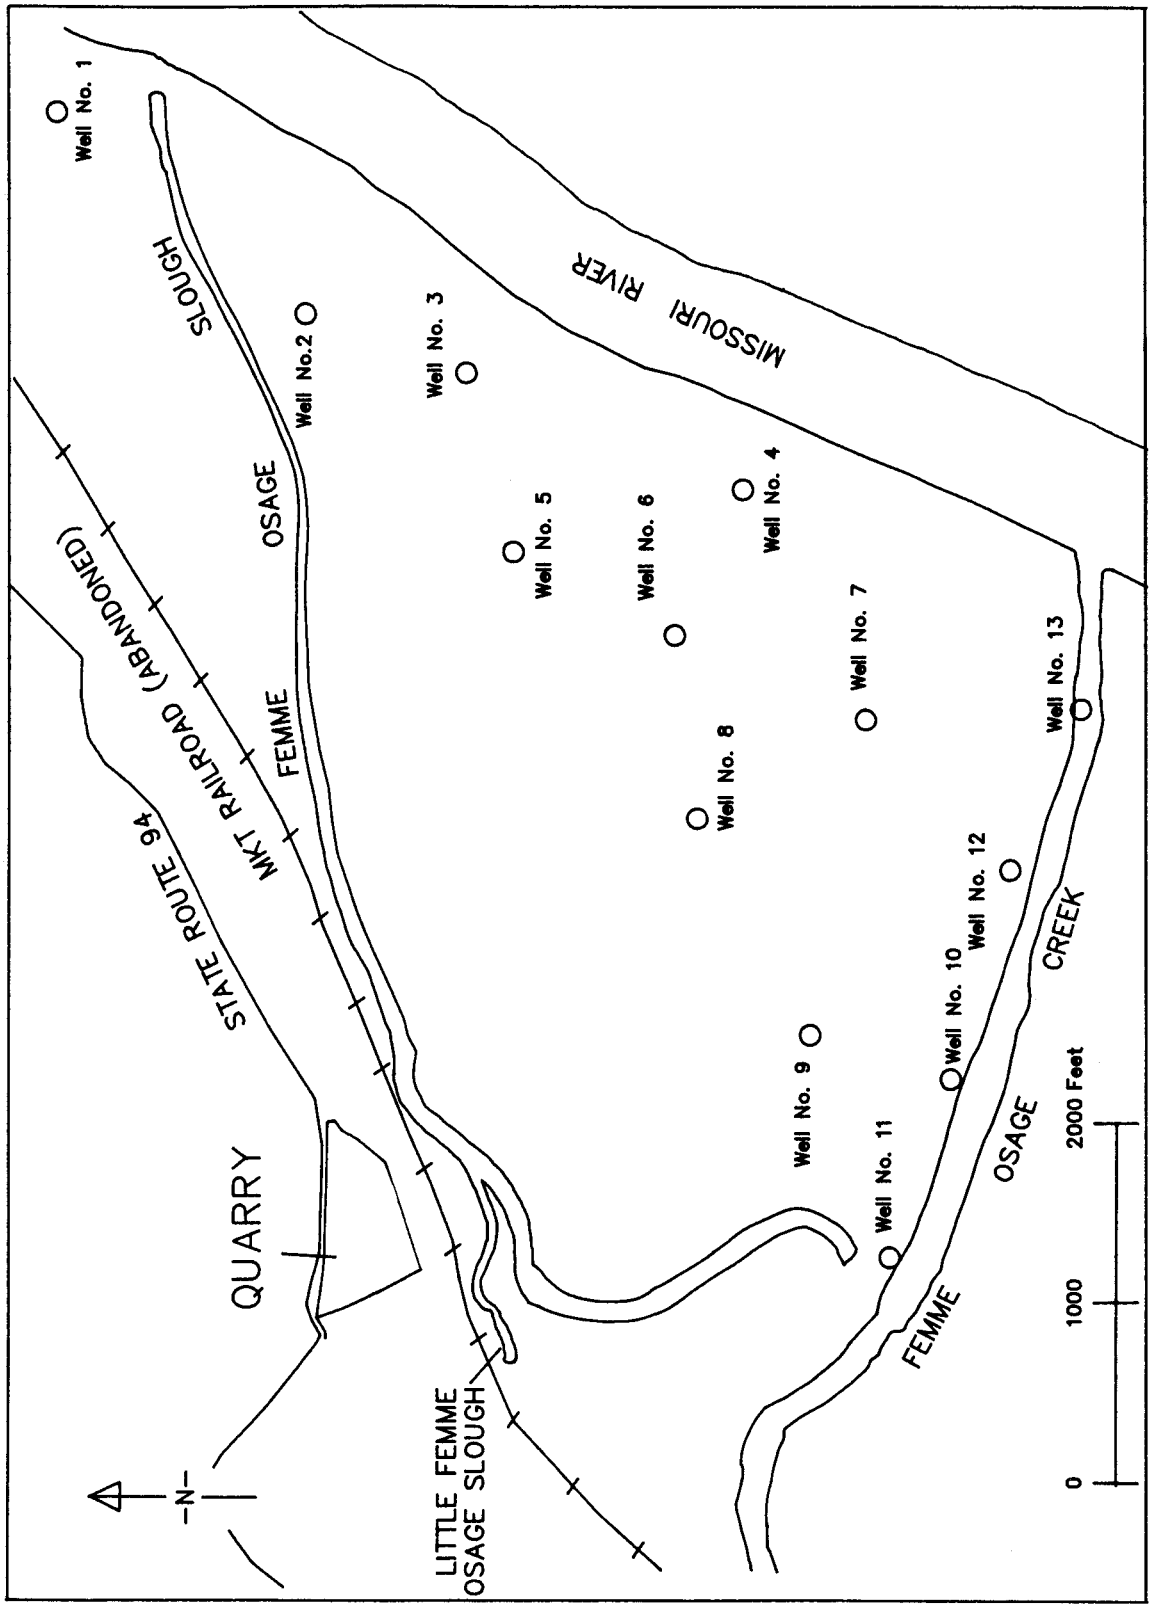

FIGURE 10 Surface Hydrological Features in the Vicinity of the Quarry and Location of Production Wells in the St. Charles County Well Field

The raffinate pits and chemical plant area is underlain by Quaternary age unconsolidated sediments and Paleozoic age bedrock formations. The unconsolidated materials in this area can be categorized into six units (see Table 1). The predominant soil type belongs to the Harvest-Urban land complex group and has a low permeability. More than 20 m (64 ft) of alluvial deposits overlie the bedrock in the Missouri River valley. Underlying the unconsolidated deposits is a thick sequence of limestones and sandstone bedrock formations of Paleozoic age. The uppermost limestone bedrock formation is fractured and contains many karst features, such as solution-enlarged cavities and voids that developed along bedding planes and northeast-trending joints. Other karst features that occur in St. Charles County include springs, losing streams, caves, and sinkholes (U.S. Dept. Energy 1987a).

TABLE 1 Unconsolidated Overburden Units in the Raffinate Pits and Chemical Plant Area

Unit	Characteristics	Thickness (m)
Topsoil	Sandy clay, blackish-brown, organic-rich.	0.15-1.5
Modified loess	Clayey silt, mottled gray-dark yellowish-orange, becomes dense and plastic with depth, manganese stained (the loess is modified in the sense that it contains higher than average clay content for loess).	0.3-4.6
Clay (Ferrelview Formation)	Clay, mottled gray-dark yellowish-orange, plastic, dense, manganese stained, contains weathered iron nodules.	0-4.6
Clay till	Clay, yellowish-brown, plastic, dense, manganese stained, blocky fractures, contains sand- to pebble-sized quartz, granitic rock, and chert dispersed throughout the clay matrix.	0.3-11.3
Basal till	Sandy, clayey silt, yellowish-brown, abundant in broken chert nodules, loosely bound by matrix.	0.3-2.4
Cherty clay	Multicolored brown, red, orange, and yellow, very dense, clay matrix with tightly bound abundant granular- to cobble-sized chert.	0-4.6

Source: U.S. Department of Energy (1987a).

The uppermost stratum at the quarry is Kimmswick limestone, and the quarry floor is Decorah shale. Limestone bedrock exposed on the quarry walls and on the steep bluffs along the Missouri River is predominantly Ordovician limestone, shale, dolomite, and sandstone.

A generalized stratigraphic column of geologic formations that are typically encountered in the vicinity of the Weldon Spring site is presented in Table 2. Also included are data on water-yielding capabilities of the different formations or formation groups. Primarily as a result of Paleozoic structural activity, the bedrock formations of the region have been formed into arches, basins, and other structures. The Weldon Spring site is located on the gently dipping east flank of the northwest-trending House Springs-Eureka anticline.

2.3.4 Hydrology

The Mississippi River is north and the Missouri River south of the Weldon Spring site. All runoff from land surfaces in the area eventually reaches the Mississippi or Missouri River. The combined flow of these two rivers at St. Louis averages about 5,100 m^3/s (180,000 cfs) (U.S. Dept. Energy 1987a).

Most of the raffinate pits and chemical plant area is located on the Mississippi River (northern) side of the drainage divide in the headwater of Schote Creek (Figure 9). Surface runoff from this area flows into nearby intermittent streams, Ash Pond, or Frog Pond on the chemical plant area (Figure 7). Surface discharges from the streams and Ash Pond combine near County Route "D" and flow northward to Lake 35 in the Busch Wildlife Area just southwest of U.S. Route 40/61; surface discharges from Frog Pond flow into Lake 36 in the Busch Wildlife Area (Figure 7). Schote Creek enters Dardenne Creek about 6 km (3.7 mi) northeast of the raffinate pits and chemical plant area and has a drainage area of about 13 km^2 (5 mi^2). Water in Dardenne Creek eventually reaches the Mississippi River near Seeburger, Missouri, about 32 km (20 mi) northwest of St. Louis (U.S. Dept. Energy 1987a).

Rainwater and snowmelt runoff and percolation enter various drains at the chemical plant area. The drains collect the water into the chemical plant process sewer, which exits on the southern slope of the drainage divide. Effluent from this exit flows to the Missouri River through a drainage ditch (Figure 7).

Preliminary estimates of flood peak discharges have been prepared by the U.S. Army Corps of Engineers, St. Louis District, for Schote Creek at several reaches and for different recurrence intervals. At the raffinate pits and chemical plant area, the 100-year and 500-year flood peak discharges at the main stem of Schote Creek are expected to be about 60 and 76 m^3/s (2,100 and 2,700 cfs). The 500-year flood elevation near the raffinate pits and chemical plant area would be about 160 m (530 ft) MSL. Thus, the area would not be affected by either a 100-year or a 500-year flood occurring in the main stem of Schote Creek (U.S. Dept. Energy 1987a).

TABLE 2 Generalized Stratigraphic Column in the Vicinity of the Weldon Spring Site

System	Series	Stratigraphic Units	Depth from Ground Level to Top of Formation (ft)	Thickness (ft)	Typical Thickness[a] (ft)	Physical Characteristics	Remarks
Quaternary	Holocene	Alluvium	0	0-65	10-30	Gravelly, silty loam over occasionally gravelly, silty clay loam.	Deposits underlie tributaries to the Missouri and Mississippi rivers.
				65-120	100-110	Silty loam, clay, and sand over sand and gravelly sand.	Deposits underlying the Missouri and Mississippi river floodplains generally yield large quantities of water to wells (600-2,600 gal/min).
	Pleistocene	Loess and glacial drift	0	0-150	5-30 30-60	Silty clay, silty loam, clay, or loam over residuum and bedrock, or both.	Yields little water to wells (<5 gal/min).
Pennsylvanian		Undifferentiated	0-120	0-75	b	Partly silty red shale with purplish-red to light gray clay.	Limited occurrence. Yields small quantities of water to wells (<1-10 gal/min).
Mississippian	Meramecian	St. Louis Limestone	0-120	0-105	70-75	Limestone: white to light gray, lithographic to finely crystalline, medium- to thick-bedded. Contains some shale.	Individually, the rock units yield small to moderate quantities of water to wells (5-50 gal/min). Collectively, these units yield sufficient water to supply most domestic and stock needs.
		Salem Limestone	0-225	0-140	90-130	Limestone: light gray to white, fine to coarsely crystalline, cross-bedded. Some siltstone and shale in lower part.	
		Warsaw Formation	0-345	0-95	70-90	Calcareous shales and interbedded shaly limestone, grades downward to shaly dolomitic limestone.	
	Osagean	Keokuk and Burlington Limestone	0-405	0-220	160-200	Limestone: white to bluish-gray, medium to coarsely crystalline, thick-bedded. Cherty.	
		Fern Glen Limestone	0-500	0-85	50-70	Limestone: yellowish-brown, fine-grained, medium- to thick-bedded. Contains appreciable chert.	
	Kinderhookian	Chouteau Limestone	0-580	0-105	50-70	Dolomitic limestone: gray to yellowish-brown, fine-grained, thin- to medium-bedded.	

TABLE 2 (Cont'd)

System	Series	Stratigraphic Units	Depth from Ground Level to Top of Formation (ft)	Thickness (ft)	Typical Thickness[a] (ft)	Physical Characteristics	Remarks
Devonian	Upper	Bushberg Sandstone	0-625	0-20	5-15	Quartz sandstone, reddish-brown, fine- to medium-grained, friable.	Yields small to moderate quantities of water to wells (5-50 gal/min).
		Lower part of Sulphur Spring Group, undifferentiated	0-625	0-60	35-40	Calcareous siltstone, and sandstone with oolitic limestone with some dark, hard, carbonaceous shale.	Group also includes Glen Park and Grassy Creek formations.
Ordovician	Cincinnatian	Maquoketa Shale	0-650	0-75	30-50	Calcareous or dolomitic shale, typically thinly laminated, silty, with shaly limestone lenses.	Yields small quantities of water to wells.
	Champlanian	Kimmswick Limestone	0-710	0-140	90-100	Limestone: white to light gray, coarsely crystalline, medium- to thick-bedded. Cherty near base.	Yields small to moderate quantities of water to wells (10-50 gal/min).
		Decorah Formation	0-810	0-35	30	Interbedded green and yellow shale, with thin beds of limestone.	
		Plattin Limestone	0-840	0-195	100-125	Limestone: light to dark gray, finely crystalline. Thin-bedded, weathers with pitted surface.	
		Joachim Dolomite	0-950	0-135	90-110	Dolomite: yellowish-brown, silty, thin- to thick-bedded. Grades into siltstone; shales common.	
		St. Peter Sandstone	0-1070	0-250	120-150	Quartz sandstone: yellowish white to white, fine- to medium-grained, massive-bedded.	Yields moderate quantities of water to wells (10-40 gal/min).
		Everton Formation	0-850	0-65	0	Sandy dolomite.	Everton Formation discontinuous.
	Canadian	Powell Dolomite	0-950	0-65	50-60	Dolomite: medium to finely crystalline, often sandy, occasionally cherty or shaly.	Generally yields small quantities of water to wells (<10 gal/min).
		Cotter Dolomite	0-1250	75-275	200-250	Dolomite: light gray to light brown, medium to finely crystalline. Cherty.	Argillaceous, interbedded with green shale.

TABLE 2 (Cont'd)

System	Series	Stratigraphic Units	Depth from Ground Level to Top of Formation (ft)	Thickness (ft)	Typical Thickness[a] (ft)	Physical Characteristics	Remarks
Ordovician (Cont'd)	Canadian (Cont'd)	Jefferson City Dolomite	100-1500	145-225	160-180	Dolomite: light brown to brown, medium to finely crystalline.	
		Roubldoux Formation	350-1700	150-170	150-170	Dolomitic sandstone.	Yields moderate to large quantities of water to wells (10-300 gal/min).
		Gasconade Dolomite	500-1850	250	250	Cherty Dolomite-Gunter Member is arenaceous dolomite.	Gunter Member is about 30 ft thick.
Cambrian	Upper	Eminence Dolomite	750-2100	190	200	Dolomite: medium- to massive-bedded, light gray, medium- to coarse-grained.	Yields moderate to large quantities of water to wells (10-500 gal/min).
		Potosl Dolomite	950-2250	100	100	Dolomite: massive, thick-bedded, medium- to fine-grained. Abundant quartz druse.	Fresh water only in southwest part of St. Charles County; saline water elsewhere in county.
		Derby Dolomite and Doe Run Dolomite	1050-2350	140	150	Dolomite: thin- to medium-bedded, alternating with thin-bedded siltstone and shale.	Hydrologic characteristics unknown in St. Charles County; occurs as a confining bed elsewhere in the state.
		Davis Formation	1200-2500	170	170	Contains shale, siltstone, fine-grained sandstone, dolomite, and limestone conglomerate.	
		Bonneterre Dolomite	1350-2650	430	400	Dolomite: typically light gray, medium- to fine-grained, medium-bedded.	Yields unknown in St. Charles County; however, water is probably saline.
		Lamotte Sandstone	1800-3100	460	450	Predominantly quartzose sandstone.	
Precambrian					2200-3500		Igneous rock. Yields no water.

[a]Typical thickness refers to thickness of formation normally encountered while drilling.

[b]Insufficient data for estimate.

Source: Data from Kleeschulte and Emmett (1986).

The quarry is located on the Missouri River (southern) side of the drainage divide (Figures 7 and 9). Surface streams in the vicinity of the quarry area include Femme Osage Creek, Little Femme Osage Creek, an unnamed tributary to Little Femme Osage Creek, and Femme Osage Slough (Figure 7). The Missouri River bottom at the quarry (river mile 49 from the confluence with the Mississippi River) is at an elevation of about 129 m (422 ft) MSL. Although the floodplain area below the quarry is partially behind a levee, the area floods occasionally to a depth of about 1 m (3-4 ft) and takes 1 to 2 months to dry; it is drained by a 41-cm (16-in.) diameter pipe through the levee (U.S. Dept. Energy 1987a).

A large volume of surface water currently exists in the raffinate pits, in ponds on the chemical plant area, and in the quarry. Although the amount of water in these impoundments varies significantly according to season, the raffinate pits generally contain about 216,000 m^3 (57,000,000 gal) and the quarry pond about 11,000 m^3 (3,000,000 gal). Two major ponds on the chemical plant area are Ash Pond and Frog Pond. Although the volume of water in Frog Pond varies throughout the year, it typically is 2,000 m^3 (500,000 gal). Ash Pond contains water intermittently, depending on seasonal precipitation events.

2.3.5 Buildings, Structures, and Other Facilities

Numerous buildings and structures associated with former ordnance works activities have been demolished or removed from the chemical plant area. The remaining buildings, facilities, and structures were used to support the chemical plant operations. Additional demolition and decontamination activities were conducted after cessation of operations. There are currently 13 major buildings, approximately 30 support structures, and other miscellaneous facilities and equipment in the chemical plant area -- including sewage treatment facilities, power lines, transformers, construction vehicles, and several office trailers. The major buildings, structures, and other facilities are listed in Table 3.

2.3.6 Local Land Use

Urban areas occupy about 6% and nonurban areas about 90% of St. Charles County (based on 1983 information). The remaining area is dedicated to transportation and water uses. It has been estimated that approximately 4% of the county's nonurban land will be converted to urban uses during 1980 to 2000 (U.S. Dept. Energy 1987a). The two closest communities to the site are Weldon Spring and Weldon Spring Heights, which are located about 3.2 km (2 mi) northeast of the raffinate pits and chemical plant area (Figure 7). The combined population of these two communities is approximately 800.

Development in the county has been dynamic in the past, and strong residential and commercial/industrial demands are anticipated to continue. The cities of St. Charles, St. Peters, O'Fallon, Lake St. Louis, and Wentzville are located along I-70 where major development has occurred. The area south of I-70 from St. Charles City to Wentzville and bounded by U.S. 40/61 to the west and the recently abandoned Missouri-Kansas-Texas (MKT) Railroad to the south is locally referred to as the "Golden

Triangle." This area is considered likely to experience the most growth in the coming decades. The Golden Triangle includes the cities of St. Charles, St. Peters, O'Fallon, Lake St. Louis, Wentzville, Weldon Spring, Cottleville, Harvester, Dardenne, and All Saints Village. In addition to development within the Golden Triangle, there is substantial development potential in other areas of the county.

The August A. Busch Memorial Wildlife Area is located to the north and the Weldon Spring Wildlife Area to the south and east of the raffinate pits and chemical plant area. Both of these wildlife areas are park-like tracts administered by the Missouri Department of Conservation and are dedicated to various kinds of recreational uses.

The University of Missouri operates the St. Charles County Extension Center and owns 300 ha (740 acres) of land to the east of the raffinate pits and chemical plant area. This land is currently used for pasture, but about 100 ha (250 acres) is being developed as a high-technology research park, which will remain under ownership of the University of Missouri. The purpose of the research park is to help stimulate the development of high-technology industries in the St. Louis area. A state of Missouri highway maintenance facility and Francis Howell High School are also located east of the raffinate pits and chemical plant area along State Route 94.

The St. Charles County water treatment plant is located on State Route 94 about 1.6 km (1 mi) northeast of the quarry. The design capacity of this treatment plant is 61,000 m^3/day (16 mgd), and it is currently processing about 76,000 m^3/day (20 mgd) from the county well field. Five workers operate three shifts over a 7-day period at the treatment plant, with three operators during the first shift and one operator during each of two subsequent shifts. During the summer months, two additional workers are hired to perform various jobs at both the water treatment plant and the nearby county well field. Subcontract personnel are utilized at the treatment plant on an as-needed basis.

The U.S. Army Reserve and National Guard Training Area is located immediately west of the raffinate pits and chemical plant area. No permanent personnel are currently assigned to the training area, although one individual may be assigned on an intermittent basis to perform such duties as answering the telephone and checking the grounds. Regular weekend training occurs at reduced levels compared to normal training operations at other facilities because certain activities (e.g., digging foxholes) are not permitted.

2.3.7 Ecology

The Weldon Spring site is located within the Bluestem Prairie, Oak-Hickory Forest Mosaic (northern) subsection of the Prairie Parkland province. The Oak-Hickory Forest (northern) subsection also occurs within the Weldon Spring area. Much of the land surrounding the Weldon Spring site is state-owned wildlife areas containing secondary growth forest (August A. Busch Memorial Wildlife Area, Weldon Spring Wildlife Area, and Howell Island Wildlife Area). Nonforested areas occur over much of St. Charles County and are largely used for crop production and pastures or are old-field habitat.

Habitat types within the vicinity of the Weldon Spring site include open fields and pastures, forests (upland, slope, and bottomland), and cultivated fields. Slope forests are similarly dominated by oak and hickory but also include sugar maple, American elm, and black walnut among the predominant species. Bottomland forests occur within the Missouri River floodplain and along stream and lake banks. Typical tree species can include willow, eastern cottonwood, silver maple, American elm, boxelder, red mulberry, pecan, oak (pin and bur), hackberry, and persimmon. Old-field habitat includes species such as Indian mallow, crabgrass, ragweed, aster, Canada thistle, mustard, fleabane, and goldenrod. Cultivated fields contain harvestable crops whereas pastures contain herbaceous plants for grazing. The raffinate pits and chemical plant area is essentially old-field habitat; however, mowing maintains much of the area in a pasture-like condition. The quarry consists of slope and bottomland forests, and eastern cottonwood is the predominant species.

Based on habitat preferences and ranges of Missouri mammals, over 30 species could be common to abundant in the area. These would include eastern cottontail rabbit, opossum, raccoon, white-tailed deer, and several species of mouse, vole, shrew, squirrel, bat, and fox. Several mammal species -- most notably the woodchuck, eastern mole, and plains pocket gopher -- dig burrows into habitat similar to that occurring at the raffinate pits and chemical plant area.

In the Busch Wildlife Area immediately north of the raffinate pits and chemical plant area, almost 300 species of birds have been observed. About one-third of these nest in the area whereas a smaller number are common to abundant throughout at least three seasons of the year. About 10 waterfowl species are common to abundant during the spring and fall migration, and a few species such as Canada goose, mallard, and wood duck nest and/or overwinter in the area. The ponds in the raffinate pits and chemical plant area and the quarry provide habitat suitable for waterfowl.

St. Charles County is within the range of more than 50 reptile and amphibian species. Some of these species occur at the Weldon Spring site due to the variety of terrestrial and aquatic habitats that are present.

Aquatic habitats in the vicinity of the Weldon Spring site include intermittent and permanent streams that drain the site, various-sized ponds and lakes, and the Mississippi and Missouri rivers that ultimately receive drainage from St. Charles County. The Busch Wildlife Area contains 32 lakes and ponds that support a warmwater fishery. Common species include carp, black bullhead, bluntnose minnow, fathead minnow, bluegill, black crappie, white crappie, gizzard shad, largemouth bass, and channel catfish (the channel catfish is regularly stocked). Lakes 34, 35, and 36 of the Busch Wildlife Area receive drainage from the raffinate pits and chemical plant area.

Based on habitats and distributions of Missouri fishes, the fish species that would most likely be abundant in streams in the site vicinity include carp, creek chub, redfin shiner, bigmouth shiner, fathead minnow, white sucker, green sunfish, orangespotted sunfish, johnny darter, and fantail darter. The major species in the Missouri and Mississippi rivers include gar, gizzard shad, carp, river carpsucker, buffalo, channel catfish, freshwater drum, white bass, sturgeon, paddlefish, blue catfish, and blue sucker. Largemouth bass, bluegill, and crappie are also abundant in backwaters and oxbows.

Three endangered species could be present in the Weldon Spring vicinity: bald eagle (*Haliaeetus leucocephalus*), fat pocketbook pearly mussel (*Potamilus capax*), and Higgins' eye pearly mussel (*Lampsilis higginsi*). No designated critical habitat currently exists in the project area. Although the specialized habitat requirements and/or preferences of these species are not generally met by the Weldon Spring site, it is possible that the more mobile species (such as the bald eagle) could intermittently occupy the site (U.S. Dept. Energy 1987a). The mussel species would not be found in any of the aquatic areas that may be designated for response action (e.g., ponds, lakes, ditches, and drainageways) because their habitat is limited to larger rivers.

2.3.8 Regional Climate

The climate in the Weldon Spring area is continental, with moderately cold winters and warm summers. Alternating warm/cold, wet/dry air masses converge and pass eastward through the area, almost daily. The variability of the climate is demonstrated by the record low and high temperatures for the state, i.e., -40°C (-40°F) and 48°C (118°F), recorded in 1905 and 1936, respectively. The monthly average temperature is 13°C (56°F), with the average daily minimum being 7°C (45°F) and the average daily maximum being 19°C (66°F).

Normal annual precipitation in the area is approximately 94 cm (37 in.), and the heaviest rainfalls occur in the spring and early summer. Summer rains frequently occur as thunderstorms, occasionally with hail and high winds. Locally, rainfalls can be very heavy; as much as 25 cm (10 in.) has been recorded in 24 hours. The three winter months are the driest, with an average precipitation totaling about 15 cm (6 in.); the three spring months are typically the wettest, with an average total near 30 cm (12 in.) (U.S. Dept. Energy 1987a).

Wind speeds and directions recorded at the Weldon Spring site during 1985 are illustrated in Figure 11. Prevailing winds in the vicinity of the Weldon Spring site are from the south during the summer and fall. Wind speeds during these months average 13.9 km/h (8.7 mph). Winds during the winter months are from the northwest and west-northwest, averaging 17.6 km/h (11 mph) (U.S. Dept. Energy 1987b). Tornadoes occur in the St. Louis area once or twice per year, most often in April and May.

2.4 RECENT ENVIRONMENTAL MONITORING AND SITE CHARACTERIZATION STUDIES

An environmental monitoring program is in place at the Weldon Spring site in accordance with DOE requirements. This program will continue for the duration of the project. During 1981 to 1985, DOE conducted environmental monitoring programs to identify changes (if any) in the radioactive contaminant levels in and around the raffinate pits and quarry. At that time, the raffinate pits and quarry were under caretaker status of the DOE, and the chemical plant was controlled by the Army. Following its assumption of responsibility for the chemical plant in 1985, DOE revised the overall environmental monitoring program to provide a more comprehensive determination of the levels of radioactive and chemical contamination in and around the chemical plant,

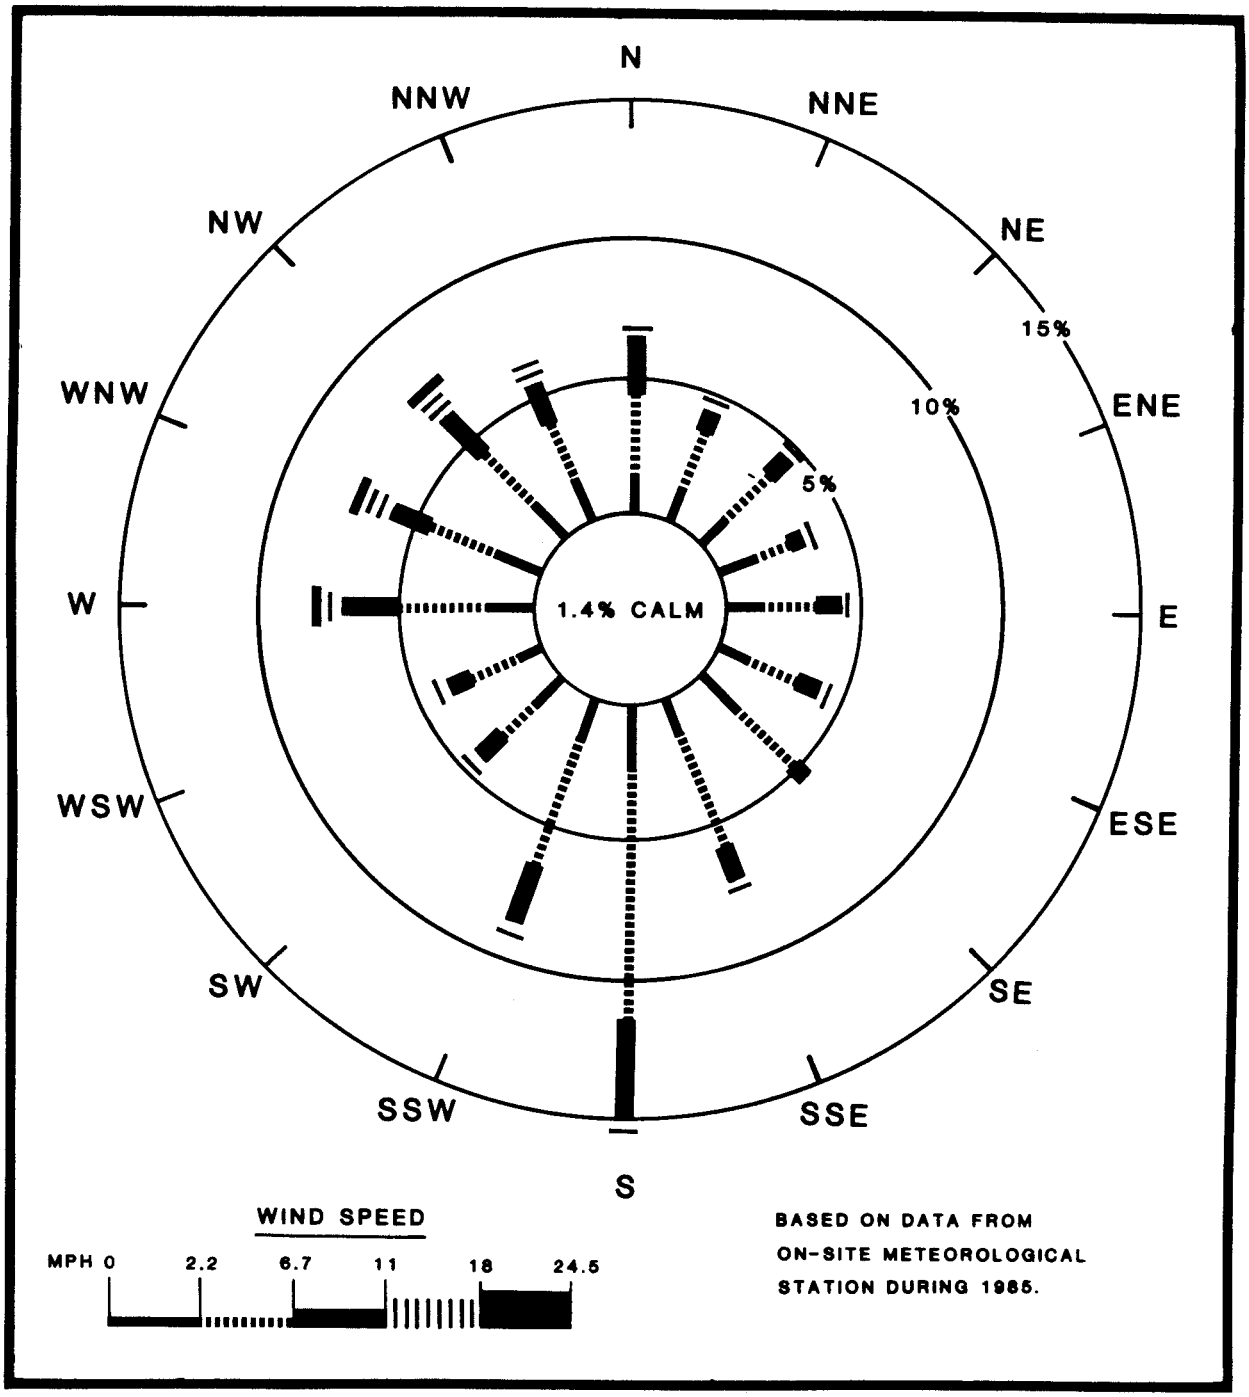

FIGURE 11 Annual Wind Rose for the Weldon Spring Site in 1985 (Source: Bechtel National 1986)

raffinate pits, and quarry. Six monitoring wells were installed in the quarry area, and 19 new wells were installed in and around the chemical plant where no monitoring wells had previously existed. These well installations were completed in late 1986. In addition, fugitive dust samplers were installed around the perimeter of the Weldon Spring site and at nearby locations (U.S. Dept. Energy 1987b).

In 1984, a radiological characterization of the quarry was completed. During this characterization effort, selected samples were analyzed for a variety of chemical species. These data became available in late 1985 and early 1986. The results led to a second, more comprehensive characterization of the quarry materials that emphasized chemical determinations. The results of the second study became available in March 1987. A sampling effort was also performed in 1986 to chemically characterize the sludge material in the raffinate pits (U.S. Dept. Energy 1987b).

Agencies other than DOE were also involved in sampling activities at the Weldon Spring site during 1986. Both the U.S. Geological Survey and the Missouri DNR collected samples from the quarry and the raffinate pits (U.S. Dept. Energy 1987b).

In 1987, DOE initiated the Phase I water quality assessment (U.S. Dept. Energy 1987c) to evaluate baseline water quality at the Weldon Spring site. Information gathered during this sampling program has been used to guide subsequent characterization activities. The Phase I program consisted of sampling 50 existing and new monitoring wells and 23 surface water locations. Groundwater samples were analyzed for nitroaromatics, select inorganic anions, various water quality indicators, radionuclides, and the complete Target Compound List (TCL) (U.S. Environ. Prot. Agency 1986a). Surface water samples were analyzed for radionuclides, select inorganic anions, various water quality indicators, and TCL metals at selected locations. Results from this monitoring program indicated the presence of high concentrations of nitrates and sulfates and significant quantities of nitroaromatics, particularly 2,6-DNT, in the groundwater at the Weldon Spring site (U.S. Dept. Energy 1987c).

An extensive field program was conducted by DOE from April to July 1987 to characterize the horizontal and vertical extent of radioactive contamination in the raffinate pits and chemical plant area (Marutzky, Colby, and Cahn 1988). This field program included exposure-rate measurements taken at the ground surface and at 1 m (3 ft) above the surface to delineate areas of elevated exposure rates. At locations exhibiting elevated exposure rates, in-situ measurements of uranium, radium, and thorium-232 were taken. If in-situ measurements showed elevated concentrations, soil samples were collected and analyzed for these elements. Randomly selected soil samples were also collected and analyzed.

Section 2.5 of this work plan summarizes the nature and extent of radioactive and chemical contamination at the Weldon Spring site, based upon currently available information. Section 4 of the work plan summarizes the rationale for developing the various field sampling and analysis plans that will be used to obtain the data needed to support detailed environmental analyses.

2.5 SUMMARY OF RECENT SITE CONTAMINATION DATA

The nature and extent of contamination at the Weldon Spring site will be further defined during the site characterization (RI) phase of this project. The following discussion is a brief summary of the known and suspected nature and extent of contamination at the raffinate pits and chemical plant area and the quarry, based upon studies that have been conducted since 1984. The individual sampling plans being developed (see Section 4.2) are designed to complete the characterization data base resulting from these studies. The discussion is generally organized by site area (i.e., raffinate pits and chemical plant area, quarry, and vicinity properties).

2.5.1 General

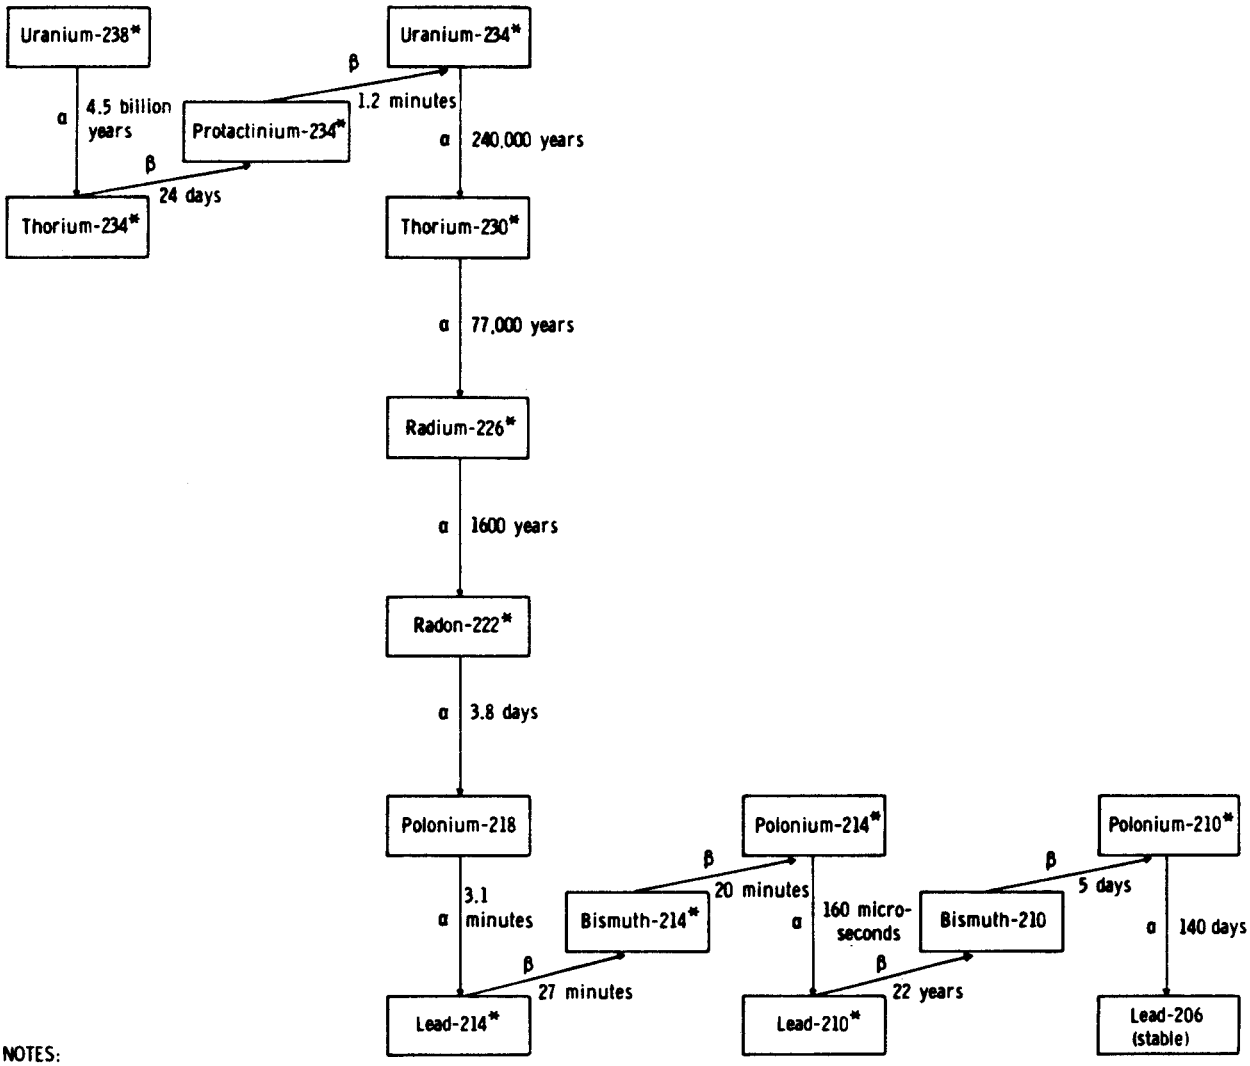
Radioactive and nonradioactive (i.e., chemical) contamination has been detected at the Weldon Spring site. In addition, some nearby vicinity properties are also contaminated with radioactive and chemical contaminants originating from the raffinate pits and chemical plant area and/or the quarry.

Uranium and thorium ore concentrates and some scrap metal were processed at the chemical plant during its operational period. An estimated 600,000 m^3 (780,000 yd^3) of radioactively contaminated materials resulted from these past operations, and these materials are currently located at the Weldon Spring site. Sludges in the raffinate pits and quarry, which comprise about one-third of the total volume of contaminated materials, contain most of the radioactive contaminants. About two-thirds of the total volume of contaminated materials consists of soil and rubble. These materials are contaminated with naturally occurring radionuclides of the uranium-238 and thorium-232 decay series (Figures 12 and 13). The estimated concentrations and inventories of the major radionuclides at the raffinate pits, chemical plant, and quarry are listed in Table 4.

Nonradioactive chemicals -- such as nitroaromatics, heavy metals, strong acid salts, and some other organics -- are present at the site due to TNT production and/or uranium-processing activities. In addition, contaminants such as polychlorinated biphenyls (PCBs) and asbestos are present because of previous uses of equipment and buildings at the site.

2.5.2 Raffinate Pits and Chemical Plant Area

Raffinate pits 1, 2, and 3 contain raffinate sludge and slag resulting from the refining of uranium ore concentrates and the recycling of scrap metal carried out at the chemical plant. Pit 4 contains similar slag and sludge as well as wastes from the processing of thorium-containing materials and drums and rubble from the partial decontamination of the chemical plant. The physical characteristics of these wastes and the volume of wastes in each pit are given in Table 5. It is estimated that the pits contain a total of about 170,000 m^3 (220,000 yd^3) of wastes.



NOTES:

Only the dominant decay mode is shown.
The times shown are half-lives.
The symbols α and β indicate alpha and beta decay.
An asterisk indicates that the isotope is also a gamma emitter.

FIGURE 12 Uranium-238 Radioactive Decay Series

The wastes in the pits are generally stratified and heterogeneous. The amount of surface water covering the wastes varies during the year. In summer, all surface water may evaporate from pits 1 and 2, but surface water is always present in pits 3 and 4. Pits 1 and 2 have not been dry since 1982. Pit 3 is designed to overflow into pit 4 through a pipe in the dike wall common to both pits. Pit 3 contains the largest volume of wastes.

Thorium-230 is the predominant radionuclide in the pit wastes. The average concentration of thorium-230 in the raffinate sludge is estimated to be 3,500 pCi/g (wet

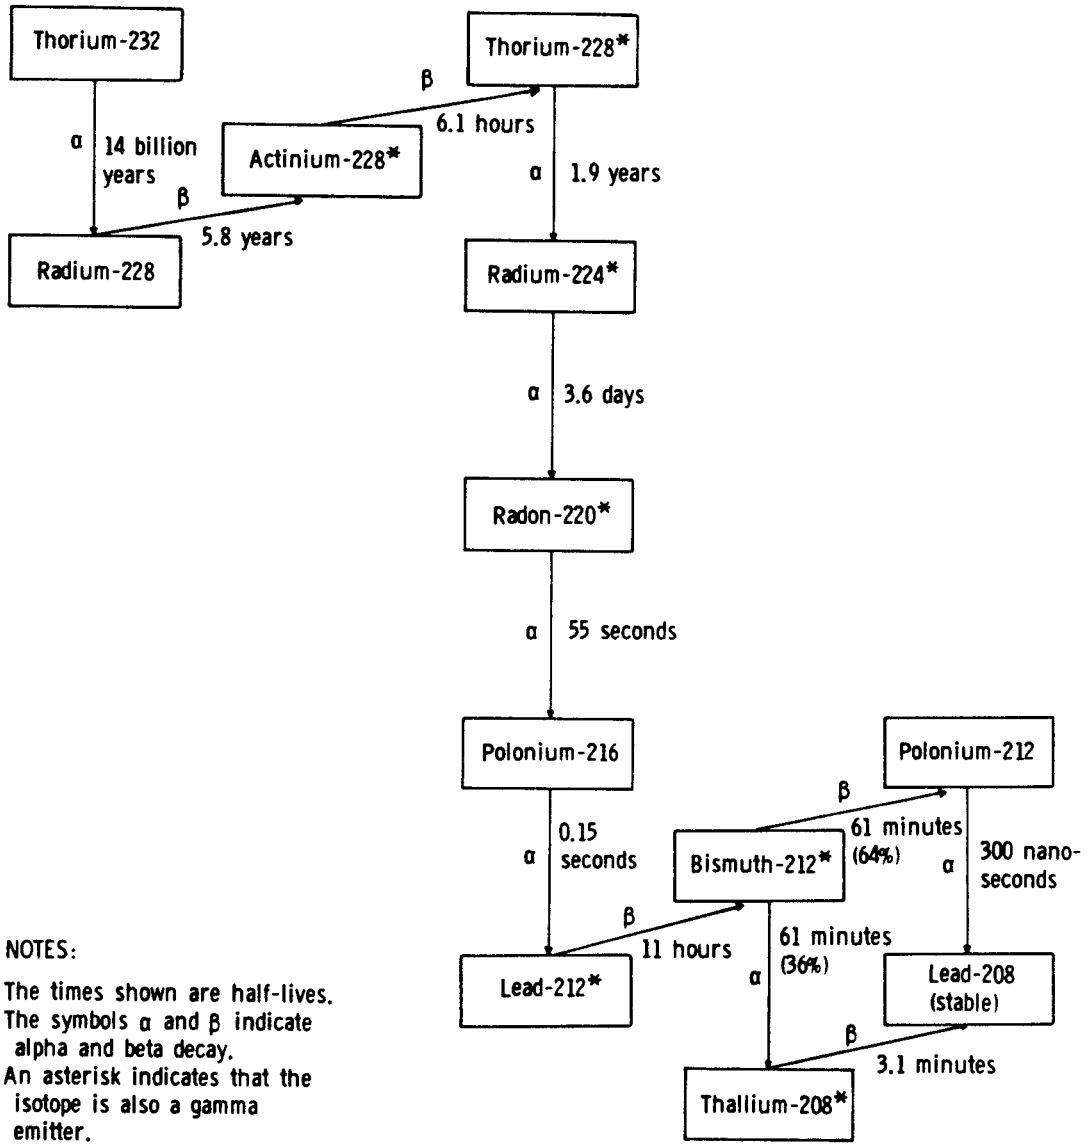


FIGURE 13 Thorium-232 Radioactive Decay Series

wt.), and the total inventory is estimated to be 700 Ci. For radium-226, the average concentration and total inventory in the wet sludge are 97 pCi/g and 20 Ci, respectively. Because of ingrowth of radium-226 from the radioactive decay of thorium-230 (which has a half-life of 77,000 years), the concentration of radium-226 in the raffinate sludge (averaged over the four pits) will increase to a peak concentration of 3,200 pCi/g (wet wt.) in about 9,000 years. After this, the radium-226 concentration will decrease at the same rate as the parent thorium-230.

The raffinate sludge has high concentrations of several metals, including iron, lead, magnesium, and molybdenum. The principal anions are nitrate, sulfate, and fluoride. In 1984, a composite sample of raffinate sludge was analyzed for 82 organic priority pollutants (19 pesticides, 7 PCBs, and 56 acid and base/neutral compounds) and

TABLE 4 Summary of Radioactive Concentrations and Inventories of the Weldon Spring Wastes

Species	Average Concentrations (pCi/g) and Inventories (Ci)[a]					
	Raffinate Pits[b]		Quarry		Chemical Plant	
	pCi/g	Ci	pCi/g	Ci	pCi/g	Ci
Uranium-238[c]	150	30	170	30	20	7
Thorium-232	32	6	16	3	3	1
Thorium-230	3,500	700	540	90	6	3
Radium-226	97	20	63	10	3	1

[a]Inventory values for all wastes and average concentrations for the chemical plant wastes are estimated to one significant figure.

[b]Concentrations are given in terms of the wet sludge.

[c]The amounts of uranium-238, uranium-235, and uranium-234 are assumed to be present in their natural activity ratio, 238:235:234 = 1:0.046:1.

13 organic nonpriority pollutants. All concentrations were reported as being below detection limits, which varied from 0.1 to 1 ppm for the different individual compounds (U.S. Dept. Energy 1987a).

Water in the pits exists in two phases: free water above the sludge and water in intimate contact and bound to the raffinate material making a sludge or gel. The water in intimate contact with the raffinate material would be expected to have higher concentrations of dissolved solids than free water standing over the sludge.

Surface water sampling locations and groundwater monitoring well locations for the raffinate pits and chemical plant area are shown in Figures 14 and 15, respectively. The radiological results of the Phase I water quality assessment are presented in Table 6 (groundwater at the raffinate pits and chemical plant area), Table 7 (surface water in the raffinate pits), and Table 8 (surface water near the raffinate pits and chemical plant area). According to these results, elevated concentrations of uranium are present in surface water in the four raffinate pits and at off-site sampling locations.

The radioactive contamination on the chemical plant area occurred during the plant's operational period. From June 1957 to December 1966, the feed materials plant was used to process uranium concentrates in the form of sodium diuranate containing 70% uranium. Small amounts of materials containing depleted and slightly enriched uranium were also processed, and thorium concentrates were processed in 1965 and 1966. Uranium is the main radioactive contaminant at the chemical plant area. Estimated concentrations of uranium-238 range from 3.9 to 50,000 pCi/g, with a total estimated inventory of 7 Ci (U.S. Dept. Energy 1987a). Estimated concentrations and inventories of radium-226, thorium-230, and thorium-232 are much lower (see Table 4).

The presence of gamma-emitting radionuclides at the raffinate pits and chemical plant area results in elevated exposure rates. The areas having exposure rates above background levels are shown in Figure 16.

The primary nitroaromatic compounds associated with the Weldon Spring site are 2,4-DNT, 2,6-DNT, and TNT. Decomposition products of these compounds are also present in small quantities. Nitroaromatics have been detected in the soil, surface water, and groundwater at the Weldon Spring site. Figure 17 shows the groundwater monitoring wells in which detectable levels of nitroaromatics have been measured at the raffinate pits and chemical plant area. Traces of nitroaromatics have also been detected in the surface waters of Frog Pond, Ash Pond, and raffinate pit 2 (U.S. Dept. Energy 1987c). Potential nitroaromatic source areas at the raffinate pits and chemical plant area are shown in Figure 18.

Metal contamination is prevalent at the raffinate pits and chemical plant area. High concentrations of lead, iron, magnesium, and molybdenum have been reported in the raffinate pit sludge (U.S. Dept. Energy 1987a). In general, metal concentrations have been at or below normal background levels in recent analyses of groundwater and surface water samples. However, elevated levels of chromium, lithium, magnesium, nickel, and vanadium have been detected in samples of groundwater from monitoring wells 3007 and 3008 (see Figure 15).

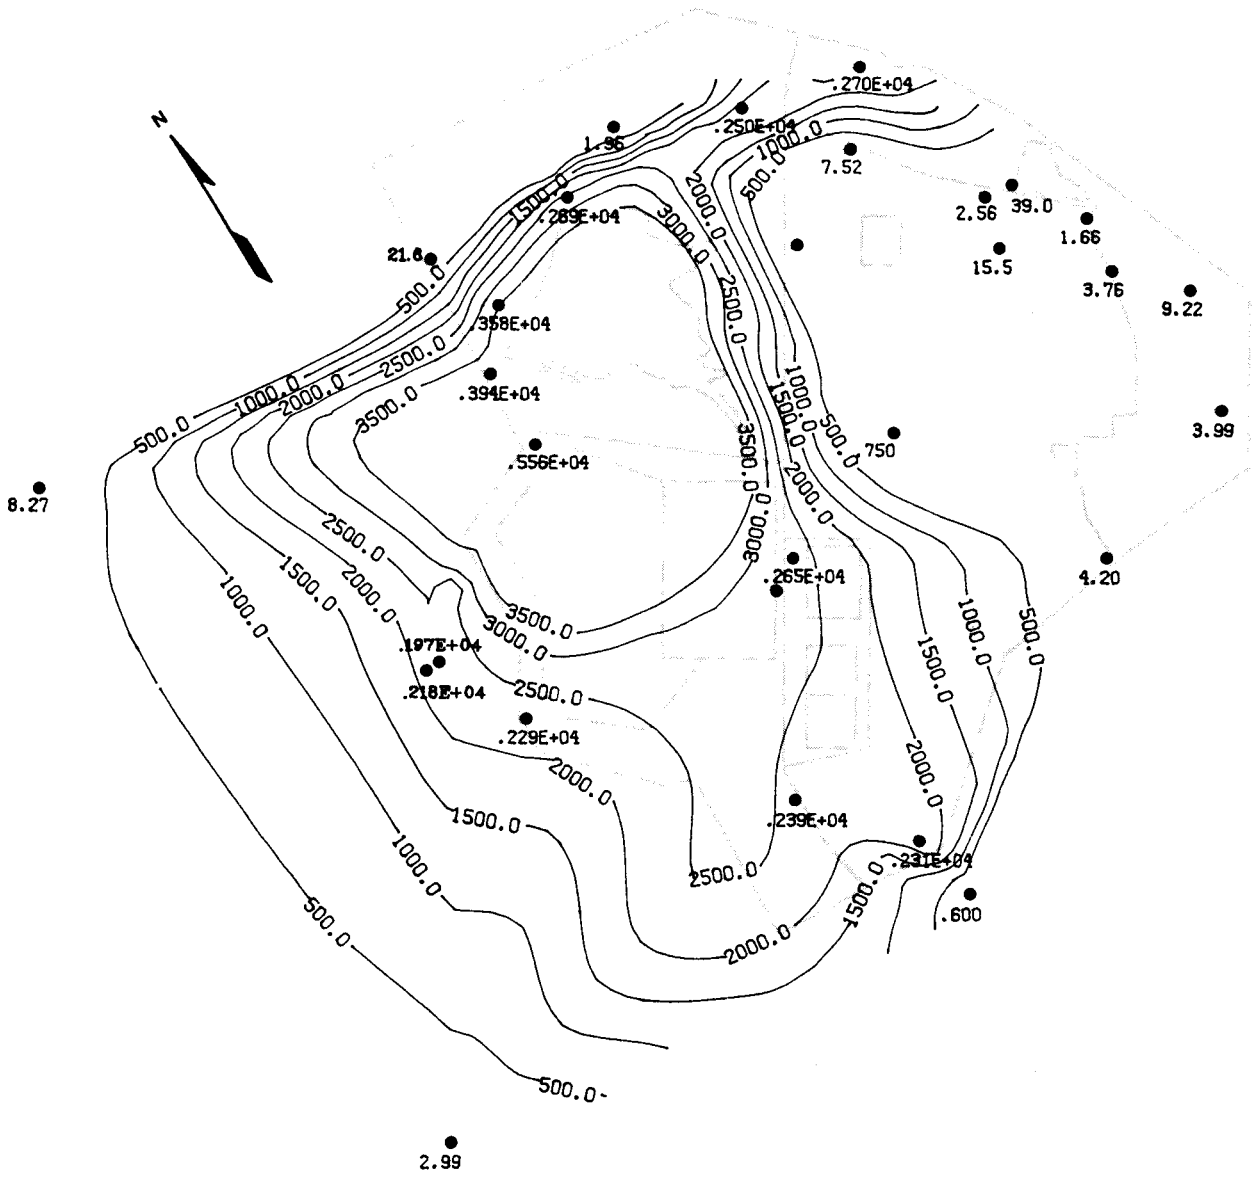

FIGURE 19 Nitrate Isopleth (mg/L as nitrate) in Groundwater at the Raffinate Pits and Chemical Plant Area (Source: Modified from U.S. Department of Energy 1987c)

Inorganic contaminants are present in the soil, groundwater, surface water, buildings, and wastes at the Weldon Spring site. Nitric acid and hydrofluoric acid were used extensively at the chemical plant. High levels of nitrates, sulfates, and fluorides are present in the raffinate pit sludge; high levels of nitrates and sulfates are present in the groundwater beneath the raffinate pits and chemical plant area (see Figures 19 and 20 for nitrate and sulfate isopleths). Inorganic anion and water quality data obtained in March and April 1987 from surface water (including raffinate pits water) and groundwater sampling are presented in Tables 9, 10, and 11.

Tributyl phosphate in hexane and other organics were used in uranium processing at the chemical plant. Two stainless steel tanks currently at the plant are partially filled

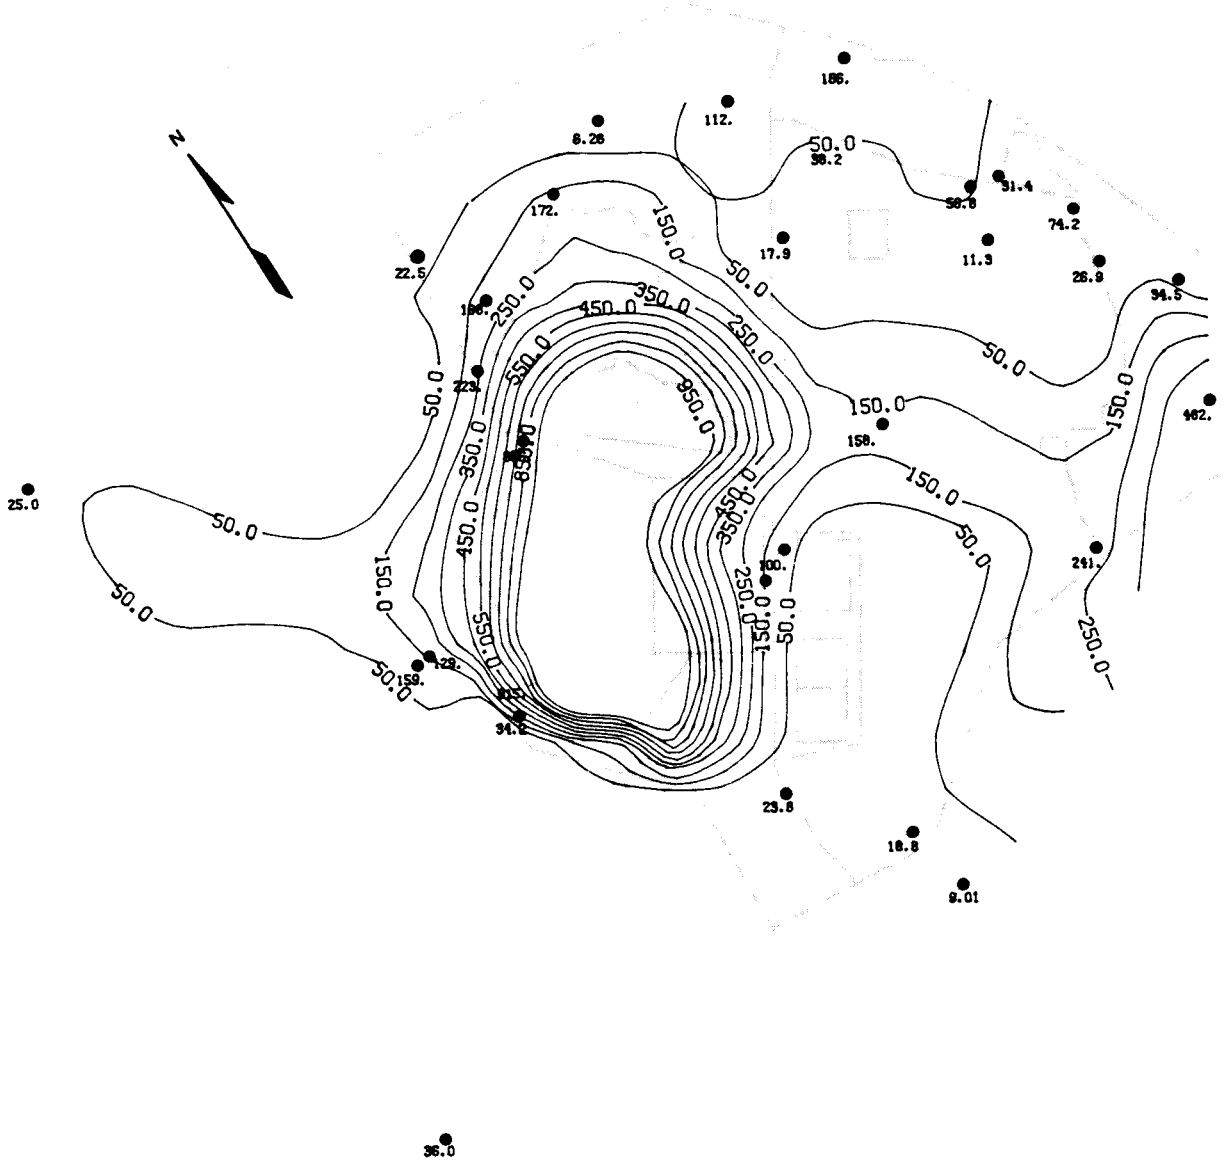

FIGURE 20 Sulfate Isopleth (mg/L) in Groundwater at the Raffinate Pits and Chemical Plant Area (Source: Modified from U.S. Department of Energy 1987c)

with solutions of tributyl phosphate/kerosene oil (a total volume of 30 m^3 [8,000 gal]), and these solutions have elevated concentrations of uranium. Samples from these tanks are currently being evaluated to assess potential reprocessing and disposal alternatives. Other tanks on-site appear empty but were previously used to store hydrofluoric acid, nitric acid, sulfuric acid, caustic soda solutions, propane, and hexane. All process tanks are located above ground; however, several underground tanks were previously used to store petroleum products.

At the chemical plant, 15 transformers contained PCB fluids in the range of 30-40% by volume. In addition, several electrical components -- including transformers, capacitors and switches -- contained PCB-contaminated fluids at PCB concentrations of

less than 500 ppm (see Figure 21 and Table 12). These fluids and electric equipment have recently been removed from the site (see Section 3.10.2.1). Also, PCB contamination has been found in storage areas, on concrete pads and some building floors, and in localized areas of soil. No PCBs have been detected in groundwater or surface water samples.

Asbestos is present in many areas of the chemical plant, including overhead pipelines inside and outside of buildings, and cement-asbestos siding and internal insulation of some buildings. Asbestos pipeline insulation is typically secured to pipelines with an outer cover of nonasbestos material; this cover has deteriorated in many areas, particularly on outside lines that are exposed to the elements, and asbestos has fallen to the ground or floor. Some pipes have been dismantled and stored in spoil piles, and asbestos remnants are visible in many areas. Asbestos contamination is likely to be present at the following locations:

- Chemical plant buildings and associated indoor and outdoor pipes,
- Pipes adjacent to raffinate pits 1 and 3,
- Soils and sediments, including those from Ash Pond, Frog Pond, and areas northwest and south of Ash Pond,
- Other on-site surface impoundments, including the raffinate pits,
- Soils in localized areas traversed by outdoor pipes, and
- Spoils piles.

Known locations of asbestos at outdoor locations of the chemical plant are shown in Figure 22.

2.5.3 Quarry

The quarry was used for the disposal of chemically and radioactively contaminated materials intermittently from the early 1940s to 1968. The chemically contaminated materials are largely TNT-contaminated rubble and soil. The radioactive materials are those associated with uranium- and thorium-processing activities previously carried out at the chemical plant and at other sites in the St. Louis area. Some of these wastes may be classified as *mixed wastes*, i.e., radioactive wastes that also meet the criteria for classification as hazardous wastes under the Resource Conservation and Recovery Act (RCRA).

The concentrations of radioactive species in boreholes drilled into the quarry wastes vary greatly, as a function of both depth within a borehole and borehole location. It has been estimated that there are 73,000 m^3 (95,000 yd^3) of contaminated wastes in the quarry (U.S. Dept. Energy 1987a). Compared with the raffinate sludge, the concentration and inventory of thorium-230 are lower in the quarry wastes, but the uranium-238 concentration and inventory are similar (Table 4). In addition to uranium,

elevated concentrations of several metals -- including arsenic, copper, lead, and nickel -- have been detected. The presence of gamma-emitting radionuclides in the quarry results in elevated exposure rates. Areas at the quarry having exposure rates above background levels are shown in Figure 23.

Organic volatile and semivolatile compounds, nitroaromatic compounds, PCBs, and pesticides were detected in samples of soils, sludges, and sediments collected from 17 borings. Volatile organics detected in one or more boreholes included methylene chloride, xylene, and ethyl benzene at concentrations ranging from 1 to 50 ppm. (Volatile compounds were probably introduced into field samples during collection or analysis, based on their presence in test and sample blanks.) Semivolatile organic compounds detected in one or more boreholes included the polycyclic aromatic hydrocarbons (PAHs) phenanthrene, fluoranthene, and benzo(b)fluoranthene at maximum concentrations of 150, 190, and 110 ppm, respectively. The maximum value detected for subsurface nitroaromatic compounds was 1,600 ppm for TNT, and the maximum value for PCBs was 120 ppm for Aroclor 1254 (Kaye and Davis 1987). Surficial discoloration of soils in the eastern portion of the quarry (Figure 24) indicates the presence of nitroaromatic compounds that were subsequently determined to be at levels of 1 to 2%.

Groundwater monitoring locations near the quarry are shown in Figure 25. Results obtained during the Phase I water quality assessment and from routine environmental monitoring are presented in Table 13 (radiological parameters), Table 14 (nitroaromatics), Table 15 (metals), and Table 16 (inorganic anion species and water

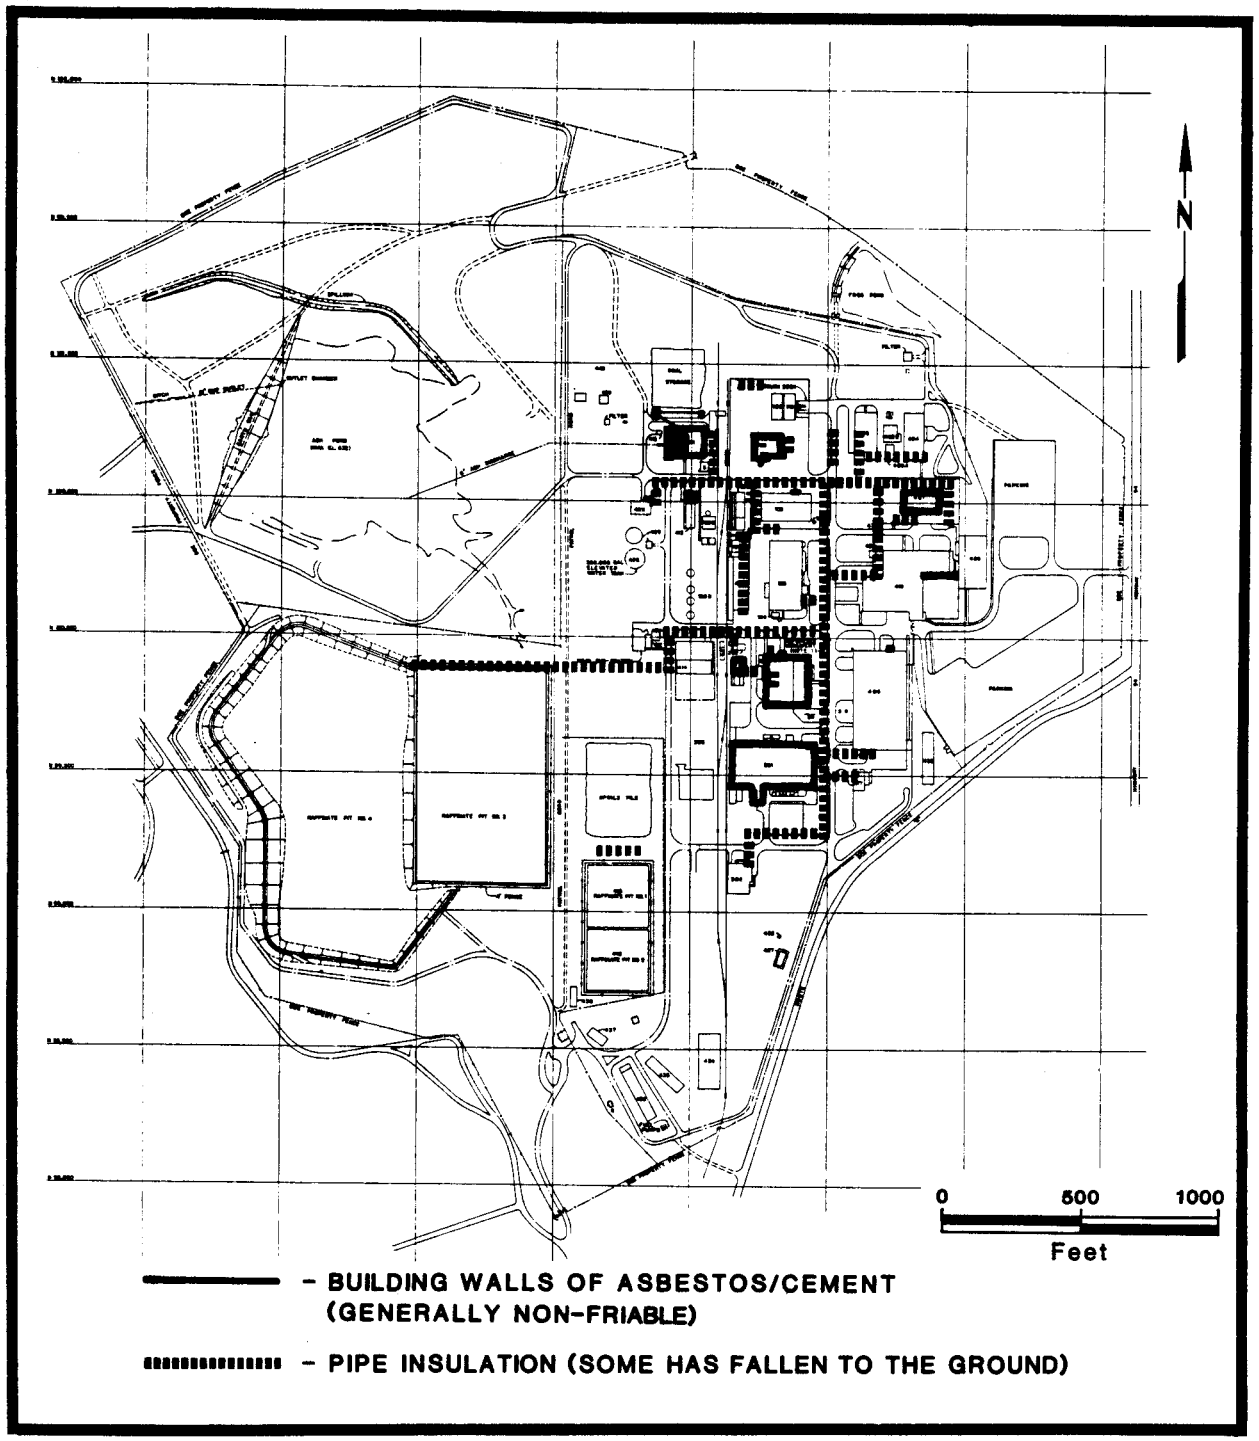

FIGURE 22 Known Locations of Asbestos at Outdoor Locations at the Raffinate Pits and Chemical Plant Area

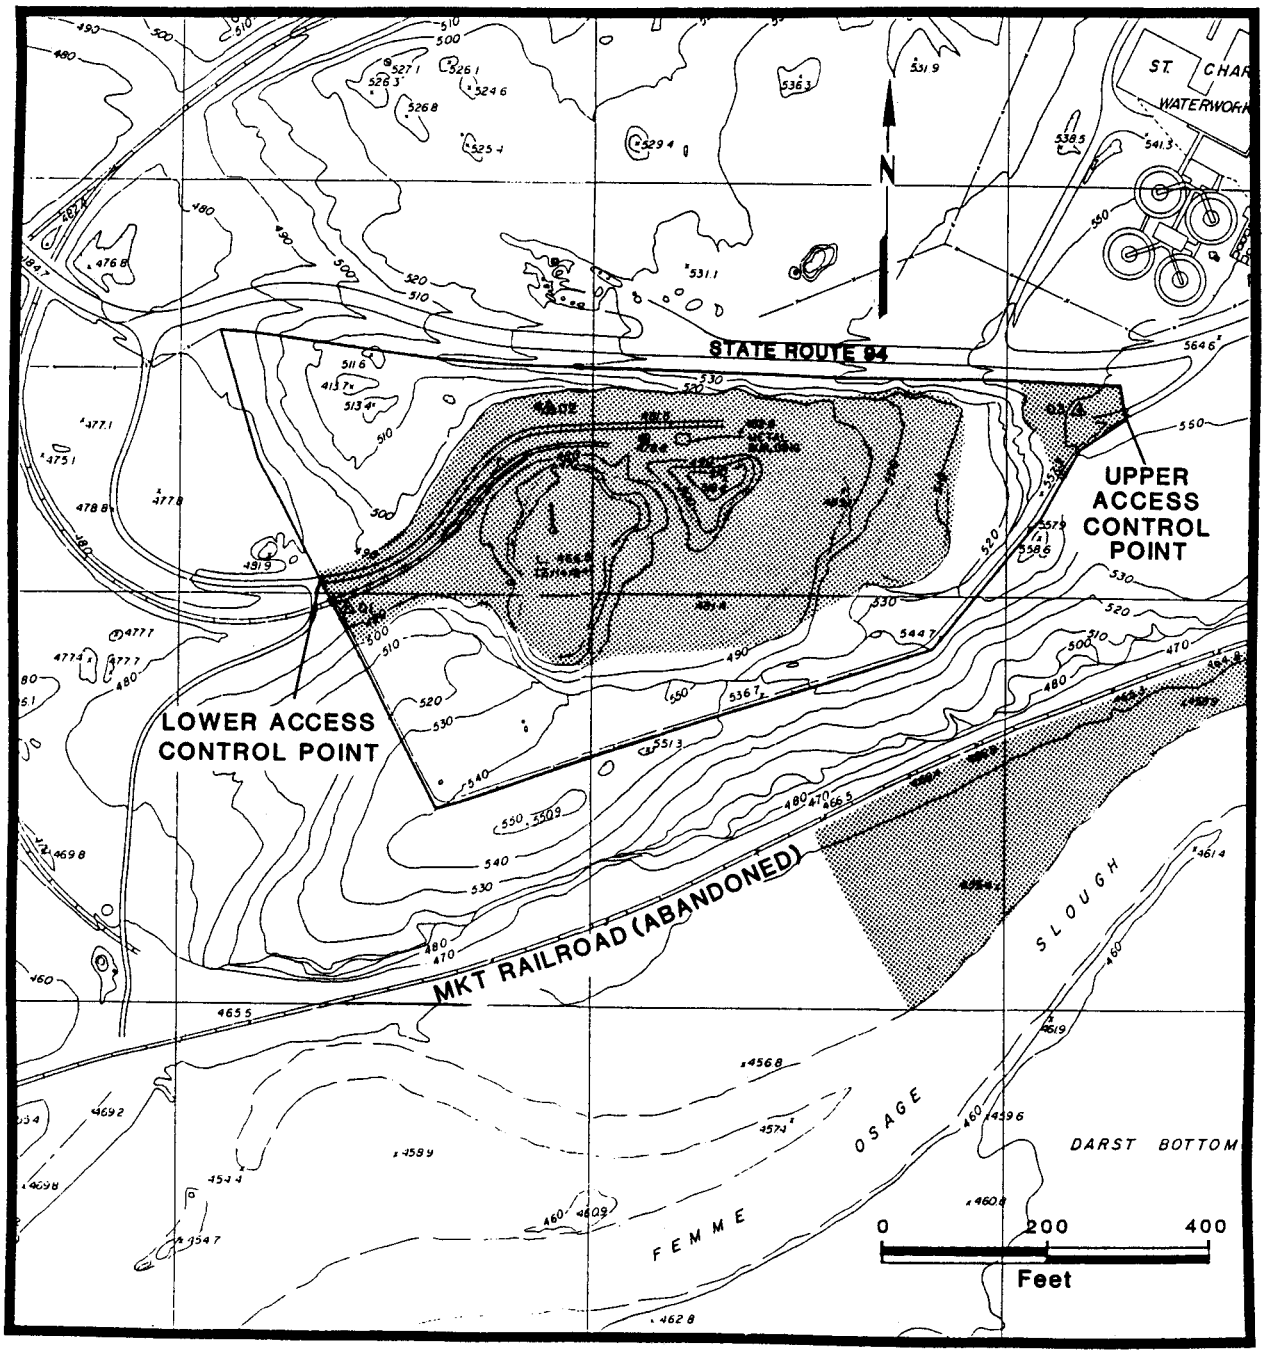

FIGURE 23 Areas at the Quarry that Have Exposure Rates above Background

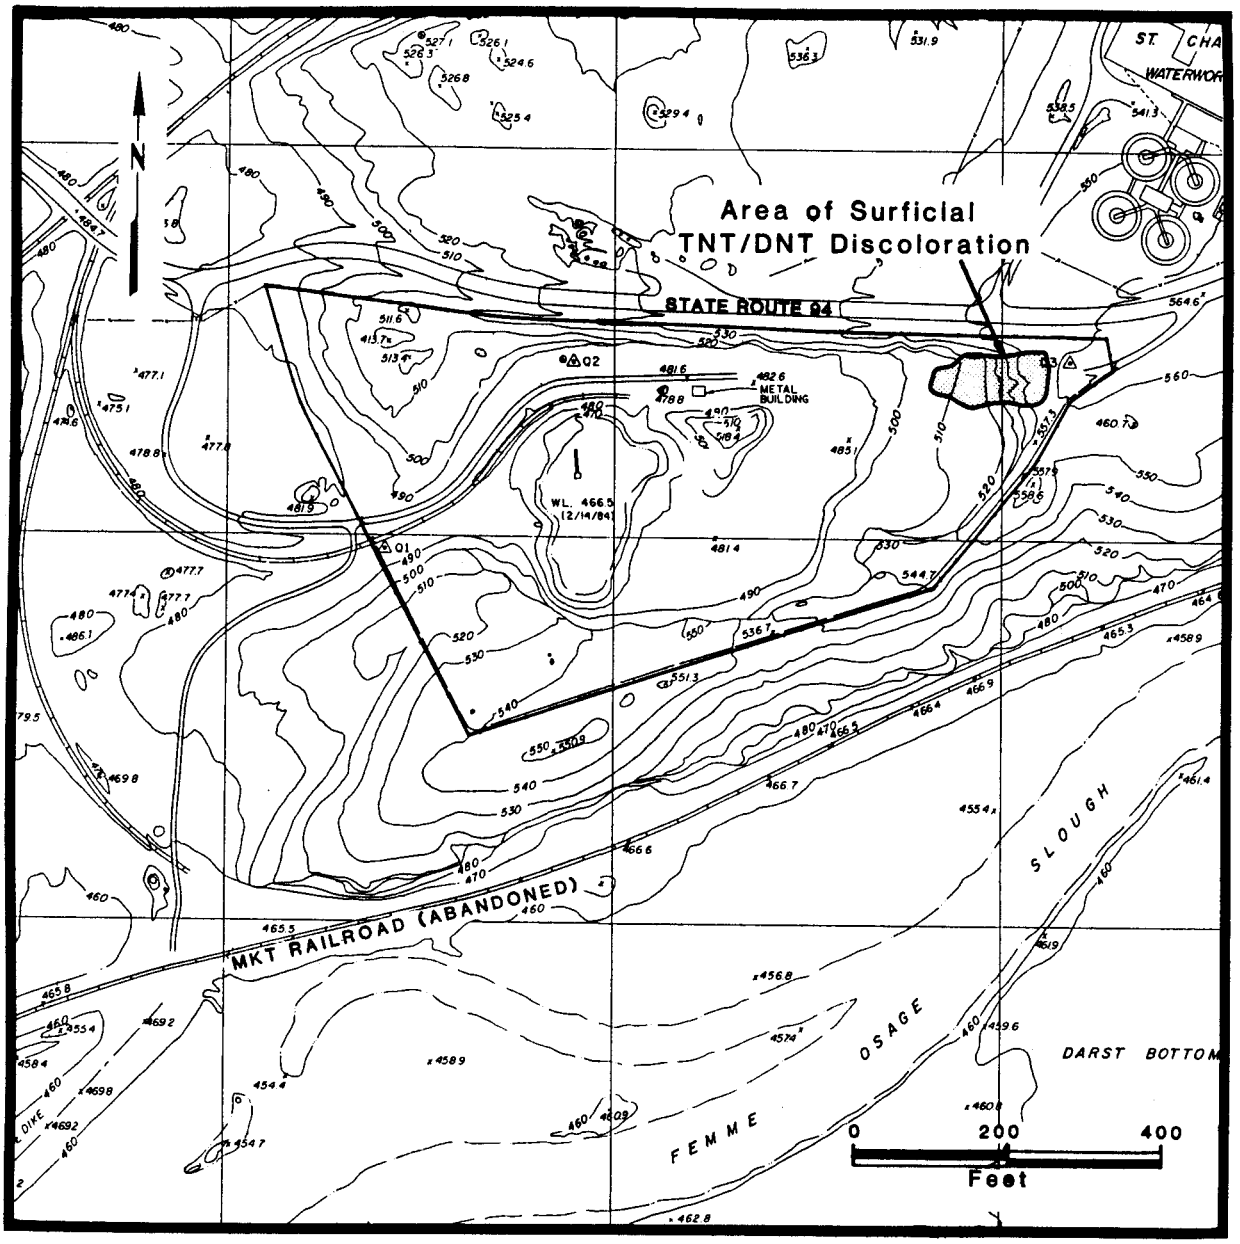

FIGURE 24 Area of Surficial TNT/DNT Discoloration at the Weldon Spring Quarry

quality parameters). The results indicate the presence of nitroaromatic compounds in wells completed in Decorah limestone and in certain alluvial wells north of the Femme Osage Slough. Three volatile organic compounds -- ethyl benzene, toluene, and xylene -- were detected in two alluvial wells (MW-1008 and MW-1009) at concentrations ranging from 8 to 20 ppb. These are the same volatile organic compounds detected in the quarry waste materials. Although subsequent quarterly sampling of these and other alluvial wells failed to detect these compounds, sampling and analysis for volatile organic compounds will continue. Semivolatile organic compounds, PCBs, and pesticides have not been detected in any of the quarry monitoring wells. The metal concentrations in both

[e]Missouri drinking water standard.

limestone and alluvial groundwater appear consistent with background levels for the respective aquifers.

Surface water monitoring locations are shown in Figure 26, and the measured radiological parameters are presented in Table 17. The main contaminant in the quarry pond (SW-1008) is uranium, which was recently measured at an average concentration of 2,100 pCi/L. Analysis of water samples from wells in the limestone bluff and in the alluvium between the quarry and the slough indicate that uranium has migrated from the quarry (Kleeschulte and Emmet 1987).

Contaminant migration from the quarry into the alluvium and Femme Osage Slough was investigated in 1987 using uranium as an indicator (Marutzky, Colby, and Cahn 1988). Samples were collected in 0.3-m (1-ft) increments along two geologic cross sections, as shown in Figure 27. The results of the analysis are shown in Figure 28. Because the water table in the area is 0.6 to 1.5 m (2 to 5 ft) below the ground surface, most of the soil samples collected were saturated. Thus, the uranium results reflect both soil and groundwater contributions. Based on typical dissolved groundwater concentrations of uranium in the quarry, ranging from 1,000 to 8,000 pCi/L, the overall groundwater contribution of dissolved uranium ranges from 5 to 20% of the alluvial uranium concentrations present. Because no samples were collected directly beneath the slough, little can be inferred about the presence of uranium in this area; however, samples collected from boreholes immediately south of the slough identified no elevated levels of uranium. Therefore, the isopleths for cross section A-A' in Figure 28 have been dashed to indicate that the uranium distribution in close proximity to the slough is only estimated.

Radiological surveys along the southern quarry wall and adjacent to the right-of-way of the recently abandoned MKT railroad failed to locate any surface contamination that could contribute to the contamination located between the slough and quarry via surface runoff. Rather, the uranium contamination present in the slough area appears to have resulted from transport via groundwater migration. Groundwater migration has deposited uranium along preferential flow pathways. Groundwater elevations fluctuate in response to changing river stages. During higher stages, the groundwater elevation has been observed at the ground surface; as the water table falls, uranium appears to remain in the upper alluvial soils.

The uranium contamination appears to be restricted to an area between the quarry and Femme Osage Slough. The slough may act as a hydrogeologic boundary for groundwater migration north of the slough. Groundwater north of the slough probably discharges into Femme Osage Slough. Seepage into the slough becomes subject to natural dilutional effects.

2.5.4 Vicinity Properties

The vicinity properties are areas near the raffinate pits and chemical plant area and the quarry -- but outside of the current fenced boundaries -- that are contaminated as a result of previous activities conducted at the site. Contamination in the vicinity properties is located mainly along ditches, drainageways, roads, and railroads; some

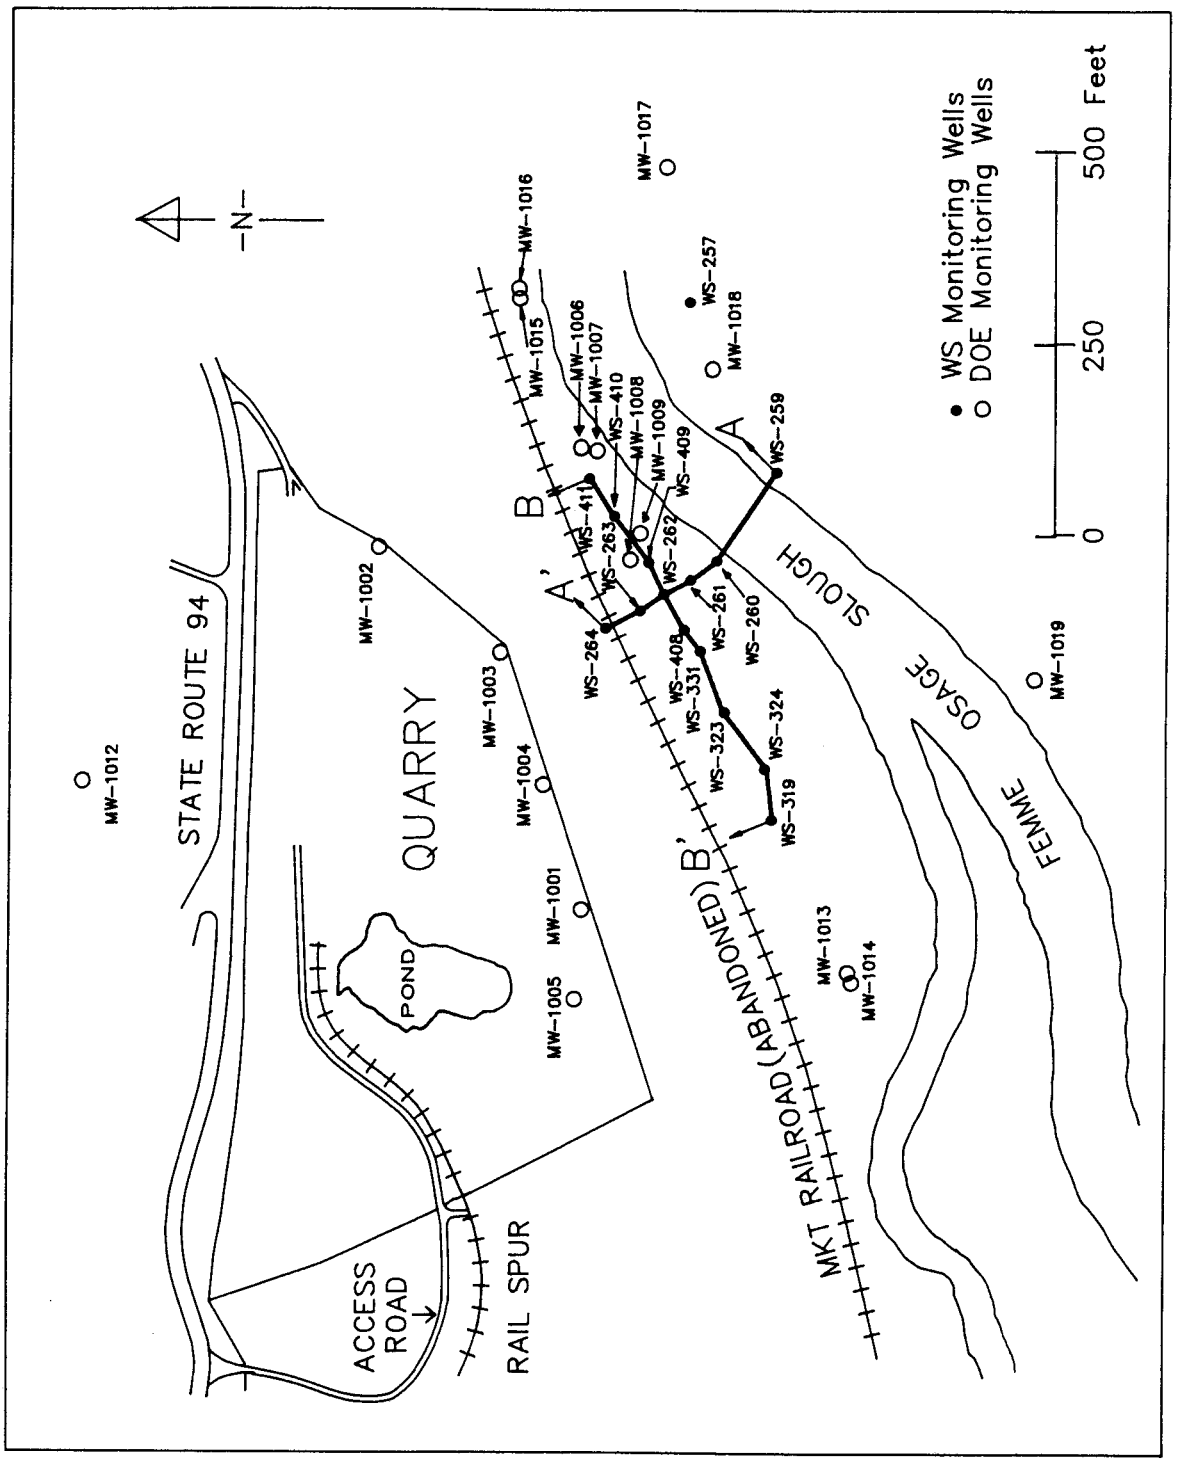

FIGURE 27 Locations Sampled in the Alluvium near the Quarry to Assess Contaminant Migration (Source: Modified from U.S. Department of Energy 1988a)

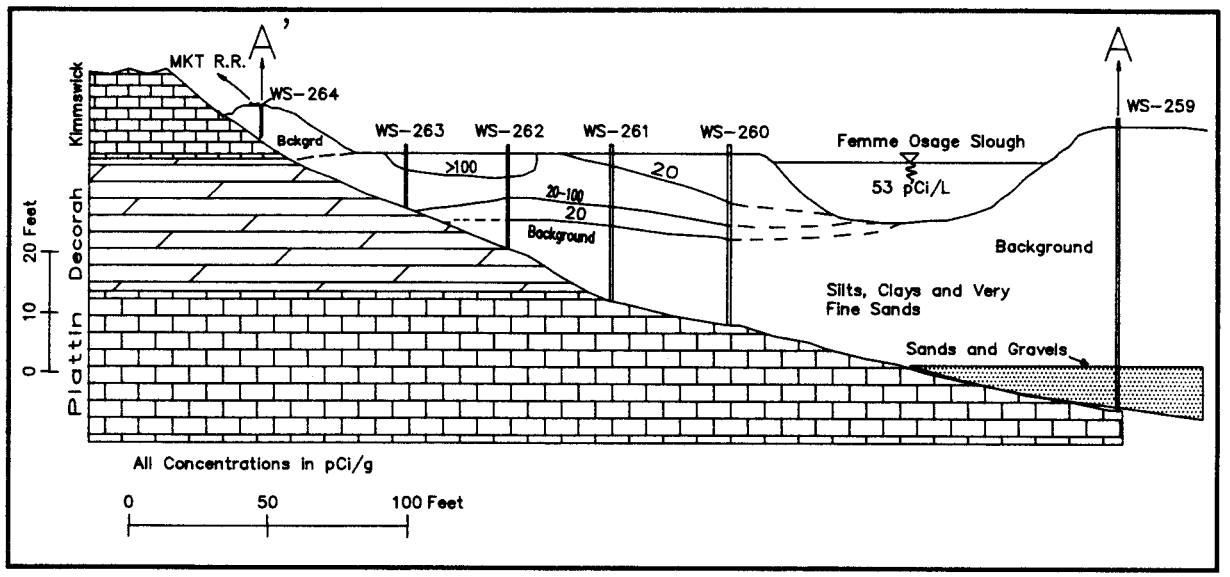

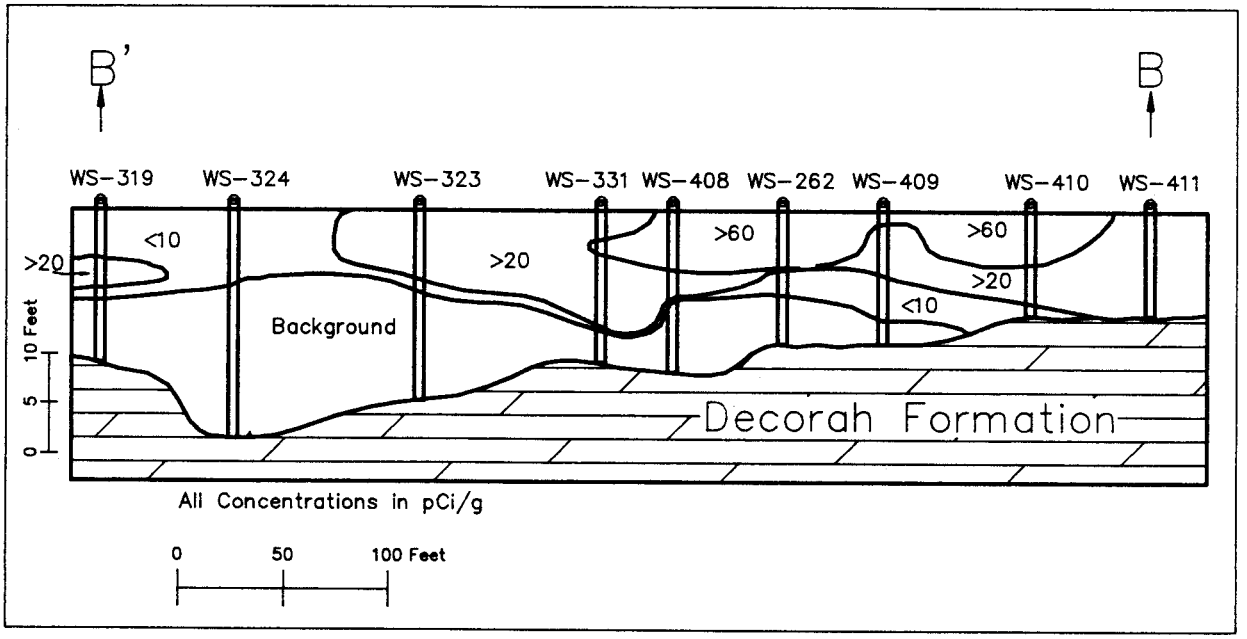

FIGURE 28 Uranium Concentrations (pCi/g) in the Alluvium near the Quarry, Cross Sections A-A' and B-B' (Source: Modified from U.S. Department of Energy 1988a)

nearby ponds and lakes are also contaminated. The contaminated off-site areas that need response action will be identified as a result of the ongoing characterization activities and assessment of potential risks to public health and the environment.

Seventeen contaminated land areas were identified in the vicinity of the Weldon Spring site during a radiological survey performed in 1986 by Oak Ridge Associated Universities at the request of DOE (Boerner 1986; Deming 1986). Seven contaminated areas are located on the U.S. Army Reserve property and ten are located on property owned by the Missouri Department of Conservation. The locations of these contaminated land areas are shown in Figure 29. (Vicinity property A7 was cleaned up in early 1988 [see Section 3.10.2.4].) In addition, some water bodies in the vicinity of the site are contaminated (e.g., Lakes 34, 35, and 36 in the Busch Wildlife Area). The contaminated areas can be grouped into two categories: (1) areas that became contaminated as a result of surface water or groundwater discharges from the raffinate pits and chemical plant area or the quarry and (2) areas that became contaminated by disposal of contaminated materials off-site or by spills from railcars carrying radioactive materials to or from the chemical plant or quarry. The characterization activities for vicinity properties are limited to those in the second category until the discharge of contaminated water from the Weldon Spring site can be stopped.

The potential for adverse human health impacts from exposure to contaminated materials on the 13 nondrainageway areas is extremely low, primarily due to the fact that these properties are uninhabited and access to them is difficult. The four contaminated areas associated with drainage of surface water from the chemical plant area are the southeast drainage (A4/B7), the Ash Pond drainage (A6), and the raffinate pits drainage (A5). The Ash Pond and raffinate pits drainageways discharge into Lakes 34 and 35 in the Busch Wildlife Area. Average annual natural uranium concentrations measured in these waters in 1987 were 25 and 15 pCi/L, respectively. However, these lakes are not used as drinking water sources and, therefore, no significant human exposure is believed to occur via this pathway. The potential doses to visitors to the area from ingesting lake water, eating fish caught in these lakes, or using the lakes for recreational purposes will be evaluated in the RI/FS-EIS.

Response actions on vicinity properties could impact several areas that are located within the Missouri River floodplain, e.g., the lower portion of the southeast drainage (B7) and a small area of land located between the quarry and Femme Osage Slough (B9). Wetlands may also exist on various vicinity properties. A floodplain/wetlands assessment will be prepared and included as a part of the RI/FS-EIS process. This assessment will describe the proposed response actions, discuss the effects of the proposed actions on the floodplain and wetlands, and discuss alternatives -- including mitigative measures. The assessment will be prepared in accordance with the requirements of Executive Order 11988 (Floodplain Management) and Executive Order 11990 (Protection of Wetlands). It is DOE's policy to avoid adverse impacts on wetlands and floodplains to the extent possible and to minimize any unavoidable adverse impacts (10 CFR Part 1022).

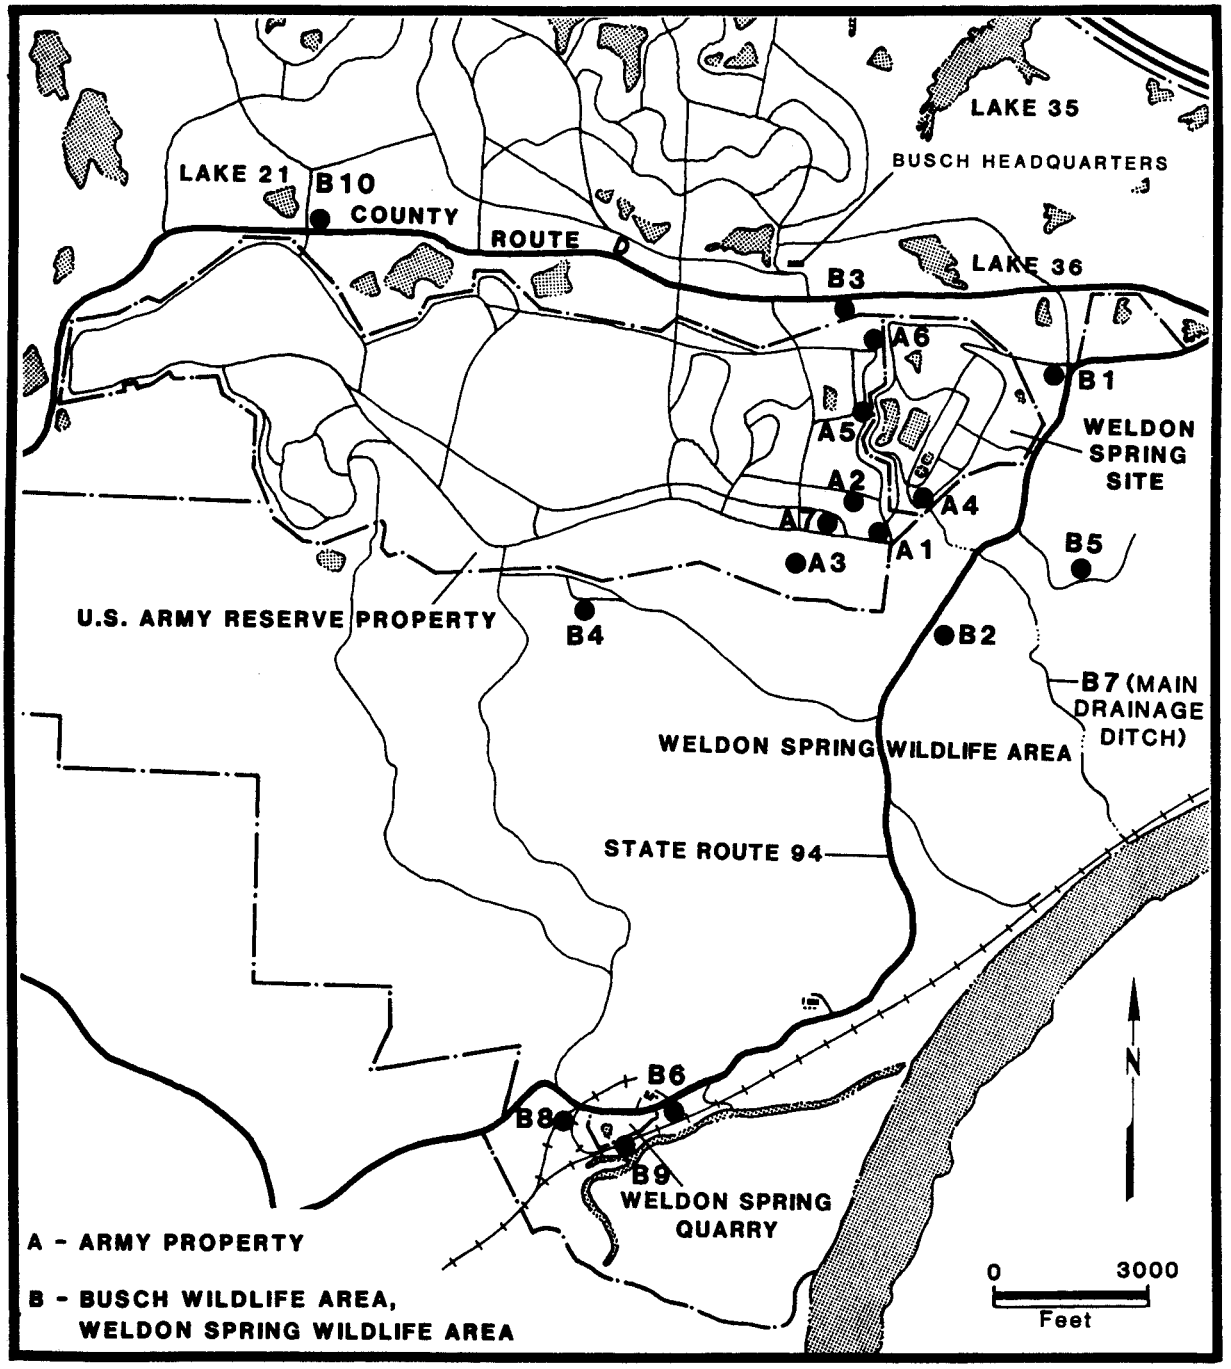

FIGURE 29 Location of Contaminated Vicinity Properties in the Area of the Weldon Spring Site (Source: Modified from U.S. Department of Energy 1988a)

3 INITIAL EVALUATION

3.1 PRELIMINARY IDENTIFICATION OF APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS

Remedial actions at the Weldon Spring site will be undertaken in accordance with all applicable or relevant and appropriate requirements (ARARs). The identification of ARARs is an iterative process. As the remedial action planning process moves from data gathering in the RI phase to selection of a remedial action alternative in the FS-EIS phase, the list of ARARs will be finalized to those required for implementation of the selected alternative.

Any regulation, standard, requirement, criterion, or limitation under any federal or state environmental law may be either *applicable* or *relevant and appropriate* to a remedial action, but not both. A regulation, standard, requirement, criterion, or limitation is *applicable* if it legally applies to a hazardous substance, pollutant, contaminant, remedial action, location, or other circumstance. A regulation, standard, requirement, criterion, or limitation is *relevant and appropriate* if it addresses problems or situations sufficiently similar to those encountered at the site such that its use is well suited to the particular site. A requirement that is determined to be relevant and appropriate must be complied with to the same extent as an applicable requirement. However, a determination of relevance and appropriateness may be applied only to portions of a requirement, whereas applicability can be determined only for the requirement as a whole. Only those state laws that are more stringent than federal laws may become ARARs.

The ARARs may be classified into three general categories:

- Contaminant-specific -- related to the level of contamination allowed for a specific pollutant in various environmental media (i.e., soil, water, and air),

- Location-specific -- related to the presence of a special geographical (e.g., floodplain or wetland) or archeological area at or near the site, and

- Action-specific -- related to a method of remedial action identified as an alternative for the site (e.g., disposal requirements or incineration standards).

The ARARs are identified on a project-specific basis -- i.e., site-specific contamination, proposed remedial action alternatives, and site characteristics influence the selection of ARARs. The selection of ARARs will be addressed at various stages in the RI/FS-EIS process as additional information becomes available:

- RI/FS-EIS work plan -- potential ARARs identified (contaminant- and location-specific).

- Completion of RI phase -- ARARs used to identify cleanup goals (contaminant- and location-specific).

- Development of alternatives -- alternatives evaluated with respect to ARARs (action-, contaminant- and location-specific).

For an alternative to be selected, it must meet the associated ARARs -- unless waiver conditions identified in SARA, Section 121(d)(4), are met.

Potential ARARs for the Weldon Spring Site Remedial Action Project are listed in Table 18. Additional federal and state requirements may also be ARARs, depending upon the alternatives identified during the RI/FS-EIS process or as a result of changes in federal or state laws. A complete list of ARARs identified for the various remedial action alternatives will be provided in the FS-EIS.

3.2 CONCEPTUAL EXPOSURE MODEL

The conceptual exposure model consists of the release mechanisms, potential receptors, and potential risks associated with the radioactive and chemical contaminants at the Weldon Spring site. This conceptual model is not intended to be an all-inclusive description of the various components associated with the evaluation of risks at the site. Rather, it is intended to indicate the nature of the evaluation that will be performed in the RI/FS-EIS. The various pathways of exposure cannot be fully determined before site characterization is complete. The conceptual exposure model presented here will be revised, as needed, to reflect the findings of the site characterization program.

3.2.1 Release Mechanisms

The migration of radionuclides and chemicals is related to the physical and chemical characteristics of the contaminants, the chemistry of the local environment, and the nature of the groundwater and surface water movement. A contaminated area can affect the quality of soil, groundwater, surface water, and air. Possible release mechanisms are:

- Dissolution, runoff, leaks, or spills that contaminate surface water;

- Contact of sediments/soils with the contaminated surface water;

- Leaching of contaminated surface and/or subsurface materials to the groundwater;

- Internal gas generation (e.g., radon) and emission to the atmosphere;

- Release of resuspended solids to the atmosphere; and
- Fugitive dust emissions from traffic, wind, and construction activities.

The RI/FS-EIS will address these release mechanisms and any others that are determined to be significant as a result of site characterization activities.

After a release has occurred, it is necessary to analyze the fate of the contaminants in the environment so that the exposure of all potential receptors can be determined. Exposure can be direct or indirect. Direct exposure can result from contact with contaminants due to work or recreational activities. Indirect exposure involves the transport of the contaminants through various media to the potentially affected receptors. The primary contaminant transport media are the atmosphere, surface water, and groundwater. The environmental fate of contaminants in these media are affected by the following factors:

- Atmospheric dispersion,
- Atmospheric transfer to surface water,
- Atmospheric deposition on soil,
- Surface water dilution,
- Groundwater transfer to surface water,
- Surface water transfer to groundwater,
- Groundwater dilution,
- Water transfer to soil, and
- Soil transfer to water.

3.2.2 Population Exposure

The assessment of population exposure consists of (1) developing scenarios of human activities that give rise to exposure, (2) assessing the transport of contaminants from the source through environmental media to potential receptors, and (3) assessing the biological uptake of these contaminants by all potential receptors. This assessment will evaluate the following means of exposure:

- Inhalation of contaminants,
- Ingestion of contaminated surface water and groundwater,

- Direct contact with contaminated soil and water,
- Ingestion of food grown in contaminated soil,
- Ingestion of contaminated meat and milk, and
- Ingestion of contaminated soil.

The assessment will include both radioactive and chemical contaminants.

3.2.3 Potential Risks

The evaluation of potential risks involves a determination of the likelihood that a given pathway of exposure will result in a deleterious health impact. The exposure pathways listed in Section 3.2.2 will be quantitatively evaluated for selected scenarios of human activity.

Exposure from the inhalation pathway will likely be quite minor for existing conditions at the Weldon Spring site. Most of the contamination at the Weldon Spring site is either below ground, below surface water, or covered with vegetation. The relationships of the receptor to the source and to the concentration of the source will be major factors in the level of exposure. The potential for inhalation of airborne particulates will increase if contaminated materials are disturbed, such as will likely occur during response action activities (e.g., demolition of buildings or excavation of contaminated soils).

Exposure through ingestion of contaminated surface water and/or groundwater is the most likely source of exposure. Elevated concentrations of uranium have been detected in the surface water runoff leaving portions of the site, and persons drinking this water could incur measurable radiation doses. On-site monitoring has also detected elevated levels of radionuclides and chemicals in the groundwater, and exposure by ingestion of this contaminated groundwater is also possible. The potential use of surface water and/or groundwater as a source of drinking water will be evaluated.

Direct contact with contaminated materials is a hazard only in areas where contamination is immediately accessible (e.g., in soil and water). Exposure by direct contact with soil is possible because radiation exposure levels in excess of background levels have been recorded at the site. Direct contact with contaminated water is also possible from such activities as swimming and fishing. Such contact could result in potential health hazards because some water bodies in the vicinity of the Weldon Spring site are currently contaminated (e.g., Lakes 34, 35, and 36 in the Busch Wildlife Area).

Exposure through ingestion of food could occur if individuals in the area grow a significant fraction of plant foods for their own consumption or if they collect and eat contaminated wild foods (e.g., mushrooms, berries, and nuts) from the surrounding wildlife areas. Exposure could also occur if there are livestock (e.g., cows) that graze in areas of contaminated soil. Contamination in the soil can be taken up by plants, and consumption of such plants by humans or animals can result in radioactive and chemical

contaminants entering the human food chain. The potential exposure from consumption of food grown in contaminated soil or from consumption of meat and milk derived from livestock feeding in contaminated areas is expected to be minimal because the contaminants have not migrated significantly from the site. Similarly, consumption of fish that live in contaminated lakes in the Busch Wildlife Area and consumption of game animals that feed on plants grown in contaminated soil are also expected to be minimal sources of human exposure.

Ingestion of contaminated soil can occur intentionally (e.g., by a small child) or inadvertently (e.g., by consuming vegetables grown in contaminated soil). There is some potential for this exposure pathway because radioactive and chemical contaminants have been detected in soil at and in the vicinity of the site.

3.3 CONTAMINANTS OF CONCERN

3.3.1 Radioactive Contaminants

Uranium and thorium ore concentrates and some scrap metal were processed at the chemical plant during its operational period. These were the only radioactive materials processed at the plant. Various waste materials associated with uranium and thorium processing at the chemical plant and at other facilities were disposed of in the quarry. Thus, the radioactive contaminants of concern for the Weldon Spring site are those associated with the uranium-238 and thorium-232 decay series (see Figures 12 and 13).

In nature, the radionuclides in a decay series are in a state of secular equilibrium in which the activities of all radionuclides are equal. However, the processing of uranium and thorium ores alters this natural state, and deviation from secular equilibrium is expected. The rate at which secular equilibrium is reestablished depends on the half-lives of the decay products. Because of their relatively short half-lives and the length of time since closure of the chemical plant (about 20 years), all radioactive decay products in the thorium-232 decay series can be assumed to be in secular equilibrium with thorium-232.

By contrast, the activities of the radionuclides in the uranium-238 decay series will change with time at a rate that depends on their original activities and half-lives and on the activities of their parent radionuclides (ingrowth effect). For example, the amount of radium-226 and its decay products in the raffinate pit sludge is estimated to increase 30 fold (from an average concentration of 97 pCi/g to 3,200 pCi/g in about 9,000 years) as a result of a gradual reestablishment of secular equilibrium (U.S. Dept. Energy 1987a). The activities of the various radionuclides in the uranium-238 decay series can be determined from the activities of uranium-238, thorium-230, and radium-226; the activities of the radionuclides from uranium-238 through uranium-234 can be assumed to be equal to that of uranium-238 (because the activities of uranium-238 and uranium-234 are equal in nature and thorium-234 and protactinium-234 have short half-lives), and the activities of the radionuclides from radium-226 through polonium-210

can be assumed to be equal to that of radium-226. The latter assumption will overestimate the short-term concentration of lead-210, bismuth-210, and polonium-210 due to the relatively long half-life of lead-210 (22 years) in comparison to the length of time since these materials were processed (approximately 20 to 30 years). This will result in an overestimate of the short-term hazard from radium-226 and its decay products.

The radioactive contaminants of concern are, therefore, uranium-238, thorium-232, thorium-230 and radium-226. The activities of all other radionuclides at the Weldon Spring site can be determined from these four species.

3.3.2 Chemical Contaminants

The following assessment of chemicals found at the Weldon Spring site is based on results of the Phase I water quality assessment (U.S. Dept. Energy 1987c), Phase I chemical soil investigation (U.S. Dept. Energy 1988b), chemical characterization of the quarry (Kaye and Davis 1987), and earlier studies summarized in the draft EIS (U.S. Dept. Energy 1987a). Investigations to date have been carried out to provide baseline information on water quality and soil contamination and to begin characterization of the wastes; however, further studies are planned to fully characterize the extent of chemical contamination.

3.3.2.1 Organic Contaminants

Nitroaromatics. Results of the Phase I water quality assessment indicate that high concentrations of nitroaromatics (mainly 2,4-DNT, 2,6-DNT, and TNT) are present in the groundwater under the northeast corner of the chemical plant and that generally low-level contamination is present throughout the raffinate pits and chemical plant area (potential source areas of nitroaromatics are shown in Figure 18). Nitroaromatics are also present in the groundwater at the quarry and in alluvial wells north of Femme Osage Slough. Surficial discoloration of soils in the eastern portion of the quarry (see Figure 24) indicates the presence of nitroaromatic compounds that were subsequently determined to be at levels of 1 to 2%. These compounds have also been detected in the surface water, sludges, sediments, and wastes at the quarry.

Volatile and Semivolatile Compounds. Volatile and semivolatile organic compounds have not been detected in the groundwater at the raffinate pits and chemical plant area. Volatile compounds detected in soil and sediment samples from the quarry are believed to be due to contamination introduced during field collection or laboratory extraction. Although three volatile organic compounds (ethylbenzene, toluene, and xylene) were detected in two alluvial wells during the Phase I water quality assessment, subsequent quarterly sampling of these and other wells failed to detect these compounds. The PAHs detected at the quarry were in borings clustered in an area adjacent to the pond.

PCBs and Pesticides. The PCB contamination is present in fluids associated with electrical equipment at the raffinate pits and chemical plant area, which have recently been removed (see Section 3.10.2.1), and in surface structures and localized areas of soil at both the raffinate pits and chemical plant area and the quarry. No PCBs or pesticides have been detected in groundwater or surface water.

3.3.2.2 Inorganic Contaminants

Inorganic Ions. Nitrate, sulfate, and fluoride concentrations have been measured in groundwater from several wells at the raffinate pits and chemical plant area at above drinking water standards (10 [as N], 250, and 2 mg/L, respectively). Elevated nitrate levels were also detected in Ash Pond and Burgermeister Spring. Soil samples collected during the Phase I soil investigation had elevated nitrates and sulfates at numerous locations, most commonly in surficial samples; some slightly elevated fluoride levels were also present. High concentrations of nitrate and fluoride were detected in the raffinate pit solids, and elevated levels of nitrate and sulfate were detected in groundwater at the quarry. Elevated levels of sulfate have also been detected in the quarry pond and in alluvial wells north of Femme Osage Slough (see Table 16 and Figure 27).

Metals. Concentrations of metals have been below background levels in most groundwater samples from the raffinate pits and chemical plant area; however, two wells had elevated levels of chromium, lithium, magnesium, nickel, and vanadium. Results of the Phase I soil investigation indicate that the soils at the raffinate pits and chemical plant area may be contaminated with low levels of metals; isolated areas also had elevated concentrations of barium, lead, and zinc. Additional investigations are required to determine actual background levels and to assess the extent of contamination. High concentrations of several metals -- including iron, lead, magnesium, and molybdenum -- are present in the raffinate pit solids. Elevated levels of iron, manganese, and arsenic have been detected in the quarry pond, but metals were not above background levels in groundwater samples from the quarry area.

Asbestos. Although asbestos is present in many areas of the chemical plant, selected surface soil samples did not have elevated levels. Asbestos levels at perimeter locations of the raffinate pits and chemical plant area were the same as background levels, and those detected in the quarry pond were below the recommended guidelines of the U.S. Environmental Protection Agency (1985).

3.4 POTENTIAL HEALTH EFFECTS

3.4.1 Radioactive Contaminants

The cause-and-effect relationships between radiation exposure and adverse health effects are quite complex, but these relationships have been more extensively

studied than have the cause-and-effect relationships for other environmental contaminants. Physiological effects to an individual are clinically detectable only from radiation exposure resulting in a dose greater than about 10 rem (to the whole body) for a few persons and about 25 rem for nearly all persons over a short period of time (hours). Doses about 10 to 20 times higher, also received over a relatively short period of time (hours to a few days), can be expected to result in some fatalities.

Lower levels of exposures also constitute a health risk, but a direct cause-and-effect relationship between a known exposure to radiation and any given health effect is difficult to define because of the many other possible reasons why a particular effect is observed in a specific individual. For this reason, such effects -- including an increased incidence of cancer in the exposed population and genetic changes in future generations after exposure of a prospective parent -- must be assessed on a statistical basis. Occurrences of cancer in the exposed population may begin to develop only after a lapse of 2 to 20 years from the time of exposure (latent period) and may then continue over a period of about 30 years (plateau period). However, in the case of exposure of fetuses (in utero), occurrences of cancer may begin to develop at birth (no latent period) and end at age 10 (i.e., the plateau period is 10 years). The occurrence of cancer itself does not necessarily result in fatality.

Most authorities agree that a reasonable -- and probably conservative -- estimate of the randomly occurring number of health effects from low levels of radiation exposure to a large number of people is within the range of about 10 to 500 potential cancer deaths per million person-rem. The radiological impacts for the Weldon Spring Site Remedial Action Project will be calculated as 50-year committed effective dose equivalents based on the methodology recommended by the International Commission on Radiological Protection (ICRP). The ICRP gives a risk estimator of 1.65×10^{-4} per person-rem for the induction of fatal cancers and serious genetic effects in the first two generations following radiation exposure (Int. Comm. Radiat. Prot. 1977). This risk estimator will be used to estimate potential health effects from radiation exposure to site-originated radioactive contaminants.

3.4.2 Chemical Contaminants

For most of the chemicals identified at the Weldon Spring site, there appears to be little potential for significant human exposure under current site conditions. An assessment of potential risks to public health from current site conditions will be carried out in the baseline risk assessment. A brief summary of the major toxic effects of selected chemical contaminants is given in Sections 3.4.2.1 and 3.4.2.2.

3.4.2.1 Organic Contaminants

Nitroaromatics. The nitroaromatics 2,4-DNT and 2,6-DNT are classified by the EPA as Group B2 (i.e., probably carcinogenic to humans) and Group C (i.e., possibly carcinogenic to humans) carcinogens. Laboratory studies have shown that TNT can induce cancer in experimental animals (Furedi et al. 1984). Nitroaromatics can induce

methemoglobinemia, a reduction in the oxygen-carrying capacity of the blood, especially in infants. Other effects include toxicity to the liver, kidney, and nervous system. Nitroaromatics can be absorbed following exposure by inhalation, ingestion, or dermal contact, although the extent of absorption depends on the specific compound.

PAHs. The PAHs are classified by the EPA as Group B2 and Group C human carcinogens, depending on the specific compound (U.S. Environ. Prot. Agency 1986b). In experimental animals, PAHs have been shown to induce tumors both at the site of application and systemically. They can also cause skin disorders, immunosuppression, and liver and kidney damage. The limited data available regarding oral absorption of PAHs indicate that some compounds are readily absorbed. Inhaled compounds can be readily absorbed. Dermal absorption can also occur, but the rate and extent are dependent on the specific compound and its concentration.

PCBs. The PCBs have been shown to induce cancer of the liver in experimental animals and are classified as Group B2 human carcinogens (U.S. Environ. Prot. Agency 1986b). In experimental animals, chronic exposure to PCBs has induced such effects as severe weight loss, liver damage, toxicity to the immune system, adverse reproductive effects, and malformations in offspring. In humans exposed to these compounds, the skin and liver are the primary sites affected, but the gastrointestinal and neuromuscular systems can also be affected. The only significant adverse health effects that have been observed in PCB-exposed workers are occasional skin irritations, usually acne-like lesions and rashes, and liver damage. Following oral exposure, gastrointestinal absorption of most isomers is greater than 90%; limited data indicate that PCBs can also be absorbed following exposure by inhalation or dermal contact.

3.4.2.2 Inorganic Contaminants

Inorganic Anions. The health hazards that are associated with nitrate result primarily from the bacterial conversion of ingested nitrate to nitrite. Nitrites alone can induce methemoglobinemia, and they can also react with other compounds, such as amines, to form N-nitroso compounds. Although most N-nitroso compounds are carcinogenic in experimental animals, the contribution of nitrate to a potential carcinogenic hazard for humans and the magnitude of the associated risk is unclear. Low levels of fluorides in drinking water are generally considered to have a beneficial effect on the rate and occurrence of dental caries. Ingestion of higher levels of fluorides can induce dental and skeletal fluoroses whereas inhalation of flourides can irritate the respiratory system.

Metals. Uranium is the most widespread of the metal contaminants at the Weldon Spring site. The two main hazards associated with exposure to uranium compounds are (1) kidney damage caused by the chemical toxicity of soluble ingested uranium compounds and (2) injury caused by the ionizing radiation resulting from radioactive

decay of ingested or inhaled uranium isotopes. The main effect depends on a number of factors, including the solubility of the compound, the route of exposure, and the relative composition of the isotopes. In addition to the adverse effects on the kidney, the chemical toxicity of uranium can also affect the cardiovascular, endocrine, hematopoietic, and immunological systems. The extent of metal contamination at the Weldon Spring site has not yet been well characterized. Of the other metals present at elevated levels, certain compounds of arsenic, chromium, lead, and nickel are carcinogenic and may induce teratogenic and other adverse reproductive effects. Metals that may be present at levels of potential significance will be identified during the baseline risk assessment.

Asbestos. Inhalation of asbestos can induce cancer of the lung and mesothelium (lining of the chest and abdomen). Exposure by inhalation may also cause asbestosis -- a progressive, irreversible lung disease. Ingestion of high concentrations of asbestos may result in damage to the gastrointestinal tract.

3.5 ENVIRONMENTAL FATE

The release, transport, and fate of contaminants in the environment depends on both the properties of the contaminant and the environmental medium in which it occurs. The primary transport media are air, surface water, and groundwater, although transport by air is of minor importance at the Weldon Spring site. The baseline risk assessment will include a comprehensive evaluation of the environmental fate of the contaminants identified at the Weldon Spring site and the potential exposure resulting from these contaminants. A brief summary of the potential transport pathways and fate of selected contaminants is given in Sections 3.5.1 and 3.5.2.

3.5.1 Organic Contaminants

3.5.1.1 Nitroaromatics

Experimental and field data suggest that nitroaromatics are not strongly adsorbed to soil or sediment and may therefore migrate to groundwater. Their residence time in soil depends on the pH and the oxygen and organic carbon content of the soil. Biotransformation can occur in the soil, and both photolysis and biotransformation may be significant fate processes in the aquatic environment (Rickert 1985).

3.5.1.2 PAHs

The PAHs are fairly persistent in the environment. They adsorb strongly to soil and sediment, particularly those with a high organic content. Atmospheric transport generally occurs by adsorption to airborne particulate matter, although PAHs with low molecular weights are typically volatile. Airborne PAHs can be returned to the aquatic

and terrestrial ecosystems by atmospheric fallout and precipitation. They can also reach groundwater and surface waters by leaching from contaminated soil. The PAHs are relatively insoluble in water, but the fraction that is dissolved may undergo rapid, direct photolysis. Although PAHs can be rapidly bioaccumulated, they are also rapidly metabolized and eliminated from most organisms (Clements Assoc. 1985).

3.5.1.3 PCBs

The PCBs are very persistent in the environment. They are relatively inert and have low vapor pressures and low water solubilities. Despite their low vapor pressures, they have high activity coefficients in water, which results in a higher rate of volatilization than would otherwise be expected. The PCBs adsorb strongly to organic soil and sediment. Adsorption to organic material in soil or sediment is considered to be the primary fate of the more heavily chlorinated PCBs. Once bound, the PCBs may persist for years, with slow desorption to the surrounding media. Bioaccumulation and biomagnification of PCBs are common, and some biodegradation can also occur.

3.5.2 Inorganic Contaminants

3.5.2.1 Inorganic Anions

Inorganic anions such as fluoride, nitrate, and sulfate are highly water soluble and therefore very mobile in the environment. This mobility can result in significant leaching from soil and diffusion in soil and water. The extent of migration to groundwater depends primarily on the type of soil affected.

3.5.2.2 Metals

Metal compounds can undergo a wide range of transformation processes, forming complexes with inorganic species or organic ligands that are present in the environment. These processes, collectively referred to as speciation, can occur in all environmental media. The speciation of a metal in a given environment affects it bioavailability, solubility, volatility, and sorptive properties. In addition to speciation, the fate of metals is affected by the properties of the environmental media; for example, the mobility of a metal compound in soil depends on the cation-exchange capacity of the soil whereas its solubility in water depends on the presence of other chemical species and on the pH.

3.5.2.3 Asbestos

Asbestos is quite stable in the environment and may be transported by water or wind dispersion. It is not prone to significant degradation in the aquatic environment. In surface waters, it remains in suspension until it physically degrades or settles by chemical coagulation into the sediment layer (Clements Assoc. 1985).

3.6 MIGRATION PATHWAYS AND POTENTIAL RECEPTORS

The extent of contaminant migration into the nearby environment is dependent, in part, upon the physical and chemical characteristics of the specific contaminants. Certain species that are relatively immobile will migrate little; other, more mobile species will migrate to a greater extent. The three general pathways by which contaminants may migrate are air transport, surface water transport, and subsurface water transport.

In general, air transport is not a significant pathway for contaminant migration at the Weldon Spring site because there is currently no processing of materials at the site. Most of the radioactive and chemical contaminants on the site are in water, in areas covered by water, or in soil, and many of the soil-contaminated areas are overgrown with vegetation. The remaining contaminants are in buildings or process equipment. Air monitoring operations by DOE have sampled for asbestos, organic vapors, and airborne radioactive particles and gases. Measurements of external gamma exposure rates have also been performed as a part of the monitoring program. Except for the quarry, measurements of both on-site (outdoor locations at the raffinate pits and chemical plant area) and off-site values of these constituents have generally been at background levels. Elevated levels of radon gas and elevated external gamma exposure rates have been measured at the quarry. However, because these levels decrease rapidly with distance, background levels are generally reached within a relatively short distance (i.e., within about 0.4 km [0.25 mi]).

The transport of contaminants via the surface water pathway is likely an important mechanism for contaminant migration from the site. Surface water runoff from the raffinate pits and chemical plant area can mobilize contaminants. Migration of these contaminants will generally follow the slope of the land surface to lower elevations. Because of the generally gentle slopes at the raffinate pits and chemical plant area, movement of contaminants for appreciable distances over unpaved surfaces or areas without defined channels is unlikely. Although transport over appreciable distances via surface channels is possible, no natural or artificial surface channels currently traverse the site except for a channel remnant that crosses through the Ash Pond area. However, there are a number of relatively short drainage channels, with and without pipe segments, that could result in the spread of contaminants from their source. Other surface drainage features that may affect contaminant migration include the Ash Pond spillway, the Ash Pond discharge line, the drainage channels to the southeast drainage easement, and the drainage channels from Frog Pond.

Potential subsurface migration pathways include (1) buried sewer and process pipelines, particularly those that have deteriorated; (2) natural subsurface features that tend to impede the downward movement of water and therefore result in lateral spreading, such as low-permeability layers or zones; (3) permeable pathways that are relatively isolated but continuous laterally or vertically, such as solution channels, caverns, or joint-sets; and (4) permeable media of a relatively continuous nature, such as permeable limestone with a combination of fractures, joints, and solution-enlarged features. All of these subsurface pathways may exist at the raffinate pits and chemical plant area to some degree.

Potential receptors of the radioactive and chemical contaminants migrating from the Weldon Spring site include:

- Students and staff of the Francis Howell High School, located east of the raffinate pits and chemical plant area on State Route 94; an estimated 2,300 persons are on campus daily during the school year (U.S. Dept. Energy 1987a).

- Visitors and staff at the St. Charles County Extension Center, located to the east of the raffinate pits and chemical plant area on State Route 94.

- Personnel at the state of Missouri highway maintenance facility, located to the east of the raffinate pits and chemical plant area.

- Personnel at the U.S. Army Reserve and National Guard Training Area, located to the west of the raffinate pits and chemical plant area.

- Other persons who live near the site, drink water from local surface water and groundwater supplies, consume locally grown plant or animal food products, and/or consume fish and game animals that inhabit the surrounding area.

- Visitors and staff at the August A. Busch Memorial Wildlife Area, the Weldon Spring Wildlife Area, and the Howell Island Wildlife Area; attendance at the Busch Wildlife Area alone has averaged 710,000 persons per year over the last 10 years (U.S. Dept. Energy 1987a).

- Trespassers who gain entry to the site in spite of existing access restrictions.

- Persons who fish or swim in nearby surface waters.

- Terrestrial and aquatic organisms.

3.7 DATA GAPS

Although much is currently known about the nature of the contaminants and their environmental fate and transport at the Weldon Spring site, several data gaps exist that must be filled before a final remedy can be selected for disposition of the contaminated materials. The field sampling plans summarized in Section 4.2 have been prepared to obtain the data necessary to fill these gaps so that, when the RI phase is completed, sufficient data will exist to allow for detailed assessment of remedial action alternatives in the FS-EIS. A summary of the current data gaps and the data collection activities being performed to obtain the necessary data is presented in Sections 3.7.1 through 3.7.3.

Potential receptors of the radioactive and chemical contaminants migrating from the Weldon Spring site include:

- Students and staff of the Francis Howell High School, located east of the raffinate pits and chemical plant area on State Route 94; an estimated 2,300 persons are on campus daily during the school year (U.S. Dept. Energy 1987a).

- Visitors and staff at the St. Charles County Extension Center, located to the east of the raffinate pits and chemical plant area on State Route 94.

- Personnel at the state of Missouri highway maintenance facility, located to the east of the raffinate pits and chemical plant area.

- Personnel at the U.S. Army Reserve and National Guard Training Area, located to the west of the raffinate pits and chemical plant area.

- Other persons who live near the site, drink water from local surface water and groundwater supplies, consume locally grown plant or animal food products, and/or consume fish and game animals that inhabit the surrounding area.

- Visitors and staff at the August A. Busch Memorial Wildlife Area, the Weldon Spring Wildlife Area, and the Howell Island Wildlife Area; attendance at the Busch Wildlife Area alone has averaged 710,000 persons per year over the last 10 years (U.S. Dept. Energy 1987a).

- Trespassers who gain entry to the site in spite of existing access restrictions.

- Persons who fish or swim in nearby surface waters.

- Terrestrial and aquatic organisms.

3.7 DATA GAPS

Although much is currently known about the nature of the contaminants and their environmental fate and transport at the Weldon Spring site, several data gaps exist that must be filled before a final remedy can be selected for disposition of the contaminated materials. The field sampling plans summarized in Section 4.2 have been prepared to obtain the data necessary to fill these gaps so that, when the RI phase is completed, sufficient data will exist to allow for detailed assessment of remedial action alternatives in the FS-EIS. A summary of the current data gaps and the data collection activities being performed to obtain the necessary data is presented in Sections 3.7.1 through 3.7.3.

3.7.1 Extent and Magnitude of Contamination

The extent and magnitude of the radiological contaminants in the soils at the raffinate pits and chemical plant area are understood, based on the history of site activities and the recently completed sampling program (Marutzky, Colby, and Cahn 1988). However, a detailed characterization of chemical contaminants in these soils is not currently available. Therefore, the soil investigation sampling plan for chemical contaminants (Section 4.2.1) will be implemented to provide a complete inventory of chemical contaminants in the soils within this area.

Although the contaminants in the raffinate pits are reasonably well defined, the waste assessment sampling plan for the raffinate pits (Section 4.2.3) will be implemented to provide a complete inventory of these contaminants. Similarly, the waste assessment sampling plan for the process buildings (Section 4.2.3) will provide a detailed inventory of contaminants in the process buildings of the chemical plant.

Results of the recent water quality assessment program have identified the chemical and radiological species present in surface water and groundwater at the Weldon Spring site (U.S. Dept. Energy 1987c). The lake and stream sediment characterization plan (Section 4.2.5) is being implemented to provide information on the nature and extent of contamination of sediments in off-site lakes and streams that have received surface and subsurface discharges from the raffinate pits and chemical plant area.

It is essentially impossible to fully characterize the quarry bulk wastes in situ because of the nature of these wastes, i.e., a heterogeneous conglomerate of steel, rubble, process equipment, and drummed and uncontained process residues intermixed in a soil matrix. It is proposed that these bulk wastes be removed from the quarry in order to minimize the potential for contaminant migration (see Section 3.11). A detailed characterization of the bulk wastes will be performed following their removal from the quarry; hence, this data gap will be filled as a part of the quarry bulk waste removal action. The nature and extent of contamination in the quarry fracture joints and cracks, and the need for groundwater restoration in this area, will be evaluated following bulk waste removal.

3.7.2 Environmental Transport Pathways

The surface pathways of environmental transport at the raffinate pits and chemical plant area (e.g., air and surface water runoff) have been identified and are currently being monitored. Although many subsurface pathways have also been identified and all known springs and seeps have been inventoried and sampled, it is possible that other, unidentified pathways exist. Implementation of the hydrogeological investigation sampling plan (Section 4.2.2) will characterize the hydrogeological conditions at the raffinate pits and chemical plant area. Data from this sampling effort will also assist in determining the need to perform groundwater restoration in this area. A biouptake study (Section 4.2.5) is currently being implemented to assess the extent to which contaminants originating from the Weldon Spring site have been incorporated into local wildlife.

3.7.3 Waste Disposition

Additional data are needed regarding the amenability of various waste materials to treatment and the suitability of the site to isolate the wastes from the public and the environment (i.e., if on-site disposal were selected as a result of the RI/FS-EIS process). The different waste forms associated with the Weldon Spring project will be studied to evaluate the feasibility of various methods of treatment and volume reduction (see Section 3.9). The results of these studies will be incorporated in the RI/FS-EIS to support the screening and evaluation of potential technologies and alternatives. The geophysical/geotechnical investigation sampling plan (Section 4.2.4) will be used to evaluate the suitability of the raffinate pits and chemical plant area for waste disposal.

3.8 RESPONSE OBJECTIVES AND CONCEPTUAL REMEDIAL ACTION ALTERNATIVES

3.8.1 Response Objectives

The objective of response action at the Weldon Spring site -- consisting of the raffinate pits and chemical plant area and the quarry -- is to decontaminate or stabilize radioactively and chemically contaminated materials to protect human health and the environment and bring the site into compliance with ARARs. The selected alternative will implement permanent solutions to the extent practicable. Vicinity properties contaminated in excess of acceptable criteria will be decontaminated and the resultant wastes will be disposed of along with wastes from the raffinate pits and chemical plant area and the quarry. Consistent with the goals of DOE's SFMP, real property will be released for unrestricted use to the extent practicable.

3.8.2 Technology Identification

Section 121 of SARA identifies a strong statutory preference for remedies that are highly reliable and provide long-term protection. In addition to the principal requirements that a selected remedy be protective of human health and the environment and be cost-effective, other selection criteria include the following:

- Preferred remedial actions are those in which the principal element is treatment to permanently or significantly reduce the volume, toxicity, or mobility of hazardous substances, pollutants, and contaminants.

- Where practical treatment technologies are available, off-site transport and disposal without treatment is the least favored alternative.

- Permanent solutions and alternative treatment technologies or resource recovery technologies should be assessed and used to the maximum extent practicable.

The following discussion provides a general overview of the technologies that could be used to protect public health and the environment, based on the current understanding of the Weldon Spring wastes and on the potential for population exposure; during implementation of the RI/FS-EIS process, additional technologies may be identified and evaluated. The discussion is divided into two general categories as prescribed in the National Oil and Hazardous Substances Pollution Contingency Plan (NCP): source control response actions and migration control response actions.

3.8.2.1 Source Control Response Actions

Source control response actions are aimed at protecting public health and the environment by altering the nature of the source (i.e., the radioactively and chemically hazardous constituents in the waste) to reduce the toxicity, mobility, and/or volume of its constituents, thereby limiting the potential for exposure to contaminants via the pathways described in Section 3.6. Potential source control response actions include access restrictions, removal, reprocessing/treatment, temporary storage, and disposal.

Access Restrictions. Access restrictions involve the use of physical barriers (e.g., fences) and/or institutional controls (e.g., deed restrictions and condemnation of property) to reduce the potential for public exposure to contaminated materials. These restrictions, in and of themselves, are not typically effective in terms of protecting public health and the environment. Therefore, access restrictions are usually implemented in conjunction with other source control response actions.

Removal. Removal of contaminated materials may involve decontamination, demolition, and/or excavation. Decontamination of structural surfaces can be accomplished using various methods of washing and/or abrading. Demolition consists of decontaminating and/or dismantling contaminated structures and disposing of the resultant rubble in a designated area. Excavation involves removing contaminated soil and hauling it to a designated area for disposal. Both the demolition and excavation technologies are reliable, can easily be implemented with common construction equipment, and can be extremely effective means of removing contaminated materials. Removal of contaminated liquids, e.g., surface water or groundwater, by mechanical means such as pumping is more difficult to implement but is technically feasible. Removed materials can then be treated and/or disposed of.

Reprocessing/Treatment. Reprocessing/treatment includes a wide range of treatment technologies. Although a number of these technologies can be implemented for contaminated liquids, sludges, and soils, they are not typically suitable for the decontamination of structural surfaces. (This decontamination would be carried out as described above, under source control actions.) In addition, only a limited number of

technologies are effective where radioactive contamination is present. Treatment technologies for radioactive wastes can be divided into two general categories:

- Those that remove radioactive constituents from the waste matrix, and
- Those that change the form of the waste, thereby reducing its toxicity, mobility, and/or volume.

Hazardous waste treatment can be accomplished by chemical, physical, and/or biological technologies.

Chemical treatment technologies are used to alter the nature of the hazardous chemical constituents and can affect waste toxicity, mobility, and/or volume. When radioactive contaminants are also present, a chemical extraction or leaching process can be used to remove the radioactive components from the waste matrix to reduce the volume and/or mobility of contaminants. The liquid leachate can then be reprocessed to recover the radioactive components. Chemical treatment of liquid wastes can involve precipitation, coagulation, adsorption, ion-exchange, or oxidation/reduction techniques.

Physical treatment technologies are used to alter the structure of the waste constituents to facilitate stabilization and management. Physical treatment can reduce toxicity, mobility, and/or volume of contaminated liquids, sludges, or soils. Contaminated liquids at the site could be treated by sedimentation, granular media filtration, microscreening, or vapor recompression/distillation. Contaminated sludges (e.g., in the raffinate pits) could be treated by dewatering technologies such as centrifugation, pressure or vacuum filtration, horizontal belt filtration, screening, drying beds, or gravity thickening. Three classes of physical treatment technologies that could be considered for contaminated soils and dewatered sludges are vitrification, stabilization, and separation.

In the vitrification process, contaminated soil and sludge are immobilized by passing an electrical current through the material, creating temperatures high enough to melt the soil. When power to the system is turned off, the molten volume cools, and a block of glass-like material resembling natural obsidian is produced. This mobility-reducing technology is developmental and has not yet been used on a large-scale project. Stabilization would involve the addition of chemical and cementitious materials to contaminated soil and sludge to produce a solid monolith. This technique would reduce waste mobility. Several separation techniques have been identified for reducing the volume of contaminated material by separating the radioactive constituents from the soil matrix. These techniques are also developmental and include sand sifting, paramagnetic separation, soil sorting, and selective mineral separation.

Biological treatment technologies can be used to alter the nature of a waste and to remove contaminants from a waste matrix. Biological processes are typically employed in conventional wastewater treatment systems and can affect waste toxicity, mobility, and/or volume. Biological treatment processes include activated sludge treatment, trickling filters, and surface impoundments.

Temporary Storage. Temporary storage is the isolation of contaminated material in a manner designed to protect public health and the environment until a permanent disposal option becomes available. Temporary storage can involve the placement of contaminated material on an engineered pad and covering the material with a synthetic membrane, clay cap, or other protective layer. Temporary storage can also be achieved by placing the contaminated material in an existing engineered structure or in a structure newly constructed for containment purposes.

Disposal. Disposal involves the placement of contaminated material in a confined environment for permanent disposition. This can be an extremely effective means of reducing waste mobility and the associated potential for population exposure. Disposal of the large volume of low-specific-activity wastes resulting from implementation of the Weldon Spring Site Remedial Action Project can potentially be on-site, off-site (land-based), or in the ocean.

On-site disposal would entail disposing of the Weldon Spring wastes in a facility designed in accordance with all ARARs. This appears to be a technically feasible source control response action. Off-site (land-based) disposal is also technically feasible; however, a disposal facility would have to be sited and constructed because none currently exists. Ocean disposal could be considered a viable alternative for disposal of some of the Weldon Spring wastes because the degree of radioactivity associated with these wastes is essentially the same as that naturally present on the ocean floor. The suitability of the disposal site (i.e., the ocean floor) would be based on such factors as levels and volumes of radioactive and chemical contamination, water depth, and ocean currents. However, the ocean disposal option has not been approved by the EPA, and it is anticipated that several years of study and a fundamental change in terms of public acceptance would be required prior to its implementation.

3.8.2.2 Migration Control Response Actions

Migration control response actions are designed to mitigate exposure of the population to contaminants that are transported via any of the pathways described in Section 3.6. An additional objective of migration control measures is to limit activities that could disturb and result in the migration of contaminated materials present at the Weldon Spring site. Potential migration control response actions include access restrictions and containment/treatment.

Access Restrictions. Access restrictions involve the use of physical barriers (e.g., fences) and/or the implementation of institutional controls (e.g., deed restrictions and condemnation of property). These methods could be used to reduce contaminant migration by human or animal activities and to limit exposure to off-site areas where contamination has already migrated. Access restrictions are not effective in reducing the impact of environmental factors (e.g., wind and precipitation) on contaminant migration. In general, access restrictions would not serve as a reliable means of protecting public health and the environment in the absence of other supporting response actions.

Containment/Treatment. Containment/treatment involves the use of media-specific technologies for migration control. The purpose of containment, which can involve containment of contaminated material within an engineered structure or in situ, is to reduce contaminant migration and, therefore, the potential exposure of the population. Containment technologies, in and of themselves, do not typically reduce waste toxicity or volume.

Media-specific containment technologies for migration control include:

- Air -- pipe and trench vents, with containment of vented air;
- Soil -- excavation/containment, liners, isolation (e.g., in situ), and stabilization via vegetation;
- Surface water -- dikes, terraces, channels, downpipes, grading, and surface seals (with containment of runoff); and
- Groundwater -- slurry/cutoff walls, grout curtains, subsurface drains/other leachate containment systems, and groundwater pumping.

When used in conjunction with containment technologies, treatment technologies for migration control may reduce waste volume as well as toxicity and mobility. Media-specific treatment technologies for migration control include:

- Air -- filtration of vented air;
- Soil -- excavation/dewatering and encapsulation (e.g., vitrification, stabilization);
- Surface water -- runoff collection (e.g., with dikes or channels) in conjunction with physical/chemical/biological treatment systems; and
- Groundwater -- groundwater pumping/leachate collection in conjunction with physical/chemical/biological treatment systems.

3.8.2.3 Summary of Potential Response Action Technologies

The potential response action technologies described in Sections 3.8.2.1 and 3.8.2.2 are summarized in Table 19 for source control and Table 20 for migration control. Additional technologies that may be appropriate for the proposed action will be identified and evaluated during the FS-EIS process.

TABLE 19 Summary of Response Action Technologies: Source Control

Response Action	Source Control Technology	Type of Contamination	Comments
Access restrictions	Physical barriers	Soils, sludges, structures, surface water, groundwater	Temporarily limits exposure to radioactive and chemical contaminants.
	Institutional controls		
	Deed restrictions	Soils, sludges, structures, surface water, groundwater	Temporarily limits exposure to radioactive and chemical contaminants.
	Condemnation	Property	Temporarily limits exposure to radioactive and chemical contaminants.
Removal	Excavation	Soils, bulk wastes	Reduces exposure to radioactive and chemical contaminants; allows unrestricted use of area. Requires storage or disposal facility and access restrictions during excavation.
	Decontamination	Structural surfaces	Reduces exposure to radioactive and chemical contaminants; allows unrestricted use of area. Requires storage or disposal facility and access restrictions during decontamination.
	Demolition	Structures	Reduces exposure to radioactive and chemical contaminants; allows unrestricted use of area. Requires storage or disposal facility and access restrictions during demolition.

TABLE 19 (Cont'd)

Response Action	Source Control Technology	Type of Contamination	Comments
Removal (Cont'd)	Pumping	Surface water, groundwater	Reduces exposure to radioactive and chemical contaminants; allows subsequent treatment. Requires containment/treatment facility and access restrictions during treatment.
Reprocessing/ treatment	Chemical treatment		
	Leaching/extraction	Soils, bulk wastes, sludges	Reduces exposure to radioactive and chemical contaminants; may reduce toxicity, mobility, or volume of waste constituents; allows unrestricted use of treated area. May require bench-scale testing; requires treatment facility and access restrictions during treatment.
	Precipitation, coagulation, adsorption, ion exchange, lime softening, etc.	Surface water, groundwater	May reduce waste toxicity, mobility, or volume; allows unrestricted use of treated area. May require bench-scale testing; requires treatment facility and access restrictions during treatment.
	Physical treatment		
	Sedimentation, filtration, vapor recompression/distillation, etc.	Surface water, groundwater	May reduce waste toxicity, mobility, or volume. May require bench-scale testing; requires treatment facility and access restrictions during treatment.
	Dewatering	Sludges	May reduce waste mobility or volume; allows unrestricted use of treated area. Requires treatment facility and access restrictions during treatment.

TABLE 19 (Cont'd)

Response Action	Source Control Technology	Type of Contamination	Comments
Reprocessing/ treatment (cont'd)	Physical treatment (cont'd)		
	Vitrification	Soils, sludges	Reduces waste mobility and possibly toxicity. Requires further testing and development; limits future land use; requires access restrictions during treatment.
	Stabilization	Soils, sludges	May reduce waste mobility. Limits future land use; requires treatment facility and access restrictions during treatment.
	Sand sifting	Soils, bulk wastes	Reduces waste volume. Suitability of process for alluvial materials is unknown. Requires further testing and development; requires access restrictions during treatment.
	Paramagnetic separation, soil sorting, selective mineral separation	Soils, bulk wastes, dewatered sludges	Reduces waste volume; may allow unrestricted unrestricted use of treated area. Requires further testing and development; requires access restrictions during treatment.
	Biological treatment		
	Activated sludge, trickling filters, surface impoundments, etc.	Surface water, groundwater,	May reduce waste toxicity, mobility, or volume. Requires treatment facility and/or area; may require bench-scale testing and access restrictions during treatment.

TABLE 19 (Cont'd)

Response Action	Source Control Technology	Type of Contamination	Comments
Temporary storage	On-site	Soils, sludges, bulk wastes, liquids	Reduces waste mobility and exposure to radioactive and chemical contaminants while a more permanent remedy is being developed. Limits future land use; requires storage facility (outdoor area or engineered structure) and access restrictions during storage.
	Off-site	Soils, sludges, bulk wastes, liquids	An off-site temporary storage facility would probably not be available for several years.
Disposal	Land-based facility		
	On-site	Soils, sludges, bulk wastes, liquids	Reduces waste mobility and exposure to radioactive and chemical contaminants. Limits future land use; requires specific siting and construction of disposal facility and access restrictions during the long term.
	Off-site	Soils, sludges, bulk wastes, liquids	Reduces waste mobility and exposure to radioactive and chemical contaminants; allows unrestricted use of decontaminated area. Requires siting and construction of a disposal facility and access restrictions at the facility for the long term. (Disposal site not currently available.)
	Ocean disposal	Soils, sludges, bulk wastes, liquids	Not currently available and may not be available within a reasonable time. Transportation to the ocean port would be expensive.

TABLE 20 Summary of Response Action Technologies: Migration Control

Response Action	Migration Control Technology	Type of Contamination	Comments
Access restrictions	Physical barriers	Soils, sludges, bulk wastes, surface water, groundwater	Temporarily limits exposure to migrated contaminants. Limits land use.
	Institutional controls: Deed restrictions	Soils, sludges, bulk wastes, surface water, groundwater	Temporarily limits exposure to migrated contaminants. Limits land use.
	Condemnation	Property	Temporarily limits exposure to migrated contaminants. Limits land use.
Containment/ treatment	Engineered system or in situ	Soils, sludges, bulk wastes, surface water, groundwater	Reduces waste mobility and, in conjunction with treatment, may also reduce waste toxicity or volume. Requires containment/treatment system(s); may require access restrictions during containment/treatment period.

3.8.3 Remedial Action Alternatives

Remedial action alternatives will be developed and assessed according to the following five categories, as recommended by the current NCP:

1. No action,

2. Alternatives for treatment or disposal at an off-site facility, as appropriate,

3. Alternatives that attain applicable or relevant and appropriate federal public health and environmental requirements,

4. Alternatives that exceed applicable or relevant and appropriate federal public health and environmental requirements, and

5. Alternatives that do not attain applicable or relevant and appropriate public health and environmental requirements but will reduce the likelihood of present or future threat from the hazardous substances and that will provide significant protection to public health and welfare and the environment. This must include an alternative that closely approaches the level of protection provided by the applicable or relevant and appropriate requirements.

Section 105 of SARA requires the President (who subsequently delegated this responsibility to the EPA) to propose amendments to the NCP by April 17, 1988. The EPA is currently drafting revisions to the NCP in response to this requirement. The revised NCP has not yet been issued in final form. Nonetheless, the identification of categories for remedial action alternatives that are recommended by the EPA in its proposed revisions will also be considered in the current evaluation, in the interest of addressing those requirements that may be promulgated before the proposed remedial actions are complete. These categories are:

- No action;

- Containment (migration control) or institutional controls -- involving little or no treatment, but protective of human health and the environment by causing a reduction in waste mobility and related exposure risks; and

- Treatment (source control) with disposal of the remaining wastes either on-site or off-site -- ranging from (a) treatment as the principal element of the alternative, to reduce the principal threat(s) posed by a site (i.e., may not involve the highest degree of treatment or treatment of all wastes) to (b) treatment that will minimize the need for long-term management of the wastes (including monitoring).

On the basis of the technologies identified to date (see Section 3.8.2), a limited number of general remedial action alternatives have been identified:

- No action,
- On-site disposal,
- Off-site disposal,
- On-site treatment with on-site disposal,
- On-site treatment with off-site disposal, and
- Off-site treatment with off-site disposal.

These alternatives address the radioactively and chemically contaminated materials -- including structures, equipment, soils, sludges, and water -- present at the Weldon Spring site and its vicinity properties. They represent a wide range of remedial actions, from no action to treatment and disposal. The following descriptions of the general remedial action alternatives include a variety of engineering options that could be implemented, either singly or in various combinations.

3.8.3.1 No Action

The no-action alternative provides a baseline for comparison to other alternatives. If this option were selected, there would be no reduction in the toxicity, mobility, or volume of the contaminated materials. The potential for human exposure to radioactive and chemical contaminants would probably continue for the short term at the levels presented in the baseline risk assessment. However, as off-site migration continued, long-term exposure would likely increase -- in terms of both levels of exposure and size of the potentially affected population. These exposures could become quite large if changes in land use near the Weldon Spring site were to occur. Redevelopment of the site could also result in the uncontrolled release of contaminated materials.

3.8.3.2 On-site Disposal

On-site disposal would reduce waste mobility. Implementation of this alternative would involve a determination of site suitability and the construction of an on-site disposal facility. After closure of the facility, monitoring and maintenance activities would be performed as needed. These activities would include periodic inspection of the cover, environmental monitoring, and security precautions. Permanent access restrictions and other institutional controls would be required to protect public health. A buffer zone would be created between the disposal facility and surrounding areas.

3.8.3.3 Off-site Disposal

Off-site disposal would reduce waste mobility. Implementation of this alternative would involve the siting and construction of an off-site disposal facility for the Weldon Spring wastes. Once an off-site disposal facility became available, the removal, transport, and disposal of the wastes from the Weldon Spring site could be implemented. Other considerations applicable to on-site disposal (see Section 3.8.3.2) would also apply to off-site disposal.

3.8.3.4 On-site Treatment with On-site Disposal

On-site treatment with on-site disposal would reduce the mobility and could reduce the toxicity and/or volume of the contaminated materials. This alternative would involve many of the same issues related to the on-site disposal alternative (see Section 3.8.3.2). In addition, treatment systems for the various forms of contaminated materials would have to be constructed and operated on-site, and access restrictions would be required during treatment operations. If this alternative were selected, contaminated surface water, groundwater, soils, and sludges would be treated and subsequently disposed of -- with all activities occurring on-site.

3.8.3.5 On-site Treatment with Off-site Disposal

On-site treatment with off-site disposal would reduce the mobility and could reduce the toxicity and/or volume of the contaminated materials. This alternative would involve the same issues related to on-site treatment that are addressed for the previous alternative (Section 3.8.3.4) and the same issues related to off-site disposal that are addressed for the off-site disposal alternative (Section 3.8.3.3).

3.8.3.6 Off-site Treatment with Off-site Disposal

Off-site treatment with off-site disposal would reduce the mobility and could reduce the toxicity and/or volume of the contaminated materials. This alternative would involve the same issues related to the off-site disposal alternative (see Section 3.8.3.3) and the identification of an off-site location for the construction and operation of the treatment facilities.

3.9 FEASIBILITY TESTING

The DOE will perform various studies to support the RI/FS-EIS process. The results of these studies will be used to screen the various technologies and define the alternatives to be assessed in the FS-EIS. The studies listed here are those currently planned. Additional studies may be performed in the future as part of the post-screening investigations that bridge Phases II and III of the FS-EIS process (see Figure 32 for a definition of the various phases of the RI/FS process).

3.9.1 Volume Reduction

The applicability of various volume-reduction techniques for solid waste will be examined relative to the wastes expected to be produced during implementation of the Weldon Spring Site Remedial Action Project. This study will include contaminated soils and sludges, metallic wastes such as equipment and siding, and other building components.

3.9.2 Sludge Stabilization

The feasibility of stabilizing the sludge in the raffinate pits with chemical and cementitious materials to reduce waste mobility will be assessed. Earlier studies conducted by Oak Ridge National Laboratory have demonstrated the technical feasibility of stabilization. Although these tests used a fairly wide range of mixtures with varying results, there is no assurance that the samples used were representative of the raffinate pit sludge at the Weldon Spring site. Additional tests will be performed to better define the quantity and quality of the additives to be used, the mixing techniques to be employed, and the chemical (e.g., leachability) and geotechnical (e.g., strength) characteristics of the resultant mixture using samples that better represent the raffinate pit sludge.

3.9.3 Waste Vitrification

The feasibility of vitrifying the raffinate pit sludge, and possibly the materials in the quarry, will be evaluated. Battelle Pacific Northwest Laboratories (PNL) has recently been testing the feasibility of treating hazardous waste by vitrification. If costs are not prohibitive, vitrification could prove to be an applicable technique for management of the raffinate pit sludge. Based on preliminary data, vitrification appears to be a feasible technology that could result in significant volume reduction. Vitrification could also dramatically reduce the leachability of hazardous substances in the sludge and decrease the rate of radon emissions, thereby reducing waste mobility and toxicity. Preliminary discussions with PNL indicate that vitrification of the raffinate pit sludge might require the addition of some siliceous material (if the current level is insufficient). If so, wastes from the quarry could be a candidate source for the additive. Thus, some of the quarry wastes might also be considered for vitrification.

3.9.4 Waste Reprocessing

The feasibility of reprocessing the raffinate pit sludge will be evaluated relative to recovering resources and reducing the toxicity, mobility, and volume of the sludge. In addition to small quantities of uranium, thorium, and radium, the sludge contains other elements -- including a significant quantity of magnesium fluoride. A preliminary review of the data indicates that removal of all of the uranium, thorium, and radium would not significantly reduce the waste volume; in fact, reprocessing is expected to involve the addition of significant quantities of reprocessing reagents to the sludge, which would increase the final waste volume. Even if the magnesium fluoride were recovered from

the sludge, it is possible that its level of radioactive contamination would render it commercially unusable. Therefore, it appears that the waste-reprocessing method used to reduce the sludge volume would have to reduce the contamination to a level at which the sludge would no longer be considered radioactively contaminated. The same processes considered for the raffinate pit sludge will also be examined for applicability to contaminated soils and sediments.

3.9.5 Lake Silt Removal

Preliminary data indicate that silt in Lakes 34, 35, and 36 in the Busch Wildlife Area is contaminated and may require response action; additional sampling will be performed to evaluate the need for such action. Although these lakes are currently filled with water, existing data indicate that only the silt is contaminated to an extent that might require remediation. If tests confirm the need for cleanup of these lakes, various methods will be evaluated for removing and treating the contaminated silt.

3.9.6 Liner Compatibility

Flexible membrane liners may be used in the construction of any required leachate collection system and/or leak detection system in the disposal facility. Such liners could be adversely affected by the wastes or leachates produced by the wastes placed in the disposal facility. In addition, underlying clays could be detrimentally affected by leachates produced during construction of the disposal facility, during operation of the leachate collection system, and especially after cessation of leachate collection. The compatibility of these potential leachates with flexible membrane liners and engineered sublayers will be evaluated.

3.9.7 Thermal Waste Destruction

The toxicity, mobility, and volume of some of the chemical wastes present at the raffinate pits and chemical plant area and the quarry could be reduced by thermal destruction. The thermal properties and off-gas treatment requirements for the various wastes will be studied. Thermal waste destruction would probably require the use of a mobile incinerator and thus would be applicable to either on-site or off-site treatment.

3.9.8 Land Treatment

The toxicity, mobility, and volume of certain liquid wastes might be reduced by applying the liquids to the ground and allowing natural processes to break down the contaminants. The soil, meteorological, and vegetative conditions at and in the vicinity of the Weldon Spring site will be assessed for compatibility with land treatment. Although the mix of constituents present in contaminated site waters probably precludes use of this method, land treatment could be appropriate when used in conjunction with other treatment methods.

3.9.9 Waste Drying/Dewatering

The volume and mobility of contaminated sludges and sediments could be reduced by drying or dewatering. Methods of drying/dewatering will be evaluated relative to specific site wastes. This technology could be used to support on-site or off-site disposal and would reduce transportation costs for off-site disposal.

3.9.10 In-Situ Leaching

The toxicity, mobility, and volume of certain contaminated soils and sludges could be reduced by in-situ leaching. In this process, a solution is pumped into or sprinkled onto a contaminated zone and allowed to dissolve the desired contaminant. The contaminant-bearing solution is then removed and treated. The appropriateness of this method for various waste types will be evaluated.

3.9.11 Groundwater Treatment

Contaminants associated with the Weldon Spring site have been identified in various samples taken from on-site and near-site monitoring wells. With the exception of nitroaromatics, these contaminants have also been identified in surface waters at the raffinate pits. If, as a result of the RI/FS-EIS process, DOE determines that groundwater at the raffinate pits and chemical plant area must be remediated, a groundwater restoration program will be implemented. Current knowledge of the local aquifer and types of contaminants suggest that groundwater pumping and treatment could be a feasible response. However, other response alternatives will also be evaluated prior to the selection of a final remedy.

3.10 EVALUATION OF POTENTIAL INTERIM RESPONSE ACTIONS

The DOE is proposing to perform various expedited response actions (ERAs) -- synonymous for this project with the term interim response actions (IRAs) -- prior to issuance of the ROD, in order to mitigate actual or potential uncontrolled releases of radioactively or chemically hazardous substances to the environment and to minimize potential health and safety risks to on-site personnel and local human and biotic populations. The scope of the IRAs will be limited to those actions that can be performed within the guidelines for removal actions of CERCLA and the NCP, and remain within the constraints of CEQ regulations for NEPA (i.e., actions will be limited to those that do not have adverse environmental impacts or limit the choice of reasonable alternatives for the ultimate disposition of the site).

Under the July 1982 version of the NCP, removal actions were divided into two categories: (1) immediate, for emergencies, and (2) planned, for near emergencies. The February 1986 revisions of the NCP expanded the definition of removal to combine three previously separate activities -- immediate removals, planned removals, and initial remedial measures -- into one general activity category of removals. The use of ERAs (i.e., IRAs) was designed to address those situations that were previously performed as

initial remedial measures. The primary purpose of conducting a removal action is to expedite response activities at those sites where cleanup solutions are straightforward. In addition, the NCP revisions extended removal authority to permit actions to be taken in response to a threat (rather than to an immediate and significant threat). Thus, removal actions can now be implemented on a non-time-critical basis, i.e., when the action does not need to be initiated within hours or days (classic emergency removal) or within six months (time-critical removal) after the preliminary assessment of a site. By definition, the IRAs proposed for the Weldon Spring site are of a non-time-critical nature.

The EPA lists the following major factors for implementing an ERA (i.e., IRA):

- The action must meet criteria for removal actions as stated in the NCP,
- The action must be implemented within the statutory limits of 1 year and $2 million, for Superfund-financed actions only (waivers of these limits are possible), and
- The action must be consistent with and contribute to the performance of the long-term remedial action for the site.

The IRAs at the Weldon Spring site will be conducted in accordance with relevant guidelines primarily to:

- Reduce the potential for off-site migration of contaminated groundwater and surface water,
- Reduce the potential for extended soil contamination,
- Reduce the potential for air contamination, and
- Protect the health and welfare of on-site personnel and nearby individuals and the environment.

A secondary objective of the IRAs will be to facilitate adequate site characterization.

3.10.1 EE/CA Documentation Process

The decision-making process DOE will follow to document the evaluation of IRA alternatives is shown in Table 21 and Figure 30. The major document prepared to analyze alternatives for implementing the various IRAs is the engineering evaluation/cost analysis (EE/CA) report. A flow chart of the EE/CA process is shown in Figure 31. The decision-making process is intended to be flexible to the specific needs of the various IRAs; not all components of the process will be needed for all IRAs. Specific documentation will be prepared for each IRA to ensure that the environmental review

[a]EPA refers to EPA Region VII and state refers to the state of Missouri.

[b]The scope of this analysis may be expanded for certain IRAs to include the level of environmental analysis required in an EA under NEPA.

[c]A memorandum-to-file is a unique DOE mechanism that was established when DOE's NEPA guidelines (U.S. Dept. Energy 1987d) were first issued in 1980. It was developed to avoid the need to prepare EAs for a large number of DOE actions that, because of limited agency experience, had not yet been added to the list of categorical exclusions.

requirements of both NEPA and CERCLA are satisfied. The DOE will consult with EPA Region VII and the state of Missouri in this regard.

3.10.2 Proposed IRAs

The IRAs proposed for the Weldon Spring Site Remedial Action Project are described in this section. The objectives of these IRAs are to (1) expedite cleanup of the site, (2) reduce threats of releases of chemical and radioactive contaminants into the nearby environment, (3) minimize for on-site personnel and local populations the health and safety risks that are associated with site conditions, and (4) contribute to the long-term, overall remedial action for the site (e.g., by reducing on-site waste volume and facilitating waste disposal activities). Additional IRAs may be proposed as the project proceeds. The selection of those actions will continue to involve coordination with EPA Region VII and the state of Missouri and will follow the guidelines described in Section 3.10 and the general process shown in Table 21.

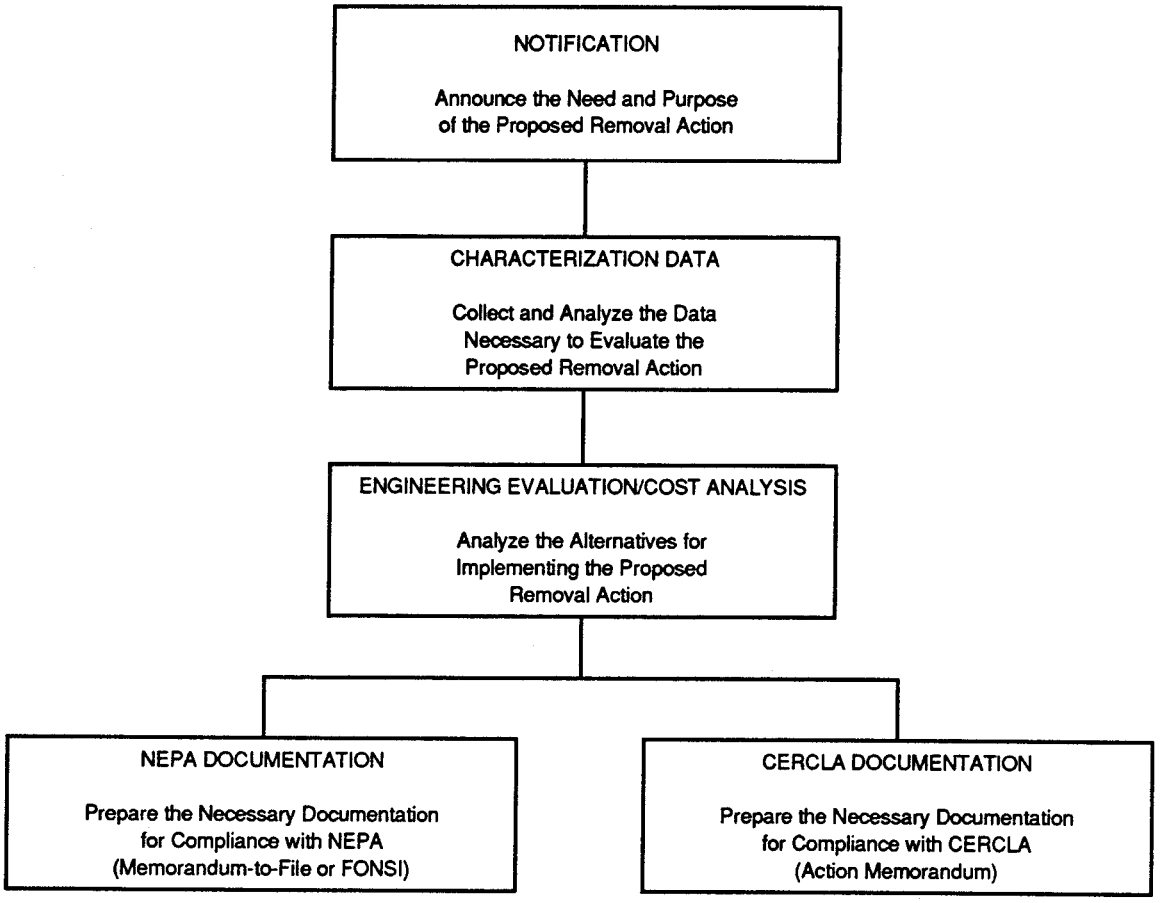

FIGURE 30 Decision-Making Process for Evaluation of IRA Alternatives

3.10.2.1 Removal of PCB Transformers

Fifteen on-site transformers and several additional electrical components on-site held an estimated 25,000 L (6,500 gal) of PCB-containing fluids. Approximately 49,000 L (13,000 gal) of PCB fluids and flushing solutions were removed and transported to an off-site licensed incineration facility; the flushed units were then transported off-site to a licensed disposal facility. Eleven non-PCB transformers were removed as well. Removal of these radioactively clean, out-of-service transformers from the site was carried out in compliance with existing regulations and will prevent leakage of the PCBs during subsequent response action activities at the raffinate pits and chemical plant area. Thus, this action has reduced the volume of on-site materials requiring disposal and has decreased the potential health threats to workers during subsequent on-site activities that would have been associated with PCB contamination.

Status: EPA and state concurrence received in November 1987.
Removal action completed in August 1988.

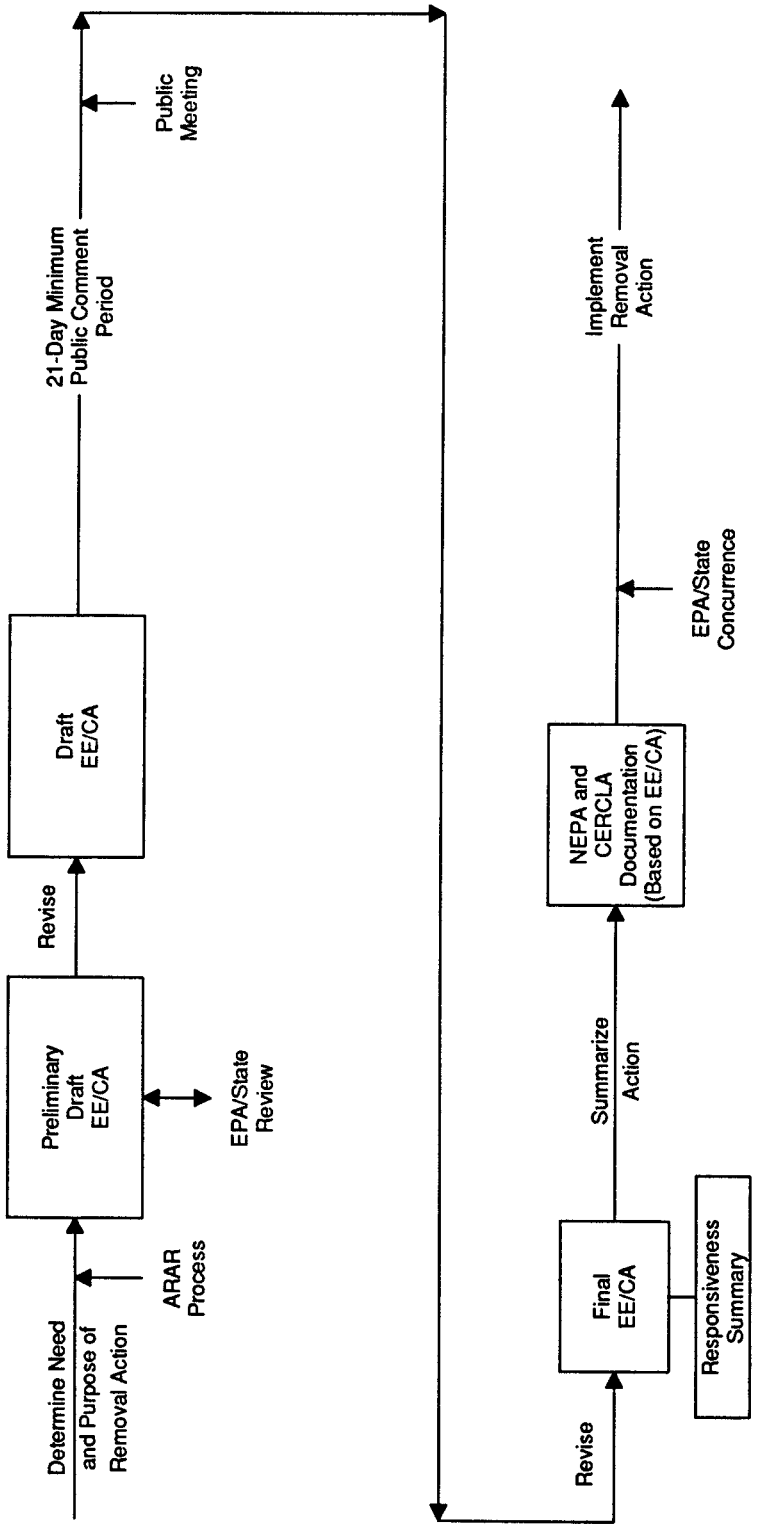

FIGURE 31 Flow Chart of the EE/CA Process

3.10.2.2 Construction of an Ash Pond Isolation Dike

Surface water runoff flowing from the east into Ash Pond, the lowest elevation on the site, is contaminated with uranium measured at levels up to 440 pCi/L. Water runoff from the south flows across a former dump area and into Ash Pond, such that the pond outflow into the Busch Wildlife Area is contaminated with uranium measured at levels up to 3,500 pCi/L. Construction of a dike and channels to divert surface runoff around the dump area and Ash Pond will minimize surface water intrusion and help control erosion. This action will reduce the levels of radioactive contamination leaving the site via surface water runoff.

Status: EPA and Missouri DNR comments received in December 1987.
Additional data were collected to address EPA and Missouri DNR concerns.
Revised documentation transmitted to EPA and state in June 1988.
Construction to begin October 1988; projected completion by November 1988.

3.10.2.3 Construction of Material Staging Area

A material staging area is needed to store, on a temporary basis, contaminated materials resulting from IRA activities at the chemical plant and vicinity properties. In addition to storage, the staging area will be used to classify and segregate materials for future disposal. This staging area will consist of approximately 1.2 ha (3 acres) of cleared ground. A low-permeability liner will be installed and a surface water diversion system and a leachate collection system will be provided. This action will facilitate the consolidation and screening of contaminated materials and will minimize potential threats to workers and the environment related to both the scattered materials and the temporary storage of the materials.

Status: To be developed.

3.10.2.4 Cleanup of Army Reserve Property A7

About 1.2 m^3 (1.5 yd^3) of radioactively contaminated soil was removed from Army Reserve vicinity property A7, which is located about 1 m (1 yd) north of Army Road No. 1 and 300 m (330 yd) west of a road intersection. The soil was placed in eight 55-gal drums, loaded onto a pickup truck, transported to the raffinate pits and chemical plant area, and then placed in storage in an on-site building. Vicinity property A7 was radiologically surveyed by an independent contractor to confirm that cleanup was effective in removing the radioactive material, thereby minimizing the potential threat to public health and the environment associated with this contaminated soil.

Status: EPA and state concurrence received in November 1987.
Removal action completed in January 1988.

3.10.2.5 Cleanup of Selected Locations on Department of Conservation Property

Radioactively contaminated soil will be removed from four isolated locations on Missouri Department of Conservation property (see Figure 29): one on the Busch Wildlife Area, north of the raffinate pits and chemical plant area (B3); and three on the Weldon Spring Wildlife Area, south of the raffinate pits and chemical plant area (B4, B5, and B8). The excavated soil will be stored in a designated, controlled-access area at the Weldon Spring site until final disposition. The current estimated volume to be removed is 400 m^3 (520 yd^3). This action will reduce potential threats to public health and the environment associated with this contaminated soil.

Status: To be developed.

3.10.2.6 Removal of Overhead Piping/Asbestos

Ten thousand linear meters (33,000 linear feet) of overhead piping and 500 structural supports, which hold 4,000 linear meters (13,000 linear feet) of asbestos-containing material, will be removed from the chemical plant area. The asbestos-containing material will be wrapped and dismantled, and soil contaminated with asbestos will be cleaned up. All materials will be surveyed and classified. Nonradioactive asbestos-containing material will be transported to an off-site licensed disposal facility; radioactive asbestos-containing material will be stored on-site. Reusable materials may be salvaged. This action will reduce potential off-site airborne releases of asbestos, reduce potential threats to the health and safety of on-site workers, reduce the volume of on-site materials requiring disposal, and facilitate future cleanup efforts.

Status: EPA and state concurrence received in November 1987.
Removal action to begin September 1988; projected completion by April 1989.

3.10.2.7 Disposal of Containerized Chemicals

There are 4,000 individual containers on-site in which 300 different types of chemicals are stored. The estimated volumes are 19,000 L (5,000 gal) of containerized liquids and 71 m^3 (93 yd^3) of containerized solids. The types of containers include laboratory vials and bottles, bags, cylinders, and drums. Although some of the containers are intact, others have deteriorated and are leaking. Radioactively contaminated materials will be stabilized and consolidated for future disposition. Nonradioactive materials will be sampled and tested for chemical compatibility, then stabilized, consolidated, and transported off-site by a licensed hauler to a licensed disposal facility. This removal will reduce the potential for future exposure of on-site workers to these chemicals and the potential for leakage of chemical containers during future cleanup activities, as well as reduce the volume of on-site materials requiring disposal.

Status: EPA and state concurrence received in November 1987.
Removal action to begin August 1988; projected completion by November 1988.

3.10.2.8 Removal of Electric Lines and Poles

All deenergized exterior power and telephone lines (an estimated 46,000 linear meters [150,000 linear feet] of cable and wire) and 300 timber poles, their cross beams, and supports have been removed from the chemical plant area. These inactive lines and poles were deteriorating, and many had fallen or were in danger of falling to the ground. All materials were radiologically surveyed and classified. Nonradioactive material was transported off-site for salvage; radioactive material is being stored on-site. Removal of these items has improved the safety conditions for on-site workers and reduced the volume of on-site materials requiring disposal; it also facilitates future cleanup activities (e.g., dismantling of area buildings).

Status: EPA and state concurrence received in November 1987.
Removal action completed in March 1988.

3.10.2.9 Consolidation of Debris

Following the inventory and characterization of containerized chemicals and the scanning of major items for radioactive contamination, action will be taken to consolidate debris (e.g., pipe, steel, and rubble) randomly scattered throughout the site. Placing this debris in one controlled area will improve environmental and safety conditions on the site. It will also facilitate groundskeeping and future dismantling and construction activities.

Status: EPA and state concurrence received in November 1987.
Awaiting construction of material staging area.

3.10.2.10 Dismantling of Building 409 (Administration)

The two-story, 3,500-m^2 (38,000-ft^2) former administration building (409) is badly deteriorated. Characterization of this building has identified the presence of asbestos pipe insulation, PCB contamination on floor surfaces, and radioactive contamination in the roofing material. The asbestos insulation and the PCB-contaminated material will be removed and transported off-site to appropriately licensed disposal facilities. The radioactively contaminated material will be containerized and stored on-site until final disposition. Internal equipment, walls, and the superstructure will then be dismantled and transported to an off-site licensed disposal facility or salvaged where feasible. This action will facilitate future cleanup activities, reduce the volume of on-site materials requiring disposal, and reduce the potential health and safety hazards to on-site workers associated with the deteriorating structure.

Status: EPA and state concurrence received in November 1987.
Removal action to begin August 1988; projected completion by April 1989.

3.10.2.11 Dismantling of Building 401 (Steam Plant)

The steam plant (Building 401) is a 1,600-m^2 (17,000-ft^2) building that contains asbestos and small radioactively contaminated areas. Asbestos from the building will be removed and transported to an off-site licensed disposal facility. The radioactively contaminated material will be containerized and stored on-site until final disposition. The equipment and building will then be dismantled and transported to an off-site licensed disposal facility or salvaged where feasible. This action will facilitate future cleanup activities, reduce the volume of on-site materials requiring disposal, and reduce the potential health and safety hazards to on-site workers associated with the structure.

Status: EPA and state concurrence received in November 1987.
Removal action to begin October 1988; projected completion by June 1989.

3.10.2.12 Construction of Southeast Drainage Dike

A dike will be constructed to isolate contaminated portions of the southeast drainage watershed from surface water intrusion. This dike, which will also provide erosion control, will be about 3.0 m (10 ft) high at its maximum elevation and about 300 m (1,000 ft) long. The southeast drainage watershed, which receives surface water as well as infiltration and inflow from the chemical plant sanitary and process sewers, flows to the Missouri River. Construction of the dike, and subsequent water management, will reduce the potential threat to public health and the environment associated with off-site discharges of contaminated surface water from this area.

Status: To be developed.

3.10.2.13 Cleanup of Army Reserve Properties A1, A2, and A3

More than 1,000 m^3 (1,400 yd^3) of radioactively contaminated soil material (up to approximately 280 pCi/g of uranium and 38 pCi/g of radium) is present on the Army Reserve property. This proposed cleanup consists of removing the contaminated soil material from vicinity properties A1, A2, and A3 (see Figure 29), hauling it to an on-site staging area at the raffinate pits and chemical plant area, verifying and certifying that the affected properties meet cleanup criteria, and then backfilling, regrading, and reseeding the disturbed areas. This action will consolidate the radioactive material in a controlled-access area at the Weldon Spring site, pending its final disposition, and will reduce potential threats to public health and the environment associated with this contaminated soil.

Status: To be developed.

3.10.2.14 Dismantling and Removal of Nonprocess Buildings, Structures, and Equipment

This action involves the dismantling and/or removal of nonprocess buildings, structures, and equipment that were not directly involved in the processing of materials and are therefore not expected to be heavily contaminated. However, many of these buildings, structures, and equipment are likely to be slightly contaminated with radioactive and chemical contaminants (including asbestos and some RCRA-hazardous materials) due to their former use to support activities at the plant and/or their close proximity to processing areas. Nonradioactive, chemically contaminated material will be transported to off-site licensed disposal facilities; radioactive material will be stored on-site. The following buildings, structures, and equipment will be addressed in this action:

Building or Area	Name/Function
104	Lime storage
109	West drum storage
110	East drum storage
202	Green salt tank farm
302	Magnesium building
406	Warehouse
407	Laboratory
408	Maintenance and stores
410	Services building
412	Electrical substation
413	Cooling tower and pump house
414	Salvage building
415	Process incinerator
417	Paint shop
426	Water tower
427	Primary sewage treatment plant
428	Fuel gas plant
430	Ambulance garage
431	Laboratory sewer sampler
432	Main sewer sampler
433-436	Storage buildings
437	Records retention building
438	Storage building
439	Fire training building
443	Fire training storage building
None	Rail and rail ties
None	Fuel tanks
None	Sewers in area

This action may be divided into several smaller actions to expedite the cleanup process. The action will facilitate future cleanup activities, reduce the volume of on-site

materials requiring disposal, and reduce the potential health and safety threat to on-site workers associated with deteriorating, contaminated facilities.

Status: To be developed.

3.10.2.15 Construction and Operation of Water Treatment System for the Quarry

Results of site characterization activities have indicated that the water currently contained in the quarry pond may be leaking from the quarry into local groundwater. It is proposed that this water be collected, treated, and then discharged after verifying that the effluent meets release limits that will be established in conjunction with EPA Region VII and the Missouri DNR. The water treatment system will be designed to continuously treat 0.0050 m^3/s (80 gpm). The initial volume of ponded water to be treated is estimated to be 11,000 m^3 (3,000,000 gal). This action will reduce the risk of contaminant migration to the nearby county well field, thereby reducing the potential threat to public health and the environment and will facilitate future remedial action at the quarry.

Status: An EE/CA for this action is currently being prepared.

3.10.2.16 Construction and Operation of Water Treatment System for the Raffinate Pits and Chemical Plant Area

Results of site characterization activities have indicated that the water currently contained in the raffinate pits is leaking from the pits into local groundwater. It is proposed that this water be collected, treated, and then discharged after verifying that the effluent meets release limits that will be established in conjunction with EPA Region VII and the Missouri DNR. The water treatment system will be designed to continuously treat 0.0063 m^3/s (100 gpm). The initial water volume to be treated is estimated to be 216,000 m^3 (57,000,000 gal). These pits contain the bulk of the surface water at the raffinate pits and chemical plant area. Additional contaminated water at the area, e.g., resulting from other IRA activities, will be treated in this plant on an as-needed basis. This action will reduce the risk of further contaminant migration to surrounding areas and groundwater, thereby reducing the potential threat to public health and the environment associated with contaminated soil and groundwater, and will facilitate future remedial action at the raffinate pits and chemical plant area.

Status: An EE/CA for this action is currently being prepared.

3.10.2.17 Decontamination of Area to Support Construction/Staging Activities at the Weldon Spring Site

Radioactively contaminated soil will be removed from an area of less than 0.4 ha (1 acre) at the quarry location currently planned for construction or staging activities. The contaminated soil will be stored in a designated on-site area until a final decision regarding waste disposal is reached. This action will permit planned activities to go

forward and will reduce the potential threat to on-site personnel that is associated with this contaminated soil.

Status: To be developed.

3.11 REMOVAL OF BULK WASTES FROM THE QUARRY

3.11.1 Proposed Action

The bulk wastes that are present in the quarry may pose a risk to both the health of the local population and the environment. Bulk wastes, as defined here, are wastes that can be removed using technologies such as excavation by standard construction equipment (e.g., backhoe and bulldozer), hydroblasting, and laser scarfing. Bulk wastes include structural debris, drums, sludges, and other solid materials. The DOE is proposing to remove these bulk wastes from the quarry and transport them to the raffinate pits and chemical plant area for temporary storage prior to the ROD for the project. The decision on the ultimate disposal of these bulk wastes will be included as part of the decision for management of the waste materials resulting from remedial action activities at the raffinate pits and chemical plant area.

Although the extent, pathways, and mechanisms of contaminant transport are not fully understood at this time, it can reasonably be concluded that the quarry wastes are the source of the contamination that has been detected in the quarry area. In addition, this contamination is of concern with respect to potential future adverse impacts to surface water and groundwater, which could subsequently represent a risk to public health and the environment. Expedited removal of the bulk wastes would mitigate these risks by eliminating the primary source of contamination and reducing the potential for migration.

Before a long-term remedial plan for the quarry can be developed, the geology, hydrogeology, and extent of residual contamination in and around the quarry must be adequately assessed. In order to accomplish this in a safe and effective manner, it is necessary to first remove the bulk wastes. Because of the nature of the quarry wastes (e.g., steel, rubble, and process equipment), conventional investigative techniques such as drilling or geophysics are infeasible. Additionally, there is a potential risk to the environment resulting from the investigation activities themselves. For example, even if boring through the wastes could be conducted successfully, the wastes could potentially migrate from the quarry via this pathway. All of these issues would be minimized or avoided if the bulk wastes were first excavated and detailed evaluation of the quarry residual materials were conducted as a follow-on activity.

Another reason for the removal and transport of these bulk wastes to the raffinate pits and chemical plant area is that such action would allow consolidation of wastes associated with the Weldon Spring site in one location, rather than their current location in two noncontiguous areas. This would enable DOE to better control access, prevent accidental releases, and provide for environmental monitoring. Finally, the removal of the bulk wastes would accomplish one step in the overall remediation of the

Weldon Spring site and would expedite the development and implementation of a long-term response action strategy at the quarry.

The public has expressed a concern that disturbing the wastes unnecessarily could result in the unintentional release of contaminants. The major mechanism for such release would be contaminant migration from the quarry via groundwater. The potential for this release would be reduced by lowering the water level in the quarry pond through pumping, treating, and discharging the effluent prior to excavation of the bulk wastes. The lowered water table would effectively turn the quarry into a sump, i.e., by reversing the gradient for groundwater movement, thereby greatly reducing the potential for contaminant migration. Treatment of this ponded water is being addressed as an IRA (see Section 3.10.2.15).

3.11.2 Documentation Requirements

Environmental compliance documentation must be prepared for the Weldon Spring site in accordance with the requirements of NEPA and CERCLA. The raffinate pits and chemical plant area and the quarry, although noncontiguous, are considered to be one site for the purpose of this remedial action project. A single, comprehensive analysis is usually prepared for each NPL site; however, it is possible to subdivide a large and/or complicated site into separate operable units to expedite the documentation and remediation processes. An operable unit is a discrete part of the entire site (or of a response action), whose management (or performance) decreases a release or threat of release, or limits a pathway of exposure. Implementation of response action at a separate operable unit must be consistent with the permanent remedy for the entire site, even though the action may be implemented prior to selection of the final remedy. By defining the quarry bulk wastes as a separate operable unit, it becomes possible to expedite this remedial action. The residual wastes (i.e., within bedrock fractures) and the groundwater will be managed as additional separate operable units after sufficient data have been obtained to define and evaluate appropriate remedial action alternatives. This can only be accomplished after the bulk wastes have been excavated and removed from the quarry.

3.11.2.1 RI/FS-EA Process

The proposed response action for this separate operable unit could be considered either a remedial action or a removal action. For CERCLA, a remedial action is supported by an RI/FS whereas a removal action is supported by an EE/CA. For this project, these two processes have been modified to allow for NEPA and CERCLA compliance with one set of documentation (see Sections 1.2 and 3.10.1). The RI/FS is a formal process that has specific data and documentation requirements. The EE/CA is a less formal process that generally focuses on one or two alternative actions and has somewhat flexible documentation requirements. Both processes consider all federal and state ARARs and stress the use of permanent solutions to the extent practicable.

A focused RI/FS is an administrative compromise between the full-scale RI/FS and EE/CA approaches for CERCLA compliance; it encompasses many of the procedural

advantages of an EE/CA while maintaining the formal nature of an RI/FS. The focused RI/FS is generally applicable to separate operable units that have limited alternatives and that subsequently allow a more simplified selection process and require only limited data gathering. When the action involves a separate operable unit rather than an entire site, EPA concurrence is in the form of an action memorandum. Otherwise, the process and format of a focused RI/FS generally comply with those of the conventional RI/FS.

The DOE is planning to use the concept of a focused RI/FS to document the removal and transport of the quarry bulk wastes to the raffinate pits and chemical plant area for temporary storage. This focused RI/FS process will be modified to include an assessment of environmental impacts associated with this action. The level of environmental review associated with an action of this nature would typically be included in an EA. The DOE is planning to use this hybrid documentation process, termed the RI/FS-EA process, for this action. Procedures for implementing this process are described in Section 3.11.7.

The two major alternatives to be evaluated in the RI/FS-EA process for quarry bulk waste removal are:

- Removing and transporting the bulk wastes to the raffinate pits and chemical plant area for temporary storage, and

- Leaving the bulk wastes in place, pending the ROD for the project.

Other alternatives will be considered, as appropriate; if detailed analyses of these alternatives are not included in the RI/FS-EA process, the reasons for not doing so will be documented. Within the removal alternative, a number of different technologies for each element of this alternative will be considered. The decision on ultimate disposition of the quarry bulk wastes will be included in the overall RI/FS-EIS process for the project.

3.11.2.2 Risk Evaluation

One of the key components of the RI/FS process is the risk assessment. This assessment is conducted for the baseline (no-action) case to determine the potential impacts to human health and the environment and to assist in the determination of the appropriate cleanup criteria. In addition, it provides a basis for evaluating the effectiveness of proposed remedial action alternatives. However, preparation of a comprehensive baseline risk assessment is not possible with the bulk wastes in place. Significant data gaps currently exist with respect to the extent, pathways, and mechanisms for contaminant migration from the quarry. These data gaps preclude the preparation of a comprehensive risk assessment for the proposed removal. Furthermore, much of this information cannot be obtained until after the wastes have been removed. To meet the risk assessment requirement for this process, DOE will prepare a limited baseline risk evaluation -- to the extent possible with existing information -- using as guidance the EPA risk assessment methodology provided in the *Superfund Public Health Evaluation Manual* (U.S. Environ. Prot. Agency 1986b). Current data are sufficient to

justify the need for this action and to allow for an assessment of environmental impacts associated with implementing the action. The need for additional cleanup at the quarry will be addressed after removal of the bulk wastes, at which time a comprehensive risk assessment will be prepared to assess potential impacts from residual materials on human health and the environment and to help establish cleanup criteria.

3.11.3 Additional Characterization

Collection of additional characterization data for the quarry would probably not significantly increase current knowledge concerning the quarry wastes. Also, the type and placement of buried materials make representative sampling difficult. Obtaining samples of the wastes, without altering their chemical properties during collection, is virtually impossible. In addition to the basic difficulty of drilling through the types of materials present and obtaining representative samples, the lubricating fluid required for drilling tends to wash and dilute the resultant samples. To conduct trenching studies of the nonhomogeneous materials would not permit characterization of the entire depth of the waste materials and would be of limited value. Therefore, it is proposed to remove the bulk wastes from the quarry on the basis of existing data regarding both the characteristics of the quarry wastes and the potential transport mechanisms and pathways.

A substantial amount of historical data currently exists on past disposal practices at the quarry, including analytical data regarding the heterogeneity of the wastes. Several characterization studies of the quarry wastes have confirmed the presence of radioactive and chemical contaminants consistent with the types of materials placed in the quarry. Radiological surveys of the quarry wastes have detected naturally occurring radionuclides of the uranium-238 and thorium-232 radioactive decay series, as well as metals associated with uranium-processing activities. The organic compounds that have been identified are those expected from past disposal activities, i.e., PCBs, PAHs, and nitroaromatic compounds. The chemical and radiological species in the quarry are not found in discrete, homogeneous areas; rather they are intermixed in a soil/rubble matrix at varying concentrations.

Additional characterization data regarding groundwater transport of hazardous contaminants from the quarry into the surrounding environment are needed to complete remedial action at the quarry. The groundwater transport is believed to occur through two distinct hydrological regimes: the bedrock and the alluvial aquifer. The bedrock regime involves the limestone walls and floor of the quarry. It is suspected that contaminated leachate migrates from the quarry through solution-enlarged joints and cracks. After passing through this first medium, contaminants are transported into an alluvial aquifer system. The mechanisms and pathways of transport at the interface between the bedrock and alluvial systems are not yet clearly defined. These pathways will be investigated in detail following removal of the bulk wastes.

In contrast, the alluvial aquifer system is fairly well understood. Past characterization and monitoring efforts have involved the drilling of a number of wells throughout the alluvial system. This has resulted in a well-documented subsurface lithology, and the aquifer transport characteristics have been modeled with a reasonable degree of confidence. Although contaminant transport through the quarry bedrock into

the alluvium has not yet been defined, the movement of the contaminants once they reach the alluvial system is well understood.

Detailed evaluation of the transport of contaminants from the quarry into the surrounding environment is not an essential part of this proposed response action. However, the RI/FS-EA process will include an assessment of the potential migration of contaminants into the limestone quarry, to the extent possible, during both the action period and the time period following bulk waste removal. A good understanding of the nature and extent of fracture joints and cracks can be developed only after the bulk wastes have been removed from the quarry and the limestone walls and floors have been exposed for study. The residual contamination in joints and cracks of the quarry -- and in the groundwater -- will be treated as separate operable units following the currently proposed waste removal effort.

3.11.4 Temporary Storage Requirements

Temporary storage of the quarry wastes at the raffinate pits and chemical plant area is a necessary component of the bulk waste removal action. Storage of the wastes will be temporary until the ultimate disposition of all Weldon Spring wastes is determined. The response action will be evaluated on the basis of compliance with potential ARARs, such as RCRA storage requirements given in 40 CFR Part 264, Subparts I and L. These regulations, which are discussed in greater detail in Sections 3.11.4.1 and 3.11.4.2, pertain to container storage and waste piles, respectively. Other requirements, e.g., those of 40 CFR Part 192 -- which provide groundwater and atmospheric protection standards with regard to the release of radioactive materials from uranium mill tailings sites -- will be considered in the determination of potential ARARs for this action.

3.11.4.1 Container Storage

In consideration of the container storage requirements of 40 CFR Part 264, Subpart I, container storage areas will be designed and operated on a base that will contain leaks, spills, and precipitation until the accumulated liquids can be analyzed and removed. The base will be sloped or the containers elevated to prevent contact of the containers with the accumulated liquids. The storage area will have sufficient volume to contain any anticipated surface water accumulation in addition to 10% of the volume of all containers that store wastes with free liquids. Accumulated liquids will be removed from the collection area in as timely a manner as is necessary to prevent overflow of the collection system.

3.11.4.2 Waste Piles

Regulations concerning waste piles (40 CFR Part 264, Subpart L) state that such a pile must be designed, constructed, and installed to prevent the migration of contaminants out of the pile at any time during its active life. Thus, the storage pile will have a containment structure composed of materials that are capable of preventing failure due to pressure gradients, stress of installation or operation, climatic conditions, or contact

with the wastes or waste leachate. It will be installed to cover all surrounding soil likely to be in contact with the wastes or leachate. If not enclosed, the waste pile will also have a leachate collection system that is designed, constructed, maintained, and operated to collect and remove leachate from the pile. To maintain the capacity of the containment system, a surface water runon/runoff control and management system will be developed, and the associated collection and holding facilities will be emptied expeditiously after storms. The pile will be covered or otherwise managed to control wind dispersal and will be inspected regularly for deterioration or malfunction.

3.11.5 Cleanup Criteria

The RI/FS process evaluates potential remedial alternatives with respect to their ability to meet cleanup criteria that have been established for each separate operable unit. These criteria are typically in the form of specific analytical parameters. Due to the sequence of events planned for the quarry, DOE proposes that the cleanup criteria be technology based rather than analytically based. The reason for this approach is recognition that the response action for this separate operable unit is only the first step in the overall remediation of the quarry. Immediately following excavation of the bulk wastes, the next phase will involve a comprehensive investigation of any residues remaining in the quarry and of the hydrogeological characteristics of the bedrock. Data gathered during this phase will support the evaluation and selection of a final remedial action for the quarry. Therefore, the establishment of temporary cleanup criteria that could change would result in no benefit and would also require the additional time and expense of a confirmatory sampling program. It is recommended instead that the final cleanup criteria for the quarry be defined pursuant to completion of the characterization efforts that will follow removal of the bulk wastes.

3.11.6 Water Treatment

Approximately 11,000 m^3 (3,000,000 gal) of ponded water is currently in the quarry. This water must be removed and treated prior to removal of the bulk wastes. Treatment of this water is being addressed as an IRA (see Section 3.10.2.15).

3.11.7 Compliance with NEPA and CERCLA

The DOE is proposing to address quarry bulk waste removal as a separate operable unit and will use the RI/FS-EA process to support this decision (see Section 3.11.2.1). This action is scheduled to occur prior to the ROD for the project. Implementation of the RI/FS-EA process will be as follows. The first two phases of the FS process will be completed concurrent with preparation of the RI and baseline risk evaluation. At this point, an assessment of environmental impacts will be performed consistent with the requirements of an EA in support of a finding of no significant impact (FONSI), if appropriate. If DOE determines that this action requires preparation of an EIS, the action will be included within the overall RI/FS-EIS process for the project, and removal of the quarry bulk wastes will not be undertaken prior to issuance of the ROD.

Because the EA is scheduled to be completed prior to issuance of the FS, the RI/FS process for the quarry bulk waste removal action will be completed only if a FONSI is issued. If an RI/FS for bulk waste removal is completed, DOE and EPA will issue decision documents under CERCLA to document the decision-making process.

4 SAMPLING AND ANALYSIS PLAN RATIONALE

The assessment of remedial action alternatives for the Weldon Spring Site Remedial Action Project involves two major phases: the RI and the FS-EIS. The RI phase consists of all activities necessary to collect data to assess the hazards at the site and to analyze various remedial action alternatives during the FS-EIS phase. In order to conduct the RI in an acceptable manner and to allow adequate oversight, review, and participation by EPA Region VII and the Missouri DNR, DOE is preparing a detailed sampling and analysis plan to define the procedures to be used in site characterization activities. The sampling and analysis plan consists of two parts: (1) a quality assurance project plan that describes the policy, organization, functional activities, and quality assurance and quality control protocols necessary to ensure that the collected data are valid for their intended use, and (2) field sampling plans that provide guidance for all field work by defining in detail the sampling and data-collecting methods to be used for the project.

4.1 QUALITY ASSURANCE PROJECT PLAN

The purpose of the quality assurance project plan (QAPP) is to focus on the programmatic steps employed during the RI phase to ensure precision and accuracy of data. The QAPP will consist of the following 16 elements:

1. Title page
2. Table of contents
3. Project description
4. Project organization and responsibilities
5. Quality assurance objectives for measurement
6. Sampling procedures
7. Sample custody
8. Calibration procedures
9. Analytical procedures
10. Data reduction, validation, and reporting
11. Internal quality control
12. Performance and systems audits

13. Preventive maintenance

14. Data assessment procedures (precision, accuracy, and completeness)

15. Corrective actions

16. Quality assurance reports

The title page will include the usual information. In addition, at the bottom of the title page, provision will be made for the signatures of approving personnel, as follows:

- Project director,
- Project manager,
- Project quality assurance manager,
- DOE project manager, and
- DOE quality assurance officer.

The table of contents will include an introduction, a serial listing of the QAPP elements, and a listing of any appendixes that are required to augment the QAPP. The end of the table of contents will include a list of the recipients of official copies of the QAPP.

The project description will consist of an introductory discussion of the proposed work and general objectives of the investigation. The location, size, and important physical features of the site will also be described. A chronological site history, including descriptions of site use, will be provided along with a brief summary of previous sampling efforts and an overview of the results. Finally, specific project objectives for this phase of data collecting will be listed, and the means by which the data will be used to address each of the objectives will be identified.

Project organization and responsibilities will be described in terms of identifying key personnel and/or organizations that are necessary for each data-collecting study. An organizational table or chart will be included.

The quality assurance objectives for measurement will be based on the intended use of the data, available laboratory procedures, and available resources. The field blanks and duplicate field sample aliquots to be collected for quality assurance purposes will be itemized for the contaminants identified in the project description. The selection of analytical methods requires a familiarity with regulatory requirements concerning data usage. Any regulations that mandate the use of certain methods for any of the sample matrices and parameters listed in the project description will be specified. The detection limits needed for the project will be reviewed against the detection limits of

the laboratory used. Quantitative limits will be established for the following quality assurance objectives:

1. Level of quality assurance effort,

2. Accuracy of spikes and reference compounds,

3. Precision, and

4. Method detection limits.

Completeness, representativeness, and comparability are quality characteristics that will be considered.

Sampling procedures will be submitted with the field sampling plans. For each major measurement, including pollutant measurement systems, a description of the sampling procedures to be used will be provided. Where applicable, the following will be included:

- Description of techniques or guidelines used to select sampling sites;

- Description of the specific sampling procedures to be used;

- Charts, flow diagrams, or tables delineating sampling program operations;

- Description of containers, procedures, and reagents used for sample collection, preservation, transport, and storage;

- Discussion of special conditions for the preparation of sampling equipment and containers to avoid sample contamination;

- Description of sample preservation methods;

- Discussion of the time considerations for shipping samples promptly to the laboratory;

- Examples of the custody or chain-of-custody procedures and forms; and

- Description of the forms, notebooks, and procedures to be used to record sample history, sampling conditions, and analyses to be performed.

Sample custody, which is an integral part of any good laboratory or field operation, is divided into three parts: (1) sample collection, (2) laboratory analyses, and (3) final evidence files. The QAPP will address all three areas of custody. In addition,

the QAPP will provide examples of chain-of-custody records or forms used to record the chain-of-custody for samples, laboratories, and evidence files.

Calibration procedures will be identified for each parameter measured and will include field and laboratory testing. The appropriate standard operating procedure will be referenced, or a written description of the calibration procedures to be used will be provided.

Analytical procedures will be developed using approved EPA procedures or their equivalent. For each measurement, either the applicable standard operating procedure will be referenced or a written description of the analytical procedures to be used will be provided.

The data reduction, validation, and reporting procedures to be used for all collected data will be described. These procedures will include a description of the equations used to calculate the concentration or value of a given parameter, based upon the collected data.

All specific internal quality control methods to be used will be identified. These methods include the use of replicates, spike samples, split samples, blanks, standards, and quality control samples. Ways in which the quality control information will be used to qualify the field data will be identified.

The internal and external performance and systems audits that will be used to monitor the capability and performance of the total measurement system will be described. The systems audits consist of evaluating the components of the measurement systems to determine their proper selection and use. These audits include a careful evaluation of both field and laboratory quality control procedures and are normally performed before or shortly after systems are operational. However, such audits should be performed on a regularly scheduled basis during the lifetime of the project.

A preventive maintenance schedule will be provided for the major preventive maintenance tasks that will be carried out to minimize the down time of field and laboratory instruments.

The precision and accuracy of data must be routinely assessed for all environmental monitoring and measurement data. The QAPP will describe specific procedures to accomplish this assessment. If enough data are generated, statistical procedures may be used to assess the precision, accuracy, and completeness. If statistical procedures are used, they will be documented.

Corrective actions, in the context of quality assurance, are procedures that might be implemented with respect to samples that do not meet quality assurance specifications. Corrective actions will be addressed on a case-by-case basis. The need for corrective actions is based on predetermined limits for acceptability. Corrective actions may include resampling or reanalysis of samples and recommending an audit of laboratory procedures. The QAPP will identify persons responsible for initiating these actions, procedures for identifying and documenting corrective actions, and reporting and follow-up procedures.

Quality assurance reports include results of performance audits, results of systems audits, and significant quality assurance problems encountered, along with recommended solutions. The QAPP will identify the method to be used to report the performance of measurement systems and data quality. The final report for the project will include a separate quality assurance section that summarizes the data quality information contained in the periodic reports.

4.2 FIELD SAMPLING PLANS

The purpose of the field sampling plans is to obtain data to confirm the presence or absence of contaminants, the contaminant sources, modes of transport, direction of contaminant migration, and the effect of the contaminants on public health and the environment. The field sampling plans include a description of objectives, work tasks, specific quality assurance procedures, and level of effort required for site characterization. It is the intent of the field sampling plans to provide a detailed sampling rationale -- including the sampling locations and the types and number of samples -- which, coupled with standard operating procedures and analytical methods/detection limits, will offer a well-defined approach. These plans are designed to permit detailed characterization of the wastes, soil, groundwater, surface water, and facilities at the Weldon Spring site. From these investigations, remedial measures can be identified, evaluated, and selected.

Five categories of field sampling plans will be prepared for the Weldon Spring Site Remedial Action Project:

- Soil investigation,
- Hydrogeologic investigation,
- Waste assessment,
- Geophysical/geotechnical investigation, and
- Other investigations.

4.2.1 Soil Investigation

The soil investigation sampling plan is designed to determine the extent and magnitude of chemically contaminated soil, evaluate contaminant migration pathways, document uncontaminated areas, establish background concentrations, and provide identification of soil contaminant concentrations in both qualitative and quantitative terms for the 88-ha (217-acre) raffinate pits and chemical plant area. The sampling plan delineates a review of historical information, identifies data needs and uses, and outlines sampling and analytical procedures, quality assurance procedures, data documentation requirements, and data reporting requirements for the soil investigation at the raffinate pits and chemical plant area. Specific soil sampling locations have been selected based

on association with the operation of either the ordnance works (explosives production) or the chemical plant (uranium processing). In addition, unbiased sampling over the raffinate pits and chemical plant area will be conducted in order to provide a statistically valid data base for soils characterization and to provide documentation for uncontaminated areas. The soil investigation will provide a data base sufficient to support consideration of remedial action options and preparation of the risk assessment. The subcontract for the soil investigation will be awarded in August 1988; sampling activities will commence immediately thereafter. Laboratory analysis and report preparation are expected to be completed by December 1988.

The radiological contamination investigation of the Weldon Spring site has already been completed. Preliminary radiological characterizations of the site have been conducted by Oak Ridge National Laboratory, Bechtel National, EG&G, and others. An extensive field program was also conducted by UNC-Geotech from April to July 1987 to characterize the horizontal and vertical extent of radioactive contamination in the raffinate pits and chemical plant area (Marutzky, Colby, and Cahn 1988). The UNC-Geotech field program included exposure-rate measurements taken at the ground surface and at one meter above the land surface to delineate areas of elevated exposure rates. At locations exhibiting elevated exposure rates, in-situ measurements of uranium, radium, and thorium-232 were taken. If in-situ measurements showed elevated concentrations, soil samples were collected and analyzed for these radionuclides. Samples were collected with a bucket auger at 15-cm (6-in.) intervals; additional boreholes were drilled where elevated concentrations extended below 45 cm (18 in.).

The UNC-Geotech field activities also included drilling 317 boreholes in the raffinate pits and chemical plant area. Samples collected from each borehole were scanned with a gamma-ray spectrometer. Selected samples were then analyzed for either total uranium, thorium-230, or both. Those samples for which the spectrometric results indicated no elevated activities were archived for possible future analysis.

4.2.2 Hydrogeologic Investigation

The purpose of the hydrogeologic investigation sampling plan is to characterize the groundwater and surface water conditions at the raffinate pits and chemical plant area. The sampling plan has been divided into subtasks that include groundwater monitoring, aquifer testing, analysis of karst hydrogeology, unsaturated zone characterization, assessment of surface water hydrology and quality, studies of regional hydrogeology and water balance, and computer modeling of the hydrologic regime.

Although substantial hydrogeologic data have been collected during past site characterization activities, a number of data deficiencies remain for the raffinate pits and chemical plant area that relate to the areal and vertical distribution of the data, the detail of the data, and the frequency of the data collection. To address these deficiencies, it is the intent of the sampling plan to accomplish the following objectives:

- Extend the monitoring well network in order to determine the vertical and horizontal extent of groundwater contamination, levels of contamination, and hydrogeologic conditions.

- Test the aquifer to (1) provide area and depth data on aquifer characteristics, such as hydraulic conductivity, transmissivity, and storativity; (2) provide information for prediction of long-term contaminant migration; and (3) assess contaminant migration effects that could result from pumping the upper limestone aquifer.

- Study the karst hydrogeology by conducting dye-tracing and streamflow studies to determine groundwater/surface water interactions and improve understanding of migration pathways and rates.

- Study the surface water hydrology and water quality to (1) define potential surface migration pathways; (2) determine the possible extent of migration; (3) define the concentration levels of contaminants in surface water; and (4) define the hydrologic characteristics associated with the surface water features.

- Characterize the unsaturated zone to (1) define chemical and physical characteristics in order to classify types and levels of contaminants; (2) estimate recharge to the groundwater system; and (3) define perched zones that may influence contaminant migration.

- Perform hydrogeologic and water balance studies to define (1) regional groundwater levels; (2) fluctuation features that influence groundwater movement and surface water/groundwater interaction; and (3) groundwater geochemistry relationships.

- Define the groundwater system through reasonably detailed and accurate computer models of groundwater flow and contaminant transport in order to predict future contaminant migration and to develop and evaluate the effectiveness of possible mitigative measures.

- Perform data evaluation analyses for the above tasks and previous studies in order to accomplish the field sampling plan objectives.

Field activities to meet the stated objectives of the hydrogeologic investigation are in various stages of completion, as described below.

- Thirty-three additional monitoring wells have been drilled on-site and nine additional wells are being drilled at various off-site locations. Well development is proceeding and is expected to be completed by September 1988. Sampling of these new wells will begin two weeks after their development is complete.

- The pumping and observation wells to test the local aquifer were completed in August 1988. The procurement activity to perform

the actual testing is under way, and the pump tests are expected to be performed in September and October 1988.

- The Missouri DNR has injected dye into four area wells and is continuing its observation of known springs and seeps for dye emergence.

- Drought conditions have generally precluded the study of surface water hydrology. Results of the Missouri DNR dye-tracing studies will be used to support the surface water hydrology investigation.

- The sampling plan to characterize the unsaturated zone has been prepared and is currently undergoing review.

- The USGS is continuing its routine monitoring of water levels in area wells and creeks. Additional monitoring equipment will be installed by the USGS in August and September 1988.

4.2.3 Waste Assessment

The purpose of the waste assessment sampling plan is to characterize the wastes, sludge, and sediment contained in the raffinate pits; and the wastes resulting from decontamination and decommissioning of the buildings and associated equipment at the chemical plant area.

The characterization of materials in the raffinate pits will include a radiological, chemical, and physical analysis of the following:

- Neutralized raffinates from uranium-refining operations, washed slag residues from uranium metal production operations, raffinate solids from the processing of thorium recycle materials, and contaminated rubble;

- Contaminated water ponded in each raffinate pit; and

- Contaminated clay and soil on the inner surfaces of the dikes surrounding the pits and underlying the pits.

Characterization of the sludge from the raffinate pits is necessary in order to define and evaluate treatment and disposal alternatives. Representative samples of the sludge will be collected and evaluated for chemical, radiological, and physical parameters. The data will then be used to support technical decisions for remedial action alternatives. The sampling of sludge in the raffinate pits began in July 1988. Subcontracts for sludge analysis are currently in place, and analytical results are expected to be available by October 1988.

A radiological characterization of the nonprocess buildings and the equipment inside the buildings will be conducted to determine what buildings and equipment can be released for unrestricted use or disposal. An asbestos and a chemical characterization of all buildings, pipelines, and equipment in the chemical plant area will also be performed. Procurement of the required radiological characterization subcontracts for the nonprocess buildings is currently in the bid cycle. Field activities to support this characterization effort are expected to begin in October 1988. Initial samples to support the asbestos and chemical characterization activities for the nonprocess buildings have been collected by the project management contractor. Full-scale characterization activities will be conducted concurrent with the radiological characterization efforts, i.e., beginning in October 1988.

4.2.4 Geophysical/Geotechnical Investigation

The purpose of the geophysical/geotechnical investigation sampling plan is to physically characterize the site soil, substrata, and bedrock; delineate the tests necessary to support the risk assessment; and evaluate on-site earthen materials proposed for suitability as a containment liner for the disposal cell. In addition, results of the sampling plan will be used to predict, from available data, the worst-case composition of a leachate that might contact the earthen liner upon failure of a primary flexible membrane liner if such a flexible membrane liner were used in the disposal cell. The inherent variability of soil and rock requires a quantitative standard for acceptability. A statistical sampling and testing plan will be developed to address the adequacy and representativeness of the sampling and testing effort. This activity is currently being performed under three separate subcontracts: geotechnical drilling and trenching, geotechnical laboratory testing, and geophysical surveying. These subcontracts are in various stages of implementation. Field activities associated with the investigation are scheduled to be completed in August 1988, and follow-up reports are expected to be available in October 1988.

4.2.5 Other Investigations

Other investigations include a lake and stream sediment characterization and a biouptake study. Additional investigations may be identified during a later stage of the RI/FS-EIS process if a specific need is determined. The purpose of the lake and stream sediment characterization is to determine the extent and magnitude of potential chemically and radioactively contaminated sediments in off-site streams and surface water bodies. The sampling effort will determine the concentrations of uranium, nitro-aromatic compounds, PCBs, semivolatile compounds, and metals in lake and stream sediments affected by drainage from the raffinate pits and chemical plant area. A statistically significant number of samples will be collected and analyzed to limit uncertainty and achieve the level of confidence required to evaluate the baseline (no-action) condition and various remedial action alternatives. Areas receiving direct runoff or subsurface recharge will be the focus of this study. Samples collected for this activity are currently undergoing laboratory analysis. The analysis is expected to be

completed in October 1988, and a characterization report is expected to be issued in November 1988.

The purpose of the biouptake study is to determine and characterize the level of potential human exposure to radionuclides, organic compounds (e.g., nitroaromatics and PCBs), and metals from food pathways in the vicinity of the Weldon Spring site. This is accomplished by sampling biota available for human consumption from various locations around and within the site. The biouptake study is expected to provide data on potential human exposure to contaminants via ingestion. The field collection activities and sample analysis for this study have been completed, and the report is currently in preparation.

4.3 HEALTH AND SAFETY PLANS

Health and safety plans have been developed to ensure the health and safety of on-site personnel during the performance of site characterization and response action activities. The plans include the safety standards that must be met by all personnel and subcontractors during the conduct of their assignments. Addressing the health and safety of on-site personnel will also serve to minimize any potential impacts to the general public and the nearby environment. Key elements of these plans are the use of appropriate protective equipment and safeguards and the performance of specific tasks under the supervision of trained technicians and safety specialists. On-site personnel are trained to be cognizant of all appropriate safety equipment and procedures, locations and types of on-site hazards, standard operating procedures, and procedures to be followed in emergency situations. Health and safety training and medical surveillance of all potentially exposed personnel are required elements of these plans. A copy of the health and safety plans will be appended to the QAPP.

4.4 COMMUNITY RELATIONS PLAN

The community relations plan describes the policy and procedures for the interaction of personnel responsible for implementing the Weldon Spring Site Remedial Action Project with the general public. The purpose of the community relations program is to ensure meaningful exchanges of information on such matters as potential health impacts, environmental issues, response action construction plans, project costs, and specific site activities. A copy of this plan will be appended to the QAPP.

4.5 EMERGENCY PREPAREDNESS PLAN

An emergency preparedness plan has been developed to provide on-site personnel with appropriate procedures for notification/reporting and organization of personnel in the event of an on-site emergency. This plan also includes the procedures for responding to potential credible emergencies that could result in the off-site release of hazardous materials. Such emergencies include fire, tornado, failure of a raffinate pits dike, and spills of hazardous materials. This plan fulfills the requirements of DOE Order 5500.2 and the applicable sections of CERCLA and the Toxic Substances Control Act. A copy of this plan will be appended to the QAPP.

4.6 SPILL PREVENTION, CONTROL, AND COUNTERMEASURES PLAN

A spill prevention, control, and countermeasures plan has been developed for the project. The plan is intended to protect navigable waterways (including groundwater and downstream habitats) from harmful oil spills and to ensure that operations at the Weldon Spring site comply with 40 CFR Part 112. A secondary goal of this plan is to minimize potential damage to the environment by identifying containment and control procedures that can be implemented rapidly. A major element of the plan is procedures for mobilizing on-site personnel to respond to a spill and for notifying appropriate federal, state, and local authorities of the spill. A copy of this plan will be appended to the QAPP.

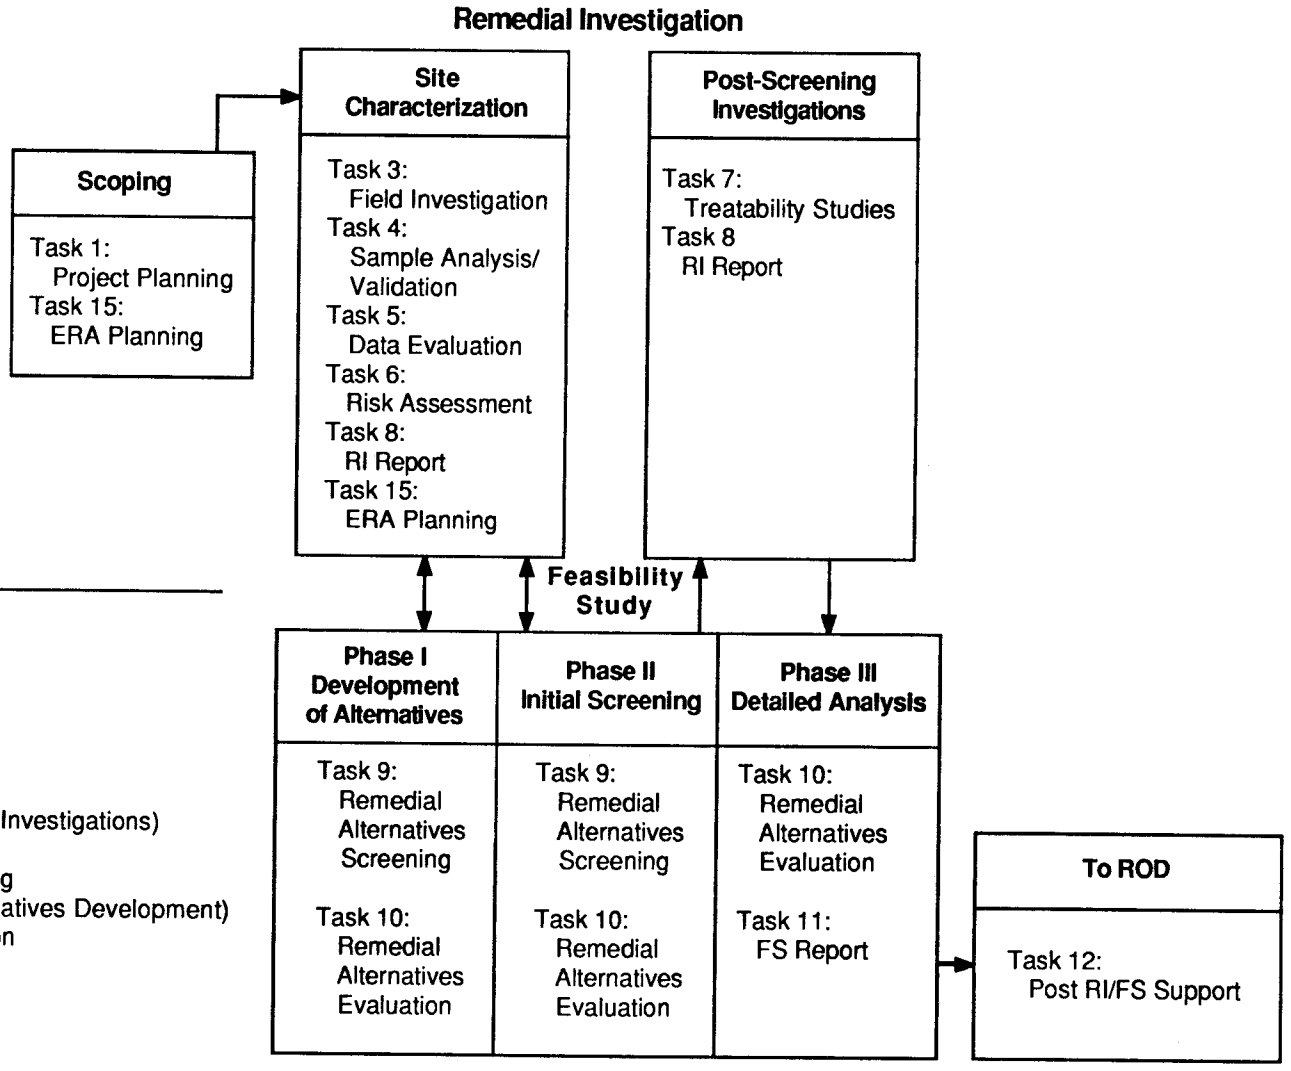
5 REMEDIAL INVESTIGATION/FEASIBILITY STUDY TASKS

Fifteen standard tasks have been defined by EPA as comprising the RI/FS process. This task structure will be used in implementing the RI/FS-EIS process for the Weldon Spring Site Remedial Action Project. This process should enhance coordination with and review by EPA Region VII, the state of Missouri, and local citizens and officials. The RI/FS tasks and the generic phased approach suggested by EPA are shown in Figure 32 and are briefly described in Sections 5.1 through 5.15. Reference is included to other sections of this work plan or other project documents to explain the means by which these 15 tasks are being implemented for this project.

5.1 TASK 1: PROJECT PLANNING

The project planning task initiates the RI/FS-EIS process and establishes the project basis by:

- Collecting and documenting scoping information (Sections 1 and 2),
- Collecting and evaluating existing data (Section 2.5),
- Compiling a list of potential ARARs (Section 3.1),
- Evaluating a conceptual exposure model (Section 3.2),
- Performing preliminary assessments of contaminant status (Sections 3.3 through 3.7),
- Developing conceptual response alternatives (Section 3.8),
- Identifying various feasibility studies to support the RI/FS-EIS process (Section 3.9),
- Identifying operable units and potential expedited (interim) response alternatives (Sections 1.2, 3.10, and 3.11),
- Establishing data quality objectives (Section 4.1),
- Identifying major project plans, including the field sampling plans (Sections 4.2 through 4.6),
- Documenting RI/FS-EIS tasks (remainder of Section 5),
- Developing schedules for completion of major project elements (Section 6), and
- Identifying project organization and project management (Section 7).



RI/FS Work Plan Standard Tasks

Task	Title
1	Project Planning
2	Community Relations*
3	Field Investigation
4	Sample Analysis Validation
5	Data Evaluation
6	Risk Assessment
7	Treatability Study/ Pilot Testing (Post-Screening Investigations)
8	Remedial Investigation Report
9	Remedial Alternatives Screening (Technology Screening/Alternatives Development)
10	Remedial Alternatives Evaluation
11	Feasibility Study Report
12	Post RI/FS Support
13	Enforcement Support*
14	Miscellaneous Support*
15	ERA Planning

* Tasks that can occur in any phase of the RI/FS

FIGURE 32 Relationship of RI/FS Tasks to the Phased RI/FS Approach

All of these elements are included in this work plan. Many elements are summaries of more comprehensive documents. Each of the summaries contained in this work plan reflects the current status of the respective task. This work plan will be updated in the future, as appropriate.

5.2 TASK 2: COMMUNITY RELATIONS

Task 2 incorporates all efforts related to the preparation and implementation of the community relations plan. Community relations are initiated at the beginning of the RI/FS-EIS process and will be completed when all community relations activities under Task 12 are complete. Task 2 does not include preparation of the responsiveness summary, which is part of Task 12. The following are typical components of Task 2:

- Community relations plan,
- Fact sheets,
- Public meeting support,
- Technical support for community relations, and
- Community relations implementation.

The DOE has already established a community relations plan for the Weldon Spring Site Remedial Action Project (see Section 4.4).

5.3 TASK 3: FIELD INVESTIGATION

Task 3 includes all efforts related to field work performed to conduct the RI phase of the RI/FS-EIS process so that adequate technical data will be available to support the development and evaluation of alternatives during the FS-EIS phase. The task begins with the procurement of subcontractors and is complete when all contractors and subcontractors performing portions of the site investigation task are demobilized from the field. The following activities are typically included in this task:

- Mobilization of field activities,
- Media sampling,
- Source testing,
- Geological/hydrological investigations,
- Geophysical investigations,
- Site surveys/topographic mapping,

- Field measurements/analyses,
- Procurement of subcontractor services, and
- RI waste disposal.

Plans for field investigations are documented in field sampling plans. Five categories of field sampling plans are being developed for the Weldon Spring site that cover the full range of contaminated and/or potentially contaminated areas at the site (see Section 4.2).

5.4 TASK 4: SAMPLE ANALYSIS/VALIDATION

Analyses of samples collected during the field investigation will be performed in accordance with the data quality objectives established for this project. The analyses will be performed by laboratories that participate in the EPA Contract Laboratory Program (CLP), using CLP analysis protocol where appropriate. Procedures to ensure quality control during sample analyses are described in EPA's CLP guidance document (U.S. Environ. Prot. Agency 1986a). Sample management and data validation will be performed using EPA-approved procedures and specifications.

Validation of measurements is a systematic process of reviewing a body of data to provide assurance that the data are adequate for their intended use. The validation process includes the following activities:

- Auditing measurement system calibration and calibration verification,
- Auditing quality control activities,
- Monitoring sample management,
- Monitoring non-CLP analyses and use of mobile laboratories (if appropriate),
- Screening data sets for outliers,
- Reviewing data for technical credibility,
- Reviewing chain-of-custody procedures, and
- Checking intermediate calculations.

Procedures that will be used to provide quality assurance for this project will be described in detail in the QAPP (see Section 4.1).

5.5 TASK 5: DATA EVALUATION

Task 5 includes efforts related to the analysis of data once the data have been verified, under Task 4, to be of acceptable accuracy and precision. Task 5 begins on the date that the first set of validated data is received and ends during preparation of the RI report when it is determined that no additional data are required. The following are typical Task 5 activities:

- Literature surveys (e.g., for relevant information on geology, hydrology, and remedial technology),
- Data evaluation,
- Data reduction and tabulation, and
- Environmental fate and transport modeling/evaluation.

These activities will lead directly to the development of the baseline risk assessment and the screening of remedial action alternatives in the FS-EIS. All calculations will be documented in calculation logs and checked by an independent reviewer prior to sign-off. Where computations are performed with computer programs, either validated software will be used or the calculation methods will be hand-verified.

5.6 TASK 6: ASSESSMENT OF RISKS

After the site information and characterization data have been validated and evaluated, a baseline risk assessment will be performed to determine the potential threats to public health and the environment in the absence of any remedial actions at the site. To determine the hazards posed by current site conditions, the assessment will analyze the environmental transport pathways to potential receptors from areas where radioactive and chemical contaminants are currently located. The risk assessment will also be used to assist in the screening of alternatives and to assist in determining acceptable levels of residual contamination (i.e., cleanup limits) for radioactive and chemical species. An overview of the risk assessment process is shown in Figure 33.

The first step in the risk assessment process is the selection of indicator chemicals and radionuclides that pose potential risks to public health and the environment. These indicator chemicals and radionuclides are those that represent the most toxic, mobile, and persistent species at the site, as well as those that are present in the largest amounts. These "highest risk" species are used to assess risks at the site. This list of indicator chemicals and radionuclides will be based on data obtained during field investigations and on usable data previously gathered. A quantitative risk analysis will be performed for all indicator species identified in this step.

The second step in the risk assessment process is the characterization of potential exposure pathways and the determination of exposure concentrations. Potential exposure pathways are described in Section 3.6. Possible pathways that will be

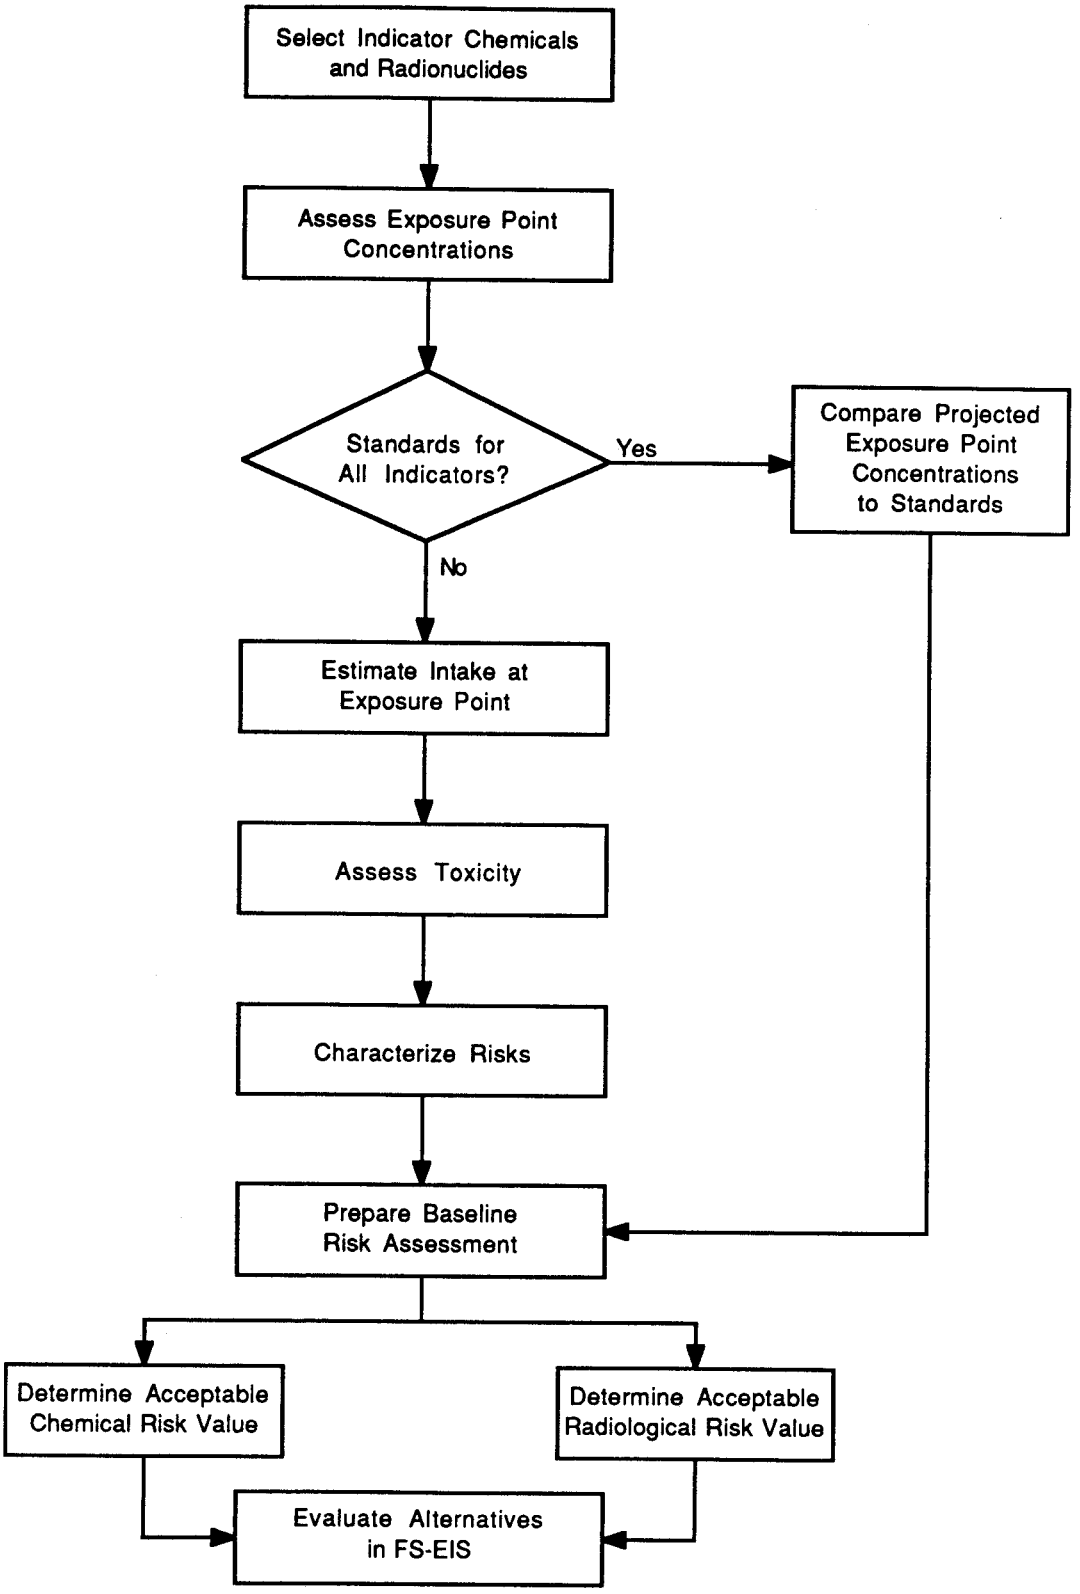


FIGURE 33 Overview of the Risk Assessment Process

evaluated include air, soil, sediment, groundwater, surface water, and biota. Site-specific exposure routes for the study area will be addressed in the evaluation. Initially, these exposure pathways will be the principal areas of focus; however, subsequent data collected during field investigations may warrant the inclusion of additional exposure pathways.

The concentrations of the indicator chemicals and radionuclides in environmental media at exposure points will be estimated using characterization and monitoring data and appropriate environmental fate and transport models. Several models are available for use. The models and input parameters to be used will be developed in cooperation with EPA Region VII and the state of Missouri. Information from the literature and prior studies regarding environmental chemistry and contaminant fates will be considered and incorporated, where valid and applicable, in all estimates of chemical and radionuclide concentrations. The estimated concentrations will then be compared to the potential ARARs. If health-based ARARs are available for all indicator chemicals and radionuclides, no further quantitative analysis of risk will be performed as part of the baseline risk assessment. The baseline risk assessment will evaluate existing data to confirm that the pollutant transport models adequately reflect conditions at the site and to determine where additional data are needed to properly characterize risks.

If health-based ARARs are not available for all indicator chemicals and radionuclides, quantitative analyses will be performed following the general procedures outlined in EPA's *Superfund Public Health Evaluation Manual* (U.S. Environ. Prot. Agency 1986b). The identification of sensitive receptors near the site will be based on demographic records and standard demographic statistical techniques. A population activity profile will be developed, based on area land use and population structure, to delineate exposure coefficients required for quantitative evaluation of exposure. The baseline risk assessment ends with the characterization of risks to human health and the environment in the absence of any remedial action at the site. The risk assessment process continues with an evaluation of risks associated with various remedial action alternatives.

The Weldon Spring site is contaminated with both radioactive and chemically hazardous substances. This situation is somewhat different than usual because most sites remediated under CERCLA are contaminated only with hazardous chemicals. Determining the significance of risks differs markedly for radiological and chemical contaminants because the radionuclides associated with the Weldon Spring site occur naturally in the environment whereas chemical carcinogens generally do not. For this reason, combining the two risks during the risk assessment process could mask distinct, relevant information. Therefore, the chemical and radiological risks associated with the various remedial action alternatives will be evaluated in parallel during the risk assessment process. This assessment will provide a mechanism for determining the range and extent of remedial action activities based upon comparison to acceptable levels of risk. The resultant risk from radioactive contaminants following remedial action activities will be evaluated as an incremental risk over that resulting from background sources of radiation whereas the residual risk from exposure to chemical carcinogens can be evaluated as an absolute risk because exposure to these chemical substances does not generally occur in our everyday environment.

The dose to any individual from background sources of radiation averages about 200 mrem/yr, which corresponds to a 70-year lifetime cancer risk of about 2×10^{-3} (this value exceeds the upper limit of the EPA acceptable risk range of 10^{-4} to 10^{-7}). This risk from background radiation sources may be contrasted to the hazards from exposure to chemical carcinogens that are not naturally present in our environment (e.g., PCBs and nitroaromatics). Using the EPA-recommended target risk value of 10^{-6}, with a range of 10^{-4} to 10^{-7}, is indeed appropriate for those types of contaminants.

Because the residual radiological risk can be interpreted only as an increment to the risk from background radiation, it is necessary to determine what an appropriate increment should be. Determination of the acceptable level of radiological risk can be developed using the "as low as reasonably achievable" (ALARA) philosophy for reducing radiation doses below acceptable limits. The point at which further reduction in radiation exposure (and hence risk) cannot reasonably be achieved is the increment in radiological risk (above the risk from background sources of radiation) that should be used to assess the scope of remedial action activities. The acceptable level of residual chemical risk will be determined consistent with EPA guidance. Hence, during the evaluation of various alternatives in the FS-EIS, radiological doses will be compared to a radiological risk value and chemical risks will be compared to a chemical risk value. The cumulative risk to potential receptors, i.e., the sum of the radiological and chemical risks, will be assessed in the FS-EIS.

5.7 TASK 7: TREATABILITY STUDIES

Task 7 is performed after alternatives have been screened in the FS-EIS phase. This task includes any efforts related to the performance of pilot and bench-scale treatability studies as well as associated procurement efforts. Such studies may be necessary to test volume reduction or treatment technologies for the waste materials at the Weldon Spring site that have not yet been proven reliable or effective in full-scale operation or on similar materials and to develop sufficient conceptual design information on which to base analyses in the FS-EIS. Several post-screening investigations have already been identified (see Section 3.9). Additional studies will be developed, as necessary, to support the screening of potential technologies with respect to availability and technical and administrative feasibility (see Section 5.9).

5.8 TASK 8: RI REPORT

Task 8 covers all efforts related to the reporting of RI findings once the data have been evaluated under Tasks 5 and 6. Task 8 covers all draft and final RI reports, and includes the following typical activities:

- Formatting data for reporting purposes,
- Writing the report,
- Preparing associated graphics,

- Providing and reviewing quality control efforts,
- Printing and distributing the report,
- Holding review meetings, and
- Revising the report based on reviewer comments.

5.9 TASK 9: SCREENING OF REMEDIAL ACTION ALTERNATIVES

Task 9 involves the screening of remedial action alternatives for the Weldon Spring Site Remedial Action Project. This evaluation is conducted subsequent to the screening of technologies and development of alternatives that is completed during the first phase of the FS-EIS process.

The objective of the Task 9 screening process is to narrow the range of alternatives that will undergo detailed evaluation. This process begins with the identification of remedial action objectives, proceeds through a screening of technologies based on implementability, and ends with the assembly of screened technologies into a set of remedial action alternatives (a preliminary set of alternatives for management of the contaminated materials at the Weldon Spring site is given in Section 3.8). Each of these alternatives may involve the application of a single technology or the combination of multiple technologies.

Task 9 consists of the following activities:

- Identifying remedial action objectives,
- Listing potential technologies,
- Screening technologies based on site-specific criteria,
- Assembling potential remedial action alternatives from the screened technologies, and
- Screening the candidate remedial action alternatives for detailed evaluation in Task 10 (Section 5.10).

5.10 TASK 10: EVALUATION OF REMEDIAL ACTION ALTERNATIVES

The candidate remedial action alternatives that pass the screening process will be evaluated in detail in Task 10. Three criteria will be used to evaluate the candidate alternatives: effectiveness, implementability, and cost.

In the effectiveness evaluation, two factors will be used for detailed analysis of candidate remedial action alternatives: (1) degree of protectiveness and (2) ability to reduce the toxicity, mobility, and/or volume of the contamination. The first factor,

protectiveness, involves the following set of subfactors, which are essentially short-term factors:

- Ability to reduce existing risks,
- Compliance with criteria, advisories, and guidelines that are pertinent to the site and have been identified during the ARAR process,
- Compliance with potential ARARs,
- Protection of the community and on-site workers during remedial action, and
- Time required until protection is achieved.

For the longer term, protectiveness involves:

- Magnitude of residual risk,
- Long-term reliability,
- Compliance with ARARs,
- Prevention of future exposure to residual contamination, and
- Potential need for future maintenance.

The second factor in the effectiveness evaluation deals with the long-term ability to bring about a permanent and significant reduction of toxicity, mobility, and/or volume of the contamination.

In the implementability evaluation, three factors will be used in the detailed analysis of candidate alternatives: (1) technical feasibility, (2) administrative feasibility, and (3) availability. Technical feasibility relates to the following, essentially short-term, subfactors:

- Ability to use the technology,
- Short-term reliability of the technology,
- Compliance with potential action-specific ARARs, and
- Status of the technology, i.e., whether or not proven.

For the longer term, technical feasibility relates to:

- Ease of undertaking additional remedial action, if necessary,

- Ability to monitor the effectiveness of the remedy, and
- Ability to perform maintenance activities.

Two subfactors will be considered in evaluating candidate alternatives with respect to administrative feasibility:

- Likelihood of favorable community response, and
- Compliance with specific ARARs.

Two subfactors will be considered in evaluating candidate alternatives with respect to availability.

- Availability and capacity of required treatment, storage, and disposal services, and
- Availability of necessary equipment and specialists.

These subfactors are expected to be reflected largely in the technology screening performed in Task 9 and generally will not be expected to be decisive in evaluating candidate alternatives.

The cost evaluation of each alternative will include capital and annual operating/maintenance costs, sensitivity of cost estimates, and present worth analyses. The total capital costs include both direct and indirect capital costs. The major direct capital cost components are based on the major functional facilities, equipment, and construction features. Operating costs for implementing temporary remedial actions and other capital costs incurred until the remedial action is completed will also be considered as part of the capital cost. Material quantities, labor, equipment, and installation costs are estimated on the basis of available sources and local wage rates. The indirect capital costs include overhead, legal fees, administrative costs, and contingency allowances.

Operating costs will be determined from estimates of labor and material requirements. Maintenance costs will be calculated as a percentage of the direct construction costs, based on standard costs and experience, but will reflect perpetual care considerations, costs of periodic reviews such as would be associated with nontreatment alternatives, and the potential for future remedial action costs.

The annual cost will be converted to a present worth capital expenditure. Inflation, discount, and interest rates will be estimated in accordance with current market values. Finally, a sensitivity analysis will be prepared of financial factors that could affect the overall costs of the various alternatives. The key financial factor to be considered is a change in the discount rate.

A summary for each alternative, including the no-action alternative, will be prepared using the criteria outlined in the preceding sections. The relative advantages and disadvantages will then be used to compare and evaluate the remedial action alternatives.

5.11 TASK 11: DRAFT RI/FS-EIS REPORT

The draft RI/FS-EIS report will contain descriptions of the activities, results, and associated conclusions for the entire RI/FS-EIS process. The report will also address those NEPA-related topics not typically addressed in an RI/FS, e.g., environmental consequences of taking each of the remedial action alternatives under consideration, long-term impacts, cumulative impacts, mitigative measures, unavoidable adverse impacts, potential impacts from loss of institutional controls, irreversible and irretrievable commitment of resources, and short-term uses and long-term productivity. The report will include a description of the screening process and a detailed evaluation of remedial action alternatives. The task is complete when the draft RI/FS-EIS is released to the public. The following are typical Task 11 activities:

- Formatting data for reporting purposes,
- Preparing associated graphics,
- Writing the report,
- Printing and distributing the report,
- Holding review meetings, and
- Revising the report based on reviewer comments.

5.12 TASK 12: FINAL RI/FS-EIS REPORT AND SUPPORTING ACTIVITIES

Task 12 includes efforts to prepare the responsiveness summary, revise the RI/FS-EIS report as necessary in response to public comments, support preparation of the ROD, and perform design engineering activities. All activities occurring after release of the draft RI/FS-EIS to the public, and prior to issuance of the ROD, should be covered under this task. The following are typical Task 12 activities:

- Attending public meetings,
- Writing/reviewing the responsiveness summary,
- Revising the RI/FS-EIS in response to public comments,
- Printing and distributing the final RI/FS-EIS,
- Supporting ROD preparation/briefings,
- Providing and reviewing task management and quality control efforts,

- Preparing the predesign report, and
- Completing the conceptual design.

5.13 TASK 13: ENFORCEMENT SUPPORT

Task 13 includes the activities associated with enforcement aspects of the project in terms of potentially responsible parties. Because DOE accepts responsibility for the waste materials that fall within the scope of this document, Task 13 is not applicable.

5.14 TASK 14: MISCELLANEOUS SUPPORT

Task 14 is used to report on work that is associated with the project but does not fall under any of the other established RI/FS-EIS tasks. Task 14 activities will vary, but may include the following:

- Specific support for review of activities of the Agency for Toxic Substances and Disease Registry,
- Special efforts related to public health assessments, and
- Support for review of special state or local projects.

5.15 TASK 15: EXPEDITED (INTERIM) RESPONSE ACTION PLANNING

Task 15 relates specifically to planning expedited response actions (ERAs), which are synonymous for this project with the term interim response actions (IRAs). The proposed IRAs for the Weldon Spring Site Remedial Action Project are discussed in Section 3.10.2 of this document.

6 SCHEDULE

6.1 RI/FS-EIS

The overall schedule for preparation of the RI/FS-EIS is shown in Figure 34. The RI/FS-EIS will address management of contaminated materials resulting from response action activities at the Weldon Spring site, including wastes from the raffinate pits and chemical plant area, bulk wastes from the quarry, and wastes from cleanup of contaminated vicinity properties. The RI/FS-EIS will also address groundwater restoration at the raffinate pits and chemical plant area. The project plan consists of the following:

- Completion of site characterization activities. Site characterization is currently being performed and is scheduled to be completed in early 1989.

- Completion of the RI/FS-EIS process consisting of an RI report, a baseline risk assessment, and an FS-EIS report. The RI/FS-EIS will be prepared with data obtained from the site characterization activities. A more detailed schedule for the baseline risk assessment is given in Figure 35. The first two phases of the FS-EIS will screen technologies and develop and screen alternatives to be evaluated in the third phase of the FS-EIS. Comments on the completed draft RI/FS-EIS will be addressed in the final RI/FS-EIS, which includes the responsiveness summary, following public review. The ROD for the RI/FS-EIS is projected to be issued in April 1991.

- Completion of the quarry bulk waste environmental process. This is described in more detail in Section 6.2.

- Development of design criteria and conceptual design information for remedial action activities at the raffinate pits and chemical plant area. The conceptual design will address location, size, layout, effluent controls, and general concepts of remediation to provide feasibility and comparative information. Remedial action activities at the raffinate pits and chemical plant area will begin in 1991, following issuance of the ROD.

- Treatment of surface water from the raffinate pits and other sources in the raffinate pits and chemical plant area. This treatment will be handled as an IRA and documented through the modified EE/CA process. Support facilities -- including utilities, decontamination station(s), and staging/parking areas -- will be designed and constructed as needed. These activities will be performed concurrently with the RI/FS-EIS process.

- Removal of the quarry bulk wastes. This action will be initiated in 1990 and should be completed by the end of 1992.

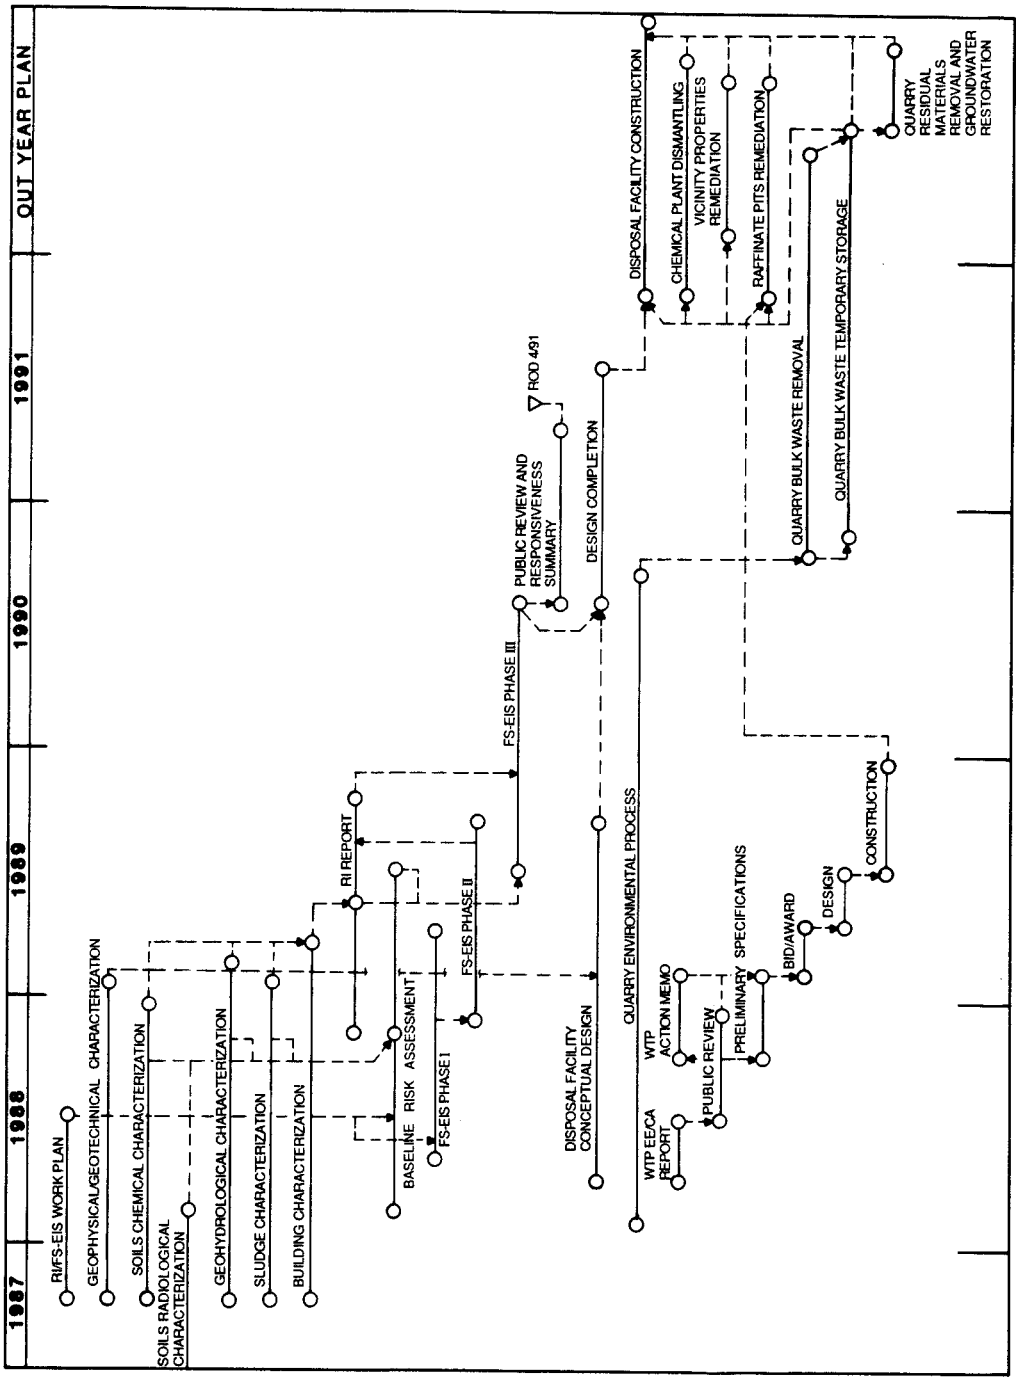

FIGURE 34 Overall Schedule for Completion of the RI/FS-EIS

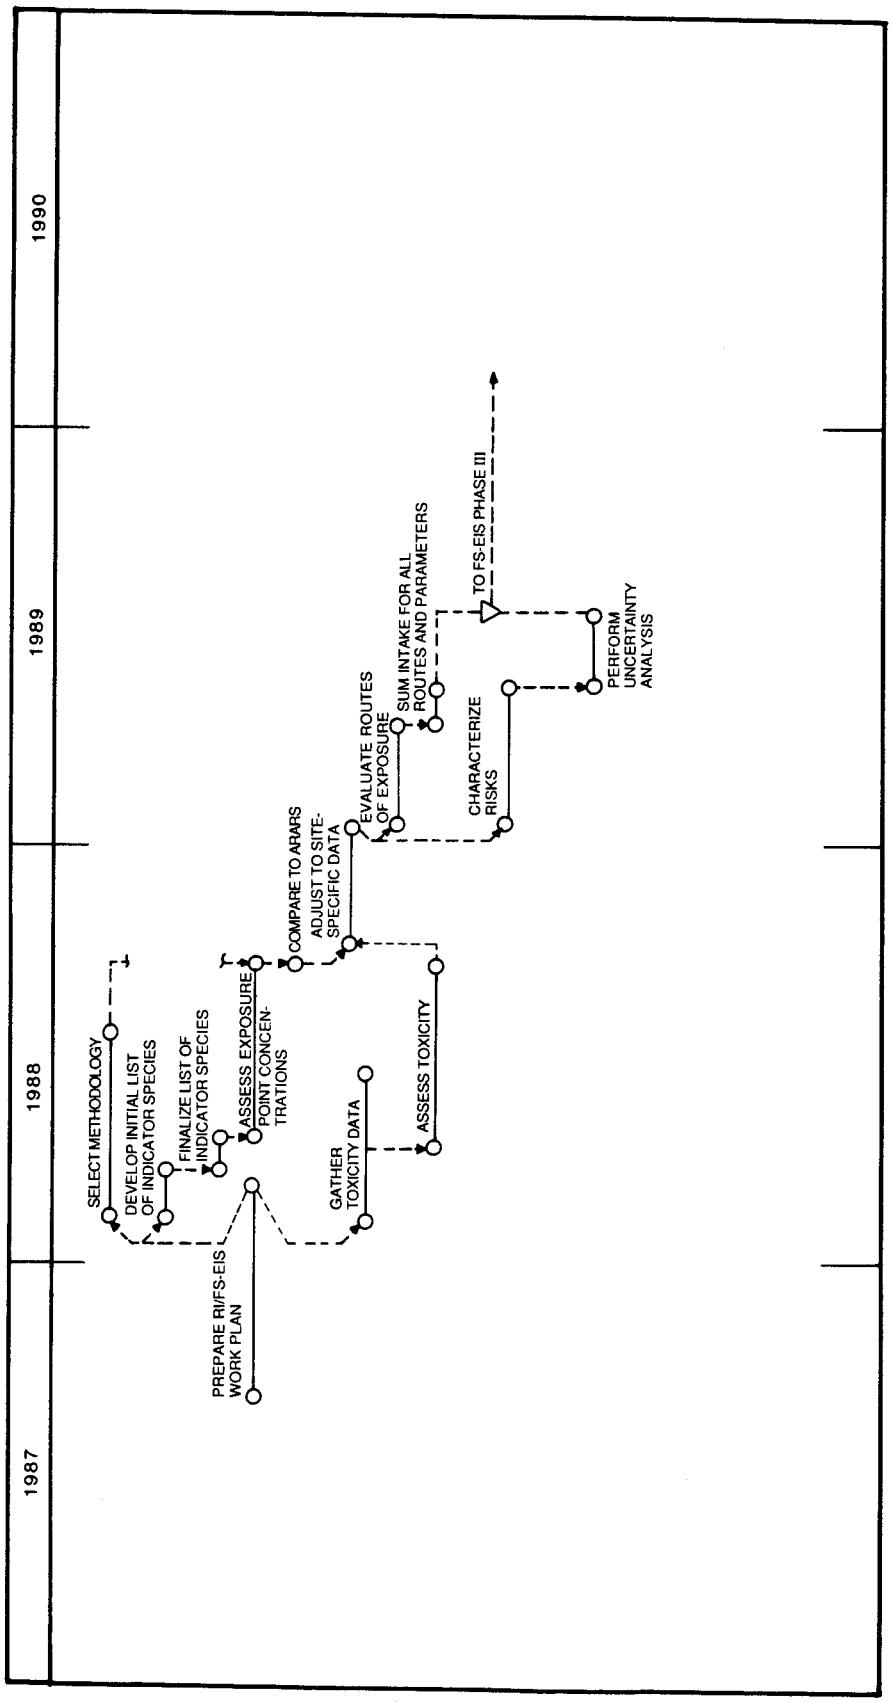

FIGURE 35 Schedule for Completion of the Baseline Risk Assessment

6.2 QUARRY

Removal of the bulk wastes from the quarry is planned to be undertaken as a separate operable unit within this project and to be documented using the RI/FS-EA process (see Section 3.11.2.1). The overall plan for implementation of activities in the quarry is shown in Figure 36. This plan consists of the following elements:

- Completion of an RI/FS for the bulk waste removal action consisting of an RI report, a risk evaluation, and an FS report. The RI/FS process will be completed using existing information on the quarry bulk wastes. Comments on the draft RI/FS will be addressed in the final RI/FS, which includes the responsiveness summary, following public review. The decision document for the RI/FS is projected to be issued in May 1990.

- Completion of an EA for the bulk waste removal action. The first two phases of the FS process will develop and screen alternatives that will be addressed in the EA. This EA, which will address environmental impacts associated with the proposed alternatives, will be issued prior to completion of the FS process.

- Development of the conceptual design for bulk waste removal activities concurrently with preparation of the RI/FS and EA. The conceptual design will include an excavation plan providing for operator controls to minimize the possibility of contaminant release during the excavation process.

- Development of design criteria and conceptual design information for the temporary storage area. The conceptual design will address location, size, layout, water runon/runoff management, and general concepts of the liner and/or cover systems.

- Treatment of the ponded water in the quarry. This treatment will be handled as an IRA and documented through the modified EE/CA process. Support facilities -- including roads/utilities, decontamination station(s), and water retention basins -- will be designed and constructed as needed.

This plan should allow for expedited removal of the bulk quarry wastes beginning in 1990.

It has not yet been determined if any residual material will have to be removed from the quarry following bulk waste removal or if groundwater restoration will be required at the quarry. Therefore, no schedules have been developed for these activities.

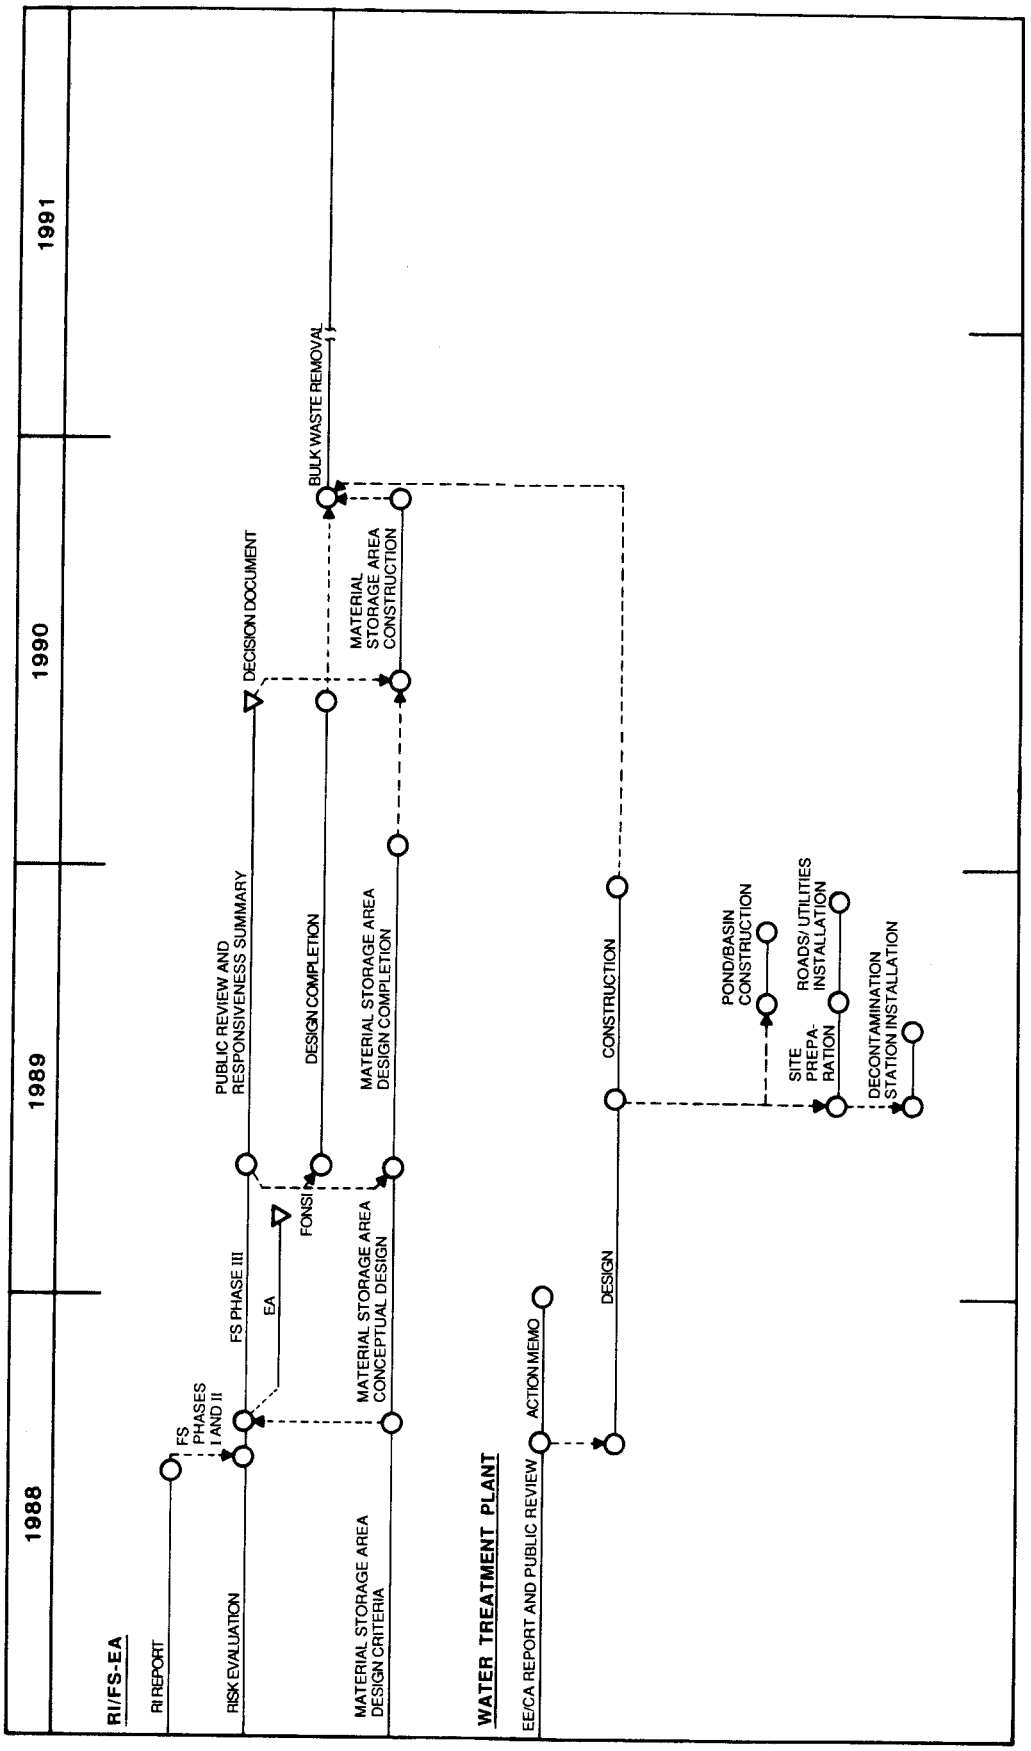

FIGURE 36 Schedule for Completion of the RI/FS-EA Process for Quarry Bulk Waste Removal

7 PROJECT MANAGEMENT

7.1 PROJECT ORGANIZATION

The Weldon Spring Site Remedial Action Project is being conducted by DOE under the SFMP, which is administered by the Division of Facility and Site Decommissioning Projects within the Office of Nuclear Energy (Figure 37). This division is responsible for policy decisions that impact the project and for coordination with the U.S. Department of the Army, which is sharing the cost of this project. The responsibility for management and technical direction of the response action activities has been delegated to the DOE Oak Ridge Operations Office, which has established a project office at the Weldon Spring site. This project office has responsibility for directing the conduct of response actions at the site.

Four separate organizations are under contract to DOE to support implementation of this project:

- MK-Ferguson Company is the project management contractor, assisting DOE in the planning and management of response action activities, and Jacobs Engineering Group, Inc., is under contract to MK-Ferguson to provide technical support for the project.

- Argonne National Laboratory, Energy and Environmental Systems Division, is the NEPA and CERCLA process management contractor and is responsible for directing preparation of appropriate environmental compliance documentation to support specific activities.

- Oak Ridge Associated Universities provides technical support, specifically for independent verification of completed response actions.

- PEER Consultants, Inc., provides administrative support to the DOE project office, and Dames & Moore has been retained by PEER to assist in this capacity.

7.2 PROJECT COORDINATION AND RESPONSIBILITIES

The response actions to be carried out by DOE at the Weldon Spring site are subject to EPA oversight under CERCLA. The oversight function is being carried out by EPA Region VII. The responsibilities of DOE and EPA are defined in the FFA signed in August 1986. This agreement, which was signed prior to the enactment of SARA in October 1986, may need to be revised to incorporate new requirements mandated by SARA. The need for such revisions is being discussed with EPA.

The state of Missouri has designated the Missouri DNR to coordinate state involvement in this project. The DNR is responsible for ensuring that the appropriate

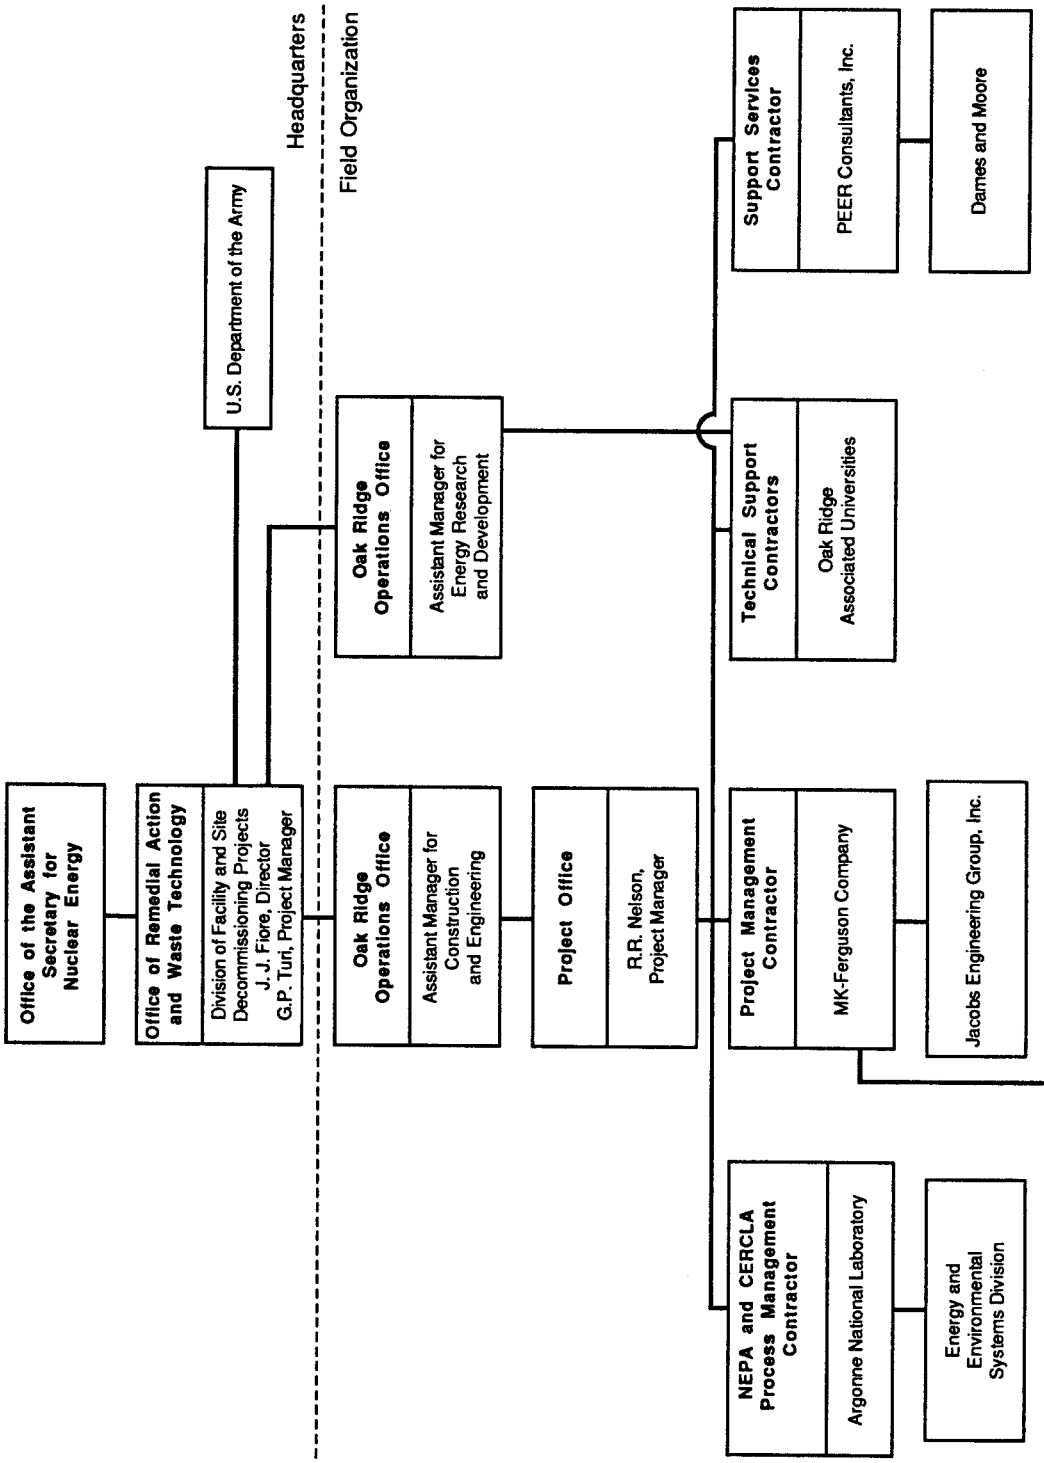

FIGURE 37 Organizational Chart for the Weldon Spring Site Remedial Action Project

state agencies are kept informed regarding project activities and that state concerns are properly reflected in project plans and actions. The relationship between DOE, EPA, and the Missouri DNR -- and the major responsibilities of each -- are shown in Figure 4 (Section 1.3).

The responsibilities of each of the major organizations under contract to DOE at the Weldon Spring site are identified as follows:

- MK-Ferguson Company (including Jacobs Engineering Group, Inc., as a subcontractor)
  - Provide overall project management support to DOE for the Weldon Spring Site Remedial Action Project.
  - Administer procurement and quality assurance functions.
  - Perform general administrative functions.
  - Administer all environmental, safety, and health programs at the site.
  - Direct all engineering activities.
  - Provide technical input to the preparation of environmental documents.
  - Perform community relations duties.
- Argonne National Laboratory, Energy and Environmental Systems Division
  - Perform environmental analyses for the RI/FS-EIS process.
  - Provide an independent analysis of environmental studies, engineering feasibility, and cost-effectiveness of response action alternatives performed by other DOE contractors.
  - Prepare additional environmental compliance documentation as needed.
- Oak Ridge Associated Universities
  - Conduct radiological surveys to identify and designate vicinity properties that require response action.
  - Conduct post-response action radiological surveys to provide an independent verification of the adequacy of cleanup and prepare associated verification reports.

- PEER Consultants, Inc. (including Dames & Moore as a subcontractor)

  - Provide technical and administrative support to the DOE project office.

  - Review environmental documents and advise the DOE project office on regulatory requirements.

  - Review and analyze resources as changes in funding and priorities occur.

  - Assist the DOE Project Office with the preparation and/or analysis of documents and reports for the annual budget process.

7.3 PROJECT CONTROLS

Project controls are implemented to provide detailed planning regarding cost, schedule, and technical performance. In this way, efforts towards achievement of project goals are maximized. A work breakdown structure is used to divide the total project into discrete work packages, thereby establishing the formal work organization and the planning and scheduling structure to permit identification of critical relationships and interdependencies among project tasks. The work breakdown structure also provides the framework for integrating budget requirements with schedule and technical performance. Finally, it establishes the management analysis and reporting structure to permit presentation of data to various levels of management.

Project controls are implemented in accordance with DOE cost and schedule control requirements. This provides a basis for assessing the quality of the cost and schedule controls used by the project participants; aids in ensuring effective planning, management, and control of project work; and provides a quick and effective means of measuring cost, schedule, and technical performance.

A project document control center is maintained at the Weldon Spring site to collect, register, distribute, and retain all documents associated with the project. This includes aerial photographs, topographic maps, reports on features of the site and its surrounding area, correspondence involving the site, findings of previous surveys, and analytical data obtained during site characterization. The types of characterization data that are on file include environmental contaminant data based on analysis of soil, groundwater, and surface water; borehole logging data; air sampling data; and information about geological and soil properties. Well construction data, field notebooks, and other documentation (e.g., chain-of-custody forms) are also on file in the document control center.

APPENDIX A:

WORK PLAN SUPPLEMENT

APPENDIX A:

WORK PLAN SUPPLEMENT

A.1 BACKGROUND

As part of its Surplus Facilities Management Program (SFMP), the U.S. Department of Energy (DOE) issued a draft environmental impact statement (EIS) in February 1987 to assess the environmental impacts of alternatives for long-term management of contaminated materials associated with remedial action activities at the Weldon Spring site in Weldon Spring, Missouri (U.S. Dept. Energy 1987a). Based on public and technical scoping input, DOE decided to take the "tiered" approach recommended by the Council on Environmental Quality (CEQ) under its regulations for implementing the National Environmental Policy Act (NEPA). The EIS was intended to support the major decisions on cleanup and long-term management of the contaminated materials at the Weldon Spring site, which consists of the raffinate pits and chemical plant area and the quarry, and at contaminated vicinity properties. However, because many of the issues associated with decontamination and decommissioning of the chemical plant were not yet ready for a decision at the time the draft EIS was prepared, cleanup of the chemical plant was to be covered in a separate NEPA document tiered to the EIS.

Ongoing well monitoring at the Weldon Spring site has provided significant new information relevant to environmental concerns at the site that was not available in February 1987 when the draft EIS was published. Results from the Phase I water quality assessment program (U.S. Dept. Energy 1987b) show significant quantities of nitroaromatics, particularly 2,6-dinitrotoluene (2,6-DNT), and high nitrate and sulfate concentrations in the groundwater at the raffinate pits and chemical plant area. In response to these new findings, DOE announced in June 1987 its intent to issue for public comment a revised draft EIS on remedial action at the Weldon Spring site. Since that time, the U.S. Environmental Protection Agency (EPA) Region VII has formally requested that DOE prepare a remedial investigation/feasibility study (RI/FS) for this project, under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) as amended by the Superfund Amendments and Reauthorization Act (SARA). The DOE and EPA have agreed that the appropriate environmental review required by an RI/FS and an EIS can be accomplished by incorporating those elements required by an EIS into the format of an RI/FS; this integrated document is termed an RI/FS-EIS. This is the process DOE intends to carry out for the Weldon Spring Site Remedial Action Project. This appendix has been written to illustrate the process by which the RI/FS-EIS will be prepared in compliance with DOE regulations for preparation of an EIS, which is necessary because DOE must comply with NEPA regulations for this project.

The DOE has specific procedures for ensuring compliance with NEPA. An EIS implementation plan must be prepared prior to preparation of an EIS to state the procedures DOE intends to use to complete the EIS process. Guidance on the content of an EIS implementation plan is given in the DOE procedures for compliance with NEPA (U.S. Dept. Energy 1987c). Many elements of an EIS implementation plan are similar to those of an RI/FS work plan. This appendix was written to supplement the information

given in the main text of the work plan to demonstrate that all of the DOE requirements for an EIS will be met by the proposed environmental compliance process for this project.

A.2 PROPOSED ACTION AND DECISION TO BE MADE

In order for DOE to determine how to manage the contaminated materials at the Weldon Spring site, environmental impacts -- in addition to engineering, cost, and other considerations -- must be factored into the decision. Therefore, in accordance with NEPA and CERCLA, DOE is preparing an RI/FS-EIS to assess and compare the potential environmental impacts of various alternatives for management of the radioactively and chemically contaminated materials at the site and for remediation of contaminated groundwater at the raffinate pits and chemical plant area.

A.3 SUMMARY OF NEPA SCOPING PROCESS

The DOE issued a Notice of Intent in the *Federal Register* on March 2, 1984, announcing its intention to prepare an EIS to assess the environmental impacts of alternatives for disposal of existing radioactively and chemically contaminated materials at the Weldon Spring raffinate pits, chemical plant, vicinity properties, and quarry. In accordance with CEQ regulations and DOE guidelines for implementing NEPA, a scoping process was conducted to determine the alternatives to be analyzed in the EIS, the significant issues to be analyzed in depth, and the issues to be eliminated from further detailed study.

Public input to this scoping process included:

- Presentations at a public meeting held in the Francis Howell High School gymnasium, St. Charles, Missouri, on March 20, 1984, and

- Letters received by DOE regarding the scope of the EIS.

The persons and organizations who provided input during this public scoping process are listed in Table A.1. Considerable input was received from private citizens; organized citizen action groups (particularly the St. Charles Countians Against Hazardous Waste); local, state, and national political representatives; and state government agencies.

Technical input to the scoping process included:

- Preliminary engineering evaluations by Bechtel National, Inc., of several alternatives for disposition of the wastes at the Weldon Spring site;

- Meetings and correspondence between Argonne National Laboratory (ANL) and DOE Oak Ridge Operations Office (DOE-OR) regarding location and conceptual designs for long-term management of the wastes;

- Meetings, correspondence, and review of alternatives and issues by SFMP program managers at DOE Headquarters (DOE-HQ) and DOE Operations Offices at Oak Ridge, Tennessee (DOE-OR), and Richland, Washington (DOE-RL);

- Preliminary evaluation by ANL and -- in consultation with Missouri state agencies, local government representatives, and members of the St. Charles Countians Against Hazardous Waste -- development of a conceptual design for an additional alternative of a new, above-grade disposal cell at the Weldon Spring site;

- Meetings with Missouri state agencies (e.g., Department of Natural Resources [DNR]) and elected officials; and

- Meetings with EPA Region VII.

The draft EIS was issued in February 1987 based, in part, on the input received during the NEPA scoping process. Many comments were received by DOE regarding the draft EIS, both by letter and at a public hearing held on April 10, 1987, at Hollenbeck Junior High School in Harvester, Missouri. The persons and organizations who provided comments on the draft EIS are listed in Table A.2. Responses to the major issues raised on the draft EIS are given in Appendix B of this work plan. All comments on the draft EIS are being treated as scoping input for the RI/FS-EIS.

A.4 ISSUES TO BE ADDRESSED IN THE RI/FS-EIS

The issues to be addressed in the RI/FS-EIS were developed based upon public and technical input. Some issues deal with potential environmental impacts, whereas others are factors that may influence or be influenced by remedial action activities. The issues have been separated into two categories: (1) primary issues to be analyzed in depth in the RI/FS-EIS and (2) secondary issues to be discussed in less detail.

A.4.1 Primary Issues

The primary issues will be analyzed more extensively than other issues. They are issues that were raised both during the initial scoping process in 1984 and during the public comment period on the draft EIS. Additional data that are being gathered on the radioactive and chemical contamination at the Weldon Spring site will be incorporated in the RI/FS-EIS. The primary issues to be analyzed in the RI/FS-EIS are as follows.

1. Potential radiological impacts

    - On people -- including workers and the general public, individuals and the total population, present and future generations.

TABLE A.2 Commenters on the Draft EIS

Oral Comments, Public Hearing on the Draft EIS, April 10, 1987

Fred Dyer, State Senator, 2nd District
Joseph Ortwerth, State Representative, 18th District
Craig Kilby, State Representative, 21st District
George Dames, State Representative, 17th District
Jane Schmidt, Western District Commissioner, St. Charles County
Nancy Becker, Eastern District Commissioner, St. Charles County
Tom Owens, Alderman, City of St. Peters
Thomas W. Brown, Mayor, City of St. Peters
Fred Brunner (for John Ashcroft, Governor)
Fred Brunner, Missouri Department of Natural Resources
Fred Bronson, St. Charles
John Crellin, Missouri Department of Health
William H. Dieffenbach, Missouri Department of Conservation
Leon Heath, Soil Consultants, Inc.
William Rebore, Francis Howell School District
Carl Johnson, Pierre, S.D.
John Shocklee, Human Rights Office, Archdiocese of St. Louis
Marty Hayden, Eastern Missouri Group, Sierra Club
Ann Hood, Wentzville
Leann Starr, O'Fallon
Bruce Thomas, St. Peters
George A. Behrens, Glendale
Roger Pryor, Coalition for the Environment
Stephen Kauffman, Coalition for the Environment
Michael Garvey, St. Charles
John C. Soucy, Jr., St. Charles
Evalena Wood, St. Charles County
Rao Ayyagari, Lindenwood College, St. Charles
Jack Sanford, St. Charles
Tom Aley, Ozark Underground Laboratory, Protem
Lisa Gruenloh, Francis Howell High School
Stan Pogue, St. Charles (for John Gofman)
Michael Hrdlicka, Francis Howell High School
Terry Mangan, New Melle
Meredith Bollmeier, St. Charles Countians Against Hazardous Waste
Lily Trimble, Coalition for the Environment
George Oliver, Chesterfield
Arlene Sandler, University City
Kay Drey, University City
Rebecca Selove, Community Mental Health Center, St. Charles
Mary Halliday, St. Charles Countians Against Hazardous Waste
Bobbie Judge, St. Charles
Beatrice Buder, Clayton
Byron Clemens, Academy of Mathematics and Science
Katherine McDaniel, St. Louis (for Rex Couture)
Dan Vornberg, Doe Run Company
Martin Pultman, Chesterfield

- On students and staff at nearby Francis Howell High School.
- In terms of both radiation doses and resulting health risks.
- Associated with various pathways to humans -- including soil; surface water and groundwater; gases, dust, and particulates; and the food chain.
- In the vicinity of the Weldon Spring site, along transportation routes, and near any alternative disposal site.
- Associated with both routine operations and accidents, including transportation accidents (using conservative assumptions with regard to potential accidents).
- Associated with off-site migration of radioactive materials.
- Of radionuclide releases due to natural forces such as erosion or seismic activity.
- Associated with human intrusion into the contaminated materials.
- On wildlife in the area.

2. Potential chemical impacts

   - Associated with the same categories as potential radiological impacts, consistent with the state of scientific knowledge regarding the toxicological effects of various chemical species.

3. Potential socioeconomic impacts

   - Associated with current and future uses of land and the St. Charles County well field located southeast of the quarry.
   - On patterns of development and population distribution.

4. Potential engineering and technical issues

   - Reasonable engineering technologies for management of the contaminated materials at the Weldon Spring site. The technologies will be systematically screened to obtain reasonable alternatives for remedial action.
   - Probable duration of isolation of the contaminated materials, and rate and magnitude of loss of containment -- including the ability to monitor and control seepage and contaminant

releases from the containment facility and the ability to repair weaknesses or failures in containment. This analysis will be performed in the context of time frames described in Section A.7.

- Site geology as related to engineering requirements.

- Characterization of the amounts and types of contaminated materials.

- Procedures to remediate contaminated groundwater at the raffinate pits and chemical plant area.

5. Potential geological and hydrological issues

   - Characterization of site-specific geological and hydrological conditions.

   - History of seismic activity in the area and discussion of potential future activity.

   - Potential contamination of groundwater from waste disposal activities and possible mitigative measures. Procedures to clean up current groundwater contamination at the raffinate pits and chemical plant area will also be assessed in the RI/FS-EIS.

6. Potential institutional issues

   - Project-specific criteria for decontamination, effluents, environmental concentrations, and release of a site for unrestricted or restricted uses. Cleanup criteria for radionuclides (e.g., uranium) and for chemical contaminants will be developed in cooperation with EPA Region VII and the state of Missouri, based on an assessment of risks to human health and the environment.

   - Compliance requirements for state and local laws and regulations.

   - Future institutional requirements related to monitoring and maintenance activities.

   - Institutional factors that need to be resolved before an alternative can be implemented.

   - Potential post-action uses of the Weldon Spring site.

7. Potential loss of institutional control

The list of ARARs to be included in the RI/FS-EIS will detail the institutional framework within which the project will be performed. Although EPA's standards and DOE's proposed remedial activities are based on continued federal ownership and control of the site, uncertainties regarding this issue increase significantly in the long term; it is reasonable to assume that federal control, including maintenance and monitoring, will be lost during the time that these wastes are hazardous. To address the impacts of loss of control (albeit unplanned and distant in time), the RI/FS-EIS will provide a systematic, but essentially qualitative, discussion of the longevity of the various containment systems and the potential failure modes that could lead to dispersal of the wastes and to human exposure following loss of institutional control at the site (including access control, monitoring, and maintenance). These include such possibilities as:

- Groundwater intrusion and leaching of wastes.
- Cap failure through cracking or differential settling.
- Erosion of cover (including gully erosion).
- Biotic intrusion (e.g., animal burrows and plant roots).
- Waste saturation and resulting releases.

The relative importance of these possibilities will be discussed to the extent possible. The estimated impacts to a resident intruder (an individual constructing a residence on the site following loss of access control, eating food from an on-site garden, and drinking water from an on-site well) will be analyzed using an appropriate pathway model. To place this in context, the likelihood of such a scenario will be addressed (qualitatively) in light of factors such as suitability for agriculture. Engineering and institutional measures to reduce the likelihood of loss of containment will be described. These generic descriptions will include a discussion of any differences that might be expected among the various alternatives.

8. Potential issues relative to mitigative measures and monitoring

- Measures to control dispersion of contaminants to the environment.
- Long-term monitoring and maintenance needs.
- Measures that could be taken to reduce impacts under each alternative.

A.4.2 Secondary Issues

Secondary issues are those that were deemed through scoping to be important, but to a lesser degree than primary issues. Secondary issues, which are analyzed in less depth than primary issues, include the following.

1. Potential socioeconomic impacts

   - On current and future local employment and industrial and commercial operations.
   - On local transportation systems.
   - On long-term use of site areas.
   - On local, municipal, and community services and organizations such as schools, government, and citizen action groups.

2. Potential engineering and technical issues

   - Specific maintenance needs.
   - Specific transportation routes, modes, and packaging.
   - Recovery of potentially valuable materials.
   - Effects of catastrophic natural events such as tornadoes, intense rains, droughts, and floods.
   - Methods for controlling surface water runoff from the site during construction.

3. Potential institutional issues

   - Costs of implementing and funding the various alternatives.
   - On-site enforcement of safety standards during remedial action.

4. Miscellaneous issues

   - Commitment or loss of resources (e.g., uranium, thorium, and energy).
   - Worker safety.
   - Site-specific meteorological conditions.
   - Mitigative measures to protect potential cultural resources.

A.5 ISSUES BEYOND THE SCOPE OF THE RI/FS-EIS

The DOE has determined that the following issues are beyond the scope of the RI/FS-EIS.

1. Psychological impacts -- In light of a U.S. Supreme Court case involving the proposed restart of one of the Three Mile Island reactors (Metropolitan Edison Company v. People Against Nuclear Energy [PANE] 103 S. Ct. 1556 [1983]), DOE considers only psychological impacts that bear a close causal relationship to the physical environment in an EIS. Psychological impacts raised to date relative to the Weldon Spring site do not bear such a relationship.

2. Impacts of past operations at the site -- The impacts of the various alternatives on the existing environment will be assessed in the RI/FS-EIS. In the above-mentioned Supreme Court decision, it was stated that "NEPA is not directed at the effects of past accidents and does not create a remedial scheme for past federal actions." Therefore, a detailed analysis of past operations, beyond that necessary to characterize the existing environment, is considered to be beyond the scope of the RI/FS-EIS.

3. Monitoring of health of students and staff at Francis Howell High School -- An ongoing environmental monitoring program is being conducted by DOE in the vicinity of the Weldon Spring site. This program includes the Francis Howell High School area. No additional monitoring studies of students and staff at the Francis Howell High School will be performed as part of the RI/FS-EIS process because the existing environmental monitoring program demonstrates that individuals at the high school are not being exposed to measurable levels of radioactive or chemical contaminants originating from the Weldon Spring site. However, potential health impacts on students and staff will be addressed in the RI/FS-EIS.

4. Excavation, transport, and temporary storage of quarry bulk wastes -- The DOE is proposing to address the removal of the quarry bulk wastes as a separate operable unit and will use the RI/FS-EA process to support this decision (see Section 3.11 of this work plan). This action will include excavation, transport, and temporary storage of the quarry bulk wastes at the raffinate pits and chemical plant area. Implementation of the RI/FS-EA process will be as follows. The first two phases of the FS process will be completed concurrent with preparation of the RI and baseline risk evaluation. At this point, an assessment of environmental impacts will be performed consistent with the requirements of an EA in support of a finding of no significant impact (FONSI), if appropriate. If DOE determines that this action requires preparation of

an EIS, the action will be included within the overall RI/FS-EIS process for the project, and removal of the quarry bulk wastes will not be undertaken prior to issuance of the ROD. Because the EA is scheduled to be completed prior to issuance of the FS, the RI/FS process for this action will be completed only if a FONSI is issued. If an RI/FS for bulk waste removal is completed, DOE and EPA will issue decision documents under CERCLA to document the decision-making process.

5. Removal of residual contamination from the quarry -- After the bulk wastes have been removed from the quarry, the quarry will be inspected to determine if additional remedial action is required. The need for any additional remedial action at the quarry cannot be determined prior to bulk waste removal and inspection of the resultant conditions in the quarry. This issue is therefore beyond the scope of the RI/FS-EIS.

6. Remediation of contaminated groundwater at the quarry -- A decision to remediate contaminated groundwater at the quarry is beyond the scope of the RI/FS-EIS. The DOE is proposing to address the issue of contaminated groundwater remediation following removal of the bulk wastes from the quarry.

7. Other radioactively contaminated sites in the St. Louis area -- EPA Region VII proposed in 1984 that DOE also consider the possibility of cumulative disposal at the Weldon Spring site of the radioactive wastes currently stored at various locations in Missouri. These wastes and their locations are as follows:

   - St. Louis Airport Site (SLAPS) and SLAPS vicinity properties -- previously used for storing ore residues, scrap, and equipment from uranium-processing operations.

   - Latty Avenue Site -- previously used for storing ore residues and wastes from uranium-processing operations.

   - St. Louis Downtown Site -- previously used to process uranium ore or concentrates to produce uranium dioxide, uranium trioxide, uranium tetrafluoride, and uranium metal; the site was also previously used for other activities associated with uranium metal and for extraction and concentration of thorium-230 from pitchblende raffinates.

   - West Lake Landfill -- previously used for disposing of soil from the Latty Avenue site.

The SLAPS, Latty Avenue, and St. Louis Downtown sites are already included in the DOE Formerly Utilized Sites Remedial Action Program; the West Lake Landfill is

under cognizance of the U.S. Nuclear Regulatory Commission. In the Congressional conference report that accompanied U.S. Public Law 98-360, DOE was directed to take the necessary steps to consolidate and dispose of the waste materials from the Latty Avenue and SLAPS vicinity properties. The report directed that the materials be disposed of locally by reacquiring, stabilizing, and using SLAPS in a manner acceptable to the city of St. Louis. Plans for disposal of wastes from the St. Louis Downtown site have not yet been formulated. The DOE has no plans to dispose of these wastes at the Weldon Spring site. Therefore, the cumulative impacts from disposal of the wastes from other sites in the St. Louis area at the Weldon Spring site will not be addressed in the RI/FS-EIS.

A.6 RELATED FEDERAL PROJECTS

The DOE has recently prepared EISs for other programs and other sites under its Remedial Action Program, including:

- U.S. Department of Energy, 1983, *Final Environmental Impact Statement, Remedial Actions at the Former Vitro Rare Metals Plant Site, Canonsburg, Washington County, Pennsylvania*, DOE/EIS-0096-F, 2 vol. (July).

- U.S. Department of Energy, 1984, *Final Environmental Impact Statement, Remedial Actions at the Former Vitro Chemical Company Site, South Salt Lake, Salt Lake County, Utah*, DOE/EIS-0099-F, 2 vol. (July).

- U.S. Department of Energy, 1985, *Final Environmental Impact Statement, Remedial Actions at the Former Vanadium Corporation of America Uranium Mill Site, Durango, La Plata County, Colorado*, DOE/EIS-0111F, 2 vol. (Oct.).

- U.S. Department of Energy, 1986, *Final Environmental Impact Statement, Remedial Actions at the Former Climax Uranium Company Uranium Mill Site, Grand Junction, Mesa County, Colorado*, DOE/EIS-0126-F, 2 vol. (Dec.).

- U.S. Department of Energy, 1986, *Final Environmental Impact Statement, Long-Term Management of the Existing Radioactive Wastes and Residues at the Niagara Falls Storage Site*, DOE/EIS-0109F (April).

In addition, the U.S. Nuclear Regulatory Commission and U.S. Environmental Protection Agency have prepared EISs on various related programs, proposed standards, and specific sites, including:

- U.S. Environmental Protection Agency, 1982, *Final Environmental Impact Statement for Remedial Action Standards for Inactive*

Uranium Processing Sites (40 CFR 192), Vols. 1 and 2; EPA 520/4/82-013-1, -2 (Oct.).

- U.S. Nuclear Regulatory Commission, 1983, *Final Environmental Statement Related to the Decommissioning of the Rare Earths Facility, West Chicago, Illinois, Docket No. 40-2061, Kerr-McGee Chemical Corporation*, NUREG-0904 (May).

- U.S. Environmental Protection Agency, 1986, *Final Environmental Impact Statement, Proposed Wastewater Treatment Facilities for Eastern St. Charles County, Missouri, Including: Duckett Creek Sewer District, St. Peters Sewer District, St. Charles Sewer District, Portage de Sioux Sewer District*, EPA 907/9-86-003 (May).

- U.S. Nuclear Regulatory Commission, 1987, *Draft Supplement to the Final Environmental Statement Related to the Decommissioning of the Rare Earths Facility, West Chicago, Illinois, Docket No. 40-2061, Kerr-McGee Chemical Corporation*, NUREG-0904, Supplement No. 1 (June).

A.7 TIME FRAME FOR COMPARATIVE ANALYSIS OF ENVIRONMENTAL IMPACTS

The potential environmental impacts will be analyzed over the following time periods:

- Action period (approximately 10 years) -- the period during which physical actions such as excavation, transportation, and stabilization will take place.

- Long-term period -- the time following the action period during which the disposal site will continue to be controlled. Human access to the disposal area will be limited, and the federal government will continue to own the area and use it solely for waste-disposal purposes. Containment structures will be maintained, any releases to the environment will be monitored, and corrective remedial actions will be taken as necessary. The cumulative impacts over 1,000 years will be assessed in the RI/FS-EIS. In addition, the RI/FS-EIS will describe the impacts that might peak after 1,000 years with continued site control and maintenance. Although the federal government intends to control the site, impacts that might occur if there was loss of institutional control will also be discussed.

The 1,000-year time frame is selected to be consistent with the time frames identified in EPA regulations for management of inactive uranium mill tailings (40 CFR Part 192). In these regulations, EPA identifies "the single most important goal of control

to be effective isolation and stabilization of tailings for as long a time period as is reasonably feasible, because tailings will remain hazardous for hundreds of thousands of years." Furthermore, "the longevity of control is governed by the possibility of intrusion by man and erosion by natural forces." After considering several time periods for control, EPA required that "control measures be carried out in a manner that provides reasonable assurance they will last, to the extent reasonably achievable, up to 1,000 years, and, in any case, for a minimum of 200 years." Uncertainties increase significantly beyond 1,000 years and it would not be reasonable to require assurances of control for longer time periods.

The naturally occurring radionuclides found in uranium mill tailings (principally the uranium-238 decay series) constitute the bulk of radioactivity in the Weldon Spring wastes. Because the 1,000-year time period has been deemed to be a reasonable basis for EPA's decisions regarding inactive uranium mill tailings and because it should also be adequate for addressing potential chemical impacts, DOE considers this time period to be a reasonable reference point for analyzing environmental impacts in the RI/FS-EIS to support DOE's decision on management of the contaminated materials at the Weldon Spring site.

A.8 COORDINATION OF NEPA AND CERCLA REQUIREMENTS

The response actions to be carried out by DOE at the Weldon Spring site are subject to EPA oversight under CERCLA. For this project, the oversight function is being carried out by EPA Region VII. The Weldon Spring Site Remedial Action Project can be described as consisting of seven separate environmental compliance components (see Section 1.2). The three major actions currently envisioned for the raffinate pits and chemical plant area are (1) management of the contaminated surface structures, raffinate pit wastes, surface water, and soils; (2) assessment of the need to restore contaminated groundwater; and (3) cleanup of contaminated vicinity properties. These three actions will be addressed in the RI/FS-EIS and supported by a single response decision. This decision will also include disposition of the bulk wastes currently in the quarry. The RI/FS-EIS to support the decision will be prepared in a format that provides the level of detail required by both NEPA and CERCLA, so that separate documentation for each act will not be required. This approach is intended to result in a single ROD by DOE and EPA. It is possible that the groundwater restoration issue will be ready for a decision at a different time than the waste disposal issue. If this is the case, DOE may handle groundwater restoration as a separate operable unit to satisfy the requirements of NEPA and CERCLA for this decision.

Four distinct response actions may be required at the quarry: bulk waste removal, removal of any residual materials following bulk waste removal, groundwater restoration, and cleanup of contaminated vicinity properties. The DOE is proposing to address removal of the quarry bulk wastes as a separate operable unit and will use the RI/FS-EA process to support this decision. This action is scheduled to occur prior to the ROD for the project. The procedure for implementation of the RI/FS-EA process is given in Item 4 of Section A.5.

The other two environmental compliance areas for the Weldon Spring project (i.e., residual material removal and groundwater restoration at the quarry) are not ready for assessment at this time. The appropriate level of environmental review will be determined as sufficient data become available to reach an informed decision. The DOE will involve EPA Region VII and the Missouri DNR in its determination regarding the need for response actions in these areas.

Prior to issuance of the ROD for the waste disposal action, various expedited response actions, i.e., interim response actions (IRAs), will be performed to mitigate actual or potential uncontrolled releases of radioactively or chemically hazardous substances to the environment. The scope of the IRAs will be limited to those actions that can be performed under CERCLA and within the constraints of CEQ regulations for NEPA (i.e., actions will be limited to those that do not have adverse environmental impacts or limit the choice of reasonable alternative for the ultimate disposition of the site). The environmental compliance process for the IRAs, developed to ensure compliance with NEPA and CERCLA, is described in Section 3.10.1 of this work plan.

A.9 TENTATIVE OUTLINE OF THE FS-EIS COMPONENT OF THE RI/FS-EIS

A tentative outline of the FS-EIS component of the RI/FS-EIS is given in Table A.3. This outline was developed by integrating those elements required by an EIS into the format recommended for an FS.

A.10 CONTRACTOR RELATIONSHIPS IN PREPARATION OF THE RI/FS-EIS

The DOE-OR has been delegated responsibility and authority for field management of the Weldon Spring Site Remedial Action Project; DOE-OR has established a project office at the Weldon Spring site (DOE-WSS). The DOE-WSS has responsibility for implementing the conduct of response action activities and also has functional responsibility for preparation of the RI/FS-EIS. The DOE-HQ will approve publication of the RI/FS-EIS.

MK-Ferguson Company is the project management contractor for response action activities at the Weldon Spring site. Jacobs Engineering Group, Inc., is under contract to MK-Ferguson Company to provide technical support for the project. The project management contractor will collect all necessary environmental data and perform requisite engineering and monetary cost studies to support the analyses given in the RI/FS-EIS. The project management contractor will oversee preparation of the RI.

The Energy and Environmental Systems Division of ANL will perform environmental analyses for the RI/FS-EIS process under contract to DOE-WSS and will oversee preparation of the FS-EIS phase of the RI/FS-EIS process. As part of this process, ANL will provide an independent analysis of the environmental studies, engineering feasibility, and cost-effectiveness of alternatives for remedial action at the Weldon Spring site performed by other DOE contractors. These environmental analyses will be performed using information supplied by the project management contractor and supplementing such information, as necessary, by site visits, meetings and consultations with other agencies, and review of existing documents.

TABLE A.3 Tentative Outline for the FS-EIS for Remedial Action at the Weldon Spring Site

---

Executive Summary

1 Introduction

- 1.1 Site Background
- 1.2 Nature and Extent of Problems
- 1.3 Justification of Need for Proposed Action
- 1.4 Objectives of Remedial Action
- 1.5 Scoping
- 1.6 Related Federal Projects
- 1.7 Consultation with Other Agencies

2 Development of Remedial Action Alternatives

- 2.1 Definition of Remedial Action Objectives
- 2.2 Identification of Potential Technologies
- 2.3 Definition of Technical Evaluation Criteria
- 2.4 Identification of ARARs and Acceptable Exposure Levels
- 2.5 Technologies Screening

A.11 PAGE LIMIT TARGETS

Because the RI/FS-EIS will address several complex alternatives and issues, it is anticipated that it will be longer than the CEQ-recommended page limit of 150 pages for an EIS but less than the recommended maximum of 300 pages. Supporting information will be included in appendixes and stand-alone documents to minimize the length of the RI/FS-EIS to that necessary to support the ROD. A preliminary outline for the FS-EIS component of the RI/FS-EIS is given in Table A.3.

A.12 TARGET DATES FOR FS-EIS PREPARATION

A schedule for preparation of the RI/FS-EIS is given in Section 6 of this work plan. The target dates for the RI/FS-EIS given below are extracted from the more detailed schedule shown in Figure 34.

Activity	Date
RI/FS-EIS work plan issued	August 1988
Draft RI/FS-EIS issued	July 1990
End of public comment period	September 1990
Final RI/FS-EIS issued	March 1991
Record of decision issued	April 1991

RESPONSES TO MAJOR ISSUES RAISED IN COMMENTS ON THE DRAFT ENVIRONMENTAL IMPACT STATEMENT

APPENDIX B

RESPONSES TO MAJOR ISSUES RAISED IN PUBLIC COMMENTS ON THE DRAFT ENVIRONMENTAL IMPACT STATEMENT

The draft environmental impact statement (EIS) for remedial action at the Weldon Spring site, Weldon Spring, Missouri, was issued by the U.S. Department of Energy (DOE) in February 1987. A public comment period followed issuance, as mandated by the Council on Environmental Quality regulations for implementing the procedural provisions of the National Environmental Policy Act (NEPA) (40 CFR Part 1503.1). As part of the public review process, a public hearing was held on April 10, 1987, at Hollenbeck Junior High School in Harvester, Missouri. Comments on the draft EIS were provided orally at the public hearing, in written material provided to DOE at the public hearing, and in individual letters sent to the DOE Weldon Spring Site Project Office. The names of individuals who provided comments on the draft EIS are listed in Appendix A, Table A.2. These comments are available for inspection at the project office during normal business hours.

The Weldon Spring quarry was listed on the National Priorities List of the U.S. Environmental Protection Agency (EPA) on July 30, 1987. On June 24, 1988, EPA proposed to expand the designation to include the raffinate pits and chemical plant area. This designation, along with promulgation of the Superfund Amendments and Reauthorization Act (SARA) in October 1986, has significantly altered the environmental compliance documentation process required to support the Weldon Spring Site Remedial Action Project. In conjunction with the EPA Region VII and the Missouri Department of Natural Resources (DNR), DOE has agreed that the appropriate environmental review for this project can be most expeditiously performed by incorporating those elements required by an EIS into the framework of the remedial investigation/feasibility study (RI/FS) process for remedial actions conducted under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). This integrated process is termed the RI/FS-EIS process.

This appendix has been prepared to address the major issues identified in comments on the draft EIS. These issues have been summarized from the various oral and written comments received during the comment period. The intent of the responses to these major issues is to illustrate the manner in which the issues will be addressed in the RI/FS-EIS process. A draft RI/FS-EIS will be issued for public review, and any significant issues concerning the draft RI/FS-EIS will be addressed in a responsiveness summary. A final RI/FS-EIS, including the responsiveness summary, will be prepared prior to issuance of the record of decision (ROD) for this project.

The major issues identified in comments on the draft EIS have been divided into five categories as follows:

1. Compliance with NEPA and CERCLA,

2. Engineering considerations,

3. Site characterization and suitability,

4. Environmental impacts, and

5. Scope and conduct of remedial action activities.

The comments and responses for these issues are presented in Sections B.1 through B.5, respectively. The issues are numbered consecutively through the five sections.

B.1 COMPLIANCE WITH NEPA AND CERCLA

B.1.1 Issue 1

Comment: The draft EIS does not have sufficient detail to allow for meaningful comment by the public. A supplement to the draft EIS should be issued for public comment. Additionally, the draft EIS does not adequately incorporate the RI/FS process under CERCLA as required by the Federal Facility Agreement (FFA) for this project.

Response: Since issuance of the draft EIS, EPA Region VII has formally requested that DOE prepare an RI/FS for this project. The DOE has committed to comply with this request. The RI/FS will be modified to include those elements of an EIS not typically contained in an RI/FS. A tentative outline for the FS-EIS component of the RI/FS-EIS is given in Appendix A, Table A.3. The RI/FS-EIS will not be issued for public comment until all site characterization activities have been completed. Hence, much more detail will be included in the RI/FS-EIS when issued for public comment than was included in the draft EIS.

B.1.2 Issue 2

Comment: The information contained in the draft EIS is too general to allow for meaningful estimation of the environmental impacts that may occur. Estimation of environmental impacts should be based on site-specific information and not national figures or hypothetical computations. The draft EIS, therefore, does not comply with NEPA regulations.

Response: Estimation of environmental impacts in the draft EIS was based on available information at the time the document was prepared. Assumptions were made for information that was not available. Because DOE will now be preparing an RI/FS-EIS, sufficient site-specific information will be available to allow for detailed estimation of environmental impacts. (See also Response to Issue 1, Section B.1.1.)

B.1.3 Issue 3

Comment: The draft EIS does not present sufficient details on the various alternatives. The draft EIS should analyze the impact of all significant and reasonable

alternatives, including combinations of design features. The alternatives presented in the draft EIS do not allow for assessment of all reasonable combinations.

Response: The procedure for developing alternatives in the RI/FS process will be used in the RI/FS-EIS. In this process, remedial action objectives are determined on the basis of existing site information regarding the nature and extent of contamination, along with potentially applicable or relevant and appropriate requirements (ARARs) and risk factors. Technologies are then screened to identify those that would be effective for the contaminants present at the site, taking into account the environmental setting of the site. Information developed for these two activities will be used to develop alternatives for assessment in the RI/FS-EIS. This approach will allow a systematic evaluation of various design features, and combinations of design features, in developing the alternatives.

B.1.4 Issue 4

Comment: The draft EIS ignored many issues brought up at the 1984 EIS scoping meeting. All of the issues brought up at that meeting, as well as those identified in comments on the draft EIS, should be addressed prior to the ROD.

Response: Issues raised at a public scoping meeting are one source of input considered in determining the scope of an EIS. Other sources of input include engineering feasibility; consultation with local, state, and federal officials; consultation with other federal agencies; and DOE policies and procedures. All issues raised at a public scoping meeting are considered in determining the scope of an EIS. However, if it is determined that an issue raised during scoping is not significant relative to the decision to be made, its inclusion in the EIS is not warranted. The DOE will reexamine all issues raised during the 1984 scoping process, as well as those raised on the draft EIS, to ensure that all significant issues are evaluated in the RI/FS-EIS.

B.1.5 Issue 5

Comment: Additional details should be provided on the "Nearby Site" as presented in the draft EIS. Potential use of the Callaway Nuclear Power Plant site should be addressed in this regard because this site will be contaminated into perpetuity. Without detailed information on the specific site to be addressed, it is impossible for an accurate comparative analysis to be performed.

Response: Under Alternative 3b in the draft EIS, the wastes are assumed to be transported to a "Nearby Site" in Missouri, within 160 km (100 mi) of the Weldon Spring site. The "Nearby Site" would be chosen to have more favorable conditions (e.g., thicker clay, lower hydraulic conductivity, deeper groundwater table, and/or higher sorption capacity) than the Weldon Spring site. This assessment was included to provide information on the feasibility of developing such a disposal site for the Weldon Spring wastes. The DOE did not undertake a detailed site-selection process to identify alternative disposal sites for wastes resulting from the Weldon Spring project in support of the draft

EIS, nor is such a detailed evaluation planned for the RI/FS-EIS. The DOE will consider the feasibility of a generic site within 160 km (100 mi) of the Weldon Spring site in the RI/FS-EIS. The use of this generic site will be analyzed according to the three screening criteria, i.e., effectiveness, implementability, and cost. Only if use of this generic site survives the screening evaluation and/or if the on-site disposal alternative is determined to be infeasible will DOE initiate off-site characterization studies as part of the post-screening investigations. It is incorrect to conclude that the Callaway Nuclear Power Plant site will be radioactively contaminated into perpetuity. Techniques for decontamination of equipment, structures, and soil are available to allow for this site to be returned to nonnuclear uses following its active lifetime.

B.1.6 Issue 6

Comment: The DOE is currently conducting geological studies at the Weldon Spring site to evaluate its suitability for waste disposal. Similar studies are not being conducted at other potential disposal sites. Not conducting such studies at alternative disposal sites could bias the decision-making process in favor of on-site disposal.

Response: A rather significant data base is needed for meaningful assessment of environmental impacts to support the RI/FS-EIS process. Data are currently being collected at the Weldon Spring site to support this process. This data-collecting process is necessary to allow for an informed assessment of current, and possibly future, environmental conditions (e.g., contaminant migration pathways). The DOE does not believe that it is necessary to perform such geological studies at other potential disposal sites at this time. (See also Response to Issue 5, Section B.1.5.)

B.1.7 Issue 7

Comment: The draft EIS should address all aspects of this project so that the full magnitude of environmental impacts is presented. Specific plans for decontaminating the buildings at the chemical plant area and the associated environmental impacts should be included in the EIS. It is not appropriate, under NEPA, to address this issue in a tiered document.

Response: When work was initiated on the draft EIS, the chemical plant area was under jurisdiction of the U.S. Department of the Army, and there was no indication at that time regarding the manner in which the Army intended to deal with this facility. Custody of the chemical plant area was transferred to DOE in October 1985. Because DOE was already in the process of preparing the draft EIS for long-term management of the contaminated materials located at the raffinate pits, quarry, and vicinity properties, DOE decided to include the impacts of disposing of the chemical plant wastes in the draft EIS. However, because characterization data to allow for assessment of the environmental impacts associated with decontamination and decommissioning of the chemical plant area were not available, inclusion of such data in the draft EIS would have unduly delayed issuance of the document. Therefore, DOE decided to implement the tiering concept for NEPA compliance. This is an acceptable use of tiering because the

main issue discussed in the draft EIS is waste disposal and the means by which the wastes are obtained from site-specific actions is a comparatively minor issue. It should be noted that decontamination and decommissioning of nonprocess buildings will be addressed as interim response actions (IRAs) for this project, as discussed in Section 3.10.2.14 of this work plan. Documentation of the proposed IRAs will be made available to the public prior to initiation of such actions. Decontamination and decommissioning of process buildings will be included in the RI/FS-EIS.

B.1.8 Issue 8

Comment: The draft EIS excluded issues from discussion that are essential to an informed decision. Additionally, not all pertinent information is included in the draft EIS, but only that information that supports DOE's preferred alternative. Therefore, the draft EIS does not comply with NEPA.

Response: The issues addressed in the draft EIS were those determined to be relevant to the decision to be made. All available information was reviewed for appropriateness relative to the analyses provided in the draft EIS. The DOE will reconsider all available information in preparation of the RI/FS-EIS, including those specific references cited in comments on the draft EIS. The DOE is currently in the process of conducting a thorough site characterization program. The results of this program will be included in the RI report and will allow for detailed estimation of environmental impacts.

B.2 ENGINEERING CONSIDERATIONS

B.2.1 Issue 9

Comment: The location of the disposal facility for the on-site alternative should be shown. The geology of the raffinate pits and chemical plant area is complex and variable. An assessment of the feasibility of on-site disposal cannot be made without knowing the exact location of the proposed containment cell.

Response: Existing borings and surface geophysical investigations have adequately characterized the unconsolidated and upper bedrock strata. Geotechnical and geophysical investigations to be conducted in the immediate future will extend our knowledge of the unconsolidated geology and the upper 60 m (200 ft) of the bedrock. These investigations will characterize the on-site areas capable of supporting a disposal facility. Results of these investigations will be discussed in the draft RI/FS-EIS issued for public comment.

B.2.2 Issue 10

Comment: The disposal facility must be designed to withstand natural forces (e.g., freeze-thaw cycles, differential settling and slumping, cracking of the cover in dry weather, burrowing animals, and vegetative root systems). The disposal facility must

also be designed to maintain its integrity against severe natural phenomena (e.g., seismic events, floods, tornadoes, heavy precipitation, water and wind erosion, and drought). A suitably designed leachate collection and monitoring system should be an integral component of cell design. A passive leachate collection system should be considered. The long-term stability of this facility must be guaranteed.

Response: The DOE is currently developing generic criteria for containment cell design. These criteria will include provisions to prevent contaminant migration as a result of natural forces and severe natural phenomena. The DOE is also evaluating the use of a leachate collection and monitoring system at this time. Such a system, if deemed appropriate, must be properly designed to ensure that it does not become a mechanism for contaminant release in the future. The DOE concurs with the need to guarantee the long-term stability of a disposal facility, wherever it is located. It should be noted that DOE is committed to monitor and maintain the disposal site for the foreseeable future.

B.2.3 Issue 11

Comment: Treatment of the wastes to reduce the potential for off-site migration should be addressed in greater detail. Special emphasis should be placed on those treatments that reduce the volume of wastes, result in recovery of usable materials, significantly reduce contaminant mobility, or result in permanent solutions.

Response: One of the first steps in the RI/FS-EIS process will be to evaluate treatment technologies for applicability to the Weldon Spring wastes (see also Response to Issue 3, Section B.1.3). These technologies will be evaluated for the parameters suggested in this comment. The DOE is currently planning numerous feasibility studies for this project (see Section 3.9 of this work plan). Additional studies may be performed as the project proceeds, pending the results of the RI phase, the development of new technologies, and the results of studies currently planned.

B.2.4 Issue 12

Comment: Various chemical species from the waste materials will be present in leachate, such as acids, organic solvents, and hexane. The effects of these chemicals on the underlying clay layer should be investigated to ensure adequate containment over long periods of time. Certain chemical species can greatly reduce the ion-exchange capabilities of clay liners. The feasibility of using synthetic geomembrane liners should be considered.

Response: The ion-exchange capabilities of clay can be greatly degraded by chemical species such as organic solvents. Tests will be performed on the wastes to determine the chemical characteristics of any leachate that may form. The feasibility of synthetic liners will also be assessed. Any containment cell would be designed to ensure that leachate would not degrade the selected liner to the extent that the liner could not adequately confine radioactive and chemical contaminants. Substances that are contaminated only with hazardous chemicals -- with no associated radiological

hazard -- will not be disposed of on-site. All such wastes will be sent for treatment or disposal to a hazardous waste facility (licensed according to requirements of the Resource Conservation and Recovery Act [RCRA]).

B.2.5 Issue 13

Comment: The draft EIS should describe in detail how contaminated water will be treated prior to disposal.

Response: The DOE is currently evaluating methods for treating the contaminated water at the raffinate pits and chemical plant area and the quarry prior to discharge. Treatment of the water is essential to the implementation of any remedial action alternative. These actions are currently being planned as IRAs (see Sections 3.10.2.15 and 3.10.2.16 of this work plan). The methods for treating the water will be detailed in engineering evaluation/cost analysis (EE/CA) reports that will be prepared to support these actions. These EE/CA reports will include an assessment of potential environmental impacts associated with water treatment alternatives. The EE/CA reports will be expanded and additional documents will be prepared, as necessary, to meet the requirements of NEPA. The DOE has consulted, and will continue to consult, EPA Region VII and the Missouri DNR regarding this issue. The public will also have the opportunity provide input on this topic.

B.2.6 Issue 14

Comment: Long-term protection of groundwater can best be guaranteed by above-grade disposal in which a synthetic membrane liner is used at the bottom of the containment cell. The 25- to 30-year lifetime of such a liner, as stated in the draft EIS, may be too short. A leachate collection and monitoring system is essential to preventing contaminant migration to groundwater.

Response: The DOE concurs that groundwater protection is an essential component of any waste disposal system. There are several means by which this goal could be accomplished. An alternative to collecting infiltrate and leachate from the wastes (such as the use of a bottom liner and leachate collection system) would be to dispose of the wastes in a manner that water is prevented from reaching the contained wastes (e.g., by use of a very impermeable cap) so that leachate is not generated. Even though the lifetime of a synthetic membrane can be longer than 25 to 30 years when not exposed to ultraviolet radiation from the sun (up to 100 to 200 years), its lifetime is very short compared to the half-lives of the radionuclides controlling the hazard of the Weldon Spring wastes. The DOE is currently evaluating various disposal system designs that would provide groundwater protection.

B.2.7 Issue 15

Comment: The disposal cell cap should be thick enough to prevent the migration of radon-222 gas into the environment. In addition, although using a lead sheet in the

cover may be technically feasible, there seem to be more disadvantages than advantages with regard to this design. The draft EIS indicates that the edge of the cover will have a slope of 20%. This slope seems excessive and could lead to slumping and increased erosion.

Response: The DOE is currently in the process of developing generic criteria for containment cell design. These criteria will lay the foundation from which various disposal cell designs could be developed and evaluated. The concerns raised in this issue will be addressed in the design criteria document. Adequate confinement of radon-222 gas is obviously required because the inventory of radium-226 (the immediate precursor of radon-222) will continue to increase for several thousand years. The use of a lead sheet in the cover, which was included in the draft EIS as a result of input obtained during the scoping process, will be reevaluated in the RI/FS-EIS. The 20% slope at the edge of the cover has been used at other sites with no apparent difficulties (e.g., the Niagara Falls Storage Site). The design of a containment cell has not yet been completed. Conceptual design information will be included in the draft RI/FS-EIS issued for public comment.

B.2.8 Issue 16

Comment: Performance standards and goals for waste confinement should be identified prior to the initiation of remedial action (i.e., regarding restricted versus unrestricted future use of the site and the potential for subsequent remedial action). It is not possible to evaluate the acceptability of the various alternatives without such performance standards.

Response: Performance standards will be developed as part of the ARAR process for the RI/FS-EIS (see Section 3.1 of this work plan). Any containment facility, whether on-site or off-site, would be designed to ensure conformance to these standards. The development and operation of an area as a disposal site would preclude its unrestricted use but not the implementation of subsequent remedial action.

B.2.9 Issue 17

Comment: The draft EIS refers to monitoring and inspecting the containment system following completion of remedial action. This is an important component of ensuring that the containment cell is performing as planned. The frequency and length of time DOE is planning to conduct monitoring, inspection, and corrective activities (as needed) must be defined. The parameters to be monitored and the party responsible for monitoring should also be identified.

Response: The DOE is committed to monitoring and maintaining the disposal site for the foreseeable future. It is premature to precisely define the parameters and the frequency with which monitoring and inspection should occur because a location for the disposal cell has not yet been identified and the disposal cell design has not been completed. Some systems may require more frequent inspections than others. At a minimum, inspections would occur annually. More frequent inspections (e.g., quarterly)

would be expected in the near term to verify the adequacy of the containment system performance.

B.2.10 Issue 18

Comment: The disposal cell should not be located in an area overlying contaminated groundwater. Otherwise, it will be impossible to monitor the performance of the disposal facility because there are no means to differentiate between current contamination and that resulting from migration of contaminants from the disposal cell.

Response: The DOE is currently evaluating the effect of groundwater contamination at the raffinate pits and chemical plant area on the ability to dispose of wastes in that area. A decision to dispose of wastes above contaminated groundwater in that area will not be made unless it can be demonstrated that either (1) remediation of the groundwater is not needed or (2) groundwater remediation can be performed without impairing the integrity of an on-site disposal facility. Disposal cell performance could be monitored by means other than environmental sampling of the contaminants currently in the groundwater. For example, different indicator species could be monitored or a leachate collection and monitoring system could be used.

B.2.11 Issue 19

Comment: The draft EIS should discuss the need for restoration of the contaminated groundwater at the Weldon Spring site. At a minimum, it should discuss mitigative measures that will be used to reduce or prevent further migration of chemical or radioactive contamination in groundwater.

Response: Insufficient data were available at the time the draft EIS was prepared to address the need for restoration of contaminated groundwater. The baseline risk assessment to be performed as part of the RI/FS-EIS process for this project will evaluate the current hazards posed by the contaminated groundwater at the raffinate pits and chemical plant area. This information will be used in assessing the need for groundwater restoration. The DOE is currently evaluating the mechanisms responsible for groundwater contamination at the raffinate pits and chemical plant area and is developing plans to ensure the safety of nearby potable water supplies. The need for groundwater restoration at the quarry will be addressed following removal of the bulk wastes.

B.2.12 Issue 20

Comment: The technology to isolate the wastes from the environment for the length of time that the wastes will be hazardous does not exist. Considering the half-lives of the radionuclides in the Weldon Spring wastes, the design life of 200 to 1,000 years is very short.

Response: Isolation of the wastes from the human environment can only be ensured through implementation of a properly designed and managed waste disposal program consisting of good engineering design, periodic monitoring and maintenance, and institutional controls. Use of a passive containment system (i.e., one not reliant on active maintenance), along with a planned monitoring and maintenance program and controls to site access, should provide for effective isolation of these wastes from the nearby environment. The 200- to 1,000-year design life for the containment system was selected to be consistent with the time frames identified by the EPA for management of inactive uranium mill tailings, which also consist of low concentrations of very long-lived naturally occurring radionuclides.

B.3 SITE CHARACTERIZATION AND SUITABILITY

B.3.1 Issue 21

Comment: The geology of the raffinate pits and chemical plant area is very complex and has not been thoroughly characterized. In addition, the geology of this area is such that long-term containment of wastes is not possible. Developing a disposal facility in an area of karst geology is not appropriate because this type of geology consists of numerous voids. The area is prone to sinkholes, solution channels, and geological instabilities.

Response: The DOE is in the process of conducting a thorough geological study of the raffinate pits and chemical plant area, the results of which will be provided in the RI report. The environmental assessment given in the RI/FS-EIS will be based upon information obtained from the detailed site characterization activities currently being conducted. No large voids have been observed in the bedrock as a result of characterization activities conducted to date. (See also Response to Issue 9, Section B.2.1.)

B.3.2 Issue 22

Comment: The raffinate pits and chemical plant area is not suitable for waste disposal because this area has numerous test wells, boreholes, and trenches that will provide additional pathways for contaminants to reach the groundwater.

Response: The geology of this area is the subject of a comprehensive, ongoing investigation (see Response to Issue 21, Section B.3.1). The raffinate pits and chemical plant area will not be used for waste disposal unless its suitability can be demonstrated. Although it is possible for test wells, boreholes, and trenches to provide pathways for contaminants, rigid protocols and procedures have been and will continue to be used to effectively eliminate this possibility (e.g., double casing of deeper wells and grouting of abandoned boreholes).

B.3.3 Issue 23

Comment: All characterization activities should be completed prior to engineering design. It is not possible to properly design a containment cell for a site that may have significant geological flaws. The containment cell must accommodate site-specific geological and hydrological characteristics.

Response: Evaluation of remedial action alternatives will utilize the RI/FS process developed by EPA for CERCLA. This is an iterative process in which site characterization (RI) activities are conducted parallel to, and have input into, the evaluation of alternatives (FS) phase. Conceptual engineering design, which occurs during the FS phase, feeds back into the RI phase as data gaps are identified for a specific technology or alternative. Conceptual design activities must therefore be initiated prior to completion of site characterization activities as required for the RI/FS-EIS. The design of any containment cell would accommodate site geological and hydrological characteristics that will be defined during the RI phase.

B.3.4 Issue 24

Comment: The raffinate pits and chemical plant area should be thoroughly characterized prior to modeling studies because the area hydrogeology is complex, consisting of features such as losing streams and springs. The on-site saturated layer may actually be a naturally occurring perched water table. Modeling studies conducted to date have not been in agreement with measured levels of contamination in groundwater at the raffinate pits and chemical plant area, indicating that there may be additional migration pathways. Local springs should be identified and analyzed for chemical contaminants. All surface water/groundwater connections at the Weldon Spring site should be identified.

Response: The DOE is currently characterizing the local hydrogeology and is working with the Missouri DNR to accurately identify the losing streams and springs in the area. The Missouri DNR expertise in conducting dye studies should be very helpful in identifying surface to subsurface water connections. The baseline risk assessment, an integral component of the RI/FS-EIS process, will address the risks associated with the contamination currently at the site and the various pathways to the potential receptors. The RI/FS-EIS will not be issued until all site characterization activities have been completed. Modeling studies to support the RI/FS-EIS process will be calibrated against current contamination conditions at the site.

B.3.5 Issue 25

Comment: The volumes and concentrations of contaminants in the waste materials must be thoroughly characterized for both radioactive and chemical species. The data presented in the draft EIS do not present sufficient detail to justify the calculations performed.

Response: The waste materials will be characterized for both radioactive and chemical species as part of the RI phase. This information will be used to determine the volumes, physical properties, specific contaminants, and hazards of the waste materials currently located at the Weldon Spring site. This information will be included in the draft RI/FS-EIS issued for public comment.

B.3.6 Issue 26

Comment: Site-specific data are needed regarding soil engineering (physical) and ion-exchange (chemical) properties and the depths of clay layers.

Response: The DOE agrees that additional site-specific data are needed to understand migration potential and to ensure that, if a containment cell is located on-site, it would be properly designed and constructed. The DOE is planning to obtain these data as part of the RI process. This information will be obtained, in part, from ongoing characterization activities. Additional data will be collected as needed.

B.3.7 Issue 27

Comment: Statements made in the draft EIS that the Weldon Spring site is located in a tectonically quiet region are incorrect. It is very likely that a significant earthquake will occur in this area in the near future.

Response: The DOE is reevaluating current data regarding the potential for seismic events that could affect the Weldon Spring area. This information will be given in the RI report. A design-basis seismic event will be defined for the Weldon Spring site. Alternatives for on-site disposal will be assessed for their ability to withstand such an earthquake without compromising the integrity of the containment cell.

B.4 ENVIRONMENTAL IMPACTS

B.4.1 Issue 28

Comment: The draft EIS should include worst-case scenarios in which either mitigative measures or engineered structures fail.

Response: The RI/FS-EIS will include an assessment of the environmental impacts associated with scenarios in which either mitigative measures or engineered structures fail. However, judgment will be used to ensure that this assessment is reasonable, i.e, only reasonably foreseeable scenarios will be evaluated.

B.4.2 Issue 29

Comment: Use of meteorological data from Lambert Airport in St. Louis to assess impacts at the Weldon Spring site may be inappropriate because the airport is about 48 km (30 mi) from the site. Data should be used that can be obtained from closer sources, such as the National Weather Service station in St. Peters. Additionally, the draft EIS should include the wind rose used in these calculations.

Response: Meteorological data will be obtained from a source closer to the Weldon Spring site than Lambert Airport. In addition to the National Weather Service station at St. Peters, data could be obtained from other points closer to the site. Current plans are to construct an on-site meteorological station, projected to be operational in late 1988. As the meteorological information provided by this station becomes available, it will be used in the RI/FS-EIS process. A 1985 annual wind rose for the Weldon Spring site is included as Figure 11 of this work plan.

B.4.3 Issue 30

Comment: The draft EIS must include the health impacts of all radioactively and chemically hazardous substances at the site. These impacts should not be limited to humans only, but should consider all living organisms. This is especially true because certain organisms, which may be eaten by humans, are known to concentrate certain radionuclides. Biouptake studies on local wildlife -- such as wild turkeys, geese, deer, largemouth bass, and algae -- should be performed as part of this project.

Response: One of the first steps in the baseline risk assessment is to identify the significant chemical and radioactive species at the Weldon Spring site with regard to potential health risks to nearby individuals. These indicator compounds -- which are selected on the basis of their abundance at the site, their toxicity to human health, and their mobility in the environment -- will be included in the analyses given in the RI/FS-EIS. The means by which these indicator compounds can move through the environment to potential human receptors, including their uptake by plants and animals in the human food chain, will be assessed in the RI/FS-EIS. The environmental impact analysis presented in the RI/FS-EIS will address the effects of radioactive and chemical contaminants on the local ecosystem. Biouptake studies are currently being performed on local wildlife (e.g., fish, squirrels, and rabbits), and the results will be reported as they become available. Biouptake studies on other wildlife -- such as wild turkeys, geese, and deer -- will not be performed unless studies of indicator animals determine such a need.

B.4.4 Issue 31

Comment: The DOE should reexamine its calculations of radiation doses because the projected doses are too low to be believable. Specific considerations include (1) the respirable fraction of dust, (2) the doses to internal organs from inhalation of radioactive particulates and radon gas, as well as the doses due to external exposure, and (3) the effect of alpha emitters being 20 times more hazardous than beta radiation. Specific concern should be given to exposure from radon gases (i.e., radon-219, radon-220, and

radon-222) because radon is estimated to cause 20,000 to 30,000 lung cancer deaths per year.

Response: The radiation doses in the draft EIS take into account all of the issues presented in this comment. However, DOE is intending to thoroughly reevaluate the estimation of radiation doses based upon the detailed site characterization activities currently being performed. Radon-219 is not a significant contributor to radiation exposure relative to radon-220 and radon-222 at the Weldon Spring site because of the low abundance of radionuclides that give rise to radon-219 and its very short half-life (approximately four seconds).

B.4.5 Issue 32

Comment: Because children are much more susceptible to radiation-induced illnesses than adults, the draft EIS should specifically address the potential doses and resultant health effects relative to children. Exposure to toxic substances should be addressed in a similar fashion. Both short-term and long-term health effects on children must be evaluated.

Response: The RI/FS-EIS will consider the toxicity of radionuclides and chemically hazardous substances on children. Data on age-specific effects will be used to the extent that they are available. Both short-term and long-term health effects on children will be assessed.

B.4.6 Issue 33

Comment: There is no safe level of radiation exposure. All exposures must be regarded as deleterious. Impacts include decreased life expectancy, genetic defects, and cancer. It should be noted that radionuclides can concentrate in certain organs, resulting in long-term radiation exposure. The people most susceptible to radiation-induced cancer are children and the elderly. The latency period for cancer induction can vary greatly in the general population.

Response: It is the policy of DOE to maintain all exposure to radiation at levels that are "as low as reasonably achievable" (ALARA). The DOE considers all radiation exposure above background to be hazardous and intends to minimize the doses incurred by both workers and the general public. The major health impacts to be addressed are cancer and genetic defects. Other impacts such as decreased life expectancy are very difficult to quantify but will be addressed to the extent possible. The calculation of radiation doses will consider organ uptakes, latency periods, and the greater susceptibility of children and the elderly.

B.4.7 Issue 34

Comment: The incidence of cancer in St. Charles County is greater than that expected in the general population. Although these data have not been substantiated by

the scientific community, they do represent a reason for concern. Specific forms of cancer that have been documented in this area include leukemia and testicular cancer. Releases from the Weldon Spring site could be responsible for these cancers. Even if the site is not responsible for past cancers, it is imperative that the site be remediated so that it is not responsible for any new cases of cancer.

Response: The incidence of cancer in St. Charles County is not greater than that in other parts of the United States. The Missouri Department of Health recently completed a retrospective study of childhood leukemia in the vicinity of the Weldon Spring site. Although this study indicated an increased level of childhood leukemia cases during the period 1975-1979, the incidence rate over the entire period of the study (i.e., 1970-1983) was not statistically different from that to be expected in the general population. The Department of Health was not able to establish a link between these leukemia cases and any specific causes. The DOE is committed to conducting the Weldon Spring Site Remedial Action Project in a manner that will minimize the likelihood for any deleterious health impacts. (See also Response to Issue 52, Section B.5.10.)

B.4.8 Issue 35

Comment: The draft EIS must explicitly evaluate the potential health impacts of response action activities on students and staff at Francis Howell High School, staff and visitors at the St. Charles County Extension Center, and residents in nearby communities such as Weldon Spring Heights. The DOE should relocate these facilities at government expense if it cannot be shown, with absolute assurance, that people using these facilities and nearby residents will be safe during conduct of response action activities at the Weldon Spring site.

Response: The impacts on nearby residents, the students and staff at Francis Howell High School, and the staff and visitors at the St. Charles County Extension Center will be explicitly evaluated in the RI/FS-EIS. All data and calculations to date show a very low risk to nearby individuals from proposed response action activities at the Weldon Spring site. (See also Responses to Issues 52 and 53 in Sections B.5.10 and B.5.11, respectively.)

B.4.9 Issue 36

Comment: The draft EIS does not accurately describe local groundwater users in the vicinity of the site. The St. Charles Countians Against Hazardous Waste (SCCAHW) has completed a survey of private wells in this area. This information, which indicates that many private wells in the area are drawing water from the shallow Burlington-Keokuk aquifer, was not incorporated in the draft EIS. Instead, the draft EIS lists only municipal and water district supply facilities. St. Charles County also contains subdivisions, mobile home parks, and institutions that are classified as users of public water supplies. Failing to use this information greatly underestimates the impact of this project on local groundwater supplies. The EIS should address actual water users.

Response: The DOE greatly appreciates the information supplied by the SCCAHW and the state of Missouri on nearby users of groundwater. This information has been very helpful to DOE in assessing the hazards associated with the groundwater contamination discovered in 1987 in the vicinity of the raffinate pits and chemical plant area. The data supplied by the SCCAHW and the state of Missouri will be used in the RI/FS-EIS to assess the environmental impacts of alternatives developed for detailed study.

B.4.10 Issue 37

Comment: The groundwater modeling results at the raffinate pits and chemical plant area are incorrect. The model used is too simple to adequately address the complex hydrogeology of this area. Nonuniform geology, possible barrier degradation, and flow through fractures and solution-enlarged cavities are factors that cannot be accurately or adequately considered using current modeling techniques. The modeling results performed to date do not agree with field-observed data.

Response: The DOE intends to conduct additional detailed groundwater modeling studies at the raffinate pits and chemical plant area following collection of relevant data. These results will be included in the RI/FS-EIS, as appropriate. Prior to performing these studies, the site geology will be thoroughly characterized. The modeling results will be calibrated to current measurements of radioactive and chemical contamination of the groundwater in the raffinate pits and chemical plant area. This should ensure that the modeling results are a reasonable representation of current conditions and can provide a meaningful estimation of future conditions.

B.4.11 Issue 38

Comment: The draft EIS underestimates the potential impact of increased use of nearby roads during response action activities on nearby facilities such as Francis Howell High School. There is a lot more traffic at the school than the draft EIS implies. In addition, contingency measures should be in place to respond to traffic accidents (such as an overturned truck transporting contaminated materials) and resultant releases of contaminants to the environment.

Response: The intersection of Missouri (State) Route 94 and U.S. Route 40/61 is very busy, especially during the morning and evening rush hours. There is also a lot of traffic at Francis Howell High School during the periods when students arrive for classes in the morning and depart in the afternoon. The DOE will coordinate all traffic associated with response action activities to minimize impacts on nearby facilities. The DOE will also require all subcontractors to develop contingency measures to deal with potential traffic accidents involving trucks transporting contaminated materials. (See also Response to Issue 51, Section B.5.9.)

B.4.12 Issue 39

Comment: The draft EIS states that the nonradioactive hazardous wastes will be transported to and disposed of at a RCRA-licensed hazardous waste facility. However, the draft EIS does not address the environmental impacts of handling and transporting the wastes.

Response: The DOE intends to dispose of all nonradioactive hazardous wastes off-site at a RCRA-licensed hazardous waste facility. The location of the facility cannot be identified until the characteristics of the wastes have been determined by the detailed waste characterization activities currently being performed by DOE. Also, because DOE is planning to perform various IRAs prior to the ROD, it is likely that much of the nonradioactive hazardous waste will be disposed of prior to the completion of the RI/FS-EIS. The environmental impacts associated with the handling and transportation of chemically hazardous wastes will be addressed in EE/CA reports or in the RI/FS-EIS, as appropriate.

B.4.13 Issue 40

Comment: The draft EIS understates the impacts of population growth in St. Charles County because most of this growth is in the direction of the Weldon Spring site. As population growth in this area continues, waste storage may prove to be a poor choice of land use. The draft EIS should include projected population estimates and a population distribution chart showing the population by sector and distance from the site.

Response: The RI/FS-EIS will include a population distribution chart showing the population by sector and distance from the site. The impact of population growth and local land use will be included for the various alternatives in the RI/FS-EIS. Projections of population growth are difficult to quantify beyond the near term because such growth is influenced by factors that cannot be estimated with any degree of precision (e.g., local economic growth and changes in land use patterns). The impacts of population growth will be assessed to the extent feasible.

B.4.14 Issue 41

Comment: The draft EIS does not adequately address the impact of the Weldon Spring site on current and long-term real estate values.

Response: The DOE is not planning to study the impact of the Weldon Spring site on local real estate values because such values can be affected by numerous factors. It is not possible to quantify the impact of the Weldon Spring site independently of other factors, such as population growth and local employment opportunities. Hence, it does not seem reasonable to address this issue in the RI/FS-EIS.

B.4.15 Issue 42

Comment: The DOE should consider the interim impacts of response action activities at the Weldon Spring site on adjacent lands owned by the Missouri Department of Conservation and should ensure that these activities will accommodate future public uses of surrounding lands and waters (including Lakes 34, 35, and 36 in the Busch Wildlife Area).

Response: The DOE will address interim impacts of response action activities in either EE/CA reports for IRAs (see Section 3.10 of this work plan) or in the RI/FS-EIS for the project. The DOE is committed to implementing response actions at the Weldon Spring site in a manner that will permit future public use of surrounding lands and waters.

B.5 SCOPE AND CONDUCT OF REMEDIAL ACTION ACTIVITIES

B.5.1 Issue 43

Comment: All areas in the vicinity of the Weldon Spring site that are contaminated with radioactive and chemical substances originating from the Weldon Spring site should be cleaned up. This includes soils, drainageways, Femme Osage Slough, and lakes and springs in the Busch Wildlife Area. At a minimum, all such areas should be clearly marked to warn people of these hazards.

Response: The DOE intends to clean up all areas in the vicinity of the Weldon Spring site for which it has responsibility that pose an unacceptable risk to public health and the environment. The DOE is continuing to work with the U.S. Department of the Army to identify off-site areas contaminated as a result of Army activities. The responsibility for cleanup of these areas rests with the Army. The DOE will inform the Missouri Department of Conservation of all contamination originating from the site that is detected in the wildlife areas administered by that department.

B.5.2 Issue 44

Comment: All of the wastes should be removed from the Weldon Spring site. This was done at the Vitro site in Salt Lake City, under similar circumstances. Under no conditions should additional wastes be brought to this site for disposal.

Response: The preference for total removal of the wastes from the Weldon Spring site is noted. The basis for the DOE decision relative to the Vitro site is provided in the ROD for remedial action at that site (U.S. Dept. Energy 1984). The DOE has no plans to move additional wastes to the Weldon Spring site for disposal.

B.5.3 Issue 45

Comment: The Weldon Spring site is responsible for current groundwater contamination. Of major concern is the quarry, which is located in very close proximity to the St. Charles County well field that supplies potable water for much of St. Charles County. Radioactive and chemical contaminants have been detected in monitoring wells between the quarry and the county wells. The groundwater in the raffinate pits and chemical plant area is also contaminated with nitrates, trinitrotoluene (TNT), and dinitrotoluene (DNT). The federal government should test all local water supplies in the vicinity of the Weldon Spring site to ensure the safety of local citizens.

Response: The DOE concurs that the Weldon Spring site is responsible for local groundwater contamination. The environmental monitoring program at the raffinate pits and chemical plant area and at the quarry includes many wells to monitor the status of groundwater contamination. One of the major components of the RI/FS-EIS will be an evaluation of the hazards posed by this contamination at the raffinate pits and chemical plant area. The DOE is planning to remove the bulk wastes from the quarry prior to the ROD to minimize the potential for increased groundwater contamination at the quarry (see Section 3.11 of this work plan). Removal of the source of this contamination should be an effective means of lowering the rate at which radioactively and chemically hazardous substances enter the groundwater in the area. The possible need to remediate the groundwater at the quarry will be addressed in the future (see Response to Issue 47, Section B.5.5). The DOE has tested several private wells in the proximity of the raffinate pits and chemical plant area and has found no contamination. The state of Missouri is responsible for ensuring that the water supplies in the vicinity of the Weldon Spring site are safe and has been carrying out this responsibility.

B.5.4 Issue 46

Comment: The draft EIS should provide specific details on how contaminated water will be treated prior to disposal. Of specific concern is the discharge of any contaminated water into the Missouri River because this is upstream of the water intakes for St. Louis City and St. Louis County. In addition, the state of Missouri has specific requirements for wastewater discharges that must be met.

Response: The DOE is addressing the treatment of contaminated water at the raffinate pits and chemical plant area and at the quarry as IRAs (see Sections 3.10.2.15 and 3.10.2.16 of this work plan). The treatment techniques to be used will be addressed in EE/CA reports prepared to support these actions. A major component of the EE/CA process will be determination of effluent limits and conditions of discharge. The DOE is working with the EPA Region VII and the Missouri DNR in developing these actions.

B.5.5 Issue 47

Comment: The DOE should commit to restoration of contaminated groundwater at both the raffinate pits and chemical plant area and the quarry.

Response: The need for groundwater restoration at the raffinate pits and chemical plant area will be addressed as part of the RI/FS-EIS process. Analysis of the groundwater contamination issue at the quarry will be addressed in a separate, but similar, process in the future. The DOE intends to address this issue for the quarry following removal of the bulk wastes and collection of sufficient data to allow for an objective decision to be made.

B.5.6 Issue 48

Comment: It is important to minimize the airborne release of radioactive particulates during response action activities. Use of water sprays during soil excavation may not be sufficient. All sources of dust should be addressed, e.g., from construction activities, building demolition, and/or truck traffic. Plans for detecting and minimizing dust releases should be developed prior to initiation of response action activities. In addition, all pertinent plans (i.e., those that address monitoring, response action, and waste storage) should be provided to the public.

Response: Use of water sprays has been shown to be an effective means of minimizing the amount of airborne particulates released during response action activities at similar sites. An aggressive environmental monitoring program will be implemented during construction-related activities to ensure a safe environment for workers and the nearby population. This program will rely primarily on air particulate monitors. All activities having the potential to generate airborne particulates will be reviewed to ensure that mitigative measures are in place prior to the initiation of field activities. The DOE intends to present its plans for conducting response action activities to the public. Included in these plans will be measures to minimize airborne particulate releases.

B.5.7 Issue 49

Comment: An important component of a remedial action plan is a determination of the mitigative measures that will be used to reduce environmental impacts. All potential exposure pathways must be identified and mitigative measures evaluated. Such mitigative measures should be detailed early in the process to allow for public review and comment.

Response: The DOE agrees that a comprehensive plan of mitigative measures is important to ensure that environmental impacts are minimized. Mitigative measures will be identified as specific actions are defined. These mitigative measures will address all potential exposure pathways. The public will have an opportunity to comment on these mitigative measures via the EE/CA and RI/FS-EIS processes.

B.5.8 Issue 50

Comment: The environmental monitoring program to be used must be defined at this time. This monitoring program should not only be in effect during the action period

but should also be maintained long after remedial action has been completed. Results of the monitoring program should be provided to local citizens upon request.

Response: The DOE currently has in place an environmental monitoring program consistent with DOE requirements. The results of this program are available to the public upon request. The DOE publishes an annual environmental monitoring report for the Weldon Spring site in May of each year. The environmental monitoring program for the project will be reevaluated annually to ensure that monitoring activities are commensurate with ongoing and planned activities. The monitoring program to be used during remedial action activities will be defined in the RI/FS-EIS process and will address both the action period and the period following completion of remedial action (see also Response to Issue 17, Section B.2.9).

B.5.9 Issue 51

Comment: Contingency plans must be developed to allow for quick enactment of emergency response measures in the event of an accidental release either on-site or during transportation off-site.

Response: The DOE has an emergency preparedness plan in place that is consistent with DOE requirements. This plan details the procedures to be used in case accidental conditions occur that could impact nearby individuals. The major thrust of the plan is immediate response and timely notification of local authorities responsible for protecting the health and welfare of the nearby population.

B.5.10 Issue 52

Comment: The DOE should establish a trust fund for an insurance program to pay medical expenses of local residents for treatment of diseases and illnesses that might be caused by exposure to radioactively and chemically hazardous substances at the Weldon Spring site. In addition, DOE should finance periodic medical monitoring of the students, faculty, and staff at Francis Howell High School.

Response: The DOE has in place an environmental monitoring program to assess the concentrations of radioactive and chemical contaminants in the nearby environment. The results to date do not indicate that releases from the Weldon Spring site could be responsible for any deleterious health effects. The monitoring program will continue for the duration of the project. The Missouri Department of Health recently completed a retrospective study of childhood leukemia in the vicinity of the Weldon Spring site and was unable to establish a link between these leukemia cases and any specific cause (see Response to Issue 34, Section B.4.7). Based on this information, there is no basis to perform periodic medical monitoring of the students, faculty, and staff at Francis Howell High School or to establish an insurance trust fund.

B.5.11 Issue 53

Comment: The DOE should conduct a comprehensive health study of individuals who live in the vicinity of the Weldon Spring site.

Response: The DOE does not believe that it is necessary to conduct a comprehensive health study of nearby residents. An environmental monitoring program is in place to measure the concentrations of radioactive and chemical contaminants in the local environment. Results of this monitoring program can be used to identify potential impacts of the project on the local environment. Additionally, the retrospective health study conducted by the Missouri Department of Health did not uncover any reasons to suspect that the Weldon Spring site has been responsible for an increased incidence of cancer in this area. The health impacts of remedial action activities will be included in the RI/FS-EIS. In addition, the Agency for Toxic Substances and Disease Registry will perform a public health assessment for this project. (See also Response to Issue 52, Section B.5.10.)

B.5.12 Issue 54

Comment: The citizens of St. Charles County deserve to have the Weldon Spring site cleaned up by the best available technology, regardless of cost. Cost should not be the overriding factor in decisions regarding the conduct of the remedial action project.

Response: The DOE is accountable to the taxpayers of this country. Therefore, DOE must consider costs in its decision. The cost of the project will be a factor, but not the overriding factor, in selecting an alternative. The most important factors to be considered will be the health and safety of persons potentially impacted by the project.

B.5.13 Issue 55

Comment: The DOE should do everything possible to maintain the viability of the rail transportation option. The impact of abandonment of the Missouri-Kansas-Texas (MKT) rail line between Machens and Sedalia, Missouri, should be addressed. The DOE should try to ensure the usability of this abandoned line.

Response: The issue of abandonment of the MKT rail line between Machens and Sedalia is beyond the scope of DOE's responsibility. The abandonment was approved by the Interstate Commerce Commission.

B.5.14 Issue 56

Comment: Alternative 3a in the draft EIS (disposal of the Weldon Spring wastes at the Hanford site in the state of Washington) should not be considered a viable alternative because the Hanford site leaks and it would not accept the wastes.

Response: The DOE agrees that disposal of the Weldon Spring wastes at the Hanford site is currently not a viable option based on all factors that affect the implementability of this alternative. These factors include the likelihood that the Weldon Spring wastes would not be accepted for disposal at the Hanford site, the distance of the Hanford site from the Weldon Spring site, the volume of wastes that would be transported, and the increased health and safety risks associated with the transportation effort.

B.5.15 Issue 57

Comment: Alternative 3c in the draft EIS (transporting the raffinate pit and quarry sludges to an existing uranium-processing facility in the southwestern United States) should not be considered viable because it is unlikely that any uranium mill would accept these materials, no economic benefit would accrue, and significant transportation impacts would result.

Response: The DOE concurs that, as evaluated in the draft EIS, the negative aspects of this alternative associated with transportation impacts outweigh any positive benefits that might accrue. However, DOE is evaluating the potential for reprocessing the raffinate pit and quarry sludges at either an on-site facility or an off-site facility to recover potentially usable materials and to reduce the toxicity, mobility, and/or volume of the contaminated materials as required by CERCLA.

B.5.16 Issue 58

Comment: All DOE actions should be subject to independent oversight and inspection by an unbiased, qualified organization because DOE's record on environmental protection, health, and safety is very poor. The DOE should also consider establishing a citizens' advisory board to monitor progress on this project.

Response: The EPA Region VII is providing independent oversight of the entire project, as mandated by CERCLA. The DOE is also working with the Missouri DNR to ensure that all state concerns are addressed. The DOE has an active community relations program to ensure that local citizens are kept informed of ongoing activities.

B.5.17 Issue 59

Comment: The draft EIS is vague regarding the standards and guidelines that will be used to direct the remedial action. It is not clear if DOE will use EPA, DOE, or state of Missouri regulations, some combination of these regulations, or the most restrictive regulations where duplication occurs. The draft EIS should discuss how each alternative implements the ALARA policy of minimizing radiation exposure.

Response: Determination of ARARs is a key element of both the EE/CA and RI/FS-EIS processes. The ARARs will define the specific requirements to be followed in conducting response action activities. The DOE will conduct the ARAR process in

cooperation with EPA Region VII and the Missouri DNR to ensure that all ARARs are determined. The DOE intends to develop an ALARA dose limit (see Response to Issue 60, Section B.5.18). The alternatives in the RI/FS-EIS will be assessed relative to this ALARA value.

B.5.18 Issue 60

Comment: The limits that DOE is using to allow release of facilities and equipment for unrestricted use will result in unacceptably high doses. Additionally, the DOE limit of 100 mrem/yr committed effective dose equivalent is too high. The International Commission on Radiological Protection (ICRP) recommended this limit for exposure from all sites and sources. This value is too high for exposure of individuals from a single site that is no longer providing any benefits to the public.

Response: The criteria DOE is using to determine release limits of facilities and equipment are based on published standards of the U.S. Nuclear Regulatory Commission and the EPA. These criteria have been used previously in similar circumstances by DOE and private industry. The DOE believes that the use of previously established criteria for this project is relevant and appropriate. The DOE dose limit for the general public is 100 mrem/yr committed effective dose equivalent for prolonged exposure; in addition, the dose must be ALARA. The DOE is intending to develop an ALARA value for the Weldon Spring Site Remedial Action Project. This value will include considerations of cost, implementability, and other relevant factors. This ALARA value will likely be much lower than 100 mrem/yr. (See also Response to Issue 59, Section B.5.17.)

B.6 REFERENCE

U.S. Department of Energy, 1984, *Compliance with the National Environmental Policy Act: Record of Decision for Remedial Actions at the Former Vitro Chemical Company Site, South Salt Lake, UT*, Federal Register, *49*(201):40436-40439 (Oct. 16).

MISSOURI DEPARTMENT OF CONSERVATION

Comment 1

Page 2-7, Figure 2.3 - The map depicts a nature trail running down the drainage ditch that flows to the Missouri River. In 1984 we relocated the trail so it no longer is in that drainage ditch.

Response to Comment 1

The nature trail has been deleted from this figure.

Comment 2

Page 2-41, Table 2.8 - Data taken from Station SW-2009, located above Burgermeister Spring, should be reported if available. If no data is available, that should be reported.

Response to Comment 2

There was no flow at this location when samples were taken. We see no need to include this explanation in the work plan since the intent of this plan is to summarize current plans for implementation of this project, not to summarize all of the results of ongoing site characterization activities.

Comment 3

Page 3-36, Paragraph 3.6.2.5 - We would strongly urge the inclusion of site B-7 in the list of areas on our property for removal of radioactive contaminated soil. Hopefully, this is an oversight and will be corrected in the next edition of this report. If there has been a decision not to remove radioactive soil from B-7, we would appreciate learning the reasons for that decision.

Response to Comment 3

Vicinity properties will be cleaned up either as interim response actions (IRAs) prior to the project record of decision (ROD) or as part of remedial actions following the ROD. Vicinity property B7 all will not be cleaned up until all potential sources of contamination that feed this drainage ditch are eliminated. This will likely not occur until the ROD has been issued. Hence, this drainage ditch will be cleaned up following the ROD and not as an IRA.

- - - -

MISSOURI DEPARTMENT OF NATURAL RESOURCES

Comment 1

Pages 1-5 through 1-11: The Weldon Spring Site Remedial Action Project is divided into five compliance components. These components do not seem to address two issues: Analysis of whether remedial action will be necessary for the soil, sediment, surface water and groundwater in the slough and nearby areas. [Note: the second issue is given in Comment 2.]

Response to Comment 1

Figures 2 and 3 have been revised to include vicinity properties at both the raffinate pits and chemical plant area and at the quarry. The text in this section has been revised to include more discussion relative to vicinity properties cleanup. The need to clean up the slough and other areas near the quarry will be included as part of the NEPA and CERCLA processes for the residual materials and groundwater restoration operable units at the quarry following bulk waste removal. Using currently available data, it is not possible to conclude that remedial action is or is not warranted in the slough and nearby areas at this time.

- - - -

Comment 3

Page 1-12, Paragraph 2: The Missouri Geological Survey (MGS) no longer exists as a separate agency; under the 1974 reorganization of Missouri state government, the MGS became the Division of Geology and Land Survey (DGLS) within the Missouri Department of Natural Resources (MDNR).

Response to Comment 3

Reference to the Missouri Geological Survey has been deleted. Since reference to the Missouri Department of Natural Resources (DNR) has already been included in the work plan, there is no need to highlight the Division of Geology and Land Survey over other divisions within the DNR.

- - - -

Comment 6

Page 1-14, Paragraph 3: The location and distance between the Francis Howell School and the chemical plant should be stated and the daytime population of this school provided.

Response to Comment 6

The following two sentences have been added to this paragraph: "The Francis Howell High School is located about 1 km (0.6 mi) east of the raffinate pits and chemical plant area on State Route 94. An estimated 2,300 persons are on campus daily during the school year (U.S. Dept. Energy 1987a)."

- - - -

Response to Comment 8

A discussion of all the areas identified in Comment 7 has been included in the section on local land use in the work plan.

- - - -

Comment 11

Page 2-69, Paragraphs 1 and 2: Because of the proximity of the slough to the public drinking water well field, the distribution of uranium in the soil and groundwater in this area should be better defined.

Response to Comment 11

The DOE concurs on the need to better define the distribution of uranium in soil and groundwater in the vicinity of the quarry. It is not possible to evaluate remedial action alternatives at the slough with the current level of information. We are intending to gather this data as part of the NEPA and CERCLA documentation process for the residual materials and groundwater restoration operable units following bulk waste removal from the quarry.

Comment 12

Page 3-8, Paragraph 2: The impact of the ingestion of wild foods (e.g., mushrooms, berries, nuts, etc.,) collected from the Busch and Weldon Spring wildlife areas should be considered in the discussion of potential risks. Data on the collection of these foods should be available from the Missouri Department of Conservation.

Response to Comment 12

This paragraph has been revised to read: "Exposure through ingestion of food could occur if individuals in the area grow a significant fraction of plant foods for their own consumption or if they collect and eat contaminated wild foods (e.g., mushrooms, berries, and nuts) from the surrounding wildlife areas. Exposure could also occur if there are livestock (e.g., cows) that graze in areas of contaminated soil."

Comment 13

Page 3-9, Paragraph 2: Discussion of air monitoring at the quarry should be included.

Response to Comment 13

This paragraph has been revised to read: "... Air monitoring operations by DOE have sampled for asbestos, organic vapors, and airborne radioactive particles and gases. Measurements of external gamma exposure rates have also been performed as a part of the monitoring program. Except for the quarry, measurements of both on-site (outdoor locations at the raffinate pits and chemical plant area) and off-site values of these constituents have generally been at background levels. Elevated levels of radon gas and elevated external gamma exposure rates have been measured at the quarry. However, because these levels decrease rapidly with distance, background levels are reached within a relatively short distance (i.e., within about 0.4 km [0.25 mi])."

- - - -

Comment 15

Page 4-7, Section 4.2.1: The title of this section should be "Soil Investigations for Chemical Contaminants".

Response to Comment 15

Soil investigations include sampling for both radioactive and chemical contaminants. It is not correct to revise the title as suggested. It should be noted that the text in this section discusses the radiological characterization activities conducted to date.

- - - -

Response to Comment 17

All NEPA requirements will be met in the RI/FS-EIS process that will be carried out for this project. The combined process will involve the same, if not greater, opportunity for public review and input as the NEPA process.

- - - -

Comment 20

Page A-15: It should be explained whether loss of federal control is intended or permitted under current federal law. What are examples of conditions which could lead to loss of federal control?

Response to Comment 20

The DOE is responsible for monitoring and maintaining the disposal site for as long as it is necessary to demonstrate that the site does not pose an unacceptable risk to the general public. Loss of federal control will be assessed in the FS-EIS only to evaluate the hazards posed by the site following completion of remedial action activities. There are no conditions that could lead to loss of federal control under current government policies.

- - - -

U.S. ENVIRONMENTAL PROTECTION AGENCY

Comment 1

We recommend that additional discussion on the contaminants of concern, their potential health effects, and their environmental fate be added to Section 3, Initial Evaluation. This could be accomplished through addition of appropriate subsections.

Response to Comment 1

The document has been reorganized in response to EPA comments (see the revised outline attached to these comment responses.) The requested information is included in Section 3.

- - - -

Response to Comment 3

The discussion of remedial action alternatives has been expanded to include the following six general alternatives: (1) No Action, (2) On-Site Disposal, (3) Off-Site Disposal, (4) On-Site Treatment with On-Site Disposal, (5) On-Site Treatment with Off-Site Disposal, and (6) Off-Site Treatment with Off-Site Disposal. A brief description of each of these six general alternatives has been included in the work plan.

- - - -

Comment 6

Remedial Investigation/Feasibility Study Tasks provides only general discussions of the various tasks to be performed. These tasks should be linked, in some manner, to the actual scope of work. For instance, Subsection 5.1 should show how certain objectives of Task 1, project planning, are being satisfied by the investigations identified in Section 4. Similarly, the descriptions of other tasks, where possible, should provide approaches specific to this project.

Response to Comment 6

Cross references to other sections of the work plan have been added to Section 5.

- - - -

Response to Comment 8

The responsibilities of each organization have been added to Section 7.2. However, these responsibilities have not been directly linked to the fifteen tasks in Section 5 since there is a significant amount of overlap of contractor responsibilities relative to these tasks.

- -

Comment 9

Proposed Removal of Bulk Wastes from the Quarry appears to be out of place. We believe that description of this action, being a remedial action alternative, would be appropriately incorporated into Section 3.

Response to Comment 9

The discussion has been moved to Section 3 (see attached revised outline).

U.S. DEPARTMENT OF ENERGY
ENVIRONMENT, HEALTH AND SAFETY

Comment 1

Page 1-4, second paragraph: State that "In their review ... 'EPA believed' rather than 'EPA determined'."

Response to Comment 1

The sentence in questions has been deleted.

- - - -

Comment 4

Page 1-5, second paragraph and elsewhere in the document: Appendix A should be referred to as an EIS Implementation Plan Supplement, or a similar title, because Appendix A does not stand alone as an implementation plan.

Response to Comment 4

The title to Appendix A has been revised to read: "Work Plan Supplement." The sentence on which this comment is based has been revised to read: "The second part of this document (Appendix A) augments the information given in the body of the RI/FS-EIS work plan and contains information necessary to ensure compliance with DOE procedures for preparation of an EIS. This appendix was prepared in accordance with DOE guidance for an EIS implementation plan.

- - - -

Comment 6

Page 1-7, third paragraph, and elsewhere in the document: The focused FS should be referred to as an RI/FS-EA.

Response to Comment 6

The second sentence in this paragraph has been revised to read: "The DOE is proposing to address bulk waste removal as a separate operable unit and will prepare a separate RI/FS and environmental assessment (EA) to support this decision (see additional discussion in Section 3.11 of this work plan)."

- - - -

Response to Comment 7

The following paragraph has been added to Section 1.1: "Several areas in the vicinity of the raffinate pits and chemical plant area and the quarry, but outside of current fenced boundaries, are radioactively and chemically contaminated as a result of activities previously carried out at the Weldon Spring site. These contaminated areas are termed vicinity properties. The DOE has responsibility for the contaminated vicinity properties associated with previous uranium-processing activities conducted at the site. This contamination consists of radioactive constituents (i.e., uranium, thorium, and radium) and any chemicals associated with the processing of these materials. The DOE is also responsible for any chemical contamination that is mixed with radioactive contamination. The U.S. Department of the Army is responsible for contamination on vicinity properties resulting from its previous ordnance production activities. The DOE is continuing to work with the Army in identifying off-site areas contaminated as a result of Army activities. To minimize disturbance of the environment, DOE will coordinate the cleanup of vicinity properties with the Army."

The following paragraph has been added to Section 1.2: "Of the vicinity properties for which it is responsible, DOE is planning to clean up those that pose an unacceptable risk to the general public. Management of the resulting contaminated materials will be included in the record of decision (ROD) for disposition of the raffinate pits and chemical plant area (including the bulk quarry wastes). Appropriate NEPA and CERCLA compliance documentation will be prepared prior to cleanup of the vicinity properties. Those vicinity properties cleaned up prior to the ROD will be addressed per the modified engineering evaluation/cost analysis (EE/CA) process discussed in Sec. 3.10.1. The cleanup of any remaining vicinity properties at the raffinate pits and chemical plant area will be included in the RI/FS-EIS. A thorough study of the need for additional cleanup of vicinity properties in the quarry area will be included as part of the NEPA and CERCLA processes for the residual materials and groundwater restoration operable units at the quarry."

- - - -

Response to Comment 8

Figures 2 and 3 have been revised to include vicinity properties at the raffinate pits and chemical plant area and the quarry. The footnote to Figure 3 has been deleted since the environmental compliance process for the quarry bulk waste removal action has been described in sufficient detail in other sections of the work plan.

- - - -

Response to Comment 11

This figure is included to illustrate how the various governmental entities will interface on a working level. It does not seem necessary to add "DOE Headquarters" to this chart because it would then be necessary to add "EPA Headquarters", "Governor," etc. for consistency. A breakdown of DOE responsibility is given in Figure 7.1.

- - - -

Comment 14

Page 2-27, last paragraph: Explain how the Target Compound List compares to the Priority Pollutant List (e.g., see page 2-33).

Response to Comment 14

The primary difference between these two lists are the points of authority and the purpose for which they were developed. The Target Compound List (TCL), formerly known as the Hazardous Substance List, was developed under CERCLA for remediation of uncontrolled hazardous waste sites. The compounds on the TCL are given in 40 CFR Part 302.4. Priority pollutants were created to limit the concentrations allowed for discharge in industrial wastewaters. Priority pollutants were identified in response to a June 7, 1978, court settlement, which has commonly been referred to as the "EPA Consent Decree." Currently, it is proposed to remove about 43 chemicals from this list. Current and future studies will utilize the TCL. However, because historical information referenced priority pollutants, we need to accurately cite this information. We do not believe that it is necessary to include this discussion in the work plan.

- - - -

Response to Comment 16

The units have been added to the figures. The nitrate concentrations are in mg/L as nitrate and the sulfate concentrations are in mg/L.

- - - -

Comment 19

Page 3-8, first sentence, second paragraph: Clarify.

Response to Comment 19

The sentence has been revised to read: "Direct contact with contaminated materials is a hazard only in areas were contamination is immediately accessible (e.g., in soil and water)."

- - - -

Comment 22

Page 3-17, Section 3.4.2.3: Cite Figure 6.1 [5.1?] for the definition of FS phases.

Response to Comment 22

Reference to Phase I of the FS-EIS process has been deleted from this sentence.

- - - -

Identify the status of IRAs described in Sections 3.6.2.1, 3.6.2.6, 3.6.2.7, 3.6.2.10, and 3.6.2.11.

The "c" footnote to Table 3.4 should state "A memorandum-to-file is a unique DOE mechanism that was established when DOE's NEPA guidelines (U.S. Dept. of Energy 1987d) were first issued in 1980. It was developed to avoid the need to prepare environmental assessment on a large number of DOE actions that, because of limited agency experience, had not yet been added to the list of categorical exclusions."

Response to Comment 24

The work plan includes all currently planned IRAs. The major difference between the number of IRAs in the work plan (17) and in the 2/24/88 letter from Nelson to Wagoner (28) is the consolidation of the IRAs associated with non-process buildings, structures, and equipment into one section (Section 3.6.2.14 in the draft work plan). The following sentence has been added to this section following the list of affected buildings or areas: "This action may be divided into several smaller actions to expedite the cleanup process."

Documentation to support IRAs will be developed in a manner consistent with the complexity of the action and the potential for impacting the environment. The IRAs planned and conducted to date have been relatively simple, with obviously no significant environmental impacts. Documentation necessary to reach this decision has been prepared. We believe that it is unnecessary to prepare lengthy documentation for relatively simple and routine tasks. The impacts associated with the storage of very small quantities of low-activity radioactive materials, including radiation exposure of workers, are obviously very small.

The documentation to support the IRAs discussed in Sections 3.6.2.5, 3.6.2.13, 3.6.2.15, and 3.6.2.16 of the draft work plan will address the issues given in this comment.

The status of all active (or completed) IRAs has been updated in the work plan.

Footnote "c" to Table 3.4 has been revised as suggested.

- - - -

Comment 25

Page 4-12: Describe the plans for assessing ecological effects of residual contamination and of remedial action.

Response to Comment 25

The purposes of the lake and stream sediment characterization and biouptake study are described in Section 4.2.5. The scope of the studies has been narrowly defined to yield specific information for the RI/FS-EIS process. Although these studies are not being performed to evaluate ecological impacts, useful ecological data will be generated from them.

- - - -

Response to Comment 27

The following has been added to this paragraph: "These indicator chemicals and radionuclides are those that represent the most toxic, mobile, and persistent species at the site as well as those that are present in the largest amounts. These 'highest risk' species are used to assess the risks at the site."

- -

Comment 28

Page 5-14, top of page: Change sentence to read "... e.g., environmental consequences of taking each of the remedial action alternatives under consideration, long term impacts, cumulative impacts, mitigative ..."

The fourth bullet should point out the 45-day public review period.

The last bullet in Section 5.12 [5.11?] should be changed to read "Revising the report based on public and agency comments."

In Section 5.12 the title is misleading or else material is misplaced because the responsiveness summary is part of the RI/FS-EIS.

Response to Comment 28

The first change has been made as suggested. The titles for Sections 5.11 and 5.12 have been revised as follows:

"5.11 Task 11: Draft RI/FS-EIS Report"

and

"5.12 Task 12: Final RI/FS-EIS Report and Supporting Activities"

We believe that it is unnecessary to state the length of the public review period, so no change has been made in response to the second comment. The following bullet has been added to Section 5.12: "Revising the RI/FS-EIS in response to public comments." The fourth comment is accommodated with the title changes to Sections 5.11 and 5.12.

- -

Comment 29

Pages 6-1 and 6-4: Indicate the public review and comment periods for particular documents.

Response to Comment 29

Section 6 summarizes the schedule for completion of the RI/FS-EIS process (including the RI/FS and EA for the quarry bulk waste removal activity); this section was revised to include more information. We believe that it is unnecessary to highlight the public review and comment periods in these schedules. However, the schedules have been revised to note that the public review period and preparation of the responsiveness summary occurs between the draft RI/FS-EIS (and RI/FS for quarry bulk waste removal) and final RI/FS-EIS (and RI/FS).

- - - -

Comment 31

Page 8-5, first paragraph: It is stated that current data should be sufficient to justify the need for this action. It should also be stated that current data should be sufficient to analyze the environmental impacts of taking the proposed action, if this is true, or plans for more data gathering should be described. It should also be stated that this analysis will consider impacts of placing the waste at the chemical plant/raffinate pit site, if it is later determined that a disposal cell cannot be sited there.

Second paragraph: Explain whether the quarry waste is sufficiently characterized for disposal.

Response to Comment 31

The sentence in question has been revised to read: "Current data are sufficient to justify the need for this action and to allow for an assessment of environmental impacts associated with implementing the action." The impacts associated with possible double handling of the wastes will be addressed in the RI/FS-EA process; however, this level of detail is not needed in the work plan. We also do not need to address the adequacy of current data relative to disposal requirements in the work plan. Additional waste characterization will be performed, if needed, prior to a disposal decision. Such characterization can be done during exhumation of the wastes, during placement of the wastes into interim storage, or during the interim storage period.

- - - -

Response to Comment 32

The last paragraph in this section has been revised to read: "Detailed characterization of the transport of contaminants from the quarry into the surrounding environment is not an essential part of the proposed response action. However, the RI/FS-EA process will include an assessment of the potential migration of contaminants into the limestone quarry, to the extent possible, during both the action period and during the time period following bulk waste removal. A good understanding of the nature and extent of fracture joints and cracks can be developed only after the bulk wastes have been removed from the quarry and the limestone walls and floor have been exposed for study. The residual contamination in joints and cracks of the quarry -- and in the groundwater -- will be treated as separate operable units following the currently proposed waste removal effort."

The sentence on which the second part of this comment is based has been revised to read: "The organic compounds that have been identified are those expected from past disposal activities, i.e., PCBs, PAHs, and nitroaromatic compounds."

- -

Comment 33

Page 8-9, third paragraph: The bulk waste will not be stored only until a decision is reached regarding the disposition of all wastes at the Weldon Spring Site but would be stored until that decision is implemented. This should be stated.

Response to Comment 33

The sentence in question has been deleted.

- -

Comment 34

Page 8-10, top of page: Explain the implication of having cleanup criteria be technology based rather than analytically based.

Last sentence: Change to read "... DOE will either issue a 'finding of no significant impact' or determine that an environmental impact statement is needed."

Response to Comment 34

The implication of having cleanup criteria being technology based rather than analytically based is discussed in the remainder of the paragraph. The DOE is not claiming that the quarry will be in a condition acceptable for unrestricted release following this action, i.e., cleanup criteria for the quarry will not be determined prior to initiation of this action. Sufficient data for such a determination cannot be determined prior to removal of the bulk wastes. The implication of having technology-based cleanup criteria is the need to perform additional characterization and analysis following removal of the bulk quarry wastes.

Section 3.11.7 has been revised to read: "The DOE is proposing to address quarry bulk waste removal as a separate operable unit and will use the RI/FS-EA process to support this decision (See Section 3.11.2.1). This action is scheduled to occur prior to the ROD for the project. Implementation of the RI/FS-EA process will be as follows. The first two phases of the FS process will be completed concurrent with preparation of the RI and baseline risk evaluation. At this point, an assessment of environmental impacts will be performed consistent with the requirements of the EA in support of a finding of no significant impact (FONSI), if appropriate. If DOE determines that this action requires preparation of an EIS, the action will be included within the overall RI/FS-EIS process for the project, and removal of the quarry bulk wastes will not be undertaken prior to issuance of the ROD. Because the EA will be completed prior to completion of the FS, the RI/FS process for the quarry bulk waste removal action will be completed only if a FONSI is issued. If the RI/FS for bulk waste removal is completed, DOE and EPA will issue decision documents under CERCLA to document the decision-making process."

- - - -

Comment 35

Page A-3, first paragraph: Rewrite the second sentence because CEQ does not define "programmatic EIS".

Response to Comment 35

The second sentence of this paragraph has been revised to read: "Based on public and technical scoping input, DOE decided to take the 'tiered' approach recommended by the Council on Environmental Quality (CEQ) under its regulations for implementing the National Environmental Policy Act (NEPA)."

- - - -

Comment 38

Page A-17: Eliminate last bullet.

Change item 1 to read as follows: In light of a U.S. Supreme Court case involving the proposed restart of one of the Three Mile Island reactors ... DOE considers only psychological impacts that bear a close causal relationship to the physical environment in its EIS's. Psychological impacts raised so far do not bear such a relationship.

Response to Comment 38

The last bullet in Section A.4.2 has been deleted. Item 1 in Section A.5 has been revised as suggested with a few minor editorial changes.

- - - -

Response to Comment 39

The third and fourth sentences of Item 3 have been revised to read: "No additional monitoring studies of students and staff at Francis Howell High School will be performed as part of the RI/FS-EIS process because the existing environmental monitoring program demonstrates that individuals at the high school are not being exposed to measurable levels of radioactive or chemical contaminants originating from the Weldon Spring site. However, potential health impacts on students and staff will be addressed in the RI/FS-EIS."

Item 4 has been revised to read: "Excavation, transport, and temporary storage of quarry bulk wastes -- The DOE is proposing to address the removal of the quarry bulk wastes as a separate operable unit and will use the RI/FS-EA process to support this decision (see Section 3.11 of this work plan). This action will include excavation, transport, and temporary storage of the quarry bulk wastes at the raffinate pits and chemical plant area. Implementation of the RI/FS-EA process will be as follows. The first two phases of the FS process will be completed concurrent with preparation of the RI and baseline risk evaluation. At this point, an assessment of environmental impacts will be performed consistent with the requirements of an EA in support of a finding of no significant impact (FONSI), if appropriate. If DOE determines that this action requires preparation of an EIS, the action will be included within the overall RI/FS-EIS process for the project, and removal of the quarry bulk wastes will not be undertaken prior to issuance of the ROD. Because the EA is scheduled to be completed prior to issuance of the FS, the RI/FS process for the quarry bulk waste removal action will be completed only if a FONSI is issued. If an RI/FS for bulk waste removal is completed, DOE and EPA will issue decision documents under CERCLA to document the decision-making process."

Item 5 is not really a change of scope from the draft EIS. "Decontaminate the quarry," as used in the draft EIS, can properly be viewed as being the same as removal of the quarry bulk wastes. Note that the analyses given in the draft EIS for the action alternatives do include an assessment of residual contamination remaining in the quarry limestone and alluvium near the quarry, following removal of the quarry wastes. Item 5 has been added for clarification; this would have been addressed in the detailed engineering phase if the draft EIS had been finalized. An assessment of the impacts of the residual contamination remaining in the quarry will be included in the RI/FS-EA process for the interim time period following bulk waste removal and prior to a decision on the need to possibly remove some of this residual contamination. However, analysis of impacts associated with removal of this residual contamination is beyond the scope of the RI/FS-EIS.

- - - -

Comment 40

Pages A-20 and A-21: Change citation to Final EIS for Grand Junction, issued 12/86.

Response to Comment 40

The citation has been revised as suggested.

- - - -

Response to Comment 42

The following has been added to the outline in Table A.3:

4.6	Environmental Consequences	4.6.7	Socioeconomics
4.6.1	Radiological Impacts	4.6.8	Historical and Archeological Issues
4.6.2	Chemical Impacts	4.6.9	Institutional Issues
4.6.3	Soils and Geology	4.7	Potential Loss of Institutional Control
4.6.4	Water Resources	4.8	Cumulative Impacts
4.6.5	Ecology		
4.6.6	Air Quality		

- - - -

The baseline risk assessment, which is the last phase of the RI process, will be performed by the project management contractor. However, as part of its responsibilities, ANL will provide an independent analysis of this assessment.

Comment 44

Page B-3, second sentence: Change NEPA reference to CEQ regulations and give citation.

Second paragraph: Change to "... (DNR), DOE has agreed that ..."

Response to Comment 44

The second sentence in the first paragraph in this section has been revised to read: "A public comment period followed issuance, as mandated by the Council on Environmental Quality regulations for implementing the procedural provisions of the National Environmental Policy Act (NEPA) (40 CFR Part 1503.1)."
The phrase "DOE has determined that" has been changed to "DOE has agreed that" in the third sentence of the second paragraph on page B-3.

Comment 45

Page B-4, first paragraph: Distinguish draft and final RI/FS-EIS.

Second paragraph: Identify the issues as those from the public comment period.

Response to Comment 45

The third paragraph in this section has been revised to read: "... The intent of these responses is to illustrate the manner in which these issues will be addressed in the RI/FS-EIS process. A draft RI/FS-EIS will be issued for public review, and any significant issues concerning the draft RI/FS-EIS will be addressed in a responsiveness summary. A final RI/FS-EIS, including the responsiveness summary, will be prepared prior to issuance of the record of decision (ROD) for this project."

The fourth paragraph in this section has been revised to read: "The major issues identified in comments on the draft EIS have been divided into five categories as follows:"

- - - -

Response to Comment 47

The response to issue 8 has been revised to read: "The issues addressed in the draft EIS were those determined to be relevant to the decision to be made. All available information was reviewed for appropriateness relative to the analyses provided in the draft EIS. The DOE will reconsider all available information in preparation of the RI/FS-EIS, including those specific references cited in comments on the draft EIS. The DOE is currently in the process of conducting a thorough site characterization program. The results of this program will be included in the RI report and will allow for detailed estimation of environmental impacts.

The first sentence to issue 9 has been deleted. The answer is responsive to this issue in that reference to ongoing and planned geological characterization studies is discussed.

- - - -

Comment 49

Page B-13, response to issue 15: Tell when the design criteria document will be prepared and how it will be available to the public. Change fifth sentence to read, "The use of a lead sheet in the cover, which was included in the draft EIS as a result of input obtained during the scoping process, will be reevaluated in the RI/FS-EIS."

Response to Comment 49

It is premature to give a date when the design criteria document will be completed because the disposal requirements have not yet been defined. The document will be made available for public inspection in the same manner as other project documents, i.e., the document will be filed in local repositories. The fifth sentence of the response has been revised as suggested.

- - - -

Comment 52

Page B-20, response to issue 28: Change to "only reasonably foreseeable" scenarios.

Page B-20, response to issue 29: State the status of the meteorological station.

Response to Comment 52

The phrase "only credible scenarios" has been changed to "only reasonably foreseeable scenarios" in the response to issue 28. The status of the meteorological station is described in the response to issue 29. Current plans are to construct an on-site meteorological station that is projected to be operational in late 1988.

- - - -

Response to Comment 54

The response to issue 41 has been revised to read: "The DOE is not planning to study the impact of the Weldon Spring site on local real estate values because such values can be affected by numerous factors. It is not possible to independently quantify the impact of the Weldon Spring site independently of other factors such as population growth and local employment opportunities. Hence, it does not seem reasonable to address this issue in the RI/FS-EIS."

- - - -

Comment 57

Page B-36, response to issue 56: Clarify whether DOE agrees that the Hanford site leaks, as the commenter states.

Response to Comment 57

We do not believe that it is appropriate to address environmental conditions at the Hanford site beyond those directly affecting a decision on the Weldon Spring site. This comment falls into that category.

- - - -

Response to Comment 59

We have reevaluated comments raised on these topics and believe that they have been adequately addressed.

- - - -

Comment 62

Section 2.4 describes the data collected at the site to date. However, it does not provide guidance on the methods to be used to determine the adequacy of the existing data or on procedures to be used to validate the data. Prior to conducting additional studies, the existing data should be evaluated for data gaps so these gaps can be filled. Evaluation areas should include (1) characterization of sources, transport pathways, and receptor impacts/effects; (2) data input requirements of models (e.g., engineering, hydrogeologic, air quality) and of statistical analyses; and (3) waste and site conditions that affect applicable types of treatment, as well as treatment effectiveness at the site.

Response to Comment 62

The information requested in this comment is included in the quality assurance project plan and the field sampling plans. These are briefly summarized in Sec. 4.1 and 4.2 of the work plan. A data gap analysis has been included in Section 3.

- - - -

Response to Comment 64

The paragraph describing on-site tanks has been revised to read: "... Other tanks on-site appear empty but were previously used to store hydrofluoric acid, nitric acid, sulfuric acid, caustic soda solutions, propane, and hexane. All process tanks are located above ground; however, several underground storage tanks were previously used to store petroleum products." Leakage and/or spillage may have occurred from these tanks and associated piping during plant operations. Contaminated on-site areas are being identified in the soil investigation program (see Sec. 4.2.1 of the work plan).

Comment 65

In Section 2.4.3, some of the wastes are described as "mixed wastes" with the definition keyed to RCRA. Care should be taken to avoid suggestions of the applicability of RCRA to the quarry. If it has not received wastes since November 1980, then RCRA does not apply.

Response to Comment 65

This section notes that some of the wastes may be classified as mixed waste. Although RCRA may not be directly applicable to the quarry if the wastes are not moved, it will likely be considered relevant and appropriate. We believe it is inappropriate to conclude that RCRA will not apply to the quarry wastes if RCRA hazardous materials are found simply because the wastes were generated prior to November 1980.

Comment 66

Section 2.4.4 discusses the vicinity properties. Contamination above criteria for unrestricted use is mentioned. Contamination values could be better appreciated if the criteria were stated.

Response to Comment 66

Reference to "unrestricted use" criteria has been deleted from the work plan. Cleanup of vicinity properties to date has been limited to thorium and radium contamination. These areas have been decontaminated to criteria given in DOE's FUSRAP and remote SFMP guidelines (which were adapted from 40 CFR Part 192). Residual contamination criteria for other radionuclides (i.e., uranium) have not yet been established. These criteria will be determined based on the risk they pose to human health and the environment.

- - - -

Response to Comment 68

Comment acknowledged.

Comment 69

Section 3.4.2.1 discusses innovative technologies. EPA guidance (referenced above) indicates that innovative technologies should be carried through the screening if there is reasonable belief that they offer potential for better treatment performance or implementability, few or lesser adverse impacts than other available approaches, or lower costs than demonstrated technologies.

Response to Comment 69

Comment acknowledged.

Comment 70

Section 4.2 discusses the field sampling plans to be developed. The discussion does not provide assurance that data gaps will be filled and that the three criteria for judging completeness of the data will be met (see Comment 62).

Response to Comment 70

See Response to Comment 62.

Comment 71

Sections 4.3 and 4.5 discuss the health and safety plan and the emergency preparedness plan, respectively. The text does not mention the OSHA requirements (provided at 29 CFR Part 1910) regarding health and safety for working on hazardous waste sites. The health and safety plan does not appear to contain all the requirements of a health and safety plan. Among other requirements, the health and safety risks associated with each site RI (or FS) task and personnel protective equipment/decontamination requirements may not be contained in the plan. It appears that the emergency preparedness plan could satisfy the requirements for a contingency plan, normally contained in the health and safety plan.

Response to Comment 71

Sections 4.3 and 4.5 are summaries of the health and safety plans and emergency preparedness plan; as such, they do not include detailed discussion of all elements of these plans. There are two health and safety plans for the project: (1) an environmental, safety and health plan and (2) a construction safety and health management program. These plans are currently being updated to include OSHA requirements for working on hazardous waste sites. On-site personnel have received the OSHA training requirements specified in 29 CFR Part 1910.120.

1.0 PROJECT DESCRIPTION

1.1 INTRODUCTION

The goal of this sampling plan is to identify and develop specific plans for those investigative actions necessary to: (1) characterize the hydrologic regime; (2) define the extent and impact of contamination; and (3) predict future contaminant migration for the Weldon Spring Site (WSS) and vicinity. The plan is part of the Weldon Spring Site Remedial Action Project (WSSRAP) sponsored by the U.S. Department of Energy (DOE) and has been developed in accordance with U.S. EPA Remedial Investigation (RI) and Data Quality Objective (DQO) guidelines. The plan consists of a sequence of activities including the evaluation of data, development of a conceptual model, identification of data uses and needs, and the design and implementation of a data collection program.

Data will be obtained to: (1) confirm the presence or absence of contaminants; (2) define contaminant sources and modes of transport; (3) delineate extent of contaminant migration and predict future migration; and (4) provide information to support the evaluation and selection of remedial actions.

This sampling plan is intended to supplement the Quality Assurance Program Plan (QAPP). It describes objectives, work tasks, quality assurance/quality control (QA/QC) procedures, and the level of effort required for site characterization and to support a feasibility study. Data developed through this sampling plan will also be used in the risk assessment evaluation.

The WSSRAP consists of remedial activities at the WSS, vicinity properties, and quarry. This sampling plan addresses activities required for the hydrogeologic investigation of the WSS. The quarry and vicinity properties associated with the quarry will be

addressed, in detail, in a separate site characterization report.

A comprehensive approach is planned for hydrogeological characterization. This includes monitoring well installation, water sampling and analysis, karst hydrologic studies, unsaturated zone studies, aquifer testing, regional studies, and groundwater modeling studies. Modeling will be performed in cooperation with the Missouri Department of Natural Resources, the U.S. Geological Survey, and the University of Missouri, Rolla.

1.2 REVIEW AND ASSESSMENT OF EXISTING DATA

Numerous studies have been performed at the WSS and vicinity. This section addresses site history and assesses those studies directly related to the WSS. The completeness, representativeness, and accuracy of collected data are briefly evaluated.

Maps, sections, and data presented in this section are, for the most part, based on information acquired prior to current (1988) characterization activities. Much of this information is not site-specific; therefore figures, tables, and data presented in this section will be modified as additional data are collected.

1.2.1 Site Background and Investigations

The WSS is located along Missouri Highway 94 in western St. Charles County, Missouri, approximately 30 miles west of St. Louis, and 2 miles southwest of the junction of U.S. Highway 40/61 and State Highway 94. The general location of the WSS is shown on Figure 1-1. An enlarged view of the site is shown on Figure 1-2. Figure 1-3 (in pocket) presents a topographic map of the Weldon Spring Site area.

The WSS described in this sampling plan consists of two adjoining

WELDON SPRING CHEMICAL PLANT AND RAFFINATE PITS (MAJOR BUILDINGS AND FEATURES)

areas: the Weldon Spring Raffinate Pits (WSRP) on the west, and the Weldon Spring Chemical Plant (WSCP) on the east, encompassing 51 and 166 acres respectively (MK-Ferguson -- MKF, 1987b). The 166-acre WSCP consists of 13 major buildings and approximately 30 support structures. The 51-acre WSRP area, located in the western portion of the site, contains four surface impoundments (raffinate pits) covering approximately 26 acres. These pits contain the residues of uranium and thorium processing from the former feed materials plant (MKF, 1987b).

Activities at the WSS have been varied. The U.S. Department of the Army (DOA) and predecessor agencies to the U.S. Department of Energy (DOE) have actively participated in developments at the site. A brief summary of these site activities is presented below.

The DOA acquired the site and surrounding areas, totaling more than 17,000 acres, in 1941 for an ordnance works to produce explosives. From 1941 to 1944, trinitrotoluene (TNT) and dinitrotoluene (DNT) were manufactured on the DOA property. Fishel and Williams (1944) reported the presence of red waste waters which were contaminating surface and groundwater during this period. At the end of World War II, the manufacturing operation was shut down and processing structures were abandoned. The Army conducted additional decontamination operations in 1946, destroying over 200 buildings and burning approximately 90 tons of nitroaromatics and residues (MKF, 1987). The ordnance works property was declared surplus in 1946, and during the next three years about 15,000 acres were transferred to other parties. By the end of 1949 only about 2,000 acres remained under the jurisdiction of the U.S. Army.

In 1956 the U.S. Army transferred about 205 acres to the U.S. Atomic Energy Commission (AEC) for the construction of a uranium feed materials plant on the Army's previous manufacturing site. The remaining TNT-processing equipment and structures were

demolished and removed to the Weldon Spring Quarry prior to construction of the AEC plant.

The AEC plant began operation in 1957. The plant converted impure uranium concentrates to pure uranium salts and metal. From 1958 to 1964 the plant operated at several times design capacity, overtaxing the facility and its waste disposal facilities, and resulting in radiological contamination of numerous buildings and land in the vicinity of the plant. Raffinate pits were excavated in 1958, 1959, and 1964 for disposal of wastes from processing uranium and thorium concentrates. Thorium oxide was processed at the plant during 1965 and 1966, with wastes being discharged to Raffinate Pit No. 4. Shutdown of the plant was initiated at the end of 1966; drums and trash were dumped into Raffinate Pit No. 4 during close-down operations.

In 1967, 166 acres of the plant site were transferred back to the Army for the intended manufacture of "Agent Orange." Some equipment removal and decontamination was accomplished for that purpose. The project was cancelled, however, in 1969. The U.S. Army Corps of Engineers took custody of the plant in 1969 after additional cleanup and shutdown work.

In 1975, the Army assessed the environmental conditions at the site and indicated that the site could not be released to unrestricted use without decontamination of the land and buildings. A similar conclusion was reached in a report to the U.S. Energy Research and Development Administration (ERDA) and recommendations were made for collection of additional data (Kleeschulte and Emmett, 1986).

The WSS remained under Army control until 1985 when custody was transferred to DOE (MKF, 1987b). Numerous efforts have been undertaken in recent years to assess the environmental problems associated with the WSS and to develop plans for remediation.

Studies providing site-specific geologic, hydrologic, and environmental information have been performed by several individuals and groups. Each investigation is briefly described in Section 5, References. In addition to these investigations, a number of environmental monitoring activities have been accomplished during the last 30 years. Data from some of these activities are included in reports by Mallinckrodt Chemical Works (1959-1965), DOA (1977-1985), Bechtel National, Inc. (BNI) (1983-1984), National Lead Company of Ohio (1981-1982), Shell Engineering (1983-1985), and MKF (1986-1987). These studies are evaluated and summarized in following sections.

1.2.2 Climate

The climate in the WSS area is continental, with moderately cold winters and warm summers. Alternating warm/cold, wet/dry air masses converge and pass eastward through the area almost daily (BNI, 1986b). Normal annual precipitation in the area is approximately 37 inches with the heaviest rainfall occurring in spring and early summer (DOE, 1987). The average temperature is 13°C (56°F), with the average daily minimum being 7°C (45°F) and the average daily maximum being 19°C (66°F). Wind speeds and directions recorded at the WSS during 1985 are summarized in Figure 1-4. Prevailing winds in the vicinity of the WSS are from the south during the summer and fall. Wind speeds during these months average 8.7 mph. Winds during the winter months are from the northwest and west-northwest, averaging 11 mph (MKF, 1987b).

The variability of the climate is demonstrated by records for the state. The range in temperatures for the 1888-1949 period was from a -40°F to 118°F and the range in annual precipitation was from less than 26 inches to more than 55 inches (Roberts, 1951). Summer rains frequently occur as thunderstorms, occasionally with hail and high winds. Locally, rainfalls can be very heavy, with 10 inches having been recorded

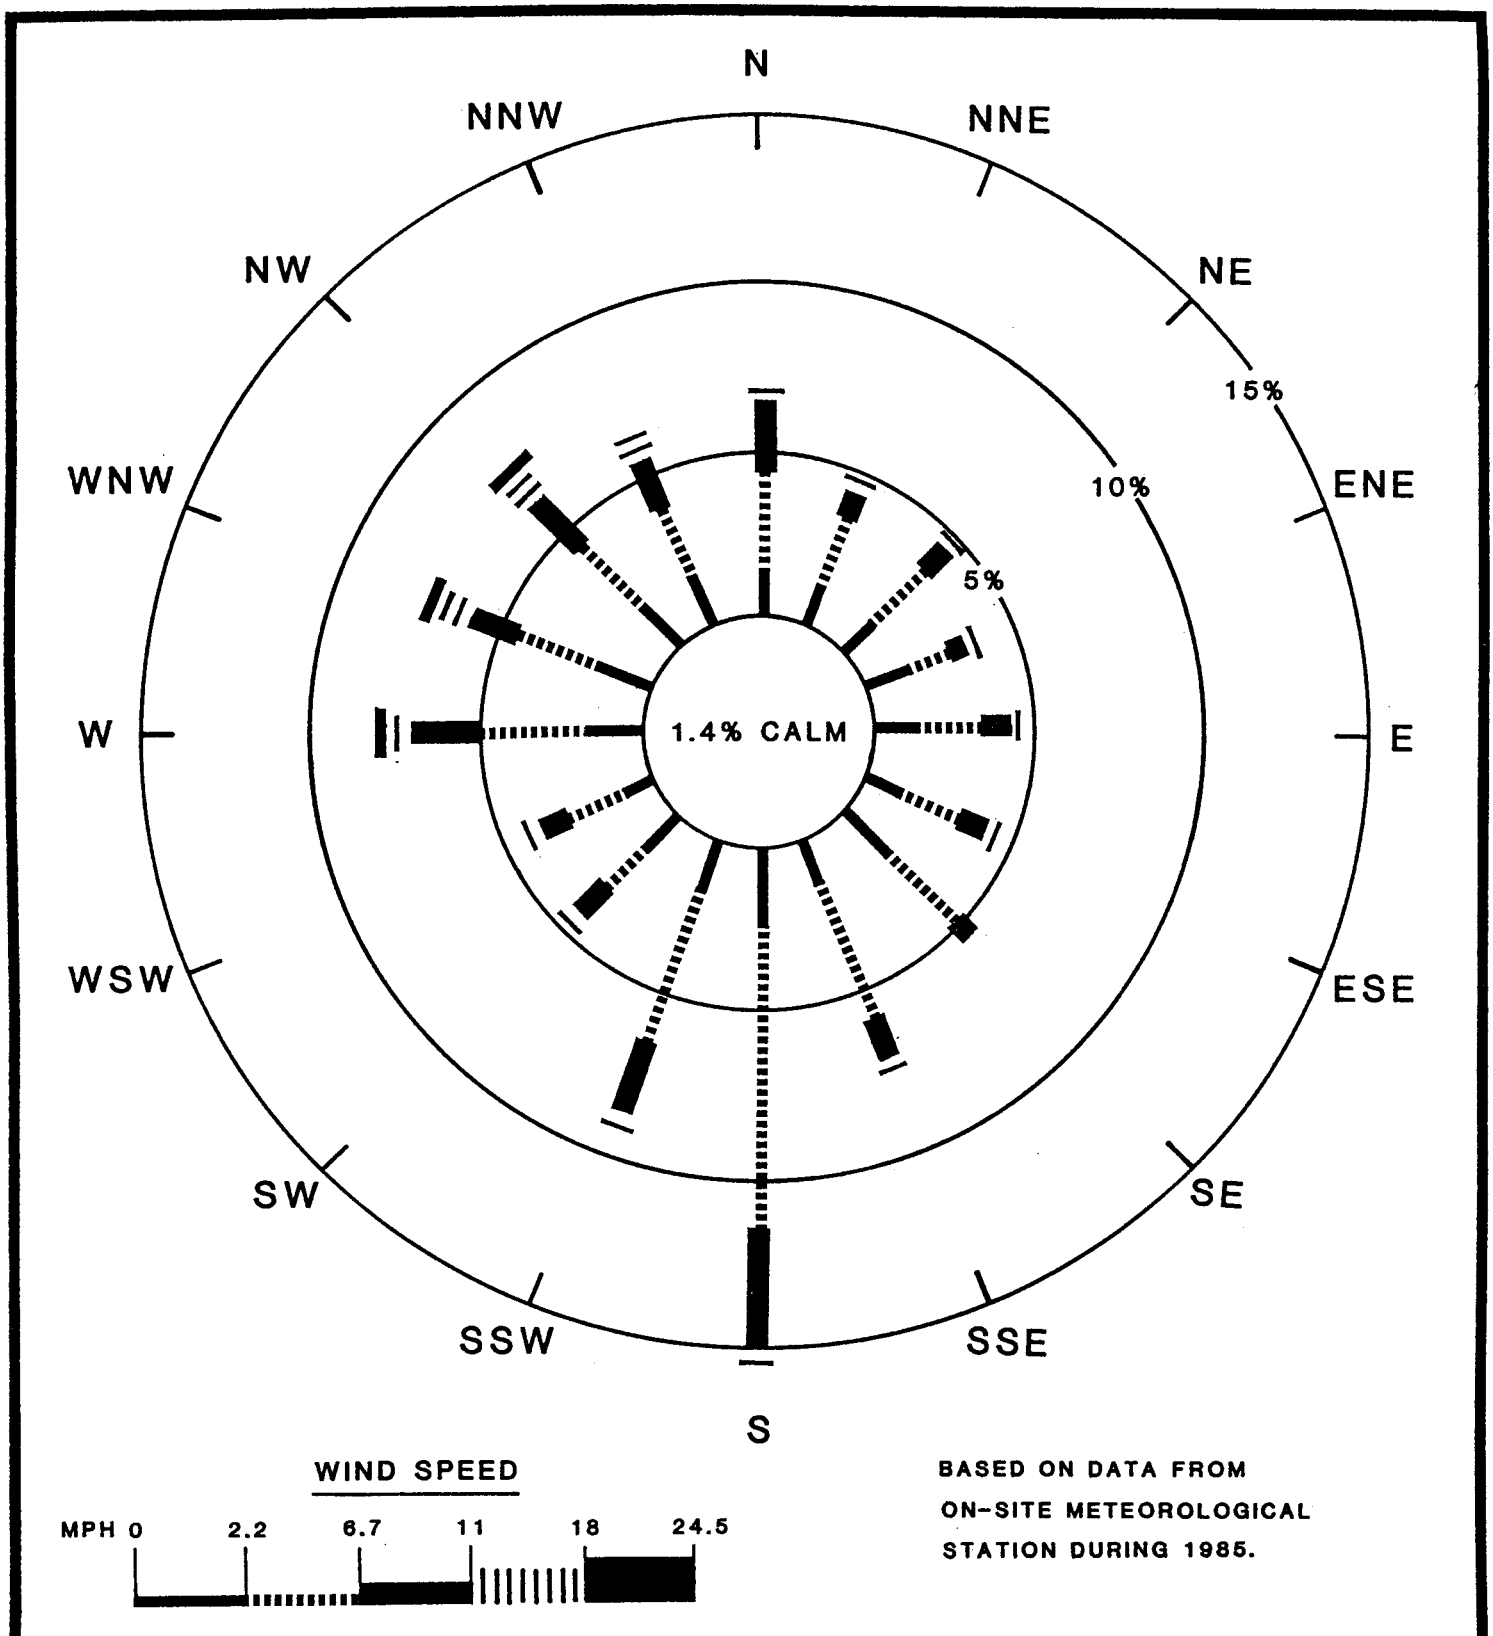

FIGURE 1-4

ANNUAL WIND ROSE FOR THE W S S, 1985.

in a 24-hour period. The three winter months are the driest, with the average precipitation totaling about 6 inches. The three spring months are typically the wettest with the average total approximately 12 inches (Ficker, 1981). Tornadoes occur in the St. Louis area once or twice per year, and occur most often in April and May (Sci. Appl., 1979).

Site-specific climatologic data are generally limited to the period beginning in April 1983 (BNI, 1986a; MKF, 1986).

1.2.3 Surface Features

The site is located on the drainage divide between the Mississippi and Missouri rivers. Drainage from the northern and western portions of the WSS trends northward to tributaries of Schote Creek, a tributary ultimately draining to the Mississippi River. The southeastern portion of the site drains generally southward to unnamed tributaries which flow to the Missouri River. Elevations on the site range from approximately 608 feet near the northern edge to approximately 672 feet near the southern edge. Land surface slopes are generally gentle except in the vicinity of embankments or levees for the raffinate pits and Ash Pond. There are no natural drainage channels traversing the site, though remnants of a channel through the Ash Pond area are present.

Figure 1-2 illustrates the current configuration of facilities on the site. In addition to the readily apparent ponds, pits, and buildings, there are numerous other features including drainage ditches and other topographic features that can influence the movement of contaminants. Some of the surface features are associated with man-made subsurface features, such as sewer lines, which can also influence the movement of contaminants. The changes that have taken place at the WSS over the years have added to the complexity of the site.

There are several localized depressions or ponding areas which have received natural runoff or process wastes over the years. These include the raffinate pits, Frog Pond, Ash Pond, the Imhoff tank (former wastewater treatment) and the Southeast Drainage Easement. Raffinate Pits 1, 2, 3, and 4 were constructed in the late 1950s and early 1960s for receiving process wastewaters. In addition to receiving process wastes, they have received precipitation and runoff. Also the topography of the raffinate pits influences the direction and rate of surface runoff originating or flowing in their vicinity. Frog Pond is a settling basin located near the east edge of the site. It receives runoff from the eastern portion of the site. Ash Pond is a major feature near the north edge of the site and receives runoff from the northern portion of the site. When runoff has accumulated sufficiently in Ash Pond, overflow occurs through its spillway with subsequent discharge from the site. The Ash Pond received ash slurry from the steam generating plant (Building 401). Another feature that influences the movement of contaminants is the Southeast Drainage Easement. Historically, contaminants have been discharged through the easement with treated wastewater. This easement is delineated on Figure 1-5.

The portion of the site that is not covered with structures or ponds is generally covered with vegetation (predominantly grasses) and gravel or asphaltic paved surfaces.

The August A. Busch Memorial Wildlife Area is located to the north of the WSS and the Weldon Spring Wildlife Area is located to the south and east of the site. These areas are predominantly covered with trees, brush, and grasses. U.S. Army Reserve property to the west of the site is predominantly covered with trees and grasses.

As indicated above, custody and operations at the site have changed over the years. Some of these changes have resulted in modifications of the buildings and other surface features. In

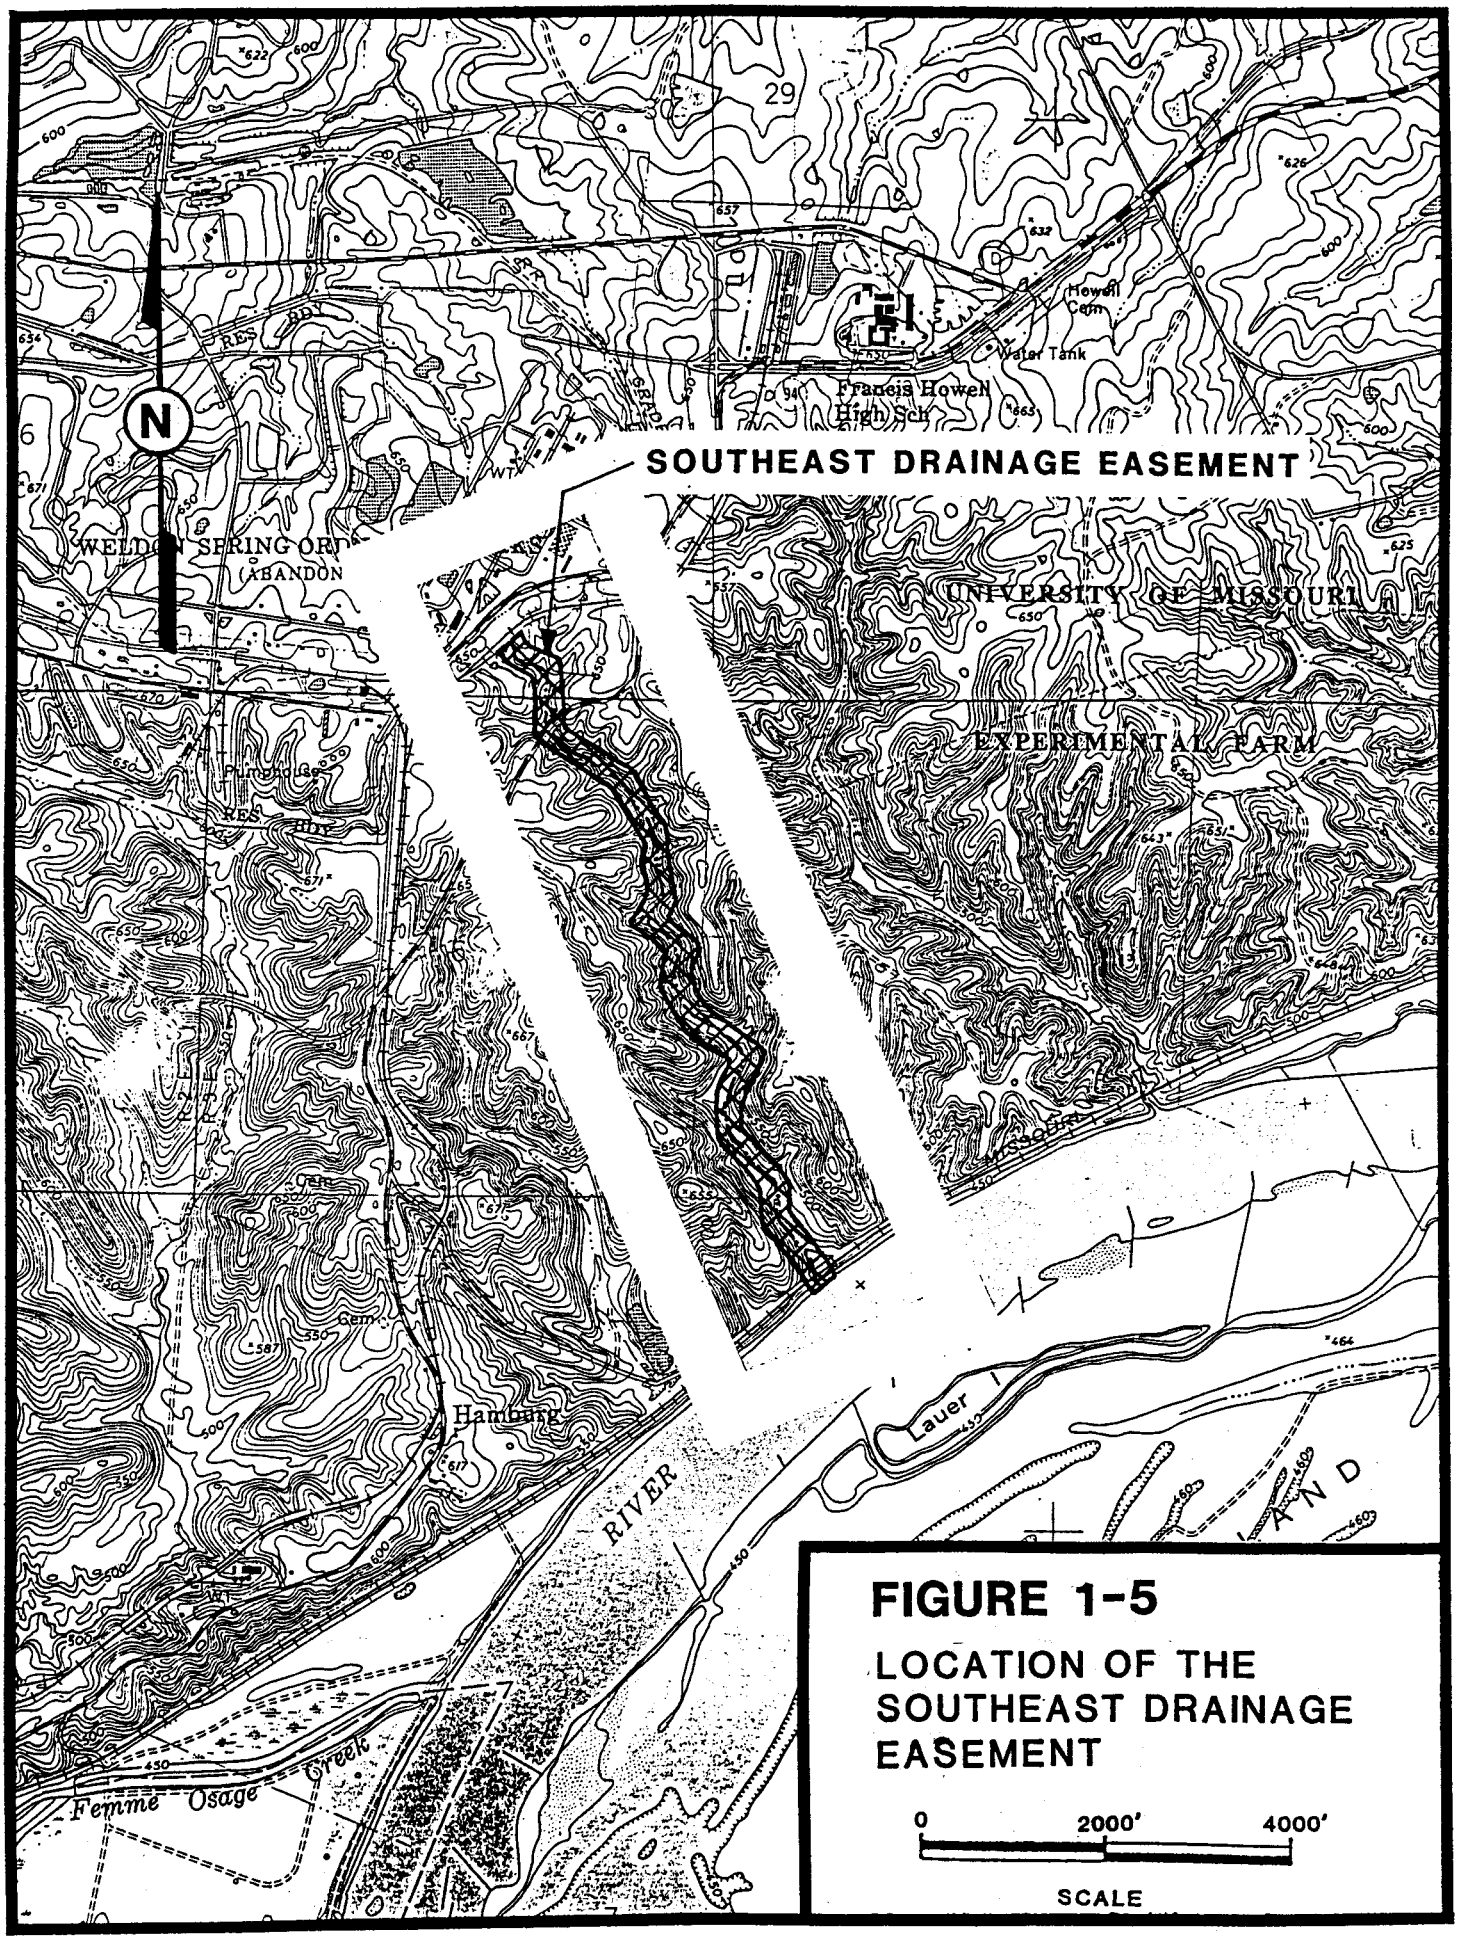

FIGURE 1-5

LOCATION OF THE SOUTHEAST DRAINAGE EASEMENT

turn, these modifications have influenced the present state and locations of contamination at and near the site.

1.2.4 Geology

The geology of the WSS has been described in some detail by BNI (1983c, 1984c, 1987) and in lesser detail by Fishel and Williams (1944), Roberts (1951), Krummel (1956), Moylan and Elser (1967), and Kleeschulte and Emmett (1986).

As indicated above, custody and operations at the site have changed over the years. Some of these changes have resulted in modifications of the buildings and other surface features. In turn, these modifications have influenced the present state and locations of contamination at and near the site. Fishel and Williams (1944) performed the first hydrogeologic investigation related to contamination at the site. This investigation was related to the Army's ordnance works operation during World War II. The investigation described the area's general geology, structural geology, groundwater conditions, and occurrences of contamination. Roberts (1951) further describes the geology in the area as it relates to groundwater movement. Krummel (1956) mapped the geology of the area just to the south of the WSS. Moylan and Elser (1967) describe the geology at the raffinate pits area. Kleeschulte and Emmett (1986) provide additional information on the stratigraphic and geologic structure in the vicinity of the raffinate pits. BNI (1983c, 1984c, 1987) provides borehole logs, geologic cross sections, and laboratory data from the chemical plant and raffinate pits areas. The following paragraphs and figures summarize and present an evaluation of the available geological information.

Table 1-1 presents a generalized stratigraphic column, which describes sediments and sedimentary rocks common to Central and East Central Missouri. This column is not to be considered site-specific due to varying thicknessess or absence of formation

TABLE 1-1
GENERALIZED GEOLOGIC STRATIGRAPHIC COLUMN
(After Kleeschulte and Emmett, 1986)

System	Series	Stratigraphic Unit	Depth from ground level to top of formation, in feet	Thickness, in feet	Typical 1/ thickness, in feet	Physical Characteristics	Remarks
Quaternary	Holocene	Alluvium	0	0-65	10-30	Gravelly, silty loam over occasionally gravelly, silty clay loam.	Deposits underlie tributaries to Missouri and Mississippi rivers.
				65-120	100-110	Silty loam, clay, and sand over sand and gravelly sand.	Deposits underlying Missouri and Mississippi river flood plains generally yield large quantities of water to wells. (600-2,600 gal/min).
	Pleistocene	Loess and glacial drift	0	0-150	5-30 30-60	Silty clay, silty loam, clay, or loam over residuum and bedrock, or both.	Yields little water to wells (<5 gal/min)
Pennsylvanian		Undifferentiated	0-120	0-75	--2/	Partly silty red shale with purplish-red to light gray clay.	Limited occurrence. Yields small quantities of water to wells (<1-10 gal/min.)
Mississippian	Meramecian	St. Louis Limestone	0-120	0-105	70-75	Limestone; white to light gray, lithographic to finely crystalline, medium to thick bedded. Contains some shale.	Individually, the rock units yield small to moderate quantities of water to wells (5-50 gal/min). Collectively, these units yield sufficient water to supply most domestic and stock needs.
		Salem Limestone	0-225	0-140	90-130	Limestone; light gray to white, fine to coarsely crystalline, cross-bedded. Some siltstone and shale in lower part.	
		Warsaw Formation	0-345	0-95	70-90	Calcareous shales and interbedded shaly limestone, grades downward to shaly dolomitic limestone.	

System	Series	Stratigraphic Unit	Depth from ground level to top of formation, in feet	Thickness, in feet	Typical 1/ thickness, in feet	Physical Characteristics	Remarks
Mississippian (cont.)	Osagean	Keokuk and Burlington Limestone	0-405	0-220	160-200	Limestone; white to bluish-gray, medium to coarsely crystalline, thick-bedded. Cherty.	(See Mississippian remarks on previous page).
		Fern Glen Limestone	0-500	0-85	50-70	Limestone; yellow-brown, fine grained medium to thick-bedded. Contains appreciable chert.	
	Kinderhookian	Chouteau Limestone	0-580	0-105	50-70	Dolomitic limestone; gray to yellowish-brown, fine-grained, thin to medium-bedded.	
Devonian	Upper	Bushberg Sandstone	0-625	0-20	5-15	Quartz sandstone; reddish-brown, fine to medium grained, friable.	Yields small to moderate quantities of water to wells (5-50 gal/min).
		Lower part of Sulphur Spring Group undifferentiated	0-625	0-60	35-40	Calcareous siltstone, and sandstone with oolitic limestone with some dark, hard, carbonaceous shale.	Group also includes Glen Park and Grassy Creek formations.
Ordovician	Cincinnatian	Maquoketa Shale	0-650	0-75	30-50	Calcareous or dolomitic shale, typically thinly laminated, silty, with shaly limestone lenses.	Yields small quantities of water to wells. (Missouri Geological Survey data indicate Maquoketa shale is absent at the Weldon Spring Site.)
	Champlanian	Kimmswick Limestone	0-710	0-140	90-100	Limestone; white to light gray, coarsely crystalline, medium to thick bedded. Cherty near base.	Yields small to moderate quantities of water to wells (10-50 gal/min).
		Decorah Formation	0-810	0-35	30	Interbedded green and yellow shale with thin beds of limestone.	
		Plattin Limestone	0-840	0-195	100-125	Limestone; light to dark gray, finely crystalline. Thinly bedded; weathered with pitted surface.	

System	Series	Stratigraphic Unit	Depth from ground level to top of formation, in feet	Thickness, in feet	Typical 1/ thickness, in feet	Physical Characteristics	Remarks
Ordovician (cont.)	Champlanian (cont.)	Joachim Dolomite	0-950	0-135	90-110	Dolomite; yellowish-brown, silty thin to thick-bedded. Grades into siltstone, shales common.	(Last remark applies to this unit also.)
		St. Peter Sandstone	0-1070	0-250	120-150	Quartz sandstone; yellowish white to white, fine to medium grained, massive bedded.	Yields moderate quantities of water to wells (10-40 gal/min). Everton formation discontinuous.
		Everton Formation	0-850	0-65	0	Sandy dolomite.	
	Canadian	Powell Dolomite	0-950	0-65	50-60	Dolomite; medium to finely crystalline, often sandy, occasionally cherty or shaly.	Generally yields small quantities of water to wells (<10 gal/min).
		Cotter Dolomite	0-1250	75-275	200-250	Dolomite; light gray to light brown, medium to finely crystalline, cherty. Argillaceous, interbedded with green shale.	
		Jefferson City Dolomite	100-1500	145-225	160-180	Dolomite; light brown to brown, medium to finely crystalline.	
		Roubidoux Formation	350-1700	150-170	150-170	Dolomitic sandstone.	Yields moderate to large quantities of water to wells (10-300 gal/min).
		Gasconade Dolomite	500-1850	250	250	Cherty dolomite; Gunter Member is arenaceous dolomite.	Gunter Member is about 30 feet thick.
Cambrian	Upper	Eminence Dolomite	750-2100	190	200	Dolomite; medium to massively bedded, light gray, medium to coarse-grained.	Yields moderate to large quantities of water to wells (10-500 gal/min).
		Potosi Dolomite	950-2250	100	100	Dolomite; massive, thickly bedded, medium to fine grained. Abundant quartz druse.	Freshwater only in southwest part of St. Charles County and saline water elsewhere in county.

System	Series	Stratigraphic Unit	Depth from ground level to top of formation, in feet	Thickness, in feet	Typical 1/ thickness, in feet	Physical Characteristics	Remarks
Cambrian (cont.)	Upper (cont.)	Derby and Doe Run Dolomites	1050-2350	140	150	Dolomite; thin to medium bedded alternating with thin bedded siltstone and shale.	Hydrologic characteristics unknown in St. Charles County. Is a confining bed elsewhere in state.
		Davis Formation	1200-2500	170	170	Contains shale, siltstone, fine-grained sandstone, dolomite, and limestone conglomerate.	
		Bonneterre Dolomite	1350-2650	430	400	Dolomite; typically a light gray, medium to fine grained, medium bedded.	Yields unknown in St. Charles County; however, water probably is saline.
		Lamotte Sandstone	1800-3100	460	450	Predominantly quartzose sandstone.	
Precambrian			2200-3500			Igneous rocks.	Yields no water.

1/ "Typical thickness" refers to thickness of formation normally encountered while drilling.

2/ -- indicates insufficient data for estimate.

at the WSS (Kleeschulte and Emmett, 1986). Data on water-yielding capabilities of the different formations or formation groups are included.

1.2.4.1 Overburden

Overburden, or unconsolidated materials, present at the site can be categorized into six units (BNI, 1984c and 1987):

- Fill/Topsoil
- Wind deposits (loess)
- Ferrelview Formation
- Clay till
- Basal till
- Residuum

The relative positions of the different units are listed above with fill/topsoil being the youngest sediments. BNI depicts the total thickness for the unconsolidated materials as well as that of some of the individual units on isopach maps (1987). The maps are reproduced here in Figures 1-6 through 1-9. The thicknesses depicted are based on boring logs from studies performed in 1983 and 1986 (BNI, 1984c, 1987). Additional boring information from further site characterization will allow for a more accurate delineation of the overburden materials and a modification of the contours. An examination of Figure 1-6 indicates that unconsolidated material underlies the entire site with thicknesses ranging from less than 20 feet to more than 55 feet. The overburden is thicker along the ridge top trending north-south through the middle of the chemical plant area. The thinner portions generally lie along the eastern and western flanks of the site.

Topsoil at the site varies in thickness from 0.5 to 3.5 feet, and is a black, organically rich, silty clay or clayey silt (BNI,

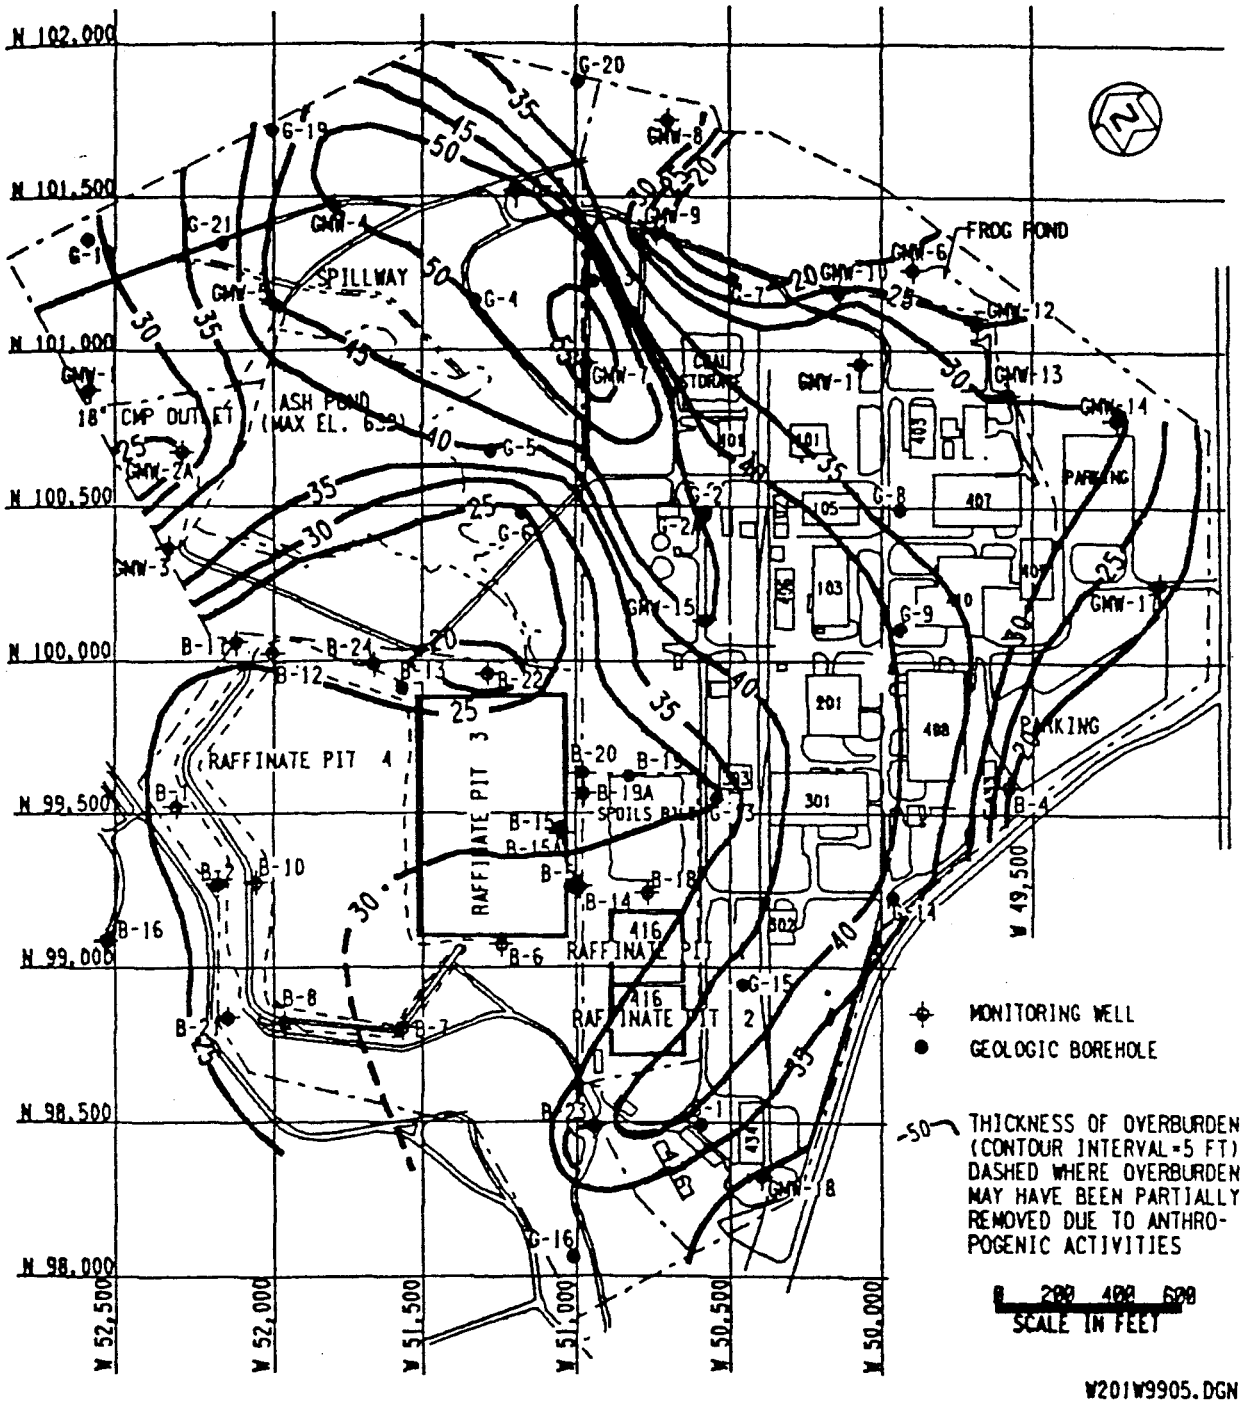

FIGURE 1-6

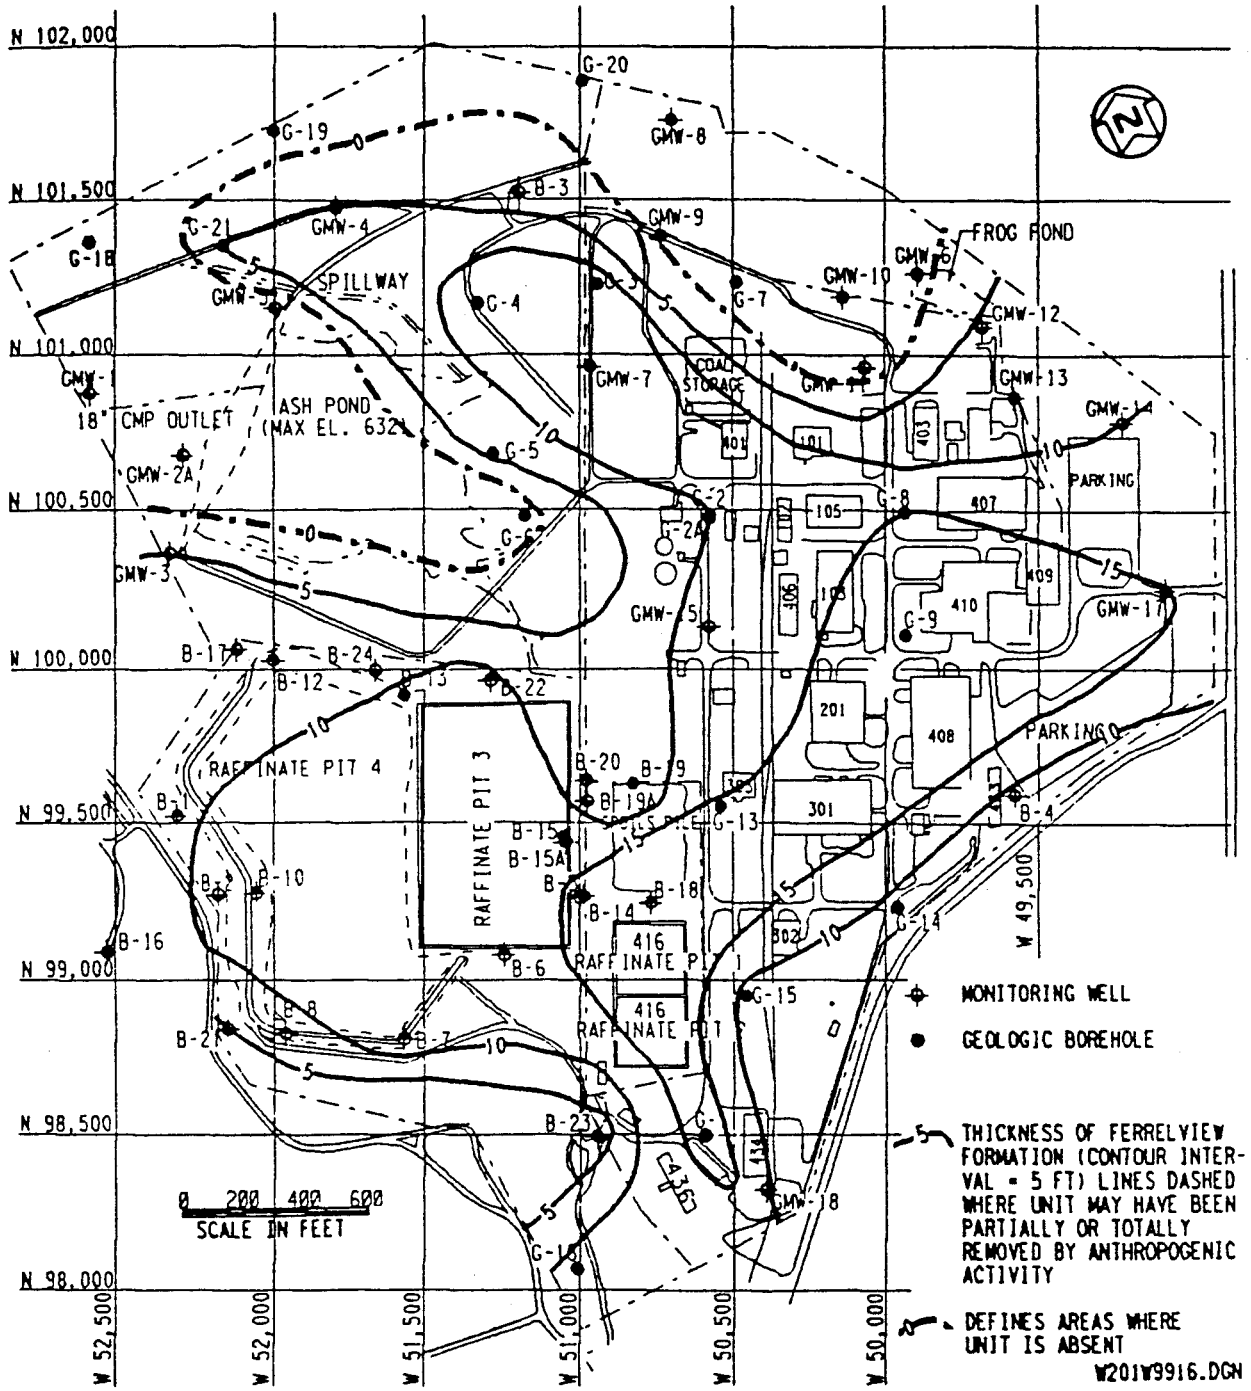

FIGURE 1-7

FERRELVIEW ISOPACH

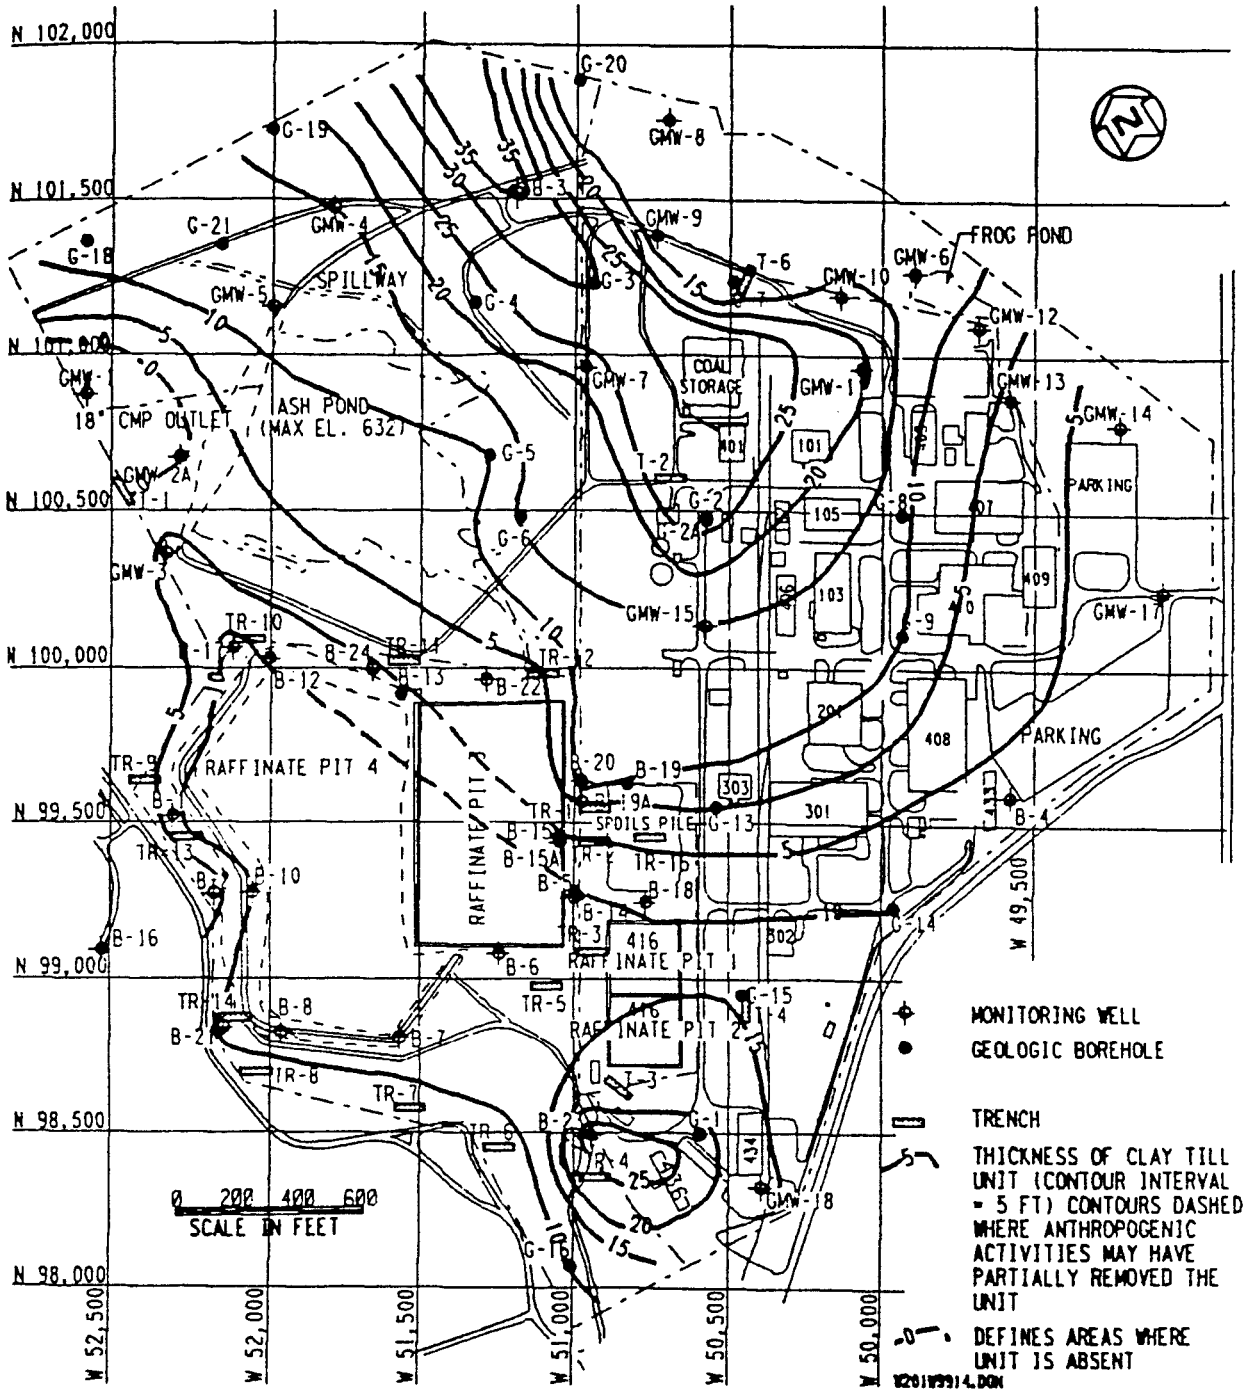

FIGURE 1-8

CLAY TILL ISOPACH

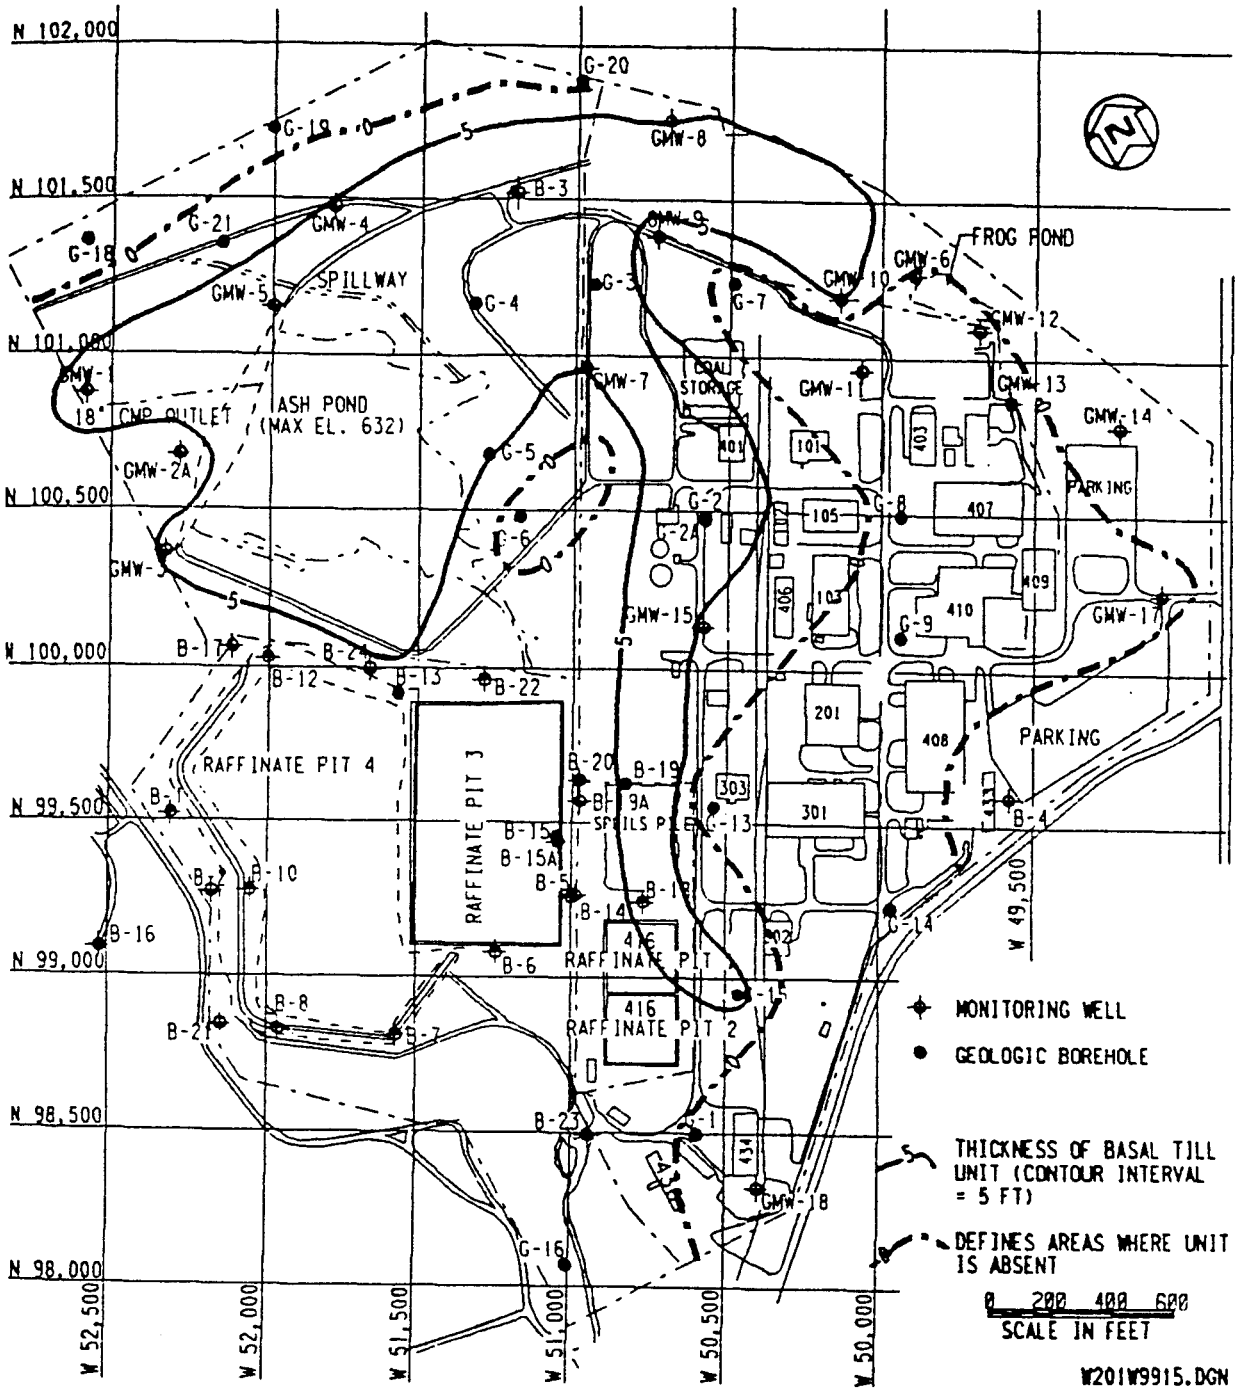

FIGURE 1-9

BASAL TILL ISOPACH

1984c and 1987).

The fill portion is quite variable in composition and thickness and is believed to be primarily local site soils which have been transported and recompacted. The thickest areas of fill are probably at the raffinate pits where up to 26 feet of fill are reported (BNI, 1987).

Loess deposits with thicknesses from 0 to 10.5 feet overlie the Ferrelview Formation or clay till across the site. The distribution and thickness of the loess in the area is quite variable and not well defined (BNI, 1987). Extensive re-working of these unconsolidated sediments occurred during original site construction.

Figure 1-7 illustrates thicknesses of the Ferrelview Formation at the WSS. The Ferrelview Formation is a dark yellowish-orange to brown silty clay to clayey silt with gray mottling. Iron oxide nodules and pyrolusite (manganese oxide) veins and stringers are common in the unit (BNI, 1987). The formation covers most of the site with thicknesses to more than 15 feet. The Ferrelview Formation is apparently absent under Ash Pond and along the northern edge of the site.

The clay till underlying the Ferrelview Formation is a yellowish-brown silty clay to clayey silt. The unit contains sand and gravel-sized particles and pyrolusite veins and stringers (BNI, 1987). Thicknesses of the unit are depicted in Figure 1-8. The unit apparently covers all of the site, except just north of Ash Pond. Thicknesses exceed 35 feet near the northernmost corner of the site.

The basal till unit underlies the clay till unit. Thicknesses of this unit are shown in Figure 1-9. The unit exceeds 5 feet in thickness under Ash Pond and the western portion of the WSCP and is absent beneath the main portion of the WSCP. The basal till

is a yellowish-brown sandy, clayey silt with angular chert gravel and cobbles (BNI, 1987).

The residuum, located at the base of the unconsolidated materials, is typically a red to yellow gravelly clay to gravelly silt. The thickness of the residuum ranges from 0 to approximately 23 feet at the WSS. The distribution and thickness of the residuum in the area is apparently related to localized weathering and erosion (BNI, 1987).

BNI gives summaries of soil testing data for samples from the different overburden units (1987). These data are summarized in Table 1-2. BNI provided the following discussion of the data:

> "Comparison of grain size distributions of the four units indicates that the basal till has the highest gravel content, the clay till has the highest sand and clay content, and the loess has the highest silt content. The Ferrelview Formation contains a higher percentage of silt than the clay till, yet the Ferrelview is thought to be derived from the clay till. The higher silt content of the Ferrelview may reflect loess deposited contemporaneously with the Ferrelview.
>
> "The parameters measured in the soil test program most directly related to the attenuation of radionuclides were effective cation exchange capacity (CEC) and distribution ratio. The clay till unit exhibited the highest cation exchange, followed by the Ferrelview Formation and finally the basal till. The loess unit was not examined in this study due to its limited areal extent on the site. The results of these tests are as could be expected from the percentages of clay in each unit. The clay till has the highest clay content and thus has the highest surface area and largest number of surface charged particles available for cation exchange reactions. The basal till has the least amount of clay and contains significant amounts of quartz and amorphous silica (chert) which provide less possibility for cation exchange sites.
>
> "Distribution ratios were measured using a 10.44 mg/l uranium source solution. The results of the distribution ratio tests indicate no correlation between absorption capacity for radionuclides and cation exchange capacity, with the basal till having the highest distribution ratio and the clay till having the lowest distribution ratio.

> Visual examination of the samples by laboratory personnel indicates that the basal till sample has the highest organic content of the samples tested. This suggests that the reactions observed in the basal till sample may be related to organic matter content rather than cation exchange capacity, since CEC measurements show the basal till has the lowest CEC. The implication of this reasoning is that the ability of the basal till to immobilize radionuclides is directly related to organic content and the geochemical environment and may vary both spatially and temporally."

Quartz, limonite, and calcium carbonate (limestone) were noted in particle size analyses of the overburden (BNI, 1987). These rock minerals are of interest as they influence solubility, groundwater chemistry, and possibly the physical nature of the unsaturated zone and the aquifer. In addition, the mineralogical composition is useful in assessing the leaching and/or attenuation of contaminants. The available data are not quantitative.

1.2.4.2 Bedrock

Geologic cross sections have been drawn to show the overburden materials and the upper part of the bedrock at the WSS with hydraulic conductivity (permeability) information. The locations of these cross sections are presented in Figure 1-10 and the cross sections are shown in Figures 1-11 through 1-13. Estimated thicknesses of the bedrock units are shown in Table 1-3. Cross-sections will be modified as additional data are obtained under this and other (e.g. soil, geotechnical, geophysical) investigative programs.

The near-surface rock units at the site are sedimentary. The first bedrock unit underlying the overburden is the Keokuk and Burlington Limestones or the Burlington/Keokuk Formation. This is a white to bluish-gray, medium to coarsely crystalline, thick bedded limestone containing chert. At the site, the Burlington/Keokuk Formation can be subdivided into two units. The uppermost unit is moderately to highly weathered and fractured,

TABLE 1-3

ESTIMATED THICKNESSES OF BEDROCK UNITS AT WSS

Stratigraphic Unit	Estimated Thickness, ft
Burlington/Keokuk Formation	160
Fern Glen Limestone	50
Chouteau Limestone	20
Bushberg Sandstone	7
Kimmswick Limestone	90
Decorah Formation	30
Plattin Limestone	120
Joachim Dolomite	90
St. Peter Sandstone	135

yellowish brown to white and consists of approximately 50% chert. This unit contains solution features ranging from vugs (up to 2 in. diam.) to small cavities (up to 5 ft diam.).

These cavities are generally filled with sand/chert gravel mixtures. Solution features and predominant fractures appear to be oriented to the bedding. Figures 1-11 through 1-13 depict the estimated base of the uppermost unit as defined by lithologic logs and hydraulic conductivity testing (BNI, 1987). Thicknesses of this unit vary from approximately 20 ft to greater than 50 ft. The variability in thickness is attributed to a variance in the depth of weathering of the limestone. There is no defined base of the weathered zone.

The lower unit of the Burlington/Keokuk Formation is slightly weathered to fresh, slightly fractured, to brownish-gray to gray limestone, and contains approximately 30% chert.

From a study of the core samples the unit appears to be massive. Solution features are limited to occasional vugs in the upper portion. Pressure solution features and/or shale interbeds are common (BNI, 1987). The thickness of the unit is not defined, but is estimated to be approximately 130 ft, based on regional data presented in Table 1-1. A 30-ft thickness for the upper unit is assumed.

The formation underlying the Burlington/Keokuk at the WSS is the Fern Glen Limestone. This is a thin to thick bedded, crystalline to argillaceous limestone. Chert is common in this formation with the occurrence of occasional calcareous shale interbeds. The thickness of this unit at the site is estimated as approximately 50 ft.

Brief descriptions of the units from the base of the Fern Glen Limestone through the St. Peter Sandstone are as follows (after BNI, 1987):

Chouteau Formation	Conformably underlies Mississippian age, Osagean series which includes the Fern Glen Limestone and the Burlington/Keokuk Limestone. Thin-bedded limestone containing a few shale partings and localized argillaceous material and chert. Unconformably overlies the Bushberg Sandstone.
Bushberg Sandstone	Fine to medium-grained quartzose sandstone with variable carbonate content. Unconformably overlies the Kimmswick Limestone.
Kimmswick Limestone	Composed of thick-bedded, high-purity limestone with local concentration of chert.
Decorah Formation	Thin-bedded argillaceous limestone with intercalated calcareous shales. Thin bed of metabentonite separates the Plattin and Decorah formations.
Plattin Limestone	Thin to thick-bedded, microcrystalline to fine-grained limestone.
Joachim Dolomite	Thin to thick-bedded dolomite which grades into siltstone.
St. Peter Sandstone	Composed of fine to medium-grained, massive-bedded, quartzose sandstone.

Krummel (1956) provides more detailed descriptions of most of the bedrock units including their lithologies.

The Burlington/Keokuk Formation, as indicated above, contains solution features. Also the Kimmswick Limestone contains stylolites (pressure solution features), commonly along bedding planes, and is well jointed and may contain caverns (Krummel, 1956). The possible existence of migration pathways in the other bedrock is not defined. However, water for wells is obtained from the permeable zones of many of the formations (see Table 1-1). Dye tracing studies by Dean (1983a, 1983b, 1983c, 1984a, 1984b, 1985) indicate the presence of subsurface pathways.

Thicknesses of the deeper units at the site are unknown but can

be estimated from the regional data shown in Table 1-1.

Figure 1-14 (in pocket) represents the configuration of the upper surface of the Burlington/Keokuk Formation at the site, and is based on recent (1988) investigations. BNI and MKF have generated contour maps of the bedrock surface (BNI, 1987; MKF, 1987b). Those maps present a similar configuration of the bedrock surface.

The rocks in the area have a regional strike of N60o$_W$ and regional dip of approximately 1/2 degree to the northeast. The regional dip is predominantly from the Ozark Dome, though several other features may influence the dip. The Division of Geology and Land Survey of the MDNR has recently mapped a fault, trending east-west, about one mile north of the WSS. The fault has approximately 60 feet of vertical displacement (memo to Dave Bedan from Dave Hoffman, MDNR, June 10, 1988). Roberts (1951) has identified two major joint sets in the area; the first set trends between N30^{o}E to N72^{o}E and the other set trends between N30^{o}W to N65^{o}W. These joints are present in the Burlington/Keokuk, the Chouteau, and the Kimmswick (Roberts, 1951). Krummel (1956) and Kleeschulte and Emmett (1986) indicated they are vertical or nearly vertical.

1.2.5 Surface Water Hydrology

The site is located on the drainage divide between the Mississippi and Missouri rivers. The northern part of the WSS drains to Schote Creek, then to Dardenne Creek, and then to the Mississippi River. Drainage from the southern portion of the site flows to unnamed tributaries flowing into the Missouri River. Topographic maps are available for the site and vicinity. These include a range of map scales from 1:24000 (USGS, 1982) to 1:600 (Surdex Corp., 1983) and were produced in the period from 1982 to 1987.

Surface water drainages from the WSS are shown in Figure 1-15. Surface water in the Mississippi River drainage is divided into three major drainage basins: Ash Pond area, Frog Pond area and raffinate pit vicinity. Both the Ash Pond and raffinate pit vicinity drainages enter an unnamed tributary to Schote Creek and flow on to Lake 35. Both streams lose water to the subsurface. Some of this lost flow resurfaces at Burgermeister Spring (Dean, 1985). Surface water from Frog Pond exits the WSCP and flows into Lake 36. Overflow from Lake 36 enters Schote Creek and flows into Lake 35.

Lake 35 has lost water to the subsurface since its construction (Meyer, 1987). Lake 35 overflows to Schote Creek only during extreme precipitation events. Schote Creek joins Dardenne Creek just east of Highway K.

In early 1987, a small swallow hole opened near the headwaters of Lake 35. Missouri Department of Natural Resources (MDNR) dye studies determined that some of the lost water resurfaces in Lake 34 and at a spring northwest of Lake 34 near Twin Island Lake. MDNR dye studies are discussed in Section 1.2.7.2. Subterranean flow surfacing at Burgermeister Spring flows into Lake 34. Lake 34 outflow enters an unnamed tributary of Dardenne Creek. Dardenne Creek flows northeast to the Mississippi River.

The 20 acres of the WSS that are in the Missouri River drainage are located in the southeast portion of the WSCP. Drainage is overland via the Southeast Drainage Easement, an intermittent stream valley approximately 1.5 miles long.

Estimates of recharge or discharge via these associated systems are not available. Kleeschulte et al, (1986) present results of streamflow measurements at 102 sites taken in April 1985 from Dardenne Creek tributaries for seepage run determinations. Other streamflow measurements for the vicinity of the WSS are also included. Further discussion of this surface-subsurface

interrelationship is included in Section 1.2.7.

Runoff from the southern portion of the site and much of the chemical plant area flows southward to the Missouri River. Some of the rainwater and snow melt enter various man-made drains in the chemical plant area. These drains flow into the process sewer which exits southward from the site to a drainage ditch and flows to the Missouri River.

As discussed earlier, four raffinate pits exist at the site -- Raffinate Pits 1, 2, 3, and 4. These are described in Table 1-4. They have served as sources of contamination (Section 1.2.8) and also provide some driving head for moving contaminants into the subsurface system. Recharge estimates for water in the raffinate pits are available for months April through October over a 3-year period (1983-1985) (BNI, 1986a). Water balance studies indicated total water losses to be on the order of one and one-half to two millimeters drop in elevation per day. Cumulative changes over a 7-month period were substantial enough to document loss of water, though magnitude of loss on a per-day basis was close to the accuracy of the monitors used. The BNI report notes that a 2 mm loss would translate to a permeability rate of 10^{-7} cm/sec. When evapotranspiration is accounted for, an average loss from the pits of less than 1 mm depth per day or less than one gpm/acre of pit area is estimated.

The U.S. Army Corps of Engineers has developed some preliminary estimates of hydrologic parameters for Schote Creek at the site (DOE, 1987). The 100-year and 500-year flood peak discharges for the main stem of Schote Creek are 2,100 and 2,700 cfs, respectively. The 500-year flood elevation near the raffinate pits was determined to be about 530 feet, which is considerably lower than the elevation of the site (DOE, 1987).

TABLE 1-4

4	444,400	55,600	43,200,000	15.0	646.4	8.8

1.2.6 Vadose Zone

Downward movement of water from the surface or near surface typically would pass through an unsaturated zone of soil, defined as the vadose zone, before proceeding to a predominantly saturated zone. Lateral movement of this water can also occur. The upper portion of the vadose zone is the soil water zone or the soils zone. The soils zone extends from the land surface to a depth corresponding to the predominant root depth for vegetation in the area, which typically is no more than a couple of feet at the WSS.

Because of local and seasonal variations in recharge and discharge, the vadose zone thickness is expected to vary locally, seasonally, and from year to year. A comparison of Figures 1-16 and 1-17 gives an indication of the seasonal variation of vadose zone thickness. Additional monitoring data will allow for a more accurate delineation of seasonal variation of groundwater levels as outlined in Section 2. Specific yield (effective porosity) in limestones, in zones with limited fracturing and solution cavities, can be assumed to range from <5 to 10%. Therefore, moderate precipitation events, perhaps in recharge areas southwest of the site can be responsible for seasonal variations in water levels as illustrated in Figures 1-16 and 1-17. An examination of cross sections in Figures 1-10 through 1-13 shows the groundwater elevations in the summer of 1986 as being typically 10 ft below the top of bedrock. The vadose zone thickness variation from more than 30 ft to more than 65 ft at different locations in the WSS is also governed, in part, by topographic and manmade features.

Also, the geological environment at the WSS exhibits complex saturated-unsaturated conditions occurring within the vadose zone. Saturated regions within the vadose zone (perched groundwater bodies) result from the presence of a lower hydraulic conductivity layer in a higher hydraulic conductivity formation.

SOURCE: MK-FERGUSON 1987

The result is the formation of discontinuous saturated lenses above the lower hydraulic conductivity clay layer, with unsaturated conditions existing both above and below these lenses.

Previous exploratory drilling investigations conducted at the WSS indicated areas of anomalously high groundwater elevations or perched groundwater in the vicinity of the raffinate pits (Lawrence Berkeley Laboratories, 1980, BNI 1984, and UNC Geotech July 1987). Fourteen observation wells and 10 vibrating-wire piezometers were installed in the overburden over the course of three investigations. Completion data for these installations is shown on Table 1-5. Wells were renumbered by WSSRAP staff along with bedrock monitoring wells at the beginning of WSSRAP efforts, prior to separation of bedrock aquifer and overburden monitoring programs. Wells to be used in further overburden studies are discussed in Section 2.4.

Of the 24 installations, 6 indicated saturated conditions during the original investigations. Pore-pressure measurements from Piezometers B-5 and B-22 indicated saturated conditions. Wells B-2 and B-14 originally penetrated saturated soils, although B-14 went dry near the end of the BNI investigation and has remained dry. Well W-2, installed by Lawrence Berkeley Laboratories, penetrates soils which are seasonally saturated. Well B-16 was installed in saturated residuum overlying bedrock on the Weldon Spring Training Area at a relatively remote location from the raffinate pits. Well B-15A, installed on the east berm of Raffinate Pit 3, was dry during the original investigation but has contained water continuously during WSSRAP efforts. Water level elevation in this well is approximately 630 feet, compared to a water level elevation of 611 feet in MW-3008 approximately 120 feet to the northeast, indicating significant, although perhaps localized mounding. Water level elevation in W-2, on the west side of Raffinate Pit 4 is approximately 612 feet, compared with a water level elevation of 607 feet in MW-3007 to the north and MW-3009 to the south, indicating a smaller degree of mounding

** BGL - Below Ground Level
*** MW-4006 is included in the bedrock monitoring well network

in this area. Further studies will more closely examine hydrogeologic conditions at the residuum/bedrock interface. Additional investigations by BNI included conducting geophysical surveys which detected seismic velocity layers of 5000 ft/s at approximately 10 feet below ground surface in the areas within, beneath, and surrounding Raffinate Pit 3. This velocity is generally indicative of saturated conditions. Figure 1-18 presents a contour map of the surface of this 5000 ft/s layer and indicates a mounding effect from Raffinate Pit 3 (BNI 1984). Two shallow overburden monitoring wells were installed in July 1987 by UNC Geotech to investigate perched groundwater due to shallow seepage from the raffinate pits. One well, OW-3501, located immediately to the north of Raffinate Pit 1, indicated a shallow saturated zone approximately 1 foot below the surface. A similar installation (OW-3502) on the north side of Raffinate Pit 3 has remained dry since installation.

A total of 10 lysimeters were installed in 3 boreholes during the period July 7-10, 1987 during the course of radiologic site characterization by UNC Geotech Inc. These multiple lysimeter installations were planned as a preliminary assessment of contaminant transport by unsaturated flow. Locations were selected from examination of color aerial photographs on which areas of dark green vegetation indicated potential seepage of raffinate pit waters with high nitrate concentrations. Figure 1-19 presents the locations of the lysimeters installed by UNC Geotech. Results of analyses for inorganic constituents from soil pore-water samples obtained on Sept. 17, 1987 indicate elevated concentrations of nitrate, calcium, and sodium at all three locations. The sample containing the highest concentrations of these parameters, especially nitrate (8,976 mg/l), was obtained from lysimeter LY-3608 at a depth of 5.5 feet. The lysimeter is located north of Raffinate Pit 1 (Figure 1-19) in an area exhibiting saturated conditions near the surface. The analytical results coupled with the saturated

surface conditions indicate seepage is occurring from Raffinate Pit 1. Additional lysimeter monitoring points will be required in order to evaluate contaminant migration.

1.2.7 Hydrogeology

This section summarizes information available in existing reports related to the hydrogeology of WSS and adjacent areas. Information on groundwater occurrences and flow and their variations is presented along with a discussion of potential areas of recharge and discharge at the WSS and vicinity. Quantitative information on background water quality and an evaluation of the adequacy of the data are also presented.

1.2.7.1 Groundwater Occurrences

As discussed in previous sections, the land surface slopes outward from the site. The sediments consist of unconsolidated material overlying slightly dipping bedrock formations of varying complexity and importance.

The USGS delineates three principal aquifer systems in the general area: the alluvial aquifers, the shallow bedrock aquifer system, and the deep aquifer system (Kleeschulte and Emmett, 1986). The alluvial aquifers include the saturated sands, gravels, and silts in the alluvium of the Missouri and Mississippi rivers and the alluvium of tributary creeks where significant groundwater yields can occur. The shallow bedrock system primarily consists of saturated rock of Mississippian and Devonian age which includes formations at the WSS from the Burlington/Keokuk Limestone down through the Bushberg Sandstone. At the WSS the shallow bedrock aquifer is subdivided into upper and lower zones. The upper zone is the weathered and fractured portion of the Burlington/Keokuk Formation. The deep aquifer system primarily consists of Ordovician and Upper Cambrian saturated rocks which include sediments from the St. Peter

Sandstone down through the Potosi Dolomite. The shallow and deep aquifers are separated by a leaky confining layer from the base of the Bushberg Sandstone down through the Joachim Dolomite (Kleeschulte and Emmett, 1986). Individual units or zones in this layer may be classified as low yielding aquifers (Kleeschulte and Emmett, 1986).

The upper zone of the shallow bedrock aquifer, as defined by the USGS, is the main emphasis and concern at the site for several reasons. First, it is in close proximity to contaminant sources. Second, it is weathered, fractured, and of higher hydraulic conductivity than deeper, unweathered zones. Finally, it is the zone most likely to permit contaminant migration.

Kleeschulte and Emmett (1986) present regional maps of the shallow and deep bedrock aquifer potentiometric surfaces. These maps are reproduced here in Figures 1-20 and 1-21. The shallow aquifer data, Figure 1-20, show a groundwater divide running approximately E-W through the vicinity of the raffinate pits monitoring wells (represented by the four dots within the delineated Army Property). The potentiometric surface elevations ranged from more than 650 ft near the west boundary of the original DOA property to less than 425 ft near the Mississippi River.

Figures 1-16 and 1-17 give site-specific groundwater levels taken from monitoring wells completed primarily in the upper portion of the Burlington/Keokuk Formation (BNI, 1987; MKF, 1987b). The monitoring well numbering system shown in Figure 1-16 differs from that of Figure 1-17. However, for the most part, the same wells have been used in providing data for the preparation of both maps. Both maps indicate a groundwater divide trending approximately SW-NE across the southeastern portion of the WSS site. The detailed shapes of the two sets of contours are different but the general trend is the same. The differences are due to the use of different monitoring wells, the seasonal and

annual variations represented by the data, and the differences in interpretation by the individual map preparers. The range in elevations is from more than 610 ft to less than 580 or 590 ft, depending on the map. Inspection of the cross sections in Figures 1-11 through 1-13 indicates that depths to groundwater vary from about 30 to 65 ft. BNI indicates a minimum depth of 18-20 ft below Raffinate Pit 4 (BNI, 1984c).

Alluvial aquifers are found along the Missouri and Mississippi rivers and major tributaries (BNI, 1987). Groundwater is present at some locations in the unconsolidated formations in the vicinity of the site. On site, groundwater is present in the overburden in areas bordering Raffinate Pits 3 and 4. This indicates that these surface-water impoundments are leaking and forming a groundwater mound in the immediate area surrounding these pits.

Groundwater in the "deep bedrock aquifer system" is represented by the regional map (Figure 1-21) of Kleeschulte and Emmett. For reference, note the boundary of the U.S. Army Property compared to that in Figure 1-20. A groundwater divide exists just north of the WSS with a large groundwater depression 4 or 5 miles further north of the divide. The aquifer system represented in Figure 1-21 includes the Ordovician shale, limestone, dolomite, and sandstone from the Maquoketa Shale to the base of the Potosi Dolomite. The approximately 350-ft-thick upper portion of the system which extends to the Joachim Dolomite is less permeable than the approximately 1000-ft-thick lower portion and tends to form a confining layer (Kleeschulte and Emmett, 1986).

Lateral boundaries of aquifer systems in the vicinity of the site are not fully delineated in the available reports. Groundwater discharges can be observed locally from the bedrock aquifer in or near gullies, at least intermittently, as seeps and springs (Dean, 1984a, 1984b, 1985). Figure 1-22 shows the locations of local springs. This map is also presented in Section 2.3.2.1

(Figure 2-6) along with a description of the WSSRAP numbering system for these springs. During the summer and fall of 1987 a complete reconnaissance survey of the area surrounding the WSS was performed to locate springs and seeps which are potentially affected by the WSS. This survey was performed by Missouri Department of Natural Resources (MDNR) and WSSRAP geologists. A total of 30 springs and seeps were identified and located on USGS 7.5-minute topographic maps. Fishel and Williams (1944) indicate that Dardenne Creek Valley intercepts flow from the shallow bedrock system. Hence, the extent of the upper and lower zones of the shallow aquifer are partially defined in the area.

There are boundaries tending to inhibit vertical transfer of water. These include the upper 350-ft-thick portion of the deep bedrock aquifer system described above, and the lower portion of the Burlington/Keokuk as previously discussed (see Section 1.2.4). Also, the Meramecian Series, where present regionally, may be a confining layer for water in the lower portion of the shallow bedrock aquifer (Kleeschulte and Emmett, 1986). Units that may minimize vertical movement of groundwater below the Burlington/Keokuk and above the Maquoketa Shale are not defined.

Porosity of the bedrock aquifers at the site is a combination of primary and secondary porosity. Primary porosity is that portion of the bedrock void space that is present within the matrix of the rock itself. Secondary porosity consists of fractures, solution channels, and fine interconnected fractures in the limestone bedrock (MKF, 1987b). The Burlington/Keokuk Formation and the Fern Glen Limestone may be deeply weathered in outcrop areas and may transmit water primarily through solution openings and joints (Kleeschulte and Emmett, 1986).

Porosity in the deep bedrock aquifer includes solution-enlarged joints in the Kimmswick Limestone (Kleeschulte and Emmett, 1986) and primary porosity in the St. Peter Sandstone. The types of porosity in the other bedrock aquifer formations are uncertain.

1.2.7.2 Groundwater Movement

Groundwater flow in the upper, weathered portion of the Burlington/Keokuk Formation occurs in two distinct flow regimes: Darcian flow and conduit flow. Darcian flow occurs through the fine fractures of the formation, which comprise an equivalent porous medium. Conduit flow occurs where subsurface groundwater pathways have developed selectively within the fracture network. These conduits are generally dendritic or trellised. Conduits typically discharge into springs, seeps or other surface water bodies such as streams, rivers or lakes. Darcian flow is dispersive, while flow in conduit systems is convergent (Quinlan and Ewers, 1985).

Figure 1-17 implies the general direction of groundwater movement in the shallow bedrock aquifer at the WSRP/WSCP. For a continuous medium which is isotropic with respect to hydraulic conductivity, the groundwater flow direction would be at right angles to the contours. However, for an anisotropic medium, such as one with conduit flow, the flow could be oblique to contours. The general flow directions for the discussion below will be estimated based on flow in an isotropic continuous medium.

Groundwater flow directions in the upper Burlington/Keokuk Formation are defined by the position and orientation of the groundwater divide. Referring to Figure 1-17, the flow is to the north from most of the WSS; in the southeastern portion of the site the flow is to the southeast or east. The regional potentiometric surface for the shallow bedrock aquifer (Figure 1-20) shows a similar pattern, indicating opposing flow directions depending on location relative to the divide.

Fishel and Williams (1944) described red water leakage from a lagoon located 100 yards east of Frog Pond and its detection at two springs north and northwest of the WSS (see Section 1.2.8).

The Missouri Department of Natural Resources further defined groundwater movement through subsurface water tracing dye studies, conducted in 1983, 1984, and 1985 (Dean 1983, 1984a, 1984b, 1985). Dean's findings are summarized below.

Rhodamine WT dye and fluorescein dyes were injected into three drill holes (B-3, now MW 2016, B4, now MW 2020, and B17, now MW 3007) in February and March 1983. No positive identification of water tracing dyes was detected at charcoal packet monitoring locations placed, primarily in stream channels, at locations to the North and South of the WSRP/WSCP.

Rhodamine WT dye was placed into surface drainage west of Raffinate Pit 4 of February 1984. This drainage is an unnamed tributary of Schote Creek draining to Lake 35. Dye was detected in packets placed at five monitoring locations:

1) At Burgermeister spring
2) At a resurging sink immediately south of Burgermeister spring,
3) At a spring south of Pond C upstream of Lake 34
4) At a creek channel 50 ft west of 2 (above) and downstream of 3 (very weak trace)
5) In the watershed just upstream of the tail waters of Lake 35 (very weak trace - negative on Feb. 17, 1984).

Dean concluded that plant area runoff trending north via the drainage west of Raffinate Pit 4 can be expected to flow underground and emerge at or in the vicinity of Burgermeister Spring, a straight line flow distance of approximately 6500 feet. Time of travel was not accurately determined but initial arrival was estimated to be 48-72 hours and would be dependent upon precipitation events.

In June 1984, Rhodamine WT dye was injected at the process sewer outfall (Southeast Drainage Easement). Dye was detected at two

springs (SP5301 and SP5303) along the drainage easement toward the Missouri River, approximately 0.25 and 0.50 miles downstream, respectively. This test established flow connection to the south of the groundwater divide.

In March 1985, Rhodamine WT dye was introduced into a sink in the Ash Pond outflow stream west of DOE property. With the detection of dye traces at the Burgermeister Spring and vicinity, a subsurface connection was established between the outflow stream drainage downstream of Ash Pond and the Burgermeister Spring area.

Additional dye tracing tests are being conducted at this time. Data received from these tests will be presented in subsequent reports.

Flow directions in the deep bedrock aquifer system are shown on Figure 1-21. Flow in the vicinity of the site in 1984 was to the northeast and southeast. Flow to the north eventually enters the groundwater depression produced by pumping of municipal wells in Wentzville and O'Fallon. The eventual discharge point(s) of flow to the south is unknown.

The potential for vertical movement of groundwater is implied by a comparison of groundwater levels in Figures 1-20 and 1-21. In 1984, there was an approximate 125-ft head differential between the deep and shallow groundwater aquifers in the vicinity of the site, with the deep aquifer system having the lower levels. Groundwater will tend to move downward with this head differential. However, the effective hydraulic conductivity between the two aquifers is unknown.

Recharge and discharge locations and quantities typically have an effect on groundwater movement. Recharge to alluvial aquifers occurs from precipitation on the alluvium; from flooding that causes surface water to go into bank storage; from flows from

contiguous bedrock aquifers; and from induced flow into the aquifer as a result of groundwater pumping (Kleeschulte and Emmett, 1986). Discharge from alluvial aquifers occurs from natural discharge via evapotranspiration (through phreatophytes), from recession periods which result in return flow from bank storage, from wells tapping the aquifer, and from discharges into the contiguous bedrock. Recharge and discharge from alluvial aquifers near the site potentially affect the aquifers at the site, as they can affect the subsurface flow between aquifers.

Discharge and recharge sources similar to those for the alluvial aquifer apply to the shallow bedrock aquifer at the WSS and vicinity with the addition of recharge from losing streams and discharge to springs. Discharge/recharge mechanisms for the deep bedrock aquifer include: recharge from precipitation directly on the area where the deep bedrock aquifer outcrops or is overlain by permeable soils; recharge from losing streams which penetrate the aquifer; downward leakage from the shallow bedrock aquifer; extraction by wells tapping the aquifer; evapotranspiration, and seepage to springs and streams (Kleeschulte and Emmett, 1986).

Groundwater usage in the Weldon Spring area has been summarized by BNI (1987). The principal groundwater extraction areas in the region of the site are the St. Charles County well field (located in the Missouri River flood plain approximately 5 miles southwest of the site), and the cities of Wentzville, O'Fallon, and St. Peters. St. Charles County and St. Peters extract groundwater from the alluvial aquifer while the cities of Wentzville and O'Fallon withdraw groundwater from the deep bedrock aquifer. The city of St. Peters formerly utilized wells in the deep bedrock aquifer. The St. Charles County well field produces approximately 10.5 mgd, and in 1985 Wentzville, O'Fallon, and St. Peters extracted 0.59, 1.22, and 2.9 mgd, respectively (Kleeschulte, 1988). The groundwater contour maps presented previously reflect the composite effect of discharges and recharges to the aquifer systems plus the hydraulic properties.

Figure 1-21 specifically identifies a groundwater depression in the deep bedrock aquifer that is a result of groundwater pumping.

There are also domestic wells being utilized in the vicinity of the site. On June 5, 1984 the St. Charles Countians Against Hazardous Waste (SCCAHW) completed a groundwater inventory of wells and springs in St. Charles, Defiance, Weldon Spring, St. Peters, Wentzville, O'Fallon, Augusta, and New Melle. The study was representative of the combined efforts of the St. Charles County Administrative Court, the Missouri Division of Health, the Missouri Department of Natural Resources (MDNR), the Missouri Department of Conservation, and SCCAHW. Figure 1-23 (in pocket) represents a compilation of private well information received from SCCAHW and recently acquired data forwarded by the USGS.

The map shown on Figure 1-23 covers the area used for the WSSRAP Groundwater Classification Study currently being prepared (October 1988). The well numbers shown on the map are those used in listings of private wells by USGS and SCCAHW. Many private wells are no longer in use and have been omitted from this map. Wells located within the present boundaries of the Busch Wildlife and Weldon Spring Wildlife areas are assumed to have been abandoned around 1941, when private properties were sold to the U.S. Government for the WSOW. These wells, which have recorded locations but no record of water samples or water-level measurements, have been omitted. It is likely that many private wells in residential areas are no longer in use due to expansion of public water systems. Future WSSRAP efforts will seek to verify locations and usage of private wells.

Table 1-6 presents information pertaining to well yields in the area around the WSS bounded by the Mississippi River (10-15 miles north), and the Missouri River (3 to 4 miles to the south and east of the site). The table lists the major aquifers which supply municipalities, communities, farms and industries. It also illustrates which productive zones are more susceptible to

contamination by vertical migration of contaminants and shows the position of shales and zones of low hydraulic conductivity that provide a barrier to vertical groundwater flow (as a confining layer). Table 1-6 was compiled from USGS data (Kleeschulte, 1988).

Hydraulic or aquifer parameters of potential importance to the WSS assessment of groundwater and contaminant movement are hydraulic conductivity (permeability), transmissivity, storativity, porosity, and dispersivity. Aquifer tests made on wells tapping the Kimmswick to the St. Peter in St. Charles County gave specific capacities of 0.07 to 0.25 gpm/ft of drawdown (Kleeschulte and Emmett, 1986). Wells penetrating deeper formations had specific capacities ranging from 0.53 to 2.64 gpm/ft of drawdown (Kleeschulte and Emmett, 1986). No estimates of transmissivities or hydraulic conductivities of these zones are available from field tests.

Hydraulic characteristics of the overburden at the WSS were also evaluated and discussed in the BNI, November 1984, and July 1987 reports. The upper few feet of overburden (mostly topsoil) are poorly drained. The materials underlying the topsoil are unsaturated. Disturbed and undisturbed samples of the major overburden units were submitted to a laboratory for soil testing. The hydraulic conductivities and moisture content of both dike fill and foundation materials were determined. The hydraulic conductivity values are generally low and range from 1.6×10^{-9} cm/s (4.5×10^{-6} ft/day) to 3×10^{-6} cm/s (8.5×10^{-3} ft/day). Hydraulic conductivity values for the silty clays and clayey silts are the highest measured. The geometric mean of the test results is 1.3×10^{-7} cm/s (3.7×10^{-4} ft/day). The moisture content of the samples ranged from 15 to 30%, indicating the materials are unsaturated. Test results for the clay materials obtained from a depth of about 3 m (10 ft) indicate a hydraulic conductivity range from 1.7×10^{-8} cm/sec

(4.82×10^{-5} ft/day) to 6.4×10^{-9} cm/sec (1.81×10^{-5} ft/day). Some laboratory test results for overburden samples from the site are summarized in Table 1-2. These indicate specific yields ranging from 1% to 12%. Borehole hydraulic conductivity test results for the overburden; and unsaturated and saturated bedrock are summarized in Table 1-7. These show hydraulic conductivities for unsaturated materials on the order of 10^{-3} to 10^{-2} cm/sec. Some of the results are also given on Figures 1-11 through 1-13 where locations of the test intervals are indicated. The types of tests were constant head, double and single packer pressure tests (BNI, 1987). Details of the specific testing procedures employed are not given.

The mean hydraulic conductivity in the weathered saturated zone was on the order of 10^{-3} cm/sec with considerable variation from the mean value; hydraulic conductivity in the slightly weathered to fresh bedrock zone averaged near 10^{-6} cm/sec with a variation of approximately one order of magnitude.

Comparison of hydraulic conductivity values in the weathered and unweathered portions of the bedrock indicate that values in the unweathered bedrock are three orders of magnitude lower than the weathered bedrock. The results indicate that the bedrock is of variable hydraulic conductivity in the horizontal plane and generally becomes less permeable with depth, due to decreased weathering and associated solution activity (BNI, July 1987).

BNI developed some estimates of hydraulic gradients and average interstitial velocities (1987). Referring to Figure 1-16, a range of hydraulic gradients exists at the site from zero at the groundwater divide to approximately 0.05 near Frog Pond. BNI estimates an average interstitial groundwater velocity of 0.04 ft/day, with an effective porosity of 30%, and a low hydraulic conductivity of 8.9×10^{-5} cm/sec (1987). Walton (1985) presents effective porosity values for limestones ranging from 1% to 24%. Assuming the above aquifer parameters, and applying more

Use of the individual values in Table 8-1 gives slightly different statistics than presented.

realistic effective porosity values of 5%, 10% and 20%, interstitial velocities of 0.25, 0.13 and 0.06 feet per day respectively are estimated. Many components of the hydrogeologic model are to be refined, e.g., recharge areas, aquifer parameters, surface run-off, groundwater levels, geology, and geochemistry, and a fuller understanding of the regime will occur with the acquisition of additional data under this plan. Velocity estimates, however, are based on the assumptions that the aquifer behaves as an equivalent porous medium. Groundwater flow velocities along preferential flow paths, such as along larger fracture openings or along solution channels, could be much higher. With a definition of time of contaminant release, these data and calculations can be used to estimate and predict rate of contaminant movement. Conversely, with a definition of the contaminant plume and a knowledge of rate of contaminant migration, possible sources can be delineated.

Seasonal variations of groundwater elevation are apparent from an examination of available groundwater level measurements. Table 1-8 gives three sets of measurements for the uppermost aquifer, two taken by BNI in 1986 approximately four months apart (BNI, 1987) and one taken by MKF in early 1987 (MKF, 1987b). The locations of the monitor wells are shown in Figure 1-16. The measurements represent three different seasons. Wells GMW-7, GMW-8, GMW-12, GMW-13, B-3, B-17, and B-19A exhibited changes in groundwater elevations of almost 2 ft to more than 7 ft for the time period represented. There was no consistent trend in the changes throughout the area.

1.2.7.3 Groundwater Quality Aspects

Water quality of the different aquifer systems is discussed by Kleeschulte and Emmett (1986). Water from alluvial aquifers is predominantly a calcium bicarbonate type, typically with high hardness and iron concentrations. The total dissolved solids (TDS) concentration is variable.

Water quality of the shallow bedrock aquifer in St. Charles County varies from a calcium magnesium bicarbonate type to a sodium sulfate, bicarbonate, or chloride type. TDS and chloride concentrations increase from west to east. Large sulfate concentrations are limited to areas underlain by Pennsylvania shale, sandstone, and siltstone (Kleeschulte and Emmett, 1986).

The water quality of the deep bedrock aquifer varies with depth and lateral extent. Samples from the confining portion of the aquifer (the Maquoketa-Joachim sequence) have TDS values ranging from 305 to more than 4,700 mg/l. Water in the north and northeast portions of St. Charles County has high TDS and is a sodium chloride type, while water to the west is generally a calcium magnesium bicarbonate type. Water samples from the more permeable portion of the deep bedrock aquifer (the St. Peter-Gasconade sequence) had a TDS ranging from 252 to 915 mg/l. The eastern half of the county yields highly mineralized sodium chloride type water, while the western half yields moderately mineralized calcium magnesium bicarbonate type water (Kleeschulte and Emmett, 1986).

The dissolution potential of the bedrock underlying the site is variable as evidenced by the differences in solution features of the various bedrock units.

1.2.8 Contaminant Sources

Past operations and waste handling practices at the WSS have resulted in several potential sources for contamination of surface water, groundwater, and soil.

Fishel and Williams (1944) provided one of the first records of contamination sources. Their report stated that there were seven lagoons receiving wastewater from the Army's operation. At various times, wastewater was discharged directly into surface streams. There were also a number of catchment tanks receiving

wastewater from the production lines. These would apparently overflow into small gullies flowing into nearby streams.

Also, red water leaking from a waste storage lagoon located 100 yards east of Frog Pond reportedly re-surfaced at springs SP6303 and SP6501, known as the Francis Howell Cemetery Wet Weather Spring and the 500-foot contour spring, respectively (Fishel and Williams, 1944; Hoffman, 1988).

Ryckman, Edgerly, Tomlinson, and Associates (RETA, 1978) indicated that wastewaters containing sulfate derivatives from DOA operations are known to have contaminated Schote and Dardenne creeks. They further indicated that explosives production resulted in chemical contamination of structures, concrete foundations, soil, underground transport lines, and catch basins. Some of the processing equipment, buildings, appurtenances, and contaminated soil were removed prior to AEC construction activities at the site. During the AEC's operation, radiological contamination of five major process buildings, most of the support buildings, and terrain behind the plant resulted from equipment being operated beyond design capacity, limitations of raffinate disposal facilities, and poor onsite "housekeeping" activities. During the decontamination operation in 1968 for conversion of part of the facility (Buildings 103 and 105) to herbicide ("Agent Orange") production, barrels of concrete and debris were left near Raffinate Pit 4 and in the Ash Pond area. These barrels have rusted, are partially deteriorated and have spilled their contents on the ground (RETA, 1978).

MKF (1987b) reported some additional contaminant sources during their Water Quality Phase I Assessment Report (1987b). Nitroaromatics and residues were burned during decontamination efforts by the Army in 1946. MKF (1987b) described potential nitroaromatic source areas associated with the Ordnance Works which are shown in Figures 1-24 and 1-25. A former surface impoundment northwest of the Missouri Highway Department was used

SOURCE : MK-FERGUSON 1987

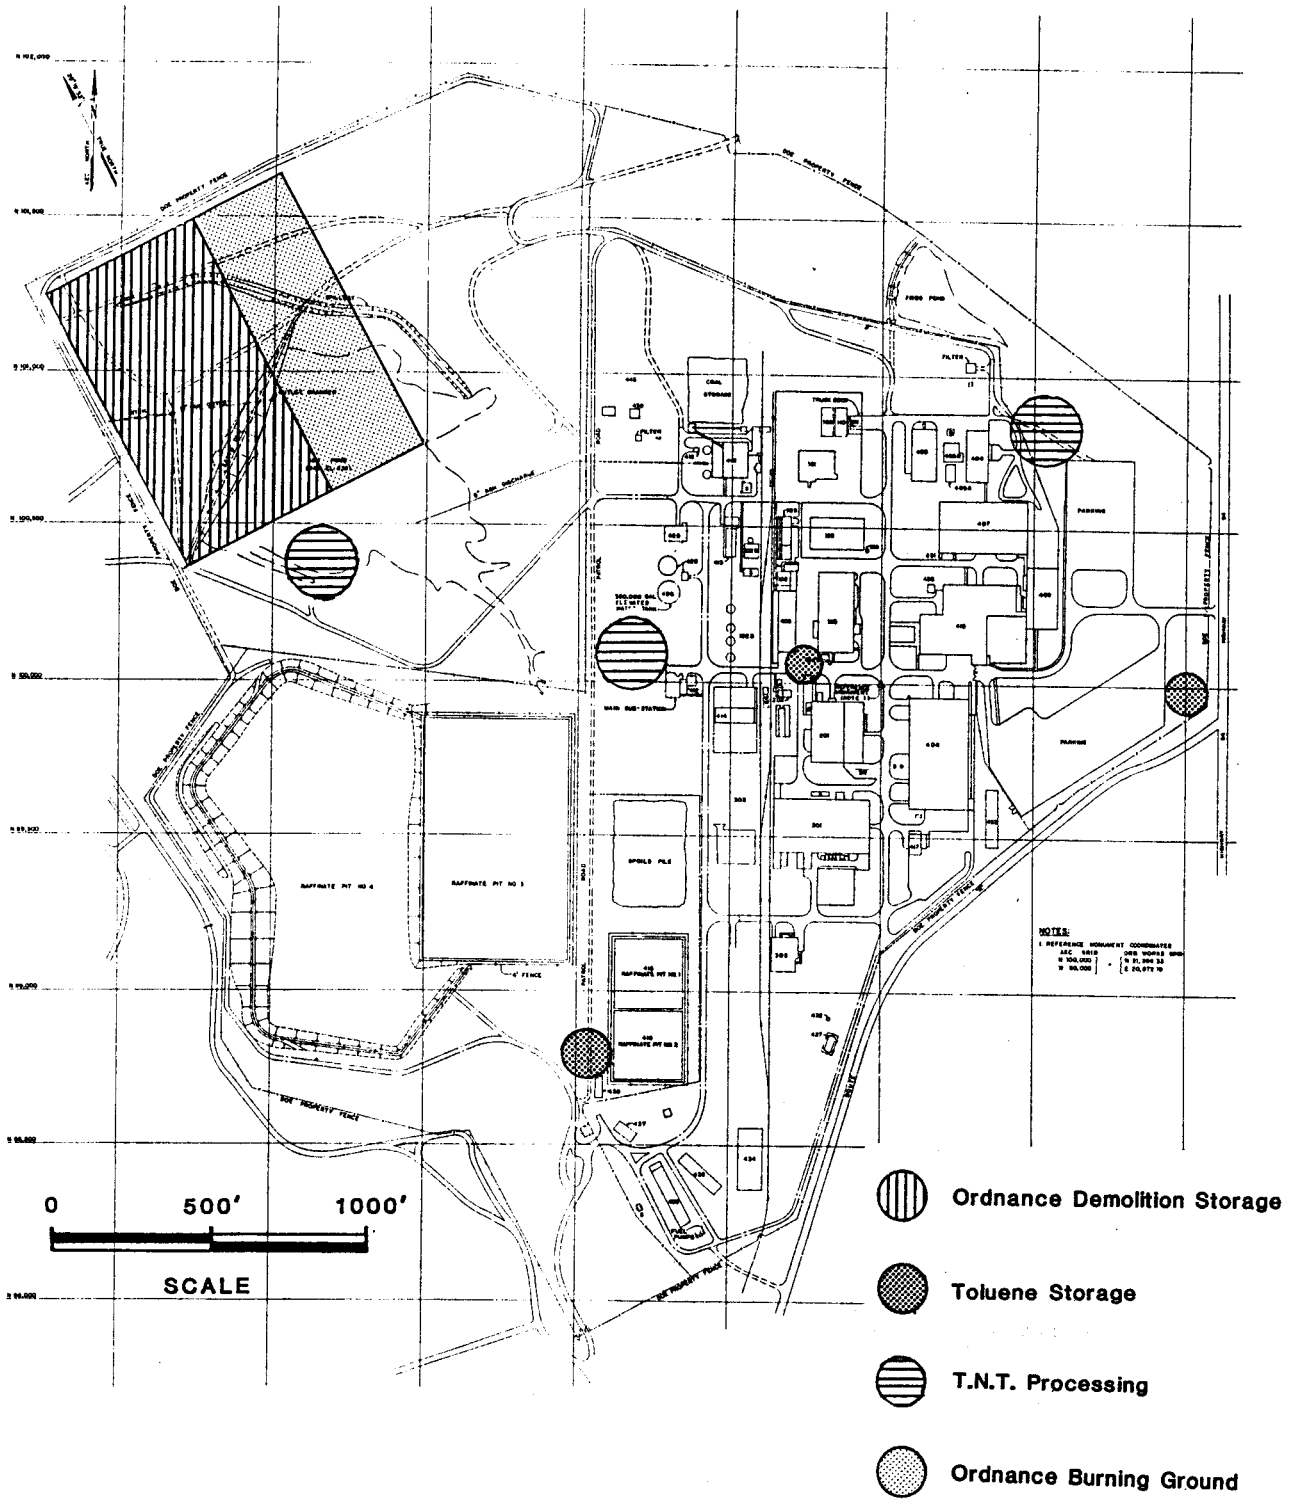

FIGURE 1-25

POTENTIAL CHEMICAL CONTAMINATION SOURCE AREAS ASSOCIATED WITH THE FORMER WELDON SPRING ORDNANCE WORKS

as a wastewater retention basin for the Weldon Spring Ordnance Works.

MKF (1987b) has also identified potential source areas for specific contaminants associated with radioactive materials processing. These are listed in Table 1-9 and illustrated in Figure 1-26. MKF also analyzed water quality in the raffinate pits. These results are shown in Tables 1-10 and 1-11. These data confirm that Pits 1 and 3 are potential nitrate sources while Pits 2 and 3 are potential sources of sulfate.

1.2.9 Potential Migration Pathways

The previous subsection has discussed potential contaminant sources. Whenever sufficient quantities of the contaminant are present, migration of some of the contaminant is likely. There are three general pathways that may be applicable at any site: air, surface, and subsurface.

Air migration pathways exist for the WSS and historically have played a role in transport of some contaminants, but documentation is limited. RETA (1978) reported that the air pathway is not a major route because there is no longer any active source of materials available for air transport. During the 1959-1965 period, environmental air sampling in the vicinity of the site indicated that the levels of uranium detected were typically less than 10% of the maximum permissible concentration (Mallinckrodt, 1959-1965).

Surface water probably was and is an important pathway for movement of contaminants from the site. The potential for distant migration of contamination via overland flow is minimal because of the generally gentle slopes. Migration via channelized flow over appreciable distances, however, is much more likely. A surface channel remnant exists through the Ash Pond area. There are also numerous relatively small drainage

channels that would tend to spread contaminants from their place of origin. Some of these drainage channels include pipelines for portions of their alignment. Section 1.2.3 briefly discussed other surface drainage features that could permit the migration of contaminants. These include the spillway for Ash Pond and the channels draining to the Southeast Drainage Easement, and channels draining to Frog Pond.

Potential subsurface migration pathways at WSS include: buried sewer and process pipelines, particularly those that have deteriorated; natural subsurface features such as relatively impervious layers that tend to impede the downward movement of water and therefore result in lateral spreading; permeable pathways that are relatively isolated but continuous laterally or vertically, such as solution channels, caverns, or joint-sets; and permeable media of a relatively continuous nature, such as permeable limestone with a combination of fractures, joints, and solution enlarged features. All of these subsurface pathways exist at the site, to some degree.

1.2.10 Contaminant Levels/Migration

Fishel and Williams (1944) presented historical accounts of observed contamination of surface and groundwater by TNT manufacturing wastes in the vicinity of the WSS. Later measurements of water quality parameters indicate contamination of the surface water and groundwater at the site and immediate vicinity. Numerous environmental monitoring reports have been produced over the years by Mallinckrodt Chemical Works (1959-1965), DOA (1977-1985), BNI (1983-1986), National Lead Company of Ohio (1981-1982), Shell Engineering (1983-1985), and MKF (1986). Other historical data are summarized in the Draft Environmental Impact Statement for remedial action at the site (DOE, 1987).

Kleeschulte and Emmett (1986) and Kleeschulte, et al (1986)

present 1984 and 1986 water quality data for the site and vicinity for groundwater and surface water. These analyses were for a limited set of parameters. Analytical results indicate elevated levels of calcium, magnesium, sodium, sulfate, nitrate, lithium, strontium, and uranium for wells near the raffinate pits with nitrate (as N) concentrations of 53 to 990 mg/l. Uranium concentrations for wells near the raffinate pits ranged from 6 to 86 ug/l. Surface water sample results showed elevated levels of TDS, nitrate, and uranium for the raffinate pits, Frog Pond tributary, and Burgermeister Spring (a spring located approximately 7000 ft north of Raffinate Pit 4).

Figure 1-27 illustrates the locations of existing monitoring wells. Well numbers, location coordinates (based on original AEC plant grid), depths, and other information are presented on Table 1-12. The 28 monitoring wells described include only those wells that are suitable for water level measurements and groundwater sampling; wells that are dry, damaged, or destroyed are excluded. Twenty-one wells are located in the raffinate pits and chemical plant area. Four wells are located outside the site boundaries in the Weldon Spring Training Area (WSTA) which is owned by the U.S. Department of the Army, and one well is located in the Weldon Spring Wildlife Area which is administered by the Missouri Department of Conservation. Monitoring wells with a 2000 series number are located within the chemical plant area; wells with a 3000 series number are located in the raffinate pits area, and wells with a 4000 series number are located outside of the site boundaries.

The wells were installed in 1983 and 1986 during hydrogeological studies by Bechtel National, Inc. (BNI). Six wells - MW-2020, MW-4002, MW-4003, MW-3007, MW-3008, MW-3009, and MW-3010 - penetrate from 21 to 76 feet of the saturated thickness of the Burlington-Keokuk aquifer. These six were constructed with 4-inch diameter PVC casing through the unconsolidated soil and an uncased open borehole in the bedrock. Although groundwater

NOTES: Static Water Levels measured 07/23/88 except as noted.

(1) Measured 06/07/88
(2) Measured 04/30/87
(3) Overburden Monitoring Well included in bedrock water level monitoring program.
(4) Wells MW 2001 through MW 2018 have one foot of blank casing below screen. Other wells are capped at base of screen.

Tabulated data are preliminary - based on partially validated data. New well designations established October 1986.

samples and water level measurements can be collected from these wells, they are not representative of discrete zones within the aquifer. It is not possible to determine vertical flow patterns or vertical distribution of contaminants from these wells.

Monitoring well MW-4006 was installed to a depth of 28.5 feet below ground surface. This well was constructed with a 2-inch PVC casing and has 0.040-inch opening factory slotted screens.

Nineteen wells (MW-2001 through MW-2015, MW-2017, MW-2018, MW-4019, and MW-4001) are screened in the upper, weathered portion of the Burlington/Keokuk Formation, penetrating from 12 to 37 feet of saturated thickness.

BNI sampled groundwater and raffinate pits water in September and October 1986 for chemical and radiological analyses. These data suggest leakage from the pits: groundwater analyses for wells upgrade of the raffinate pits are significantly different from sample analyses from the pits, while analyses from wells downgrade of the pits are of similar water quality (BNI, 1987). None of the previously mentioned data and reports contain sufficient information regarding sample collection, preservation and analytical methodologies to allow the presented data to be validated according to the data validation procedures in the QAPP. However, these data are useful as background information.

MKF presents the first comprehensive water quality assessment for groundwater and surface water systems at WSS and vicinity in the Phase I Water Quality Assessment (1987b). This assessment consisted of sampling 50 monitoring wells and 23 surface water locations. Groundwater samples were analyzed for the complete hazardous substance list, nitroaromatics, selected inorganic anions, water quality indicators, and radionuclides. Surface water samples were analyzed for radionuclides, selected inorganic anions, water quality indicators, and metals as listed on the EPA Contract Laboratory Program (CLP) list.

Conclusions from the Assessment (MKF, 1987b) include:

- Raffinate Pit 3 appears to be contributing nitrate and dissolved metals to the groundwater.
- Raffinate Pit 4 appears to be contributing sulfate to the groundwater.
- Nitroaromatics are present in groundwater at high concentrations (400 ppb total) under the northeast corner of the WSS.
- General low-level nitroaromatic contamination exists over most of the WSS.
- Three lakes on the Busch Wildlife Area receive radiological contamination from the site.

Nitrate concentrations in monitoring wells are shown in Table 1-13. Sample numbers correspond with monitoring well numbers. Nitrate isopleths are presented in Figure 1-28.

The apparent contamination source for the nitrate is Raffinate Pit 3. This conclusion was drawn by correlating metals (antimony, chromium, magnesium, and vanadium) and nitrate concentrations in Raffinate Pit 3 water and sludge with concentrations in monitoring wells. Concentrations of nitrate in the plume do not decrease gradually as would be expected, but decline rapidly between the northern edge of the raffinate pits and the northern site boundary. It is possible that this decline is due to a hydrogeologic discontinuity such as a series of solution-enlarged joints or fractures which intercept the plume. Elevated sulfate concentrations were detected in the western portion of the site, centered under Raffinate Pit 4 (see Table 1-13). Sulfate contamination may occur from water percolating through raffinate pit sludges, known to contain high

NOTE : NITRATE SHOWN AS NO3

concentrations of sulfur. Computer-generated sulfate isopleths are presented in Figure 1-29. Sulfate concentrations gradually decrease with distance from the source, also suggesting a different source from the nitrate contamination.

Figures 1-28 and 1-29 depict nitrate and sulfate contamination. These isopleths are computer generated, based on limited data, and shape configuration is governed by reading monitor wells in existence in March 1987. Other factors that may modify configuration include rock fracture orientation, gradient, the existence of perched groundwater zones, and the chemical, physical and biological processes in the vadose zone and aquifer. They present only a general representation of extent of contamination.

Nitroaromatics were detected at low ug/L concentrations in most monitoring wells sampled during the Phase I Assessment (see Table 1-14). Nitroaromatics were also observed at high concentrations in the northeast portion of the WSCP. The highest concentrations were present near the final production area of TNT Line No. 1, which is a potential source area. Another potential source is the former site of the Weldon Spring Ordnance Works wastewater lagoon, located just north of the site boundary and immediately west of the Missouri Highway Department's maintenance facility. Soil sampling performed in 1987 indicated nitroaromatic concentrations as high as 1% by weight in soil samples from the old waste lagoon.

Surface water sampling at and near the WSCP/WSRP confirmed earlier monitoring results which concluded that Busch Wildlife Area Lakes 34, 35, and 36 receive direct or indirect uranium-contaminated runoff from the WSCP/WSRP. No significant chemical contamination attributable to the WSCP/WSRP was observed in any surface water. Slightly elevated nitrate levels were observed in Burgermeister Spring which receives water from at least two losing streams draining the site.

Note: Nitroaromatics Analysis Following USATHAMA Method (HPLC)

Besides detecting the previously described contamination, the Phase I Water Quality Assessment established the absence of organic (other than nitroaromatics) and significant metals contamination in WSCP/WSRP groundwater. Due to limited organic compound usage in processes at the WSCP/WSRP, their absence in groundwater was expected.

The Phase I Water Quality Assessment detected groundwater contamination and has partially defined the horizontal extent. Additional investigations are required to define the horizontal and vertical extent of contamination, define aquifer properties, and establish chemical contamination source areas.

1.3 CONCEPTUAL MODEL

Data collected from prior and current sampling operations, including that presented in the Phase I Water Quality Assessment Report (MKF, 1987), have been subjected to QA/QC evaluation. Those data evaluated for adequacy and validity have been utilized, with the incorporation of available areal geological, hydrological, climatological and other information as presented in Section 1.2 of this report, to establish the physical and chemical characteristics of the site and used to construct a conceptual model to describe the WSS.

The hydrogeological components of this WSCP/WSRP model illustrate the following known and potential groundwater and surface water contaminants, their sources, known affected aquifers and surface impoundments, routes of migration, and potential receptors.

- Potential or known contaminants are:

    1) Radiological constituents, including radium-226, radium-228, thorium-230, thorium-232 and uranium.
    2) Inorganic anions including nitrates, sulfates, and fluoride

3) Nitroaromatics, primarily 2,6-DNT, 2,4-DNT, 2,4,6 TNT and 1,3,5 Trinitrobenzene.

- o Potential or known sources include the WSRP, WSCP, Ash Pond, Frog Pond, and drainage from the plant area and nearby properties. Source areas are depicted on Figures 1-24 to 1-26.
- o Potential affected aquifers are the fractured and solutioned limestones, other consolidated sediments, and unconsolidated sands and gravels deposited in stream valleys. These are depicted on Figure 1-30.
- o Potential migration routes include surface drainage ways from the site, pervious and semi-pervious zones in the unconsolidated overburden that mantles bedrock, and the fractured and solutioned limestone bedrock which underlies the WSS as depicted on Figures 1-10 to 1-13, 1-30, and 1-31.
- o Potential receptors include users of the Busch Wildlife Lakes, and the local streams, springs, and wells serving nearby farms, rural homes, schools, and local communities. (A detailed exposure evaluation will be presented in the RI/FS work plan.)

Significant preliminary conclusions can be interpreted from this model. They are:

1) A N-NE trending groundwater divide traverses the eastern third of the WSS. Groundwater flow is primarily northwest and southeast away from the divide toward the Mississippi and Missouri rivers, respectively.

2) Perched and mounded groundwater zones are present in the vicinity of the raffinate pits, which suggests leakage at these pits and variable horizontal and vertical hydraulic conductivities in the overburden materials.

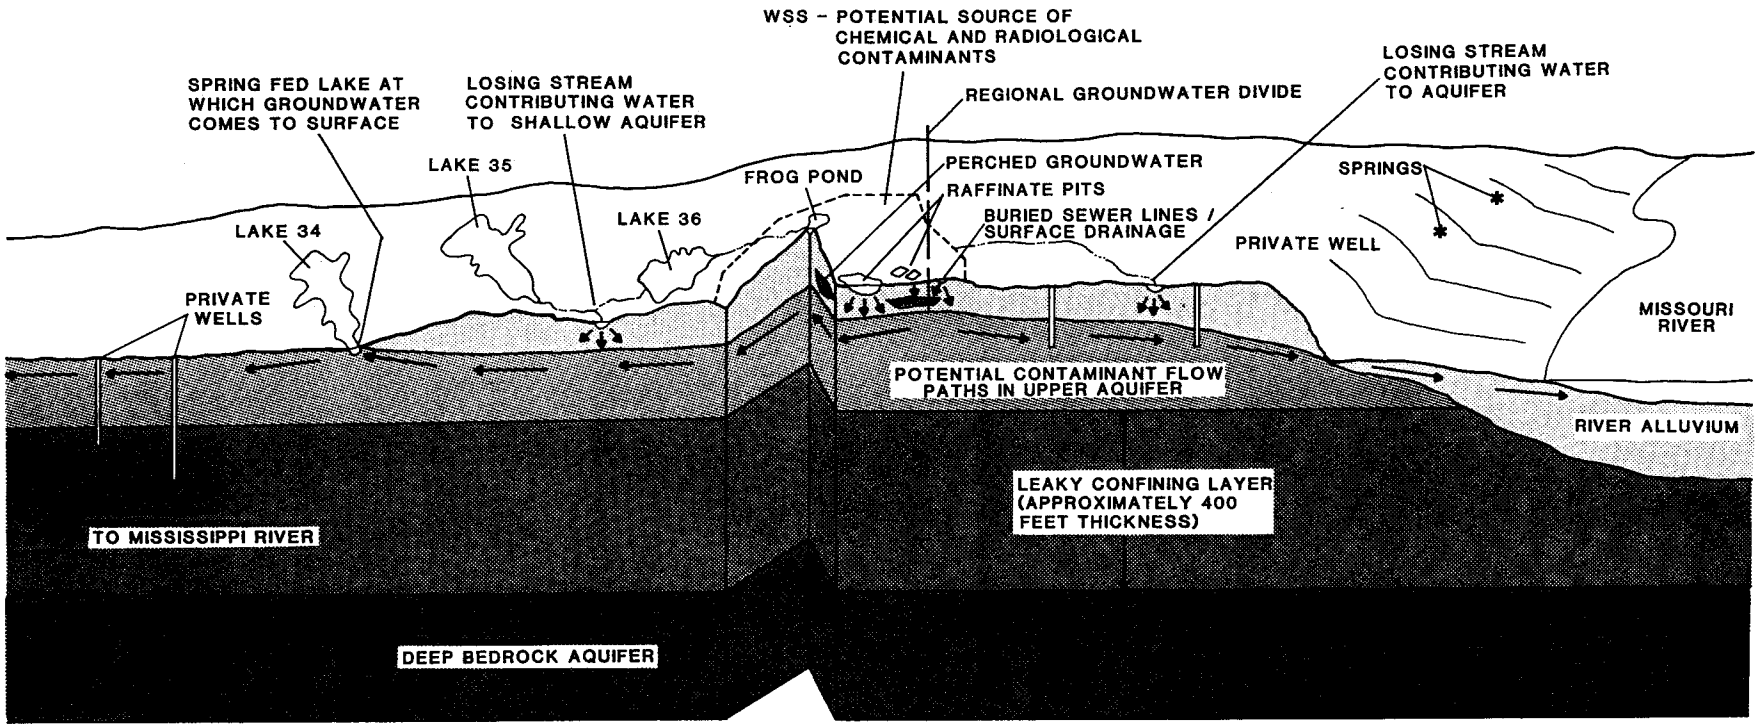

FIGURE 1-30

PRELIMINARY ILLUSTRATION FROM THE WSS OF POTENTIAL SUBSURFACE FLOW PATHS

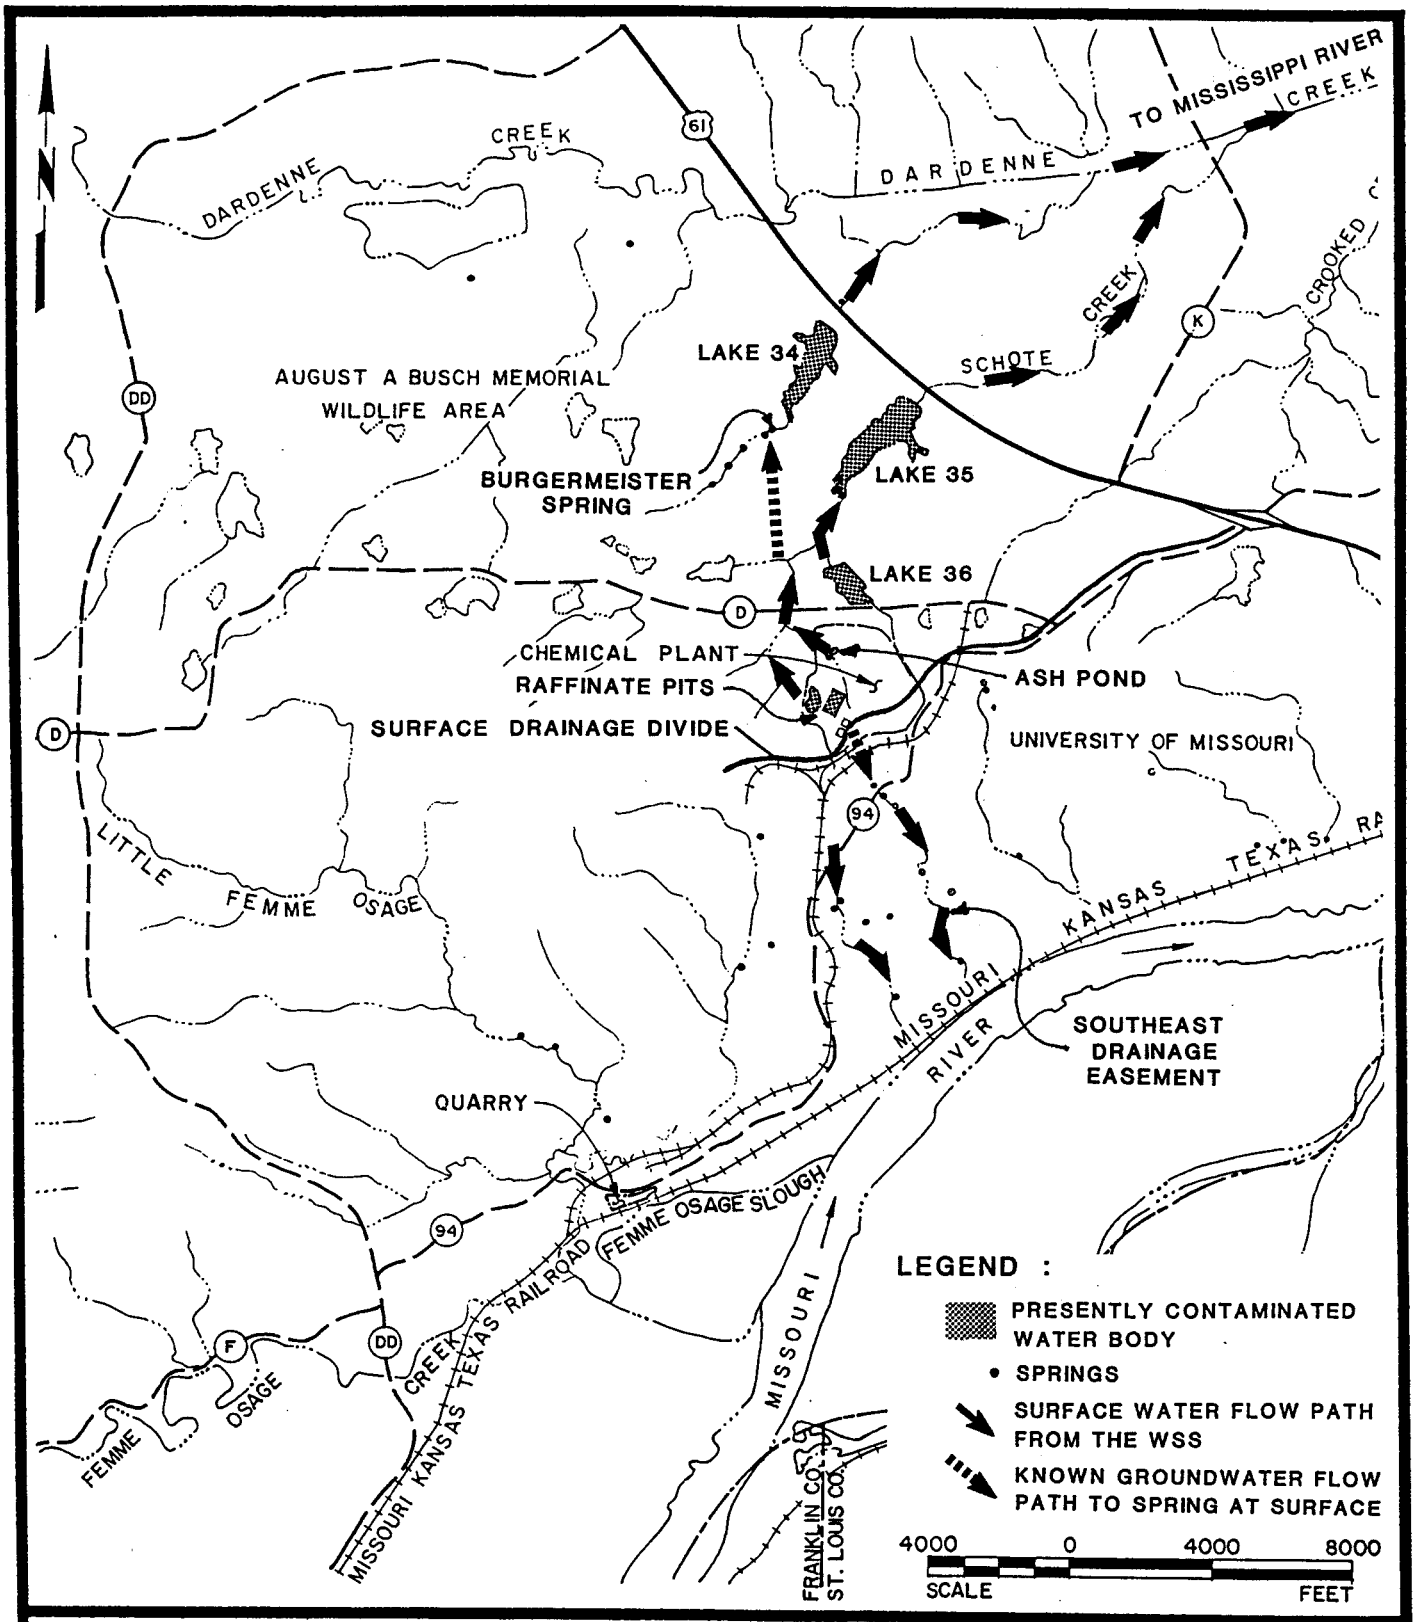

FIGURE 1-31

PRELIMINARY ILLUSTRATION OF POTENTIAL SURFACE FLOW PATHS FROM THE WSS

3) The raffinate pits appear to be contributing nitrates, sulfates, and dissolved metals to the groundwater. Nitrate contaminated groundwater is issuing from Burgermeister Spring, approximately 7000 feet north of Raffinate Pit 3, a possible source.

4) Nitroaromatics and radiological constituents are also present at Burgermeister Spring. The probable sources are surface waters from Ash Pond and other areas of the WSCP.

5) The major groundwater aquifer to be affected by contaminants and to allow contaminant transport is the upper weathered and fractured zone of the Burlington/Keokuk Formation.

6) Vertical migration of contaminants will be impeded by a thick sequence of sedimentary rocks, classified by the USGS (1986) as a leaky confining bed of low hydraulic conductivity. These rocks, including the Kimmswick Limestone, shales in the Decorah Formation, and underlying Ordovician siltstone, limestones and dolomites, would tend to preclude contamination of deep productive aquifers, e.g. St. Peter Sandstone.

7) Surface water pathways and storm sewers present at the site (e.g. Southeast Drainage Easement; Frog Pond and Ash Pond spillways and appurtenances) contribute contaminants to groundwater and surface waters (e.g. Busch Wildlife Lakes).

8) Overburden, or unconsolidated materials, mantles WSS bedrock units. It ranges in thickness from 20 to more than 55 feet and has variable chemical and physical characteristics. Those gravelly clay and silt materials at the overburden-bedrock contact are classified as residuum and are the result of bedrock weathering and erosion.

9) Surface water features displaying hydraulic connection to groundwater contaminant migration pathways are Burgermeister Spring, Busch Wildlife Lakes No. 34, 35, and 36, the Southeast Drainage Easement and associated springs.

The preliminary conceptual model of the site has utilized the hydrogeologic data obtained from previous sampling operations. Data obtained from future sampling activities described in this plan (Section 2.0) will be incorporated into the conceptual model which, upon refinement, will allow for a better definition of site conditions. This refined conceptual model and more sophisticated computer models more thoroughly portray:

- The physical characteristics of the site, i.e. the environmental setting, surface features, hydrology, geology, meteorology, overburden and aquifer parameters, contaminant pathways, and other factors related to the hydrogeologic regime.

- The source of contaminants and the chemical and physical characteristics of that source.

- The nature and extent (horizontal and vertical) of contamination. This is established after an analysis of physical, chemical, and source studies described above and includes analysis with the use of computer models. Additional data relating to contaminant release times and rate of migration will be incorporated into these models.

1.4 DATA USES/NEEDS

Previous sections of this Hydrogeologic Investigation Sampling Plan have described known existing conditions on the site and have partially defined areas or investigative categories where data are deficient. The EPA has provided guidelines and

requirements through the Data Quality Objective (DQO) process (Data Quality Objectives for Remedial Response Activities, 540/G-87/003, March 1987) and RI/FS guidance documents for the delineation of data uses and needs.

Analysis of existing data under the DQO process, as applied on the Weldon Spring Project, has provided for: 1) a limited physical and chemical characterization of the site; 2) the construction of a preliminary conceptual model; 3) the identification of data needs and uses; and 4) the initial scoping of additional sampling and data collection activities. A component of the process includes the identification of potential remedial technologies. At the WSS there has been a preliminary delineation of possible hydrogeologic-related Expedited Response Actions (ERA's), e.g., construction of drainage dikes, design and construction of contaminated water treatment plants, and removal of possible contaminant sources. Selected ERA's have been submitted to EPA for approval as Interim Response Actions (IRA's).

General data use categories, such as risk assessment and remedial design, are presented in the DQO manuals. These categories are applicable for the Weldon Spring Project and previous investigations have provided information for the following RI/FS hydrogeologic or other related components: 1) site characterization; 2) health and safety; 3) risk assessment; 4) remedial alternatives evaluation and design (including expedited response actions); and 5) community relations plans. Additional data collection activities conducted at the WSS will provide information for the refinement or revision of the foregoing RI/FS use categories.

Section 2.0 describes sample collection and rationale for the various components of the program. Listed below are the data needs and rationale for correcting data deficiencies on the WSS, as follows:

- The surface hydrology of the site and vicinity has been partially defined. Additional data pertaining to possible contaminant transport mechanisms, source areas, stream recharge/discharge and pond storage capacity are needed to fully define the hydrogeological regime. Data gathered from this study will also be included as a component of the water balance study which will be incorporated into USGS computer models of the site.

- A review of the available climatologic data indicates site-specific climatologic data are lacking. Extension of this data base to include precipitation, temperature, evaporation, wind, and relative humidity will be needed for water balance and contaminant migration studies.

- The geologic investigation will further define the bedrock geology at the site and immediate vicinity for zones underlying the upper portion of the Burlington/Keokuk Formation. More data on the competency of the lower unit of the Burlington/Keokuk will be obtained. Site-specific data on underlying bedrock units are needed for definition of thicknesses, physical character, and potential migration pathways, including further definition of solution channels and impervious strata or zones. Specific lithologic data and potentiometric head data on Ordovician and Devonian formations underlying the Burlington/Keokuk Formation is needed to define direction of groundwater movement.

- The thickness of the overburden units is well defined. The physical properties affecting water and contaminant presence, movement, storage, and migration in the vadose zone require additional definition and verification. These data are needed for determination

of the effect of the overburden materials in immobilizing, attenuating, or slowing contaminant transport. Also, localized saturated contaminated lenses have been identified in the overburden in the raffinate pit area. Geophysical surveys have identified other potential contaminated zones. Additional data are needed to fully define the nature and extent of these zones.

- Two groundwater flow regimes are prevalent on the WSS, i.e. Darcian flow and conduit flow. Numerous studies have been completed within both groundwater flow regimes. Definitive modeling of groundwater flow and contaminant migration specific to each regime has not been completed. Aquifer parameters have not been defined. Hence, field tests are needed to provide hydraulic conductivity, transmissivity, storativity, and recharge/discharge data. For the conduit flow regime, specific site-related connections to several discharge points have been verified. A more thorough inventory of potential discharge points and verification of any additional site-related connections is needed. Refinement of the predictive models of the groundwater migration pathway will improve understanding of the impact of groundwater contamination and facilitate the endangerment assessment.

- The karst hydrogeology needs to be fully characterized. Seeps, springs, solution cavities, channels, and possible ancestral sink areas need to be defined as they are potential conduits for contaminant flow to nearby surface impoundments, e.g. Lake 36 on Busch Wildlife Area, and to springs.

- Several groundwater contaminant plumes have been identified beneath and in the vicinity of the site. Refinement and definition of the lateral and vertical extent of these plumes is needed. Data are lacking to confirm which nearby areas are not affected.

- The Water Quality Phase I Assessment Report (MKF Dec. 1987) recommends the acquisition of additional water quality data, including stream, lake, and groundwater sampling and analyses. These data, coupled with soil and sediment analyses, are needed to fully characterize existing and potential contamination and contaminant transport and fate.

1.5 SAMPLING PLAN OVERVIEW

There are eight major tasks designed to acquire the needed data described above. They are:

- Extend network of monitoring wells in order to determine vertical and horizontal extent of groundwater contamination, the levels of contamination, and the hydrogeologic conditions at the WSS.

- Perform aquifer testing to: (1) provide area and depth data on aquifer characteristics, such as hydraulic conductivity, transmissivity, and storativity; (2) to provide information for prediction of long-term contaminant migration; and (3) assess effects of pumping the upper limestone aquifer.

- Study the karst hydrogeology by including dye tracing and stream flow studies to determine groundwater/surface water interactions and improve understanding of migration pathways and rates of flow.

- Study surface water hydrology and water quality to: (1) define potential surface migration pathways; (2) determine the possible extent of migration; (3) measure concentrations of contaminants in surface water; and (4) define the hydrologic characteristics associated with the surface water features.

- Characterize unsaturated zone to: (1) define chemical and physical characteristics of the media for classifying types and levels of contaminants; (2) estimate recharge to the groundwater system; and (3) define perched zones that may influence contaminant migration.

- Perform hydrogeologic and water balance studies to define: (1) regional groundwater levels; (2) groundwater fluctuations; (3) features that influence groundwater movement and surface water/groundwater interaction; and (4) groundwater chemistry relationships.

- Develop computer models of the groundwater flow and contaminant transport in order to predict future contamination migration and evaluate the effectiveness of possible mitigation measures.

- Perform evaluation analyses from the above tasks and previous studies in order to accomplish the sampling plan objectives described in this section.

2.0 HYDROGEOLOGIC SUBTASKS

Complementary hydrogeologic investigations will be conducted by the WSSRAP, MDNR and the USGS on a site-specific and regional basis. The WSSRAP program (described in Sections 2.1 through 2.5) will investigate surface and subsurface hydrogeologic conditions at the WSS. The USGS will investigate regional groundwater flow, water balance, and water chemistry (as summarized in Section 2.6). Although the investigations will be performed independently by WSSRAP and the USGS, the programs have been designed cooperatively to be consistent, so that information from each study can be utilized for incorporation into a consistent interpretive model.

2.1 GROUNDWATER MONITORING

Groundwater monitoring is part of an integrated program designed to characterize the hydrogeologic regime at the Weldon Spring Site (WSS) and its immediate vicinity. Other aspects of this program are discussed in subsequent sections. The groundwater monitoring efforts described in this section will focus on the bedrock aquifer in the Burlington-Keokuk Formation.

Groundwater monitoring for Remedial Investigation (RI) activities will include installation and sampling of new monitoring wells as well as continued monitoring of existing wells. These efforts are designed to more accurately define the extent and magnitude of groundwater contamination which was indicated by previous studies (MK-F, 1987).

In the first quarter of 1987, Weldon Spring Site Remedial Action Project (WSSRAP) initiated an Environmental Monitoring Program. This program is more comprehensive than previous monitoring programs. Water quality monitoring includes: (1) sampling of monitoring wells primarily near the site perimeter; (2) sampling of surface water bodies potentially affected by runoff from the

site; and (3) sampling of runoff under provisions of a NPDES permit.

A Phase I Water Quality Assessment conducted during March 1987 began assessing the overall quality of groundwater at the WSS. Results of the Phase I Water Quality Assessment indicated a plume of contaminated groundwater containing high nitrate and sulfate concentrations underlying the western half of the site and a plume containing high nitroaromatic concentrations in the northeast corner of the site. These results are discussed in detail in the Phase I Water Quality Assessment Report (December 1987) and summarized above in Section 1.2.10. Plans for additional groundwater monitoring, as discussed in the following sections, are based on results of the Phase I Water Quality Assessment and review and interpretation of other existing information.

2.1.1 Extended Monitoring Well Network

2.1.1.1 Existing Monitoring Wells

The existing monitoring wells described in this section will be retained to monitor water levels and groundwater contamination. Combined with the additional monitoring wells described in the following section, the existing wells will form an extended monitoring well network for determination of groundwater quality and flow parameters.

Locations of existing monitoring wells are illustrated on Figure 2-1. In order to provide a consistent identification system for existing and future monitoring wells, new 4-digit well numbers have been assigned to all existing wells. New and old well numbers, location coordinates (based on original AEC plant grid), depths, and other information are presented on Table 1-12. Monitoring wells to remain in service are listed on Table 2-1. The 26 monitoring wells to remain in service include only those

wells which are suitable for water level measurements and groundwater sampling; wells that are dry, damaged, or destroyed are excluded. Monitoring wells with a 2000 series number are located within the chemical plant area, wells with a 3000 series number are located in the raffinate pits area, and wells with a 4000 series number are located outside of the site boundaries.

Of the 29 wells that were sampled for the Phase I Assessment study, 28 are screened in the bedrock aquifer. Existing monitoring wells are included in the extended monitoring well network based on the following criteria:

- Complete lithologic log and construction details.
- Screened in the bedrock aquifer.
- Documentation of quality control/decontamination procedures.
- Factory-slotted PVC or wire-wound stainless steel screens (open borehole in bedrock with casing grouted through the unconsolidated soils is of limited use, but acceptable).
- Filter pack (sand or gravel) surrounding screen.
- Bentonite seal above the filter pack.
- Grout to surface.
- Locking protective casing.

Existing monitoring wells that will be included in the extended monitoring well network were installed in 1983 (seven wells) and 1986 (nineteen wells) during hydrogeological studies by Bechtel National, Inc. (BNI).

Six of the monitoring wells installed in 1983 were constructed with 4-inch diameter PVC casing through the unconsolidated soil and an uncased open borehole in the bedrock. The six wells include: MW-2020, MW-4002, MW-4003, MW-3008, MW-3009, and MW-3010. Although groundwater samples and water level measurements can be collected from these wells, these samples and

measurements are not representative of discrete zones within the aquifer. It is not possible to determine vertical flow patterns or vertical distribution of contaminants from these wells. Monitoring well MW-4006 was also installed in 1983 by BNI to a depth of 28.5 feet below ground level. This well was constructed with 2-inch PVC casing and has a 0.040-inch opening factory-slotted screen.

Monitoring wells MW-2001 thru MW-2015, MW-2017, MW-2018, MW-4019, and MW-4001 were installed in 1986 by BNI. These wells were constructed with 2-inch diameter, Type 316 L Schedule 40 stainless steel casing and .010-inch opening wire-wound screen. The wells are predominantly located in the upper, weathered portion of the Burlington-Keokuk Formation penetrating from 12 to 36 feet of saturated thickness.

Saturated overburden (perched and mounded conditions) will be addressed in Section 2.4, Overburden Hydrogeology; existing overburden wells are not included in the extended monitoring well network. Due to poor construction, two original wells (MW-2016 and MW-3007) were plugged and each was replaced with a two-well cluster.

Of the 26 remaining bedrock wells, 21 wells are located in the raffinate pits and chemical plant area, four wells are located outside the site boundaries in the Weldon Spring Training Area (WSTA) owned by the U.S. Department of the Army, and one well is located in the Weldon Spring Wildlife Area which is administered by the Missouri Department of Conservation.

2.1.1.2 Additional Monitoring Wells

Additional monitoring wells have recently been installed to further investigate the vertical and horizontal extent of groundwater contamination and characterize groundwater flow patterns. These wells are a component of the overall site

characterization program initiated in 1988. Well installation was scheduled to allow for early acquisition of additional data. These supplementary data, incorporated into hydrogeologic and other models, will also allow for the delineation of additional data needs. It should be noted that these monitoring and pumping wells have been designed and placed to monitor and test the Darcian flow regime beneath and near the site. Darcian flow occurs through the pores and fine fractures in the bedrock formation and is considered the transport mechanism for the contaminant plumes beneath and in the vicinity of the site. Conduit flow occurs through enlarged or preferential fractures and conduits and is considered to be the transport mechanism for the contaminants found in off-site springs and seeps. The conduit flow regime will be investigated through dye tracing studies and off-site spring, seep, and stream monitoring discussed in Section 2.3.

Locations and depths of additional monitoring wells to complete the extended monitoring-well network have been selected to accomplish several goals:

- Critical areas will be monitored for horizontal and vertical contaminant migration. These areas include known contaminated areas, areas downgradient from contaminated areas, and areas in which contaminant migration is not expected, to confirm that it is not occurring.

- Monitoring wells are located in a consistent horizontal and vertical network. Wells are evenly spaced horizontally, and at depths related to those nearby upgradient wells, as described below.

- Well installation and sampling can be accomplished within a reasonable period of time.

The additional wells include: (1) deep wells installed in clusters with existing wells where elevated concentrations of contaminants have been detected; and (2) wells installed downgradient of the farthest documented extent of contaminant plumes to determine the horizontal extent of contamination.

Groundwater flow in the shallower, more highly weathered zones of the Burlington/Keokuk Formation is likely to be predominantly horizontal, eventually discharging to nearby springs and streams. The existing monitoring wells and additional shallow wells will effectively monitor this zone. A portion of the flow could also migrate to deeper zones within the aquifer below the elevation of the known discharge points. The deep monitoring wells are installed to monitor deeper zones below the apparent flow paths to springs and streams.

Locations of additional monitoring wells are shown on Figure 2-2. Criteria for the location of these wells include:

- All individual wells and well clusters have been located within 500 to 1000 feet of two or more other well or well-cluster locations to effectively map groundwater flow patterns by comparing three or more water-level elevations.

- Deep monitoring wells are located adjacent to selected wells in which contaminant concentrations above U.S. EPA Drinking Water Standards were detected in Phase I Water Quality Assessment samples.

- Screened intervals of deep monitoring wells are set approximately 50 feet below the screened intervals of adjacent shallow wells.

- Shallow wells are located downgradient from existing wells and areas with significant groundwater

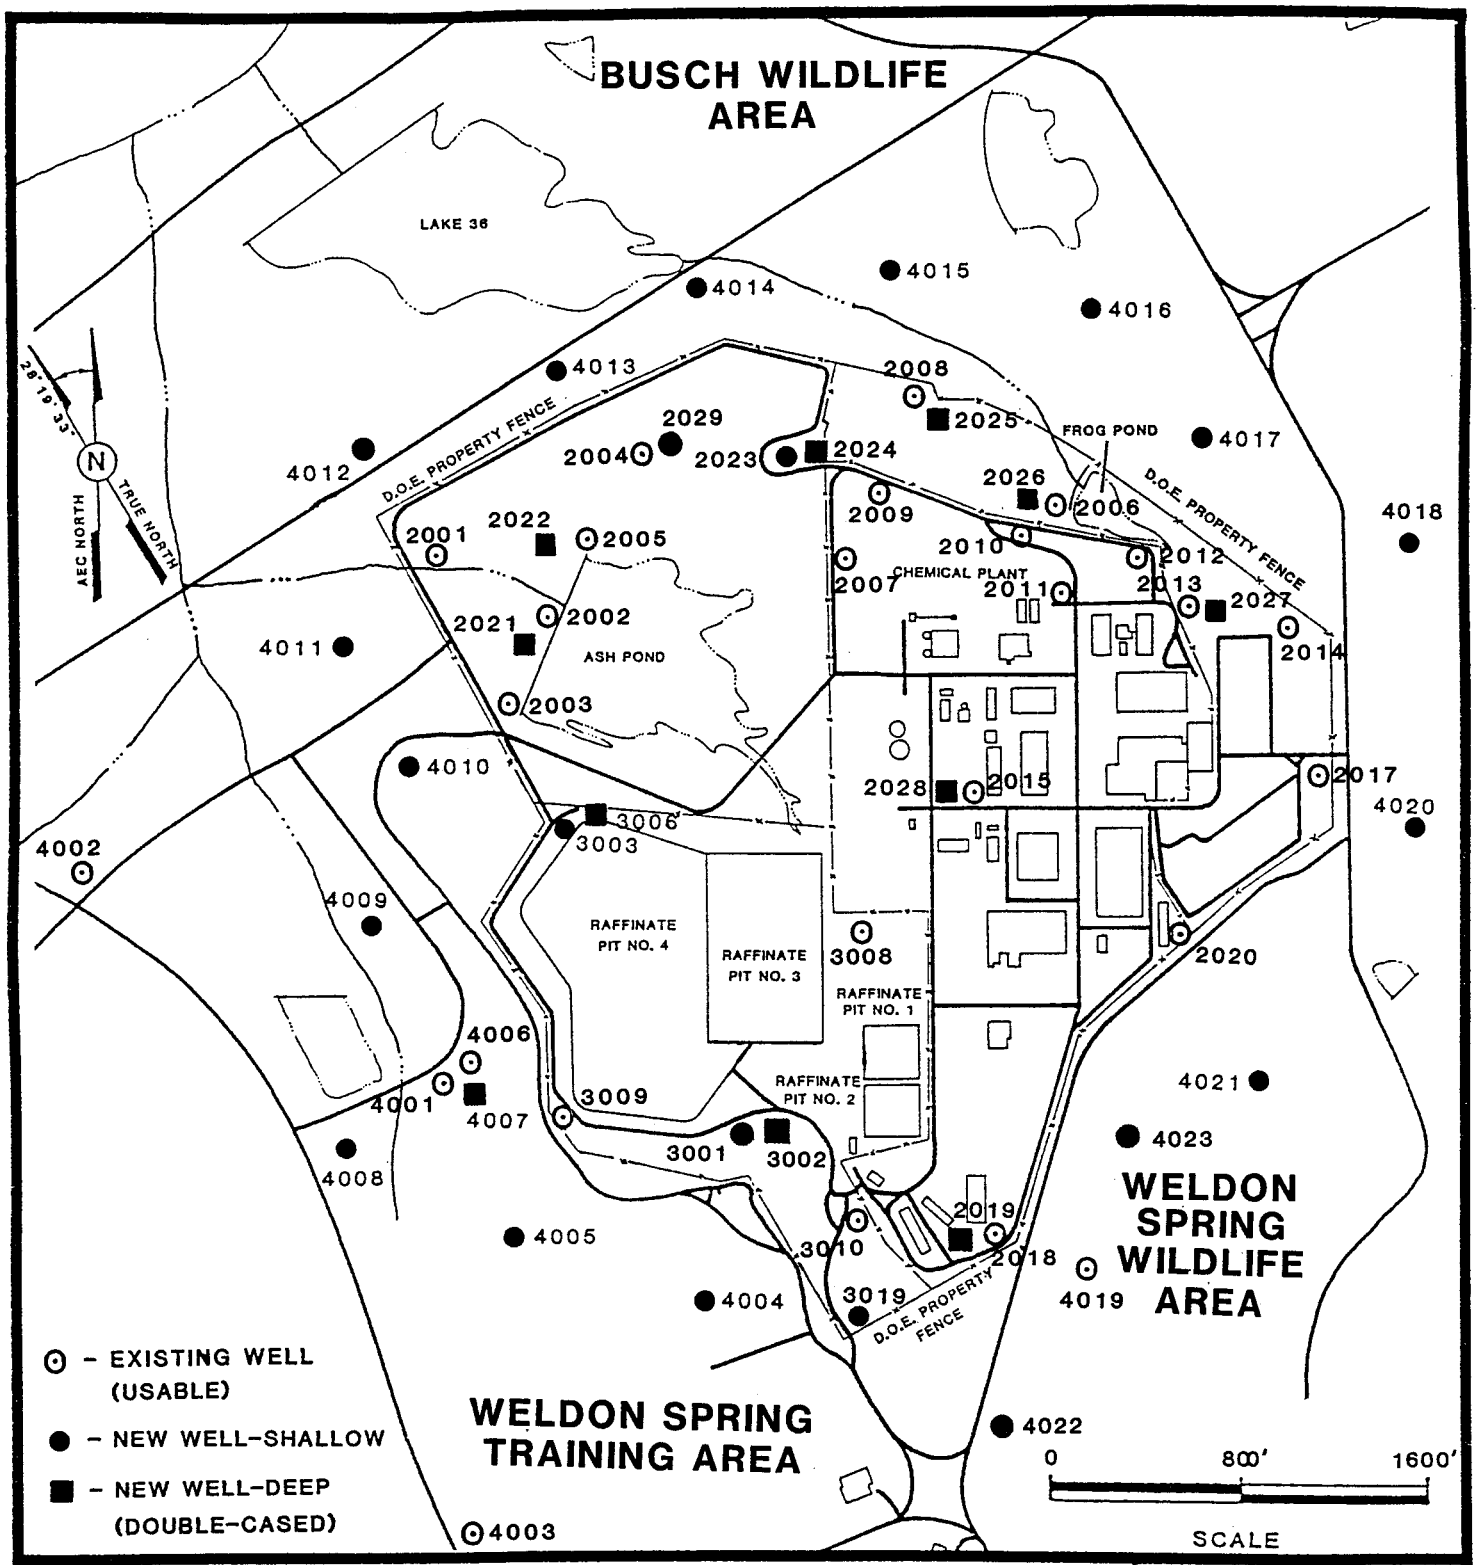

FIGURE 2-2

EXTENDED MONITORING WELL NETWORK

contamination.

- Screened intervals of shallow wells are set in permeable fractured zones of the bedrock aquifer as observed from downhole video surveys or as defined by an analysis of rock cores, water level data, and information obtained from nearby wells which have screened sections in permeable zones.

These criteria have been modified as necessary when selecting individual well locations and/or depths. A total of 33 new monitoring wells have been installed. This total includes 11 deep wells and 20 shallow wells. Rationale for well placement is presented in Table 2-2.

Two of the existing monitoring wells, MW-2016 and MW-3007 (Figure 2-1), have been plugged and replaced with two-well clusters. MW-3007 has an open borehole extending through approximately 54 feet of saturated thickness in the bedrock. The highest nitrate concentrations in the Phase I Water Quality Assessment were detected in this well. MW-2016 was constructed using 2-inch diameter PVC casing with a screen 7 feet in length and a filter pack 88 feet in length. This well is the deepest of the existing monitoring wells and also had a high nitrate concentration during the Phase I Water Quality Assessment. At each of these locations, it is critical to establish the depth of nitrate contamination and to measure the vertical gradients which could be producing downward migration of contaminants. The clustered replacement wells, each monitoring a discrete depth interval, will allow these determinations.

The locations of the additional monitoring wells placed downgradient from wells with known groundwater contamination have been selected anticipating that they will be beyond the extent of contaminant plumes. This selection was based on the known distribution of groundwater contamination and assuming Darcian

Table 2-2

ADDITIONAL MONITORING WELLS

LOCATIONS AND RATIONALE

WELL NUMBER	LOCATION	RATIONALE
MW-2019	Clustered with MW-2018 at southern end of site	Deep well to monitor vertical gradients and vertical extent of contamination detected in MW-2018
MW-2021	Clustered with MW-2002 to the north of Ash Pond	Deep well to monitor vertical gradients and vertical extent of contamination detected in MW-2002
MW-2022	Clustered with MW-2005 at northeast corner of Ash Pond	Deep well to monitor vertical gradients and vertical extent of contamination detected in MW-2005
MW-2023	Northern edge of site, midway between Frog Pond and Ash Pond; at location of MW-2016 (B-3)	Monitor contamination detected in MW-2016; MW-2016 will be replaced by 2-well cluster to monitor discrete shallow and deep intervals
MW-2024	Clustered with MW-2023 as described above	Deep well to monitor vertical gradients and vertical extent of contamination at this location
MW-2025	Clustered with MW-2008 on northeast edge of site	Deep well to monitor vertical gradients and vertical extent of contamination at this location
MW-2026	Clustered with MW-2006 on north side of Frog Pond	Deep well to monitor vertical gradients and vertical extent of nitroaromatic contamination detected in MW-2006
MW-2027	Clustered with MW-2013 approximately 500 feet south of Frog Pond	Deep well to monitor vertical gradients and vertical extent of nitroaromatic contamination detected in MW-2013
MW-2028	Clustered with MW-2015 near center of Chemical Plant Area	Deep well to provide vertical gradient data from center of monitoring well network near apparent groundwater flow divide; document presence or absence of contamination in deeper zones
MW-2029	Clustered with MW-2004 between Ash Pond and DOE Property Fence	Anomalously low nitrate concentrations detected in MW-2004, which penetrates only 18 feet of saturated thickness. MW-2029 installed to determine presence or absence of contamination at slightly greater depths, still within upper zone of aquifer

LOCATIONS AND RATIONALE

WELL NUMBER	LOCATION	RATIONALE
MW-3001	Southern end of Raffinate Pit 3	Detect potential contamination and monitor water levels in center of Raffinate Pits Area
MW-3002	Clustered with MW-3001 at southern end of Raffinate Pit 3	Deep well to provide vertical gradient data in center of Raffinate Pits Area; detect potential contamination in deeper zones
MW-3003	Northern end of Raffinate Pit 4, at location of MW-3007 (B-17)	Monitor contamination previously detected in MW-3007; MW-3008 has been replaced by 2-well cluster monitoring discrete shallow and deep intervals
MW-3006	Clustered with MW-3003 as described above	Deep well to monitor vertical gradients and vertical extent of contamination previously detected in MW-3007
MW-3019	Southern end of site, approximately 500 feet west of MW-2018/MW-2019 cluster, approximately 500 feet southwest of MW-3010	Detect contaminant migration from immediate vicinity of MW-3010; define contaminant levels and flow patterns near apparent groundwater flow divide
MW-4004	Southwest of site boundary along Raffinate Pits, approximately 600 feet west of MW-3010	Detect westward extent of contaminant migration in conjunction with other monitoring wells beyond southwestern edge of site
MW-4005	Southwest of site boundary along Raffinate Pits, approximately 500 feet southwest of MW-3009	Detect westward extent of contaminant migration in conjunction with other monitoring wells beyond southwestern edge of site
MW-4007	Clustered with MW-4001 west of Raffinate Pit 4	Deep well to monitor vertical gradients and vertical extent of contamination detected in MW-4001
MW-4008	Southwest of site boundary along Raffinate Pits; approximately 500 feet west of MW-4001/MW-4007 cluster	Detect westward extent of migration of contaminants detected in MW-4001

ADDITIONAL MONITORING WELLS

LOCATIONS AND RATIONALE

WELL NUMBER	LOCATION	RATIONALE
MW-4009	Beyond site boundary west of Raffinate Pits Area, approximately 800 feet north of MW-4001/MW4007 cluster	Detect westward extent of contaminant migration in conjunction with other monitoring wells
MW-4010	Beyond site boundary west of Ash Pond, approximately 600 feet northwest of MW-3003/MW-3006 cluster	Detect westward extent of contaminant migration in conjunction with other monitoring wells to west of site
MW-4011	Approximately 800 feet west-northwest of MW-2002/MW-2021 cluster	Monitor extent of contaminant migration in the upper part of Burlington-Keokuk aquifer from Raffinate Pits and Ash Pond area
MW-4012	Outside northern corner of site near Highway D	Detect northward extent of contaminant migration in conjunction with other downgradient wells
MW-4013	Near Highway D along northern edge of site, approximately 800 feet north-northwest of MW-2005/MW-2022 cluster	Detect northward extent of contaminant migration in conjunction with other downgradient wells
MW-4014	North of site boundary near Highway D and drainage from Frog Pond to Lake 36, approximately 800 feet north of MW-2023/MW-2024 cluster	Detect northward extent of contaminant migration in conjunction with other downgradient wells
MW-4015	North of site boundary and north of the drainage from Frog Pond to Lake 36, approximately 600 feet north of MW-2008/MW-2025 cluster	Detect north and northeastward extent of contaminant migration; possibly delineate eastern edge of contaminant plume
MW-4016	North of site boundary, approximately 1000 feet north of Frog Pond	Detect north and northeastward extent of contaminant migration from Frog Pond Area; possibly delineate eastern edge of contaminant plume

Table 2-2

ADDITIONAL MONITORING WELLS

LOCATIONS AND RATIONALE

WELL NUMBER	LOCATION	RATIONALE
MW-4017	North of site boundary, approximately 500 feet east-northeast of Frog Pond	Detect northeastward extent of contaminant migration from Frog Pond Area; detect contamination in immediate vicinity of former Ordnance Works waste impoundment
MW-4018	Beyond northeastern corner of site, on east side of Highway 94, approximately 800 feet east of MW-2013/MW-2027 cluster	Detect contaminant migration east and south from Frog Pond Area; further delineate groundwater flow divide
MW-4020	East of site boundary on east side of Highway 94, approximately 600 feet south-southeast of MW-2017	Detect potential contaminant migration to the southeast; define groundwater flow patterns and gradients southeast of site
MW-4021	Southeast of site boundary, approximately 1000 feet south of MW-2020, between site boundary and Highway 94	Detect potential contaminant migration to the southeast; define flow patterns and gradients southeast of site
MW-4022	Southeast of southern end of site, approximately 800 feet south of MW-2018/MW-2019 cluster, between site boundary and Highway 94	Detect potential migration to the southeast of contamination detected in MW-2018 and MW-3010; define groundwater flow patterns
MW-4023	East of southern end of site. Approximately 800 feet southwest of MW-4021.	Detect potential contaminant migration at the upper end of the southeast drainage. MW-2020, approximately 1000 feet north has yielded samples which indicate the presence of uranium in the groundwater

flow conditions in an equivalent porous medium. Small fractures were observed during downhole video surveys. No major fractures or conduits were observed.

Although it is anticipated that the additional wells will provide "negative documentation" serving to delineate the limits of contaminant plumes, it is possible that some of the additional wells may have elevated concentrations of contaminants. Such conditions could occur due to migration of a contaminant plume further than anticipated, or "breakthrough" of contaminants through zones of higher permeability. If such conditions occur, additional monitoring wells may be installed to monitor contaminant migration in the specific areas affected. Installation of additional downgradient wells is not warranted at this time. The areas of potential contaminant migration beyond the planned extended monitoring-well network cannot readily be predicted. The hydrogeologic regime beyond the extended monitoring-well network may vary from on-site conditions in regard to Darcian vs. conduit flow conditions, gradients, and flow patterns. This is of particular concern to the north of the site where artificial lakes in the Busch Wildlife Area may produce mounding effects and recharge from losing streams could alter flow patterns. The necessity for installation of additional downgradient wells will be evaluated following receipt of initial sampling results from the extended monitoring-well network.

Similar considerations apply to monitoring of vertical distribution of contaminants utilizing the clustered monitoring wells. The monitoring-well clusters installed as part of the extended monitoring-well network will provide information on vertical distribution of contaminants and vertical gradients. The actual vertical extent of contamination and vertical gradients producing downward migration can only be determined following initial sampling and water level measurements.

Following receipt of the sampling results, the necessity for any additional deep monitoring wells will be evaluated.

2.1.2 Well Installation

Monitoring well drilling, installation, and development was performed in accordance with accepted procedures as discussed in the U.S. EPA RCRA Technical Enforcement Guidance Document (1986). Standard Operating Procedures have been developed for WSSRAP based on EPA guidelines. A supervising geologist was present to document well drilling, installation, and development.

2.1.2.1 Decontamination

All drill bits, drill rods, casing, well logging and measurement equipment, and miscellaneous hand tools were decontaminated by hot steam-cleaning prior to use and between boreholes. Equipment damageable by steam cleaning, e.g., video cameras, was rinsed with potable water from on-site supplies. The entire drilling rig was decontaminated upon arrival on-site, and upon completion of drilling activities. Interior portions of equipment, such as pumps and hoses, which are not accessible for cleaning with a steam-cleaner were thoroughly cleaned and flushed with potable water.

Screen and casing was also decontaminated inside and out by steam-cleaning and wrapped or covered. The screen and casing was stored above ground to avoid contact with potentially contaminated soils prior to installation.

All surge blocks, bailers, and other development equipment were decontaminated by steam-cleaning before development begins at each well.

2.1.2.2 Drilling Methods

Drilling has been performed using rotary techniques or a combination of hollow-stem auger and rotary techniques. A supervising geologist has recorded a lithologic log for each borehole. When drilling through unconsolidated soils at new locations, split-spoon samples have been collected at intervals of 5 feet. All contaminated cuttings not sampled for laboratory analysis were collected and retained on the site. In drilling the boreholes for shallow monitoring wells, a 7-inch minimum diameter borehole was drilled to the bedrock surface. The bedrock was then cored to define weathered - unweathered limestone contact (generally less than 100 feet below ground surface). After completion of coring, the boreholes were reamed to a final diameter of 8.5 inches. Table 1-12 lists well location coordinates, elevation, depth, and other relevant well data. The shallow wells were screened in the upper, weathered portion of the Burlington/Keokuk Formation, as defined by an analysis of cores and down-hole video surveys.

The deep monitoring wells were double-cased through zones of known groundwater contamination to prevent contaminants from being transported downward during drilling and well installation. A 12-inch diameter borehole was drilled to a depth of at least 10 feet below the depth of the adjacent well. A 10-inch diameter steel outer casing was placed in the borehole and the annular space outside of the casing sealed with cement-bentonite grout to surface. The bottom of the casing was backfilled with at least four feet of grout which was allowed to set for a minimum of 72 hours before work continued. The drilling sequence of coring and reaming continued through this outer casing to a depth ranging from 108 to 150 feet. The deep wells were screened in the unweathered portion of the Burlington-Keokuk Formation.

2.1.2.3 Monitoring Well Construction

Monitoring wells were constructed using Type 316 stainless steel, threaded, flush-jointed screen and casing. Shallow wells (generally less than 100 feet deep) were constructed using 2-inch inside diameter (ID) screen and casing. Deep wells were constructed using 4-inch ID screen and casing to assure that pumps and other sampling and measuring devices can be readily lowered into and removed from the wells. Screen was of wire-wound construction with 0.010-inch slots. Screen length was 10 feet. Only non-hydrocarbon-based lubricants, such as silicon or Teflon, were permitted for use on pipe threads or drilling rods.

Continuous bedrock cores were collected from the top of bedrock to the total depth of the borehole in the shallow wells. In the deep wells, coring of the bedrock commenced at the base of the outer casing and continued for the total depth of the hole. This method of coring assured a detailed and accurate log of the bedrock at each monitoring-well location. When drilling through the interval that was cased off in the deep monitoring wells, grab samples of the drill cuttings were collected at intervals of five feet as drilling proceeds. Cores were inspected by a geologist for the presence of fractures and voids. Drilling rates, fractures, and voids detected by the driller were noted.

The core samples will be used to determine bedrock lithology, mineralogy, permeability, porosity, and evidence of bedrock contamination. Because lithologic logs were already available, coring was not done in the replacement wells (MW2023, MW2024, MW3006, and MW3003) that are adjacent to the wells that were abandoned (MW3007 and MW2016).

The screen and casing were lowered into the borehole using centralizers to insure that the casing was plumb and centered in the borehole. A filter pack of coarse (20-40 mesh) sand was

placed around the screen by tremie pipe to a point 2 to 4 feet above the top of the screen.

A bentonite pellet seal was placed above the filter pack. The minimum thickness was 3 feet of dry pellets. The pellets were allowed to set for at least one hour before work continued. The annular space was sealed to the frost level with cement/bentonite grout.

A steel protective casing was set in a 2.5-foot square concrete pad at ground surface. The protective casing has a gas vent installed and will be locked. The concrete pad has a minimum thickness of 6 inches and slopes away from the casing. Concrete extends down the borehole to the frost level. Three protective iron posts filled with concrete were installed approximately 3.5 feet from the protective casing and 120^{o} apart.

Well-construction details are illustrated on Figure 2-3. Further details on well installation were stipulated in the drilling specifications developed for the drilling subcontractors.

2.1.2.4 Well Development

Monitoring well development was completed in September 1988. Development techniques included downhole pumps (hand-operated or mechanically driven), bailers, and double-tube air-lift devices. Any equipment placed down the well was constructed of stainless steel, teflon, PVC, or tygon. No glues, solvents, pipe dope, or adhesive tapes have been used on any development equipment which is placed down a well. All air-lift devices utilized a separate air line and discharge line and are operated in such a manner that air cannot be injected into the filter pack or formation. The air lines have an in-line oil filter between the compressor or air tank and the air line entering the well.

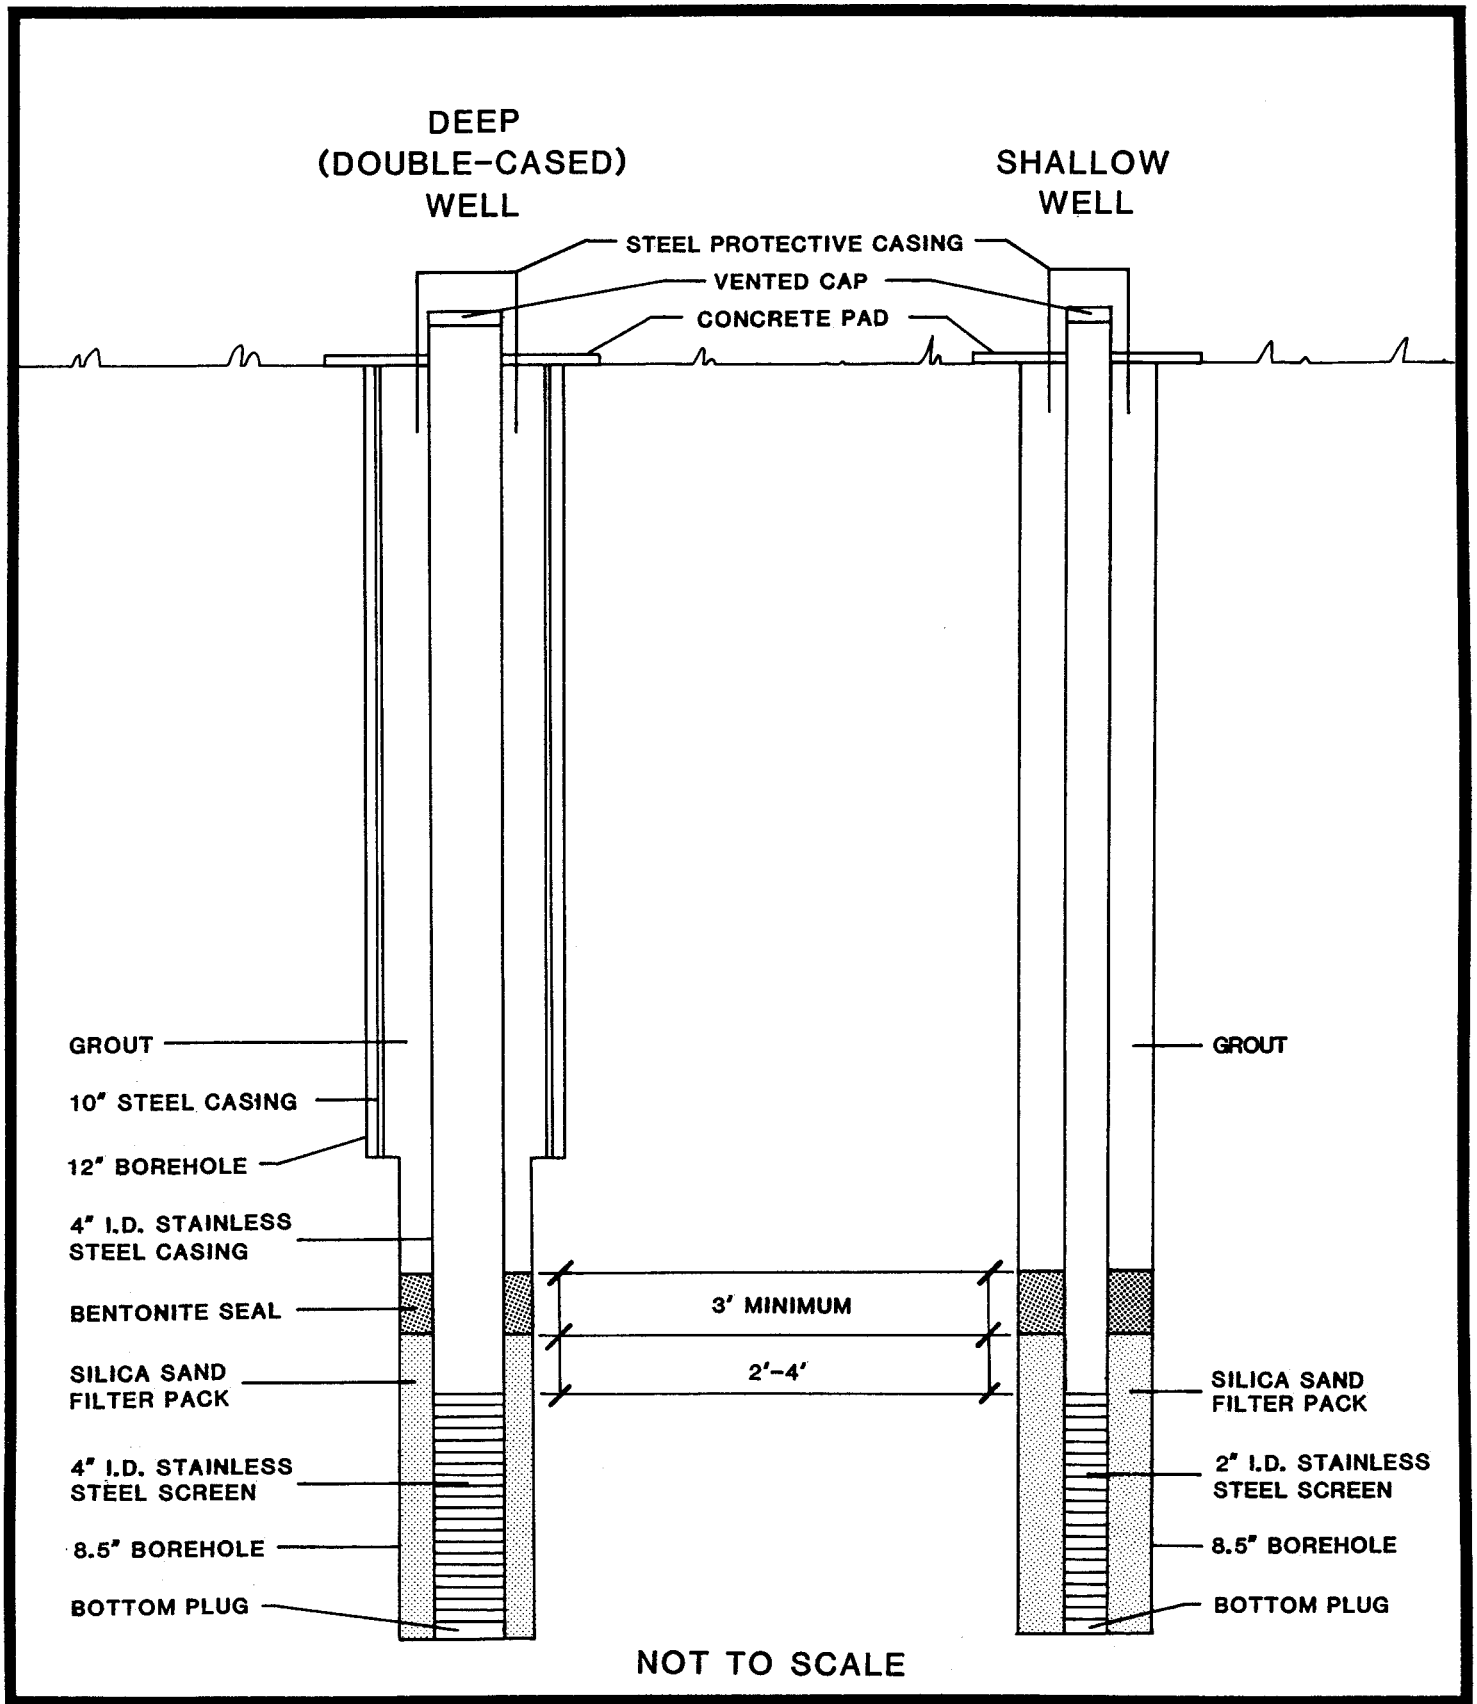

FIGURE 2-3

TYPICAL MONITORING WELL CONSTRUCTION

Each well was developed for a minimum of four hours or until clear, sediment-free water was produced as determined by the supervising hydrogeologist. The standard for clear, sediment-free water will be five Nephelometric Turbidity Units (NTU) determined by field or laboratory measurement. In all cases, a minimum of five volumes of standing water in the well and filter pack is being removed.

If water pumped from a monitoring well remains visibly turbid after five well volumes have been removed, measurements of pH, conductivity, and temperature were used to determine completeness of development. Three (3) additional volumes were then removed from each well. The pH, temperature, and conductivity were measured at the completion of removal of each well volume. For wells that were pumped or bailed dry and that recharge slowly, these measurements may be performed after completely purging the well after at least 50% recharge. Development was considered complete when three consecutive measurements showed conductivity to be stable within plus or minus 20%, pH stable within plus or minus 0.2 standard units, and temperature stable within 1 degree Celsius.

2.1.2.5 Abandonment of Wells and Boreholes

Any boreholes which were unsuitable for monitoring-well installation due to misalignment, contamination, lost drilling tools, or other reasons were abandoned by grouting.

Cement-bentonite grout was pumped into the borehole using a tremie pipe. The tremie pipe was placed initially at the bottom of the borehole and gradually raised as the borehole is grouted to the surface.

MW-2016 was abandoned by drilling out the PVC casing and filter pack using a four-inch minimum diameter roller bit. The borehole was then grouted to the surface as described above. The steel

protective casing was removed.

MW-3007, which consists of an open borehole in bedrock with four-inch diameter PVC casing through the overburden, was abandoned by grouting as described above. The steel protective casing was removed.

2.1.3 Groundwater Sampling

Groundwater sampling will be performed in conjunction with and will expand the quarterly monitoring program described in the 1987 Environmental Monitoring Program Plan. At present, quarterly sampling is primarily concerned with monitoring of existing wells at the site perimeter to detect off-site migration of contaminants. For the remedial investigation, groundwater sampling will include the entire extended monitoring-well network including existing and additional wells as described above. The purpose of the sampling is to further define: (1) horizontal and vertical extent of contamination; (2) potential sources; (3) migration pathways; and (4) potential future contaminant migration.

2.1.3.1 Sampling Techniques

WSSRAP has developed detailed procedures for groundwater sampling and sample handling to insure that samples are representative and analytical results are accurate and defensible. The WSSRAP Environmental, Safety, and Health SOP No. 4.04.01 describes sampling equipment and step-by-step procedures for groundwater sample collection. These procedures are summarized below; the complete SOP is in the WSSRAP procedures manual as referenced in the Quality Assurance Program Plan (QAPP).

Submersible bladder pumps will be used for well purging and sample collection. Dedicated bladder pumps are in place in 20 existing monitoring wells which are sampled quarterly as part of

the WSSRAP Environmental Monitoring Program. The pumps are constructed of stainless steel with Teflon bladders and Teflon lined discharge tubing. The new monitoring wells will be sampled using portable bladder pumps of similar construction which will be thoroughly decontaminated before reinstallation in monitoring wells.

Following two quarterly rounds of sampling from the extended monitoring-well network, additional dedicated bladder pumps will be installed, as appropriate, for future sampling operations. Five volumes of the well casing will be purged prior to sample collection. Field personnel will measure temperature, pH, and conductivity when beginning purging and immediately before sample collection. A SOP for each of these measurements is in the WSSRAP procedures manual as referenced in the QAPP. Samples will be collected in appropriate containers directly from the pump discharge. Samples will be placed in coolers immediately and will arrive at the laboratory within eight hours of collection. Groundwater sample labels, field forms, and chain-of-custody procedures are discussed in Section 3.3.

Internal quality control checks include checks on both laboratory and field activities. The QA/QC procedures for groundwater sampling have been developed in accordance with EPA protocols. Quality control samples for groundwater sampling will consist of duplicates, field blanks, and trip blanks.

Duplicate samples will be collected from 10 percent of the monitoring wells during each round of sampling. Duplicate samples will be collected and submitted for analysis at the same time as the original sample.

At least two field blanks will be collected during each round of groundwater sampling. These blanks will consist of distilled, deionized water pumped through the portable bladder pump, collected in the appropriate sample container, and submitted for

analysis. These blanks will confirm the effectiveness of decontamination procedures and the absence of cross-contamination in sampling procedures.

Trip blanks will consist of distilled, deionized water placed in sample containers in the on-site laboratory, sealed, and transported with the samples in the field and to the laboratory.

2.1.3.2 Sample Analysis

All groundwater samples will be picked up and preserved on a daily basis by the analytical laboratory, metaTRACE, Inc. The lab is located in St. Louis County, Missouri and is approximately 20 miles from the WSS. Where applicable, the analytical procedures employed by metaTRACE will conform to CLP Methodologies. The laboratory procedures manual contains the analytical methods that will be followed and their respective detection limits.

Table 2-3 contains a listing of the analytical parameters, sample containers supplied by the laboratory, and the preservation methods used by the laboratory. The analytical parameters were selected based on the constituents detected by the Phase I Water Quality Assessment (1987). The radiologic parameters, nitroaromatics, and inorganic anions were either present at elevated concentrations in groundwater samples from the Phase I Water Quality Assessment or are present at on-site source areas.

2.1.4 Groundwater Level Monitoring

Static water levels will be measured monthly in all of the wells in the extended monitoring-well network. The water level measurements will be taken in accordance with SOP No. 4.04.02 located in the WSSRAP procedures manual as referenced in the QAPP. Generally measurement accuracy is achieved to 0.01 foot. Potentiometric surface elevations will be calculated from the

TABLE 2-3

GROUNDWATER SAMPLE ANALYSIS AND PRESERVATION

Analytical Parameter	Sample Container	Sample Preservative Used by Lab
TOC	1-8 oz amber jug	HCL to pH <2.0 and refrigerated
Inorganics		
Nitrate Sulfate Fluoride Chloride Total Dissolved Solids	1-500 ml polyethylene plastic jug	refrigerated
Nitroaromatics		
2,4,6 trinitrotoluene 2,4 dinitrotoluene 2,6 dinitrotoluene 1,3,5 trinitrobenzene 1,3 dinitrobenzene Nitrobenzene	1 gallon amber jug	refrigerated
RAD Parameters		
Natural uranium (dissolved) Radium 226 Radium 228 Thorium 230 Thorium 232 Gross Alpha Gross Beta	1 gallon polyethylene plastic jug	HNO3 or HCL to pH <2.0 and refrigerated

static water level measurements. Representative potentiometric surface maps will be constructed to illustrate the groundwater flow patterns present on site. Through interpretation of the data a more accurate delineation of the groundwater divide and of specific horizontal groundwater flow directions will be possible as well as seasonal or temporal changes in flow patterns. Additional refinement of the current understanding of the on-site recharge and discharge dynamics of the upper bedrock aquifer is also anticipated. Gradients on the potentiometric surface combined with interpretation of vertical gradients measured in the clustered wells will provide information regarding the hydraulic gradients on site.

2.2 AQUIFER TESTING

Aquifer testing will consist of single-well hydraulic conductivity (permeability) tests, and pumping tests to define the hydraulic characteristics of the aquifer to aid in predicting contaminant migration and assessing groundwater remediation alternatives.

2.2.1 Single-Well Hydraulic Conductivity Tests

Single-well hydraulic conductivity tests ("slug tests") will be performed to provide information on areal variations in permeability within the Burlington-Keokuk Formation.

2.2.1.1 Test Design

Slug tests will be performed in each new monitoring well installed as described in Section 2.1. These tests will also be performed in selected existing monitoring wells to verify the results of packer tests performed during well installation. Existing monitoring wells selected for slug tests are:

MW2002	MW2013
MW2005	MW2015
MW2006	MW2018
MW2008	MW4001

Criteria for selecting monitoring wells for slug testing were: 1) availability of packer test data on original boreholes; 2) presence of recently completed monitoring wells in close proximity to original boreholes; and 3) screened intervals of original and newly installed wells. These wells provide an evenly spaced distribution for confirming the packer test results. In addition, deep monitoring wells to be installed adjacent to each of these wells will be tested, allowing for comparison of hydraulic conductivity values at varying depths.

Slug tests are performed by displacing, adding or removing a known volume of water within the well. The volume change is produced as close to instantaneously as possible, and the volume is controlled to a premeasured amount. Readings of water levels within the well during the test will be made using a pressure transducer and electronic data logger, which will permit measurements to be made at one-second intervals during the early part of the test.

Slug tests, analyzed with formulae derived by Cooper, Bredehoeft, and Papadopulos, Ferris and Knowles, and Skibitzke, provide the most valid information when conducted in confined aquifers. In unconfined aquifers the Bouwer and Rice or Hvorslev procedures are applicable. In all cases, assumptions for application of formulae and analysis of data are not satisfied in the unconfined, anisotropic, fractured finite aquifer present on site. Also, slug testing procedures are applicable in an equivalent porous medium and are not valid if solution cavities exist and conduit flow is prevalent. Hydraulic conductivity values (K) yielded by slug tests primarily reflect K in horizontal directions. Therefore, only representative,

approximate values are expected from slug tests on site.

Lohman (1979) suggests the applicability of slug testing in wells penetrating aquifers of rather low transmissivity, and presents a value of less than 7000 ft^2/day. At the Weldon Spring Site, an arbitrary upper hydraulic conductivity (K) limit for slug testing is considered to be on the order of 0.05 cm/sec. Formations with K values higher than 0.05 cm/sec will exhibit rapid recovery; hence, the acquisition of accurate recovery measurements is likely not feasible.

2.2.1.2 Test Performance

To begin the test, a pressure transducer will be installed in the well and static water level will be measured by wetted tape to calibrate pressure transducer readings. The water levels will be observed to ensure that the aquifer is under steady-state conditions. The volume change will take place within the well and water levels will then be measured as the well recovers to the static water level.

Slug tests will be performed by inserting a solid rod or similar object slightly smaller than the well diameter below the water level in the well in order to displace the water to a higher level. Water levels will be measured frequently as the water level falls to the original level. At this point the rod will be removed and water levels will be measured as the water level rises to the original level. The use of this test method allows for both falling head and rising head measurements. A tripod apparatus will be used to raise and lower the slug in the deep, 4-inch diameter monitoring wells.

Field measurements collected by the electronic data logger will be transferred to a computer data base. If warranted, after an analysis of data received from the slug tests, other tests such as borehole dilution and tracer tests may be deemed necessary to

define aquifer parameters.

Borehole dilution or point dilution tests may be applicable to estimate linear velocity in selected wells. This test can be performed in a segment of the well screen which is isolated by packers. A tracer is introduced which is diluted by lateral groundwater flow which mixes and removes the tracer from the well bore. Dilution versus time relationship is determined and the linear velocity is computed by analytical formulae (Freeze and Cherry, 1979).

2.2.1.3 Data Analysis

The data will be analyzed to determine a hydraulic conductivity value using a standard formula such as the Hvorslev method. The hydrologic formula will be chosen to fit the conditions in the aquifer and well being tested. A qualified hydrogeologist will determine conditions of the aquifer and well, the formulae to be used, and the data points for the hydraulic conductivity calculation.

2.2.2 Pumping Tests

Long-term pumping tests will be performed at three locations on-site in order to determine aquifer properties such as transmissivity and specific yield. Also, anisotropic aquifers are prevalent at the Weldon Spring Site. The size, shape, orientation and spacing of fractures and the presence of solution cavities affect the aquifer yield and drawdown by distortion of the distribution of flow. The distortion is related to the distance to the observation wells, aquifer thickness, the ratio of the horizontal thickness, and vertical hydraulic conductivities and to the degree of aquifer penetration by the pumping well. Theoretical methods for determining hydraulic conductivity values from analysis of pumping test data have been developed (Kruseman and Ridder 1976). The results of long-term

pumping tests will allow prediction of contaminant migration and assessment of the effects of pumping on groundwater flow patterns and contaminant levels. Pumping tests affect a much larger portion of the aquifer than the single-well tests and consequently yield more accurate hydraulic conductivity values. Transmissivity, specific yield, and anisotropy can be determined accurately only from pumping tests.

2.2.2.1 Pumping Test Design

Pumping tests have been designed based on the known characteristics of the Burlington-Keokuk Formation. The upper, weathered zone of the formation comprises an unconfined aquifer. Yields are expected to be relatively low, based on reported yields of 5-50 gallons per minute (gpm) for wells in this formation (USGS, 1986). Recently acquired data, on site, indicate well yield will be less than 10 gpm. Locations for pumping and observation wells are shown on Figure 2-4. The locations were selected to determine aquifer conditions in areas where contaminants have been detected in the groundwater and could potentially migrate off-site, and also at a location adjacent to the site proposed for the disposal facility for final remedial actions. Pumping Well 1 (PW-1) is located to the north of the apparent groundwater flow divide in the area where relatively high concentrations of nitroaromatic compounds were detected in groundwater samples. Pumping Well 2 (PW-2) is located adjacent to the proposed disposal facility near the southern end of the site. Results from the pumping tests at this location will allow for an assessment of aquifer conditions under this disposal cell site. The pumping and observation wells are located adjacent to, rather than within, the disposal cell area in order to minimize the number of wells and other boreholes within the disposal cell area that would need to be drilled out and grouted prior to disposal cell construction. Pumping Well 3 (PW-3) is located in the area where the highest nitrate concentrations were detected in groundwater samples from the

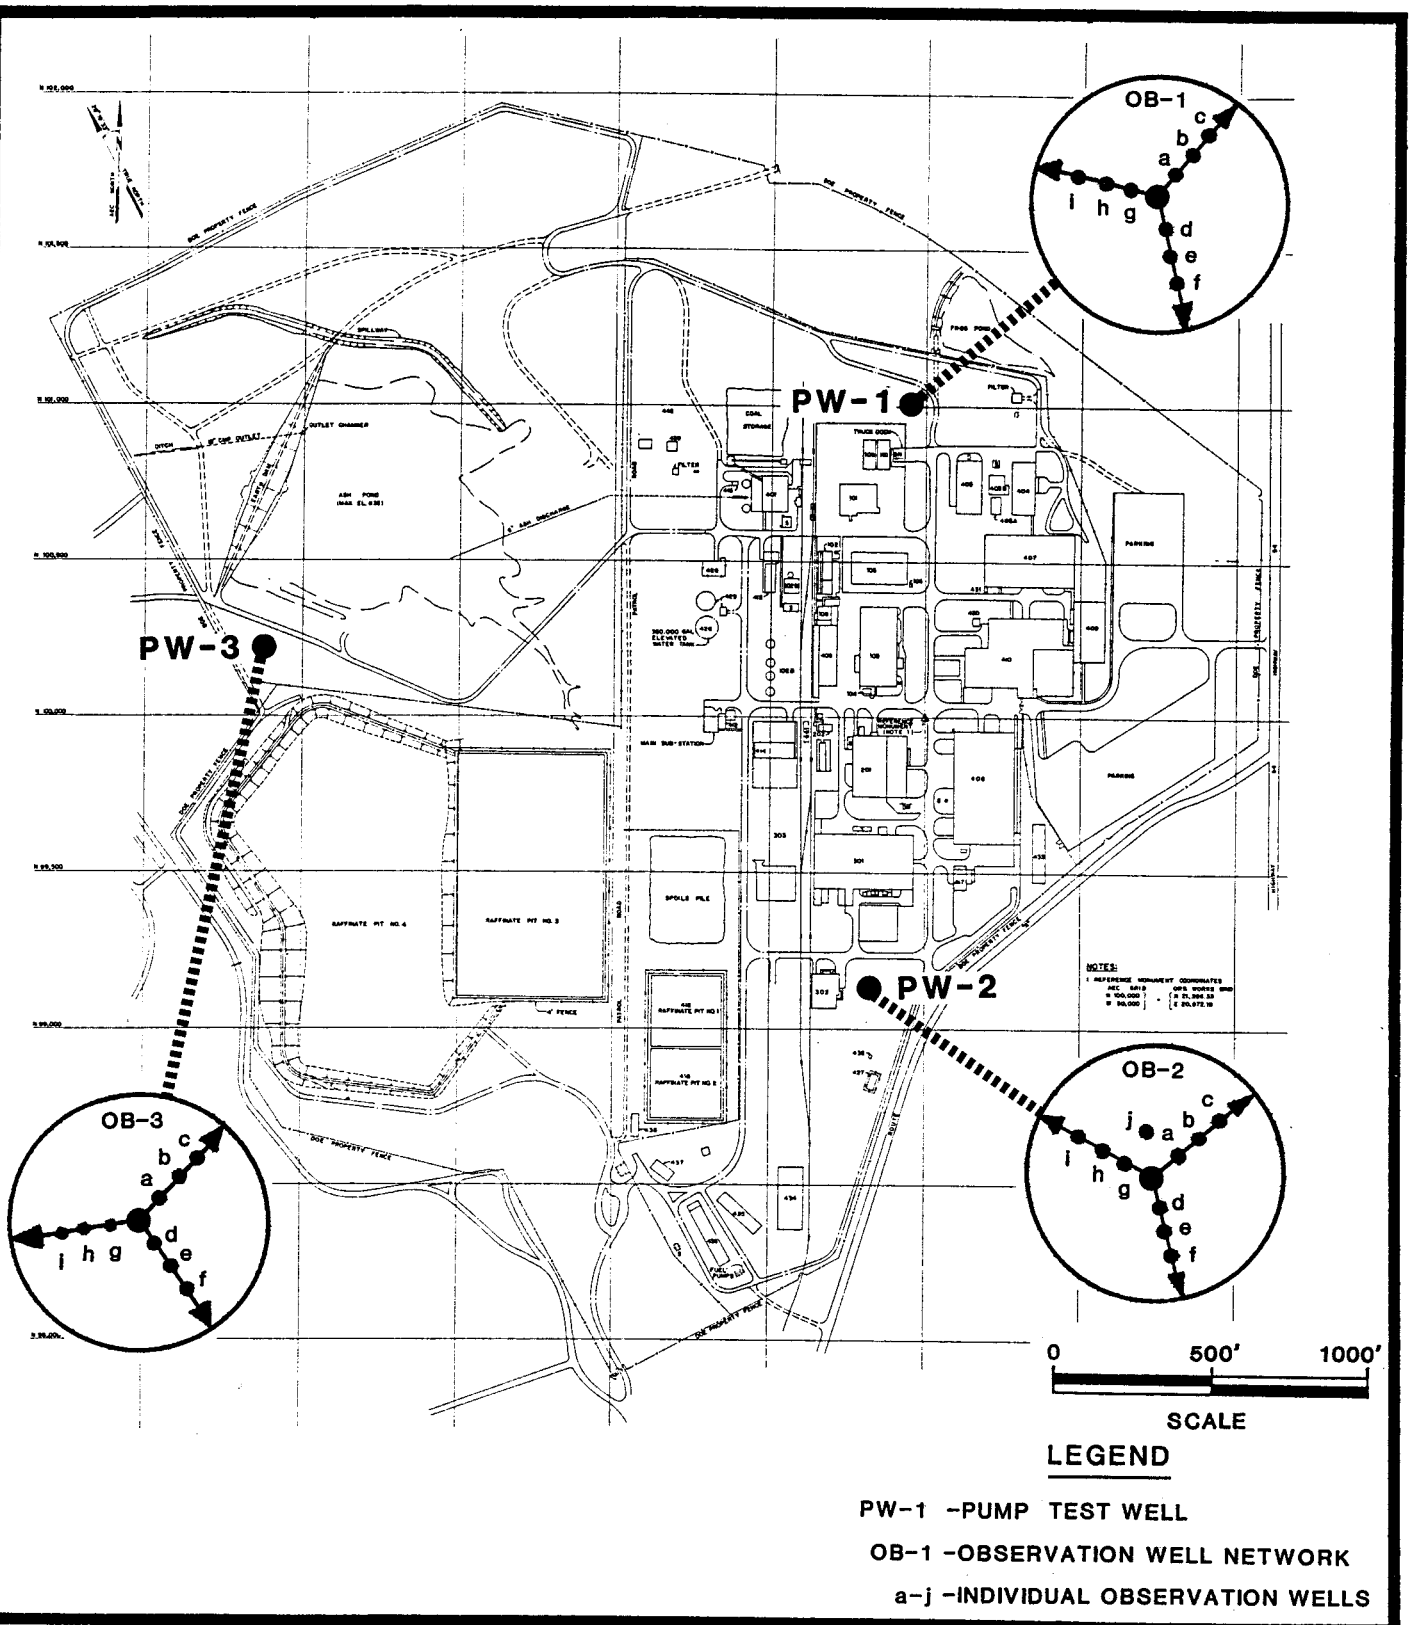

FIGURE 2-4

PUMPING AND OBSERVATION WELL LOCATIONS

Phase I Assessment.

The pumping wells are designed to be fully penetrating (continuously screened) through approximately 40 feet of saturated thickness of the Burlington-Keokuk Formation. This interval has been selected to encompass the weathered, more permeable zone in which groundwater contamination has been detected. This weathered zone will be defined from an analysis of cores and from observations by video survey. The test interval is limited to avoid providing vertical pathways through which contaminants could migrate into deeper zones in the aquifer when these wells are not being pumped. The fully screened interval will allow for the application of standardized techniques for pumping-test interpretation and calculations.

Each pumping test will utilize 9 or 10 observation wells oriented so as to determine the distribution of drawdown due to pumping of the aquifer. A set of nine observation wells, labeled "a" to "i" on Figure 2-4, have been completed at the same depth within the Burlington-Keokuk Formation, with the same screened interval as the pumping well. These wells are placed on three lines radiating from each pumping well with 120 degrees of arc between lines. One line is placed on a bearing of N60^{o}E, aligned with the predominant northeastward orientation of fractures in the Burlington-Keokuk Formation. The other two lines are located relative to this primary line. Following installation and development of the pumping well, a step-drawdown pumping test was performed to determine the optimum distance from the pumping well for placement of the observation wells and optimum pumping rate for long-term pumping tests. Water levels were measured in nearby monitoring wells during the step-drawdown test to allow for a modification of the observation well network configuration. Pumping rates will be relatively low and all observation wells are within 100 feet of the pumping well.

One additional observation well (designated "j" on Figure 2-4)

has been installed in a lower zone in the Burlington-Keokuk Formation at the PW-2 location. This well is placed approximately 40 feet north of the pumping well, equidistant from the shallow observation hole lines in order to prevent grout migration between wells. It is screened from 40 to 50 feet below the bottom of the pumping well. This well is double-cased and grouted to a depth below the weathered, fractured, upper aquifer, as defined by an analysis of core borings and video surveys in order to prevent transport of contaminants to lower zones during drilling operations and to avoid providing new, artificial vertical channels in the formation. Drawdown measurements in this well will allow for a determination of the degree of hydraulic connection between shallow and deeper zones in the Burlington-Keokuk Formation.

During the pumping tests, water levels will also be measured in monitoring wells within a radius of approximately 500 feet from the pumping well in order to observe any effects of pumping at greater distances.

The pumping tests will be 10 days (240 hours) in duration to allow for observation of delayed-yield effects, determination of specific yield, and observation of other effects of long-term pumping. Recovery measurements will continue until full recovery, or for a minimum of 24 hours under any circumstances. The duration of any individual pumping test may be modified by the project hydrogeologist as the test proceeds, based on drawdowns observed and determination of whether sufficient data has been collected. Water pumped from wells will be collected and stored on-site in Raffinate Pit 4 until remedial action activities commence.

The pumping tests have been designed primarily to assess aquifer properties of the upper, weathered zone of the Burlington-Keokuk Formation. The aquifer properties determined from these tests will be primarily applicable in assessing horizontal contaminant

migration in the upper zone. Drawdown measurements from the deeper observation well (j) will indicate the extent of hydraulic communication between shallow and deeper zones in the bedrock. This information, combined with single-well test results and groundwater sampling results, will permit an assessment of the extent and/or potential for downward migration of contaminants. If substantial vertical migration or potential migration is present, further aquifer testing of deeper zones may be necessary. Additional testing could include further pumping tests, single-well tests, and/or packer tests. The necessity for further testing, and the type, locations, and depths of testing will be determined from the results of pumping tests, single-well tests, and groundwater sampling.

Aquifer parameters obtained from pumping tests will be based on the assumption that the aquifer is an equivalent porous medium. Therefore, pumping tests and the accompanying monitoring program are not specifically designed to trace discrete fracture flow. If major vertical fractures or solution channels are encountered during drilling operations, specific analytical models may be used as both predictive and parameters-boundary evaluation tools under water-table conditions with these fractured rock systems. Tracer tests and point dilution tests may be applicable if conduit flow is indicated or suspected.

2.2.2.2 Pumping and Observation Well Installation

Drilling operations for pumping well installation have included hollow-stem auger boring and bedrock coring to provide an accurate lithologic log of the formation at each pumping test location, followed by reaming to the final diameter by air-rotary techniques. Split-spoon samples were collected at intervals of five feet during auger drilling in the unconsolidated soils. The bedrock was cored from the bedrock surface to the total depth of the well. The log was recorded by a supervising hydrogeologist.

The borehole was reamed to a final diameter of 10 inches. The well was constructed using 6-inch inside diameter (ID) Schedule 40 PVC screen and casing. Screen length is 40 feet, encompassing the entire saturated thickness penetrated by the pumping well. Screen slot size is 0.020 inch. A filter pack consisting of 6-20 mesh silica sand was emplaced through a tremie pipe to a point 2 to 4 feet above the top of the screen. A bentonite seal, a minimum of 3 feet thick, was emplaced above the filter pack, after which the annular space was grouted to the surface using a tremie pipe.

Observation wells were installed using air-rotary techniques to drill from the land surface to the total depth. The borehole diameter is 5.5 inches. Wells were constructed using 2-inch ID Schedule 40 PVC screen and casing. Screen length for the observation wells at equal depth with the pumping well is 40 feet; slot size is 0.020 inch. A filter pack was emplaced around the screen and the annular space sealed with bentonite and grouted to the surface as described above for the pumping well.

In drilling the borehole for the deep double-cased observation well, a 10-inch diameter borehole was drilled to a depth of 10 feet below the bottom of PW-2. A 6-inch ID PVC casing was placed in the borehole for the total depth. The annular space was grouted and a grout plug at least 4 feet thick was emplaced to seal the bottom of the borehole. Drilling operations continued after the grout had set for a minimum of 72 hours. The borehole was drilled to the final depth and diameter of 5.5 inches without coring. The observation well was then installed as described above. Typical construction for pumping and observation wells is illustrated on Figure 2-5.

After each pumping or observation well installation was complete and the grout had set for a minimum of 72 hours, each well was developed to produce clear, sediment-free water and to insure hydraulic communication between the well and formation for

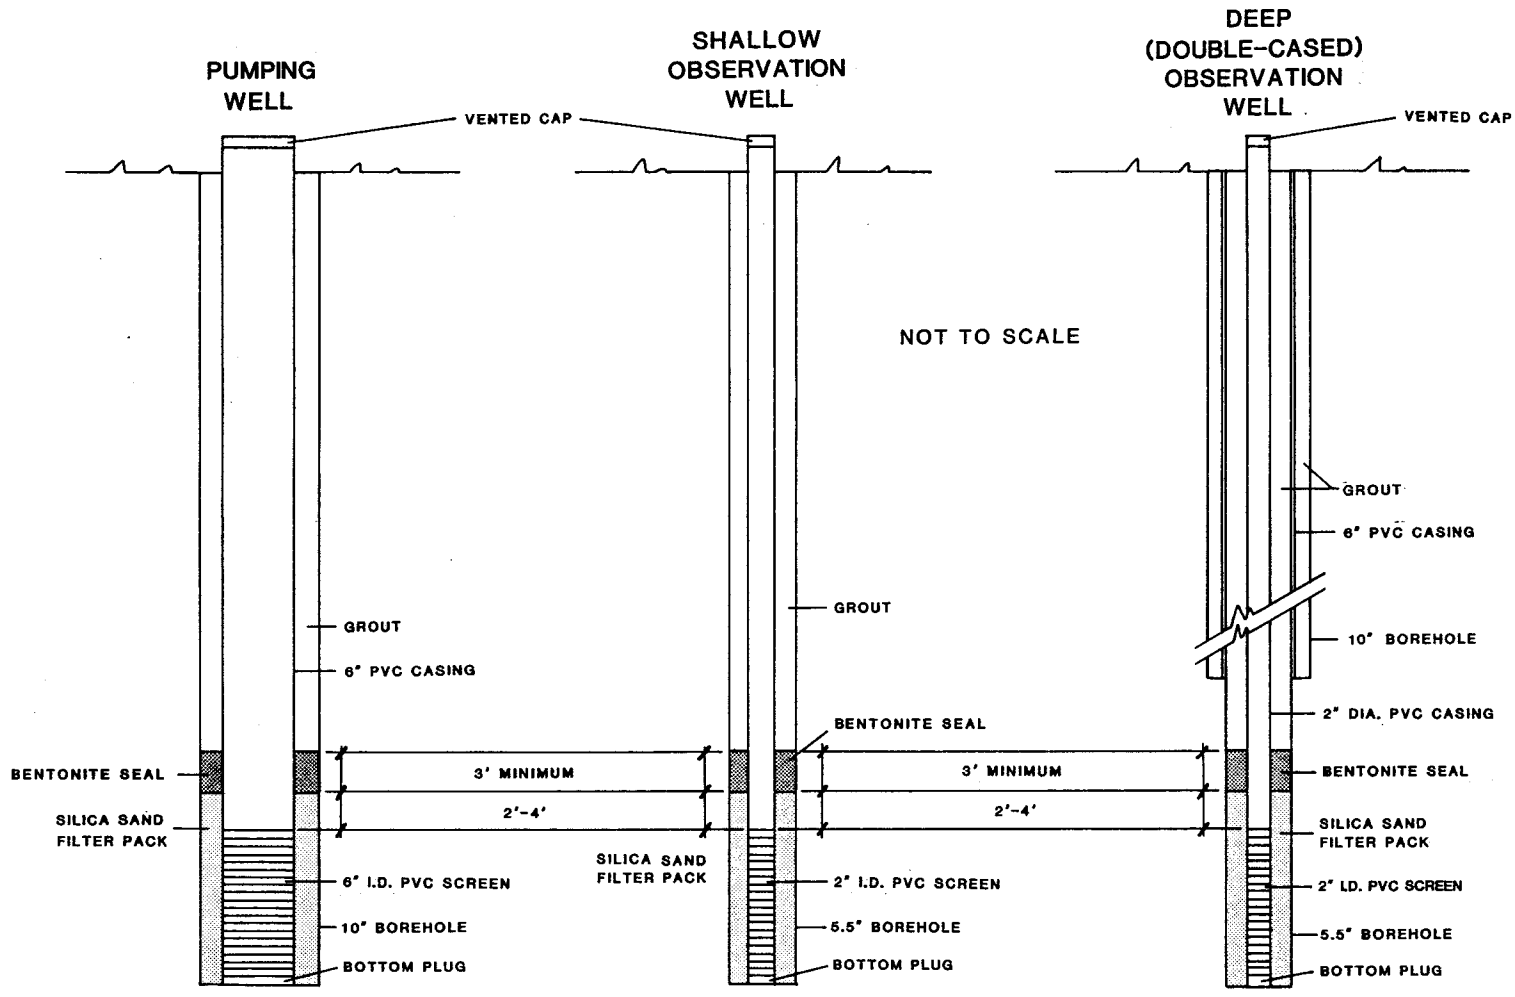

FIGURE 2-5

PUMPING AND OBSERVATION WELL CONSTRUCTION

accurate drawdown and recovery measurements.

Well development is accomplished by surging and pumping. Due to the low yield of the formation, potable water was added selectively to produce more rapid, complete surging of the filter pack. This water was pumped out immediately to avoid infiltration into the formation. The 5 NTU standard was applied as a goal for completion of development and the same decontamination procedures as used for monitoring well development were followed.

2.2.2.3 Pumping Test Performance

Electric submersible pumps will be used for the pumping tests. Discharge will be held at a constant rate through the use of a gate valve. Pumping rates less than 10 gpm will be measured with a calibrated container and stop watch. Flow measurements will be recorded hourly throughout the duration of the test. During pumping the well water will be discharged to a holding tank, after which it will be pumped and transported by tank truck or pipeline to Raffinate Pit 4. Water pumped from PW-1 will be discharged through a carbon adsorption unit to remove nitroaromatics prior to discharge to Raffinate Pit 4. All raffinate pit waters will be treated prior to discharge during remedial action.

Each pumping test will begin by recording static water level measurements in the pumping well, observation wells, and nearby monitoring wells including a minimum of one well outside the radius of influence. Static water levels will be monitored for at least 48 hours prior to beginning each pumping test to ensure that steady-state conditions are present. During pumping, water levels in the pumping well will be measured and recorded using a pressure transducer and electronic data logger. Water levels in observation and monitoring wells will be measured using an electrical water level indicator or wetted tapes. Multichannel

data loggers with pressure transducers in observation wells will be utilized as appropriate. Water level measurements will be recorded to the nearest 0.01 foot.

Water level measurements in the observation wells will be measured at logarithmic time intervals as pumping progresses, beginning with measurements at 1-minute intervals and increasing to 2-hour intervals after eight hours of pumping. Water levels in the pumping well will be recorded by the data logger at 1-second intervals initially, followed by a logarithmic increase in time intervals that will coincide with the observation well measurements after one hour of pumping.

After 240 hours of pumping, the pump will be shut off and recovery measurements will be collected as the aquifer recovers to the initial static water levels. Measurements will be collected during recovery at the same logarithmic time intervals used during the pumping period. Measurements will continue until all wells have recovered to the original static water levels. It is expected that the recovery period will be a minimum of 24 hours.

2.2.2.4 Data Analysis

The collected data will be analyzed to determine aquifer characteristics including hydraulic conductivity, storage parameters, anisotropy, and boundaries. Data analysis will begin by correcting the drawdown data recorded during the test for antecedent water level trends (as determined during monitoring of static water levels), partial penetration, residual drawdown (recovery data) and barometric pressure variations, and effect of precipitation events. Barometric pressure and other meteorological data are available from a National Oceanic and Atmospheric Administration (NOAA) meteorological station approximately 12 miles northeast of the WSS, the Spirit of St. Louis Airport (compiled and available upon request from National

Climatic Center, Asheville, NC) and from meteorological stations at Busch Wildlife Area Headquarters and at a utility plant approximately 10 miles to the southwest. The corrected data will be plotted for type curve analysis using methods such as those developed by Boulton and Neuman for unconfined aquifers. A qualified hydrogeologist will determine the appropriate hydrologic analyses to be performed.

In addition to calculating aquifer parameters from pumping test results, a qualitative analysis will estimate the degree to which the fractured bedrock responds to pumping as an equivalent porous medium. This will indicate the reliability of the calculated parameters. Recent publications on pumping tests in fractured bedrock will be consulted and applied as appropriate to both the quantitative and qualitative analyses.

Observation well configuration was intended to accommodate the anisotropic aquifer test analysis described by Papadopulos (1965) and Hantush and Thomas (1966). Also, Walton (1985) describes those analytical models useful in the analysis of fractured rock aquifer-test data. He presents formulae governing drawdowns with constant pumping which have been derived by Boulton and Streltsova, (1976, 1978). Recent publications pertaining to the analysis of pumping test data in fractured rock aquifers will be reviewed; and analytical models, structured to solve partial differential equations governing the flow of groundwater to wells, will be applied to evaluate data and define aquifer parameters. Neuman, at a recent (1987) NWWA symposium, described and distributed recent publications pertaining to flow in fractured rocks which may prove applicable to analysis of data obtained at the site.

The combination of quantitative and qualitative analyses will allow pumping test results to be used in conjunction with groundwater monitoring data to predict contaminant migration, and also to predict the effects of future pumping on groundwater flow

patterns and contaminant concentrations.

2.3 KARST HYDROGEOLOGY

Studies of karst hydrogeology related to the WSS will be performed by the Missouri Department of Natural Resources (MDNR)--Division of Geology and Land Survey in cooperation with WSSRAP staff. MDNR efforts will focus on conduit flow from the site to local springs, both from the aquifer immediately underlying the site and from losing stream reaches draining the site. WSSRAP efforts will include sampling of springs under varying climatic conditions to determine the presence and magnitude of contaminant migration through conduit flow.

2.3.1 Flow Studies

This investigation will be divided into three phases. The most intensive efforts will occur during Phase I; Phases II and III will refine the initial findings and will aid the design of long-term monitoring and remediation programs. The conclusion of the first two phases will be followed by interim reports which will present the basic data and interpretations, including refinements of the conceptual model of the hydrogeology of the shallow bedrock aquifer system. At the conclusion of Phase III, a final report will be published as a Missouri Department of Natural Resources, Department of Geology and Land Survey (DGLS) Open File Report. This report will contain the compiled basic data with interpretations including a conceptual model of the shallow groundwater system, maps and drawings illustrating the locations of:

- Groundwater basins and divides
- Discrete and diffuse recharge areas
- Springs
- Gaining and losing stream reaches
- Conduits and voids

- o The relative volume of spring flow arising from areas of discrete versus diffuse infiltration
- o The relative volume of spring flow arising from conduit flow versus Darcian flow
- o Recommendations for refinements and improvements in the groundwater monitoring system at WSS

2.3.1.1 Recharge and Discharge

Recharge to the shallow aquifer, which includes the karst conduit system, occurs by discrete recharge primarily from losing streams; and by diffuse recharge from general infiltration through the surficial materials. The most significant discharge from the shallow aquifer occurs through spring flow.

Field reconnaissance of all streams draining the site plus the adjacent drainage basins will be made to locate gaining stream segments, losing stream segments, springs, and seeps. Visual observations during repeated visits under differing climatic conditions will be used to identify significant springs and to classify all stream segments as either gaining or losing. More than 40 springs and seeps have already been located, of which about 20 are considered significant.

Some stream segments may not be easy to classify visually as gaining or losing. Seepage runs on these stream segments will be made to aid the classification effort. The seepage run simply consists of a series of discharge measurements made along a stream segment during a short time period to see if the flow consistently increases in the downstream direction, as would be expected for a gaining stream. If flow decreases in the downstream direction, then the stream is losing water to the subsurface and groundwater system. Seepage runs can also be used to locate groundwater discharge points where significant increases to the stream flow occur.

An effort will be made to determine what portion of the shallow aquifer discharge near the site is contributed directly by losing streams (discrete recharge) and what portion comes from infiltration of the surficial materials (diffuse recharge). This will be done by using water tracing with fluorescent dyes (see Section 2.3.1.3) to identify the springs which have groundwater drainage basins under or adjacent to the site. Gaging stations, consisting of a calibrated weir in a small dam and a water level recorder, will be established at these springs to continuously monitor their flow. Stream gaging stations will also be placed upstream of all losing stream segments that water tracing has shown are contributing to the identified springs. The difference between the total discharge at a spring and the sum of the discrete recharges (losing streams) tributary to that spring should equal the diffuse recharge component for the groundwater basin contributing to that spring.

Stream gaging stations will also be placed along the lower stretches of losing stream segments to measure flow during high runoff events when all flow is not lost to the subsurface. (During normal or low flow conditions most losing stream segments lose all of their flow to the subsurface.)

The difference between the flow entering a losing stream segment and the flow leaving it represents the maximum loss capacity of that stream segment. By using gaging stations upstream and downstream of the losing segment, recharge to the spring flow can be determined during different climatic conditions.

The diffuse recharge component of spring flow is of particular interest because it could potentially contain contaminants contributed by infiltration at the chemical plant and raffinate pit site, i.e. from contaminated groundwater plumes under the site which are connected to the karst conduit system. The discrete recharge could contain contaminants from the site but they would have to first be transported off site by surface flow

to the losing stream segments. An understanding of these flow characteristics coupled with spring water quality results should suggest the probable migration pathway for contaminants.

2.3.1.2 Conduit Flow Paths

Major fractures and voids encountered during drilling for monitoring well installation will be investigated using a combination of borehole video cameras, borehole still cameras taking stereo photography, and borehole sonar mapping equipment. The results will be compared to bedrock cores. These techniques will allow better definition of the size, shape, orientation, and extent of voids and fractures.

Up to four boreholes with major voids or fractures will be used for conducting water tracing tests. Fluorescent dyes will be injected into the boreholes and significant down-gradient springs will be monitored for dye resurgence. Water tracing techniques are discussed further in the following subsection.

Spontaneous potential (SP), a geophysical technique, will be used in an attempt to locate shallow karst groundwater conduits which contain flowing water. The flowing water in the subsurface conduit creates an electrical charge surrounding the conduit. This in turn sets up a voltage potential in the ground. A digital voltmeter connected to electrodes placed in the ground is used to measure the natural voltage potential in the subsurface. A conduit containing flowing water is associated with high negative voltage readings, which are usually measured in millivolts. A square, rectangular, or concentrically circular array of electrodes is driven in the ground along with one reference electrode. The voltmeter is connected successively between the reference electrode and each electrode in the array. If a conduit with flowing water exists, it is located beneath or near the array electrodes with the most negative readings. On a map of the electrode array, a line connecting the electrodes with

the most negative readings would indicated the approximate course of the conduit.

This technique will be applied to Burgermeister Spring and its subsurface tributaries. If the conduit supplying Burgermeister Spring can be successfully located, SP surveys will trace conduits upstream toward the chemical plant and raffinate pits. This effort is directed toward determining the relative contribution to flow at Burgermeister Spring from on-site and off-site sources.

As part of the geophysical/geotechnical program, geophysical surveys are planned to: 1) define depth to bedrock, 2) locate, if possible, karstic features, 3) delineate perched water zones, and 4) augment geotechnical, geological, and hydrogeological data gathered from the soils and groundwater monitoring drilling program. Data from these surveys will be evaluated and used to identify anomalies and, therefore, possible locations for additional monitoring wells. Details of geophysical, geotechnical, and soils investigation programs are presented in individual sampling plans.

Angled boreholes will be drilled under the geotechnical investigation program. Cores and logs obtained from this operation will be evaluated under the hydrogeologic plan.

2.3.1.3 Water Tracing

Water tracing using fluorescent dyes will be conducted from losing streams and from boreholes. These tracer tests will confirm, expand, and refine the understanding of the conduit flow regime developed in previous studies. Two sets of water traces are anticipated for Phase I; traces from surface locations (losing streams), and traces from subsurface locations (boreholes). The results of Phase I tests will be reported in an interim report by the MDNR and incorporated into WSSRAP RI/FS

documentation. Additional water tracing tests during Phase II and Phase III will involve injection and possibly monitoring points not used for previous water tracing tests and will repeat previous traces under different climatic conditions.

Water tracing is performed by injecting fluorescent dye into the groundwater system via losing streams (where surface water streams discharge water to the subsurface) or direct injection into boreholes. Down-gradient springs or gaining stream segments are then monitored to see if the dye is present in these groundwater resurgences. Normally the groundwater discharge is sampled by anchoring packets of activated coconut charcoal in springs or in the flow of gaining stream segments. The charcoal packets, usually referred to as "bugs," are made by folding a 6-inch by 6-inch piece of nylon window screening in half and stapling the three cut edges. About 2 cubic inches of charcoal is placed inside the packet before the last edge is stapled closed. Dye is absorbed onto the charcoal as the dye-containing water flows through the bug. This sampling technique is qualitative but relatively inexpensive. A large number of locations can be continuously sampled while unattended. Bugs are periodically picked up for analysis and replaced by new ones to continue the sampling.

An alternative sampling technique is to use an automatic water sampler to take raw water samples at specified intervals. This technique allows quantitative testing to be done and more precise time of travel determinations to be made. This technique will be used at loctions where travel times are of particular interest.

Analysis for the presence of dye is done with a synchronous scanning spectrofluorometer. In the case where raw water samples are available, the raw water itself is analyzed. When charcoal bugs have been used, the dye is elutriated from the charcoal using a solution of 5% ammonium hydroxide and 95% ethyl alcohol. The elutriant is then analyzed using the spectrofluorometer.

The synchronous scanning spectrofluorometer shines an excitation light beam through a sample. When a fluorescent material is present and excited by light of the proper wavelength, the material will emit light at a longer wavelength. The wavelength and intensity of emitted light is measured by a light detection system within the spectrofluorometer. The wavelength of both the excitation light and the light being measured by the detection system (the emitted light) are varied simultaneously (synchronously scanned) over a range which includes the known characteristic excitation and emission wavelength(s) of the fluorescent material being investigated. For each sample the emission wavelength and intensity data are recorded and plotted as emission spectra. Peaks in the emission spectra can be correlated to the known wavelength peak(s) for individual dyes. The peak intensity can be correlated with the dye concentration.

The spectrofluorometer results can identify a specific dye type or types in the sample. In the case of raw water samples it can also give a quantitative concentration. In the case of charcoal bug elutriant samples, the intensity of the peak only yields a qualitative estimate of the dye concentration emerging from a spring because of variables associated with adsorption and release of dye from the charcoal and the potentially changing concentration of dye in the spring water during the sampling interval.

Before dye is injected, background samples are collected from all monitoring points and spectrofluorometric analysis is completed to record background fluorescent spectra. Dye is then injected only if the background spectra indicate there is nothing in the water that would interfere with detection of the dye to be injected. After dye has been injected and detected at one or more springs, monitoring and sampling is continued to verify that the dye pulse is decaying with time. After the groundwater system is purged of the dye or flushed and diluted to a low concentration, another injection of the same dye at a different

location may be made. Experience with conducting water traces in the Weldon Spring area has shown that it usually takes about 4 months for a dye to be flushed out of the karst spring systems.

The dye type issuing from a spring can be analytically verified. However, the water tracing and sampling technique normally used provides only a qualitative result because the relative concentration is normally all that is determined. Sample chain of custody is not an issue because all sampling and testing is done in-house by the same MDNR technician or, on occasion, by another technician working with him. No special preservation of the charcoal bug is needed other than sealing each labeled bug in a separate plastic bag. Raw water samples require no preservation techniques other than keeping them protected from sunlight because the fluorescent dyes photodecay in sunlight. The plastic water sampler housing and the locking steel antitheft and antivandalism cabinet for the water sampler provide the necessary protection from sunlight. Normally, blank samples and duplicate samples are not taken. Charcoal bugs from springs outside the groundwater basin being tested serve the same purpose as a blank sample.

Standard concentrations of dye are periodically tested to calibrate the spectrofluorometer. In order to minimize the potential for contamination of the charcoal bugs with dye, the dye is always handled and injected by someone other than the technician who collects and analyzes the bugs. The dye is always sealed in a plastic bag and placed inside a second container during transportation to the injection site in order to minimize the potential for contamination of the vehicle and subsequent contamination of the bugs. At the state office building, dye is stored in a locked closet well away from the laboratory where sample preparation and spectrofluorometric analysis is done. Signs are posted on the laboratory door that indicate that no raw dye is to be taken into the laboratory.

The fluorescent dyes that will be used most extensively are Fluorescein and Rhodamine WT. Each has an approximate detection limit of 50 parts per trillion (ppt) using the spectrofluorometer and peak emission wavelengths of approximately 512 and 572 nanometers (nm) respectively. Other fluorescent dyes that will be used to a lesser extent are Tinopal CBS-X and Pyranine Impurity. These dyes have approximate detection limits of 100 and 500 ppt respectively and peak emission wavelengths of 427 nm for Tinopal and two peaks of 381 and 400 nm for Pyranine Impurity.

Because of the limited number of dyes available, the relatively long time required to flush a dye from the karst spring system, and the short window of availability (a few hours) for dyeing a monitoring well borehole before the well is constructed, not all boreholes can be dyed. Of the 33 new monitoring well boreholes, probably only four can be dyed. Therefore, a system for selecting the boreholes to be dyed has been established. The selection procedure identifies boreholes which have a high potential for open connection(s) to the karst conduits and therefore rapid movement of dye and water away from the borehole, into the karst conduits, and then to a local spring or springs. Boreholes with high potential are dyed on a first found, first dyed basis until all four dyes have been used. Subsequent boreholes with high potential will not be dyed unless additional acceptable dyes can be identified or the dye from earlier tests have been flushed from the groundwater system.

Selecting boreholes with a high potential for open connection(s) to the karst conduits is based on a review of drilling logs, examination of rock cores, and a downhole video camera examination of the borehole. The drilling logs and core are examined to locate potentially permeable zones which may be indicated by poor or no core recovery, lost circulation of drilling fluid, and fractured or solutioned rock. The video camera is then used to examine the in-situ condition of the bedrock, especially in the zones of poor or no recovery.

Presence of solution openings, highly fractured zones, and zones of groundwater inflow to the borehole are features that indicate that a borehole has a high potential for connection(s) to the karst conduits. These boreholes are then injected with dye and the dye is flushed out of the borehole, into the surrounding bedrock, and into the assumed nearby karst conduits by a follow-up injection of one to several thousand gallons of water. In some cases water may be injected before the decision is made to inject dye. In these cases, the water is used to test the ability of the borehole to accept and distribute water to the surrounding bedrock, thereby providing further information about the potential for conducting a successful tracer test.

Dye detector packets (charcoal bugs) have been placed in the perennial springs and some of the more significant wet weather springs in all the drainage basins surrounding the site. In addition, in some basins where significant springs do not exist or are located in places that are hard to monitor, dye detectors have been placed in gaining stream segments. These locations and the rationale for monitoring them are given in Table A (in Appendix) and are shown on Figure 2-6.

2.3.2 Spring and Seep Sampling

During the summer and fall of 1987, a complete reconnaissance survey of the area surrounding the WSS was performed to locate springs and seeps which are potentially affected by the WSS. This survey was performed by MDNR and WSSRAP geologists.

2.3.2.1 Sampling Locations

A total of 30 springs and seeps were identified and located on USGS 7.5-minute topographic maps. Locations of known springs and seeps and drainage divides are shown on Figure 1-22. The numbering system operates as described below.

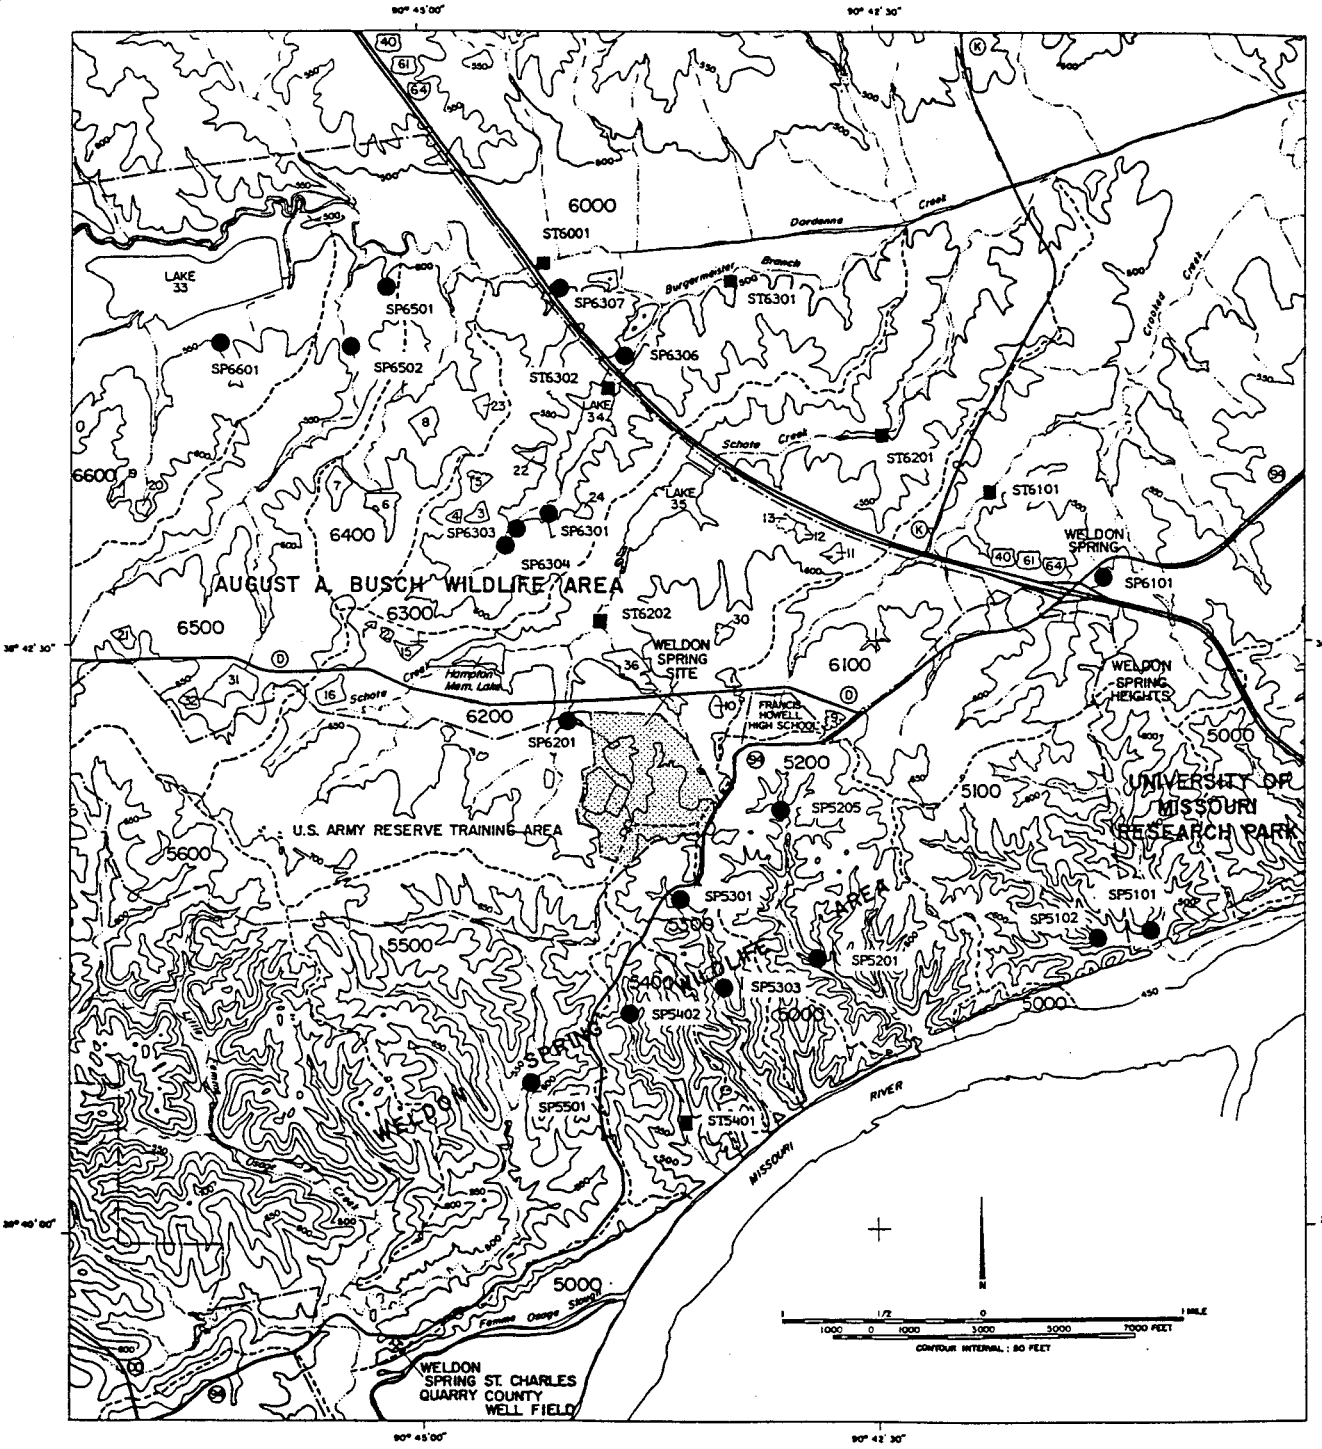

FIGURE 2-6

WATER TRACING SAMPLE LOCATIONS

Due to the uncertainty associated with the detection of contaminants and unpredictable intermittent flows at each spring, a flexible numbering system has been developed. This has been accomplished by subdividing the area-of-concern, covering over 30 square miles, into logical, discrete units. The units are defined by the surface drainage divides.

- The numbering system is in accordance with the existing WSSRAP Environmental Numbering System S.O.P.
- The prefix "SP-" denotes that the number refers to a spring or seep.
- The site and surrounding area-of-concern drain to both the Missouri and Mississippi rivers. The Missouri River drainage area is numbered along the 5000 series; the Mississippi River drainage area is numbered along the 6000 series (Figure 1-22).
- Within each thousand series, the major drainages are numbered as a hundred series from east to west as shown on Figure 1-22.
- Finally, within each drainageway, springs are numbered lowest in the series (from 1 to 99) according to permanence and volume of flow. For example, Spring Number SP-5201 represents Missouri River drainage Number 2, spring Number 1.
- Those features of concern which do not lie within one of the numbered drainages are to be placed in the zero hundred series for the appropriate thousand series. Individual spring numbers will be assigned in the chronological order of discovery of that feature.

Perennial springs are numbered first by rough estimate of greatest flow volume, the lowest number corresponding to the highest flow in each drainageway. The seeps and wet-weather springs are then numbered in order of relative flow volume. This

approach will reduce the number of "holes" which can be expected to develop in the numbering sequence due to infrequent wet-weather flow or misidentification of wet-weather features. Additional springs or seeps which may be discovered at a later date in any given drainage will be numbered in chronological order of discovery.

2.3.2.2 Spring and Seep Sampling Strategy

The strategy for sampling springs and seeps to determine the volume of contaminants discharged by way of conduit flow is a dynamic program. Sampling points, frequency, and analytical parameters will be adjusted as each round of spring sampling results is interpreted.

The Phase I Spring and Seep Assessment has been undertaken to provide an initial assessment of water quality of springs and seeps. This assessment will consist of two rounds of sampling of all identified springs and seeps. One round will occur under low-flow conditions following approximately one week of no significant precipitation or snowmelt; the other round will consist of samples collected under high-flow conditions during or immediately after a significant precipitation event.

Phase I Spring and Seep samples will be analyzed for the parameters listed on Table 2-4.

The high-flow sampling was performed on December 8 and 9, 1987, following more than 24 hours of continuous rainfall. Samples were collected from 27 springs. Samples were not collected from seeps with insufficient flow or springs emerging in streambeds which were obscured by surface flow.

Low-flow sampling was performed between February 24 and 26, 1988. A Phase I Spring and Seep Assessment report presenting and interpreting analytical results from both the high-flow and

low-flow sampling events is presently in draft form.

Results of the Phase I Spring and Seep Assessment and results of previous dye traces will be used to design a continuing sampling strategy. Selected springs with elevated levels of contaminants may be included in routine quarterly monitoring under the WSSRAP Environmental Monitoring Program (EMP). (Burgermeister Spring and the adjacent wet-weather spring are currently included in the EMP.) Further spring and seep sampling will include sampling during and following storm events as well as routine sampling to accurately characterize the range and peak concentrations of contaminants discharged at springs (Quinlan and Alexander, 1987). Sampling strategy will be re-evaluated as results of new dye traces are received.

2.4 OVERBURDEN HYDROGEOLOGY

Studies of overburden hydrogeology will be performed to determine whether contaminants present in an unsaturated flow regime or in perched or mounded zones represent a continuing source for groundwater contamination. These studies will focus on determining the presence of contaminants and of unsaturated flow conditions which could transport contaminants to the groundwater. The results will be used for computer modeling of unsaturated flow, groundwater flow, and contaminant transport.

The materials comprising the overburden at the site include the upper 10-20 feet of weathered limestone bedrock, a well developed layer of residuum in most areas, basal till, clay till, silty clay, loess, and topsoil/fill. Total overburden thickness ranges from 20 feet to 50 feet. The overburden is generally unsaturated. A detailed description of the overburden material is presented in Section 1.2.4.1

2.4.1 Unsaturated Flow Conditions

The movement of water through unsaturated soils is a function of gravity and tension (or suction) forces. Tension forces are referred to as the tension head or suction head, and are expressed in terms of negative atmospheric pressure.

To estimate the rate of flow through unsaturated soils, the modified form of Darcy's equation may be used:

$$V = -K(\theta)\, H$$

Where V is the flux, K is the hydraulic conductivity at a specific moisture content θ (unsaturated hydraulic conductivity is a function of moisture content), and H is the hydraulic gradient vector, which is the sum of the soil-water pressure head and the gravity (elevation) head expressed as a vector. Moisture content may be used as an estimate of the pore space available for flow. Thus, the above equation is divided by the moisture content to obtain an estimate of the average linear velocity (v) through a particular soil. The equation then becomes:

$$v = \frac{-K(\theta)\, H}{\theta}$$

In order to use this equation to estimate flow rate, the unsaturated hydraulic conductivity, moisture content, and the hydraulic gradient must be determined by field and laboratory measurements.

Previous efforts to characterize the saturated hydraulic conductivity of the vadose zone were performed by Bechtel National, Inc. (1987). Section 1.2.6 presents a summary of these tests on the vadose zone. Packer tests in the unsaturated bedrock zones indicate variations in saturated hydraulic conductivity of up to four orders of magnitude ranging from 6.8 x

10^{-6} to 8.5 x 10^{-3} cm/s. The results indicate that the bedrock is of variable hydraulic conductivity in the horizontal plane and generally becomes less permeable with depth, due to decreased weathering and associated solution activity (BNI, July 1987). Overburden characteristics at the WSSRAP were also evaluated and discussed in the BNI, November 1984, and July 1987 reports. The upper few feet of overburden (mostly topsoil) are poorly drained. The materials underlying the topsoil are unsaturated. Disturbed and undisturbed samples of the major overburden units were submitted to a laboratory for soil testing. The saturated hydraulic conductivities and moisture content of both dike fill and foundation materials were determined. The saturated hydraulic conductivity values are generally low and range from 1.6 x 10^{-9} cm/s (4.5 x 10^{-6} ft/day) to 3 x 10^{-6} cm/s (8.5 x 10^{-3} ft/day). Saturated hydraulic conductivity values for the silty clays and clayey silts are the highest measured. The geometric mean of the test results is 1.3 x 10^{-7} cm/s (3.7 x 10^{-4} ft/day). The field moisture content of the samples range from 15% to 30%. This is approximately 90-100% saturated moisture content. Test results for the clay materials obtained from a depth of about 3 m (10 ft) indicate a saturated hydraulic conductivity range from 1.7 x 10^{-8} cm/s (4.82 X 10^{-5} ft/day) to 6.4 X 10^{-9} cm/s (1.81 x 10^{-5} ft/day).

Comparison of grain size distributions of the four units indicates the basal till has the highest gravel content, the clay till has the highest sand and clay content, and the loess has the highest silt content (Table 1-2). The clay till exhibited the highest cation exchange capacity, followed by the Ferrelview Formation and lastly, the basal till (BNI, July 1987).

Relevant soil parameters measured by the laboratory for the Ferrelview Formation, the clay till unit, and the basal till unit are discussed in Section 1.2.4.1. Table 1-2 presents a summary of the overburden test results. These data indicate that the

Ferrelview Formation has the highest saturation, specific retention, and activity, and the lowest specific yield (BNI, 1987).

2.4.1.1 Unsaturated Zone Storage Potential

The physical properties of the vadose zone that influence water storage potential include: (1) thickness, (2) porosity, (3) bulk density, (4) water content, (5) soil-water characteristics, (6) field capacity (specific retention), (7) specific yield, and (8) fillable porosity (Everett, 1984). The evaluation of these parameters is necessary to properly assess the hydraulic properties of the unsaturated zone in order to predict contaminant migration.

- Thickness

  A determination of the thickness of the vadose zone will be based on borehole information and current water level measurements from existing and proposed monitoring wells. In areas underlain by perched groundwater, the depth to the perched water table will be used as the depth of the vadose zone.

- Bulk Density and Porosity

  Bulk density values are required for the estimate of total water storage in the vadose zone.

  Bulk density and porosity results from previous studies by BNI will be combined with new data from the geotechnical investigation efforts to produce a body of data suitable for unsaturated flow calculations and model calibration.

- Water Content

  The total porosity (n) of the unsaturated zone materials corresponds to the upper limit for water storage in the unsaturated zone. However, for $\theta<n$, the available porosity for liquid flow is a function of the water content. Field techniques for determining water content of the unsaturated zone will utilize tensiometers and neutron moisture probes. A more detailed discussion of the use and field implementation of these instruments is presented in Section 2.4.1.3.

- Soil-Water Characteristics

  The relationship between soil-water tension and water content is referred to as the soil-water characteristic curve. As a soil drains, a range of soil-water content values are possible, depending on the various forces acting on the soil-water system. These forces include matric forces, osmotic forces, and gravity. Usually, the matric force is dominant. When expressed on a unit volume basis, the energy associated with these forces is termed soil-water pressure (Everett, 1984).

  Tensiometers will be used to measure the soil suction negative pressure head in the field at a specific point in the soil column. Tensiometers may be used only when soil-water negative pressures are greater than -0.8 bar (i.e. between -0.7 and 0.0 bar) (Everett, 1984). They must also be correlated to measurements of soil moisture. This can be done by reference to an existing soil-moisture characteristic curve. If such a curve is not available, it must be developed from additional laboratory testing. Field sampling and measurement may also be used to supplement laboratory testing. The soil may be sampled at the time of tensiometer

installation and the moisture content of this sample compared to the initial tensiometer reading. However, this will supply only one point on the curve relating soil moisture and soil suction.

In the case of the WSS, a soil-moisture characteristic curve is not available. A combination of field and laboratory methods will be used to develop a soil-characteristic curve for the soils at the WSS which relates moisture content and soil suction. Laboratory testing using pressure plate analysis or other methods must be used to determine additional points along the curve relating soil moisture and soil suction. Once this relationship has been established, the soil characteristic curve can be used to determine the soil moisture based on future tensiometer readings.

- Field capacity (specific retention)

Field capacity is related to the volume of water that a unit volume of soil will retain against the force of gravity. Approximate values of field capacity (on a mass/mass basis) vary from 4% in heavy clays up to 100% or more in organic soils. In terms of matric potentials, values for sands range from 0.1 to 0.15 bar at field capacity. For medium- to fine-textured soils, the corresponding range is 0.3 to 0.5 bar (Everett, 1984).

- Specific yield

Estimates of the specific yield values for areas near the water table and perched areas of saturation in the vadose zone will be obtained from water content profiles as determined from neutron moisture logs. The neutron moisture data will be used to determine the

volume of water drained during the decline in the water table.

- o Fillable porosity

  The fillable porosity is the volume of water that an unconfined aquifer stores during a unit rise in the water table per unit surface area. Neutron moisture logs may be used to estimate the fillable porosity of sediments near the water table.

2.4.1.2 Unsaturated Flow Potential

The vadose zone flow regime at this site may be characterized as two flow regimes, Darcian (capillary) flow and macropore flow. Darcian flow describes a uniform, slowly advancing wetting front, while macropore flow is the relatively rapid transmission of free water through large, continuous pores or channels (such as root channels, desiccation cracks, or fractures). The principal unsaturated flow parameters that need to be evaluated at this site are: 1) infiltration, 2) the amount of water moving into the lower vadose zone, 3) the direction of unsaturated water movement, 4) hydraulic gradients, 5) the unsaturated hydraulic conductivities, and 6) flow rates (flux).

The method to be used at the site to estimate infiltration is the instantaneous rate method which involves measuring seepage loss over a short time interval at an excavated impoundment.

The determination of direction of water movement and hydraulic gradient in the unconsolidated material will rely primarily on neutron probe measurements. Measurements will be taken by inserting the neutron probe into the infiltration tubes and recording the neutron response to moisture content of the soils at various depths. Using this method, the neutron source and neutron counter are contained in the same unit and high energy

neutrons, which have about the same mass as hydrogen, are emitted from the source into the soil. As these neutrons collide with hydrogen they lose part of their energy and are counted as they are scattered back toward the probe. The number of counts that are recorded in a specified time can be related to the hydrogen content of the soil, which is primarily the soil moisture content.

A soil characteristic curve is then used to estimate the soil suction (negative pressure head). One tensiometer nest will also be used as a correlation of field measurements. Tensiometers are used to measure the soil suction or negative pressure head at a specific point in the soil column. A soil characteristic curve is then used to estimate the moisture content of the soil (see 2.4.1).

In order to characterize the direction of unsaturated water movement in the vadose zone, an array of three neutron probe infiltration tubes will be installed at each selected location to determine variations in soil moisture with respect to depth. A nest of three tensiometers will be installed at one infiltration tube location with individual cups terminating at varying depths. This will be located as close as possible to the location of the infiltration tube. Disturbance of soils will be minimized. Correlation between the neutron soil moisture readings and the tensiometer soil suction can be made at this location and the results used at other points in the vadose zone monitoring network.

Hydraulic gradients will be used to estimate flux in the vadose zone. The hydraulic gradients in the vadose zone will be derived from tensiometer and neutron probe data. Soil-characteristic curves derived from lab and field data will be used to relate negative pressure measurements (from tensiometers) or the moisture content measurements (from neutron probes) to water content and unsaturated hydraulic conductivity (Everett et al,

1984).

2.4.1.3 Site Monitoring

The vadose zone monitoring network is designed to investigate the vertical and horizontal extent of contamination and to provide insight into the potential for movement of fluids in the vadose zone. Monitoring of the vadose zone will involve a combination of field and laboratory techniques. Neutron probes will be the primary technique used to measure moisture content at most locations in the vadose zone. Neutron moisture logging will provide detailed information on the relationship between moisture content and negative pressure. Advantages of the neutron probe are its abilities to obtain soil moisture measurements over a wider range of soil moisture content than tensiometers and to allow measurements of a continuous soil moisture profile (with depth). A tensiometer nest will be used to correlate the in-situ soil suction or pressure head with the soil moisture measurements (determined by neutron probe measurement) at one monitoring point in the vadose zone. The data derived from the tensiometers and neutron probes will facilitate the determination of hydraulic gradients and, indirectly, fluid movement (flux) in the vadose zone.

At the time of installation of the in-situ devices, the moisture content of the soil from the neutron probe access wells and the tensiometer cup locations will be determined from undisturbed samples (see Section 2.4.1.5 for sampling technique). These data will be used to supplement laboratory data to create a soil-water characteristic curve which can then be used to estimate the moisture content of the soil and allow subsequent neutron probe and tensiometer readings to be used to estimate flux.

2.4.1.4 Location and Rationale

This section presents the proposed locations and rationale for

vadose zone monitoring points and for the field implementation of the monitoring program. The goals of the vadose zone monitoring program are to:

(1) Investigate vadose zone processes in and near suspected source areas for continuing groundwater contamination.

(2) Provide information for the evaluation of contaminant migration in the vadose zone.

(3) Provide representative data on vadose zone parameters throughout the site for input to computer models.

(4) Provide long-term monitoring data to allow for the estimation of seasonal variation of potential paths of migration.

(5) Evaluate the effectiveness of the soil zone in terms of the degradation, transformation, or immobilization of contaminants.

Proposed locations for the neutron probe monitoring network are presented on Figure 2-7. The locations were selected to determine unsaturated flow conditions in areas where contaminants have been detected in the groundwater and could potentially migrate off-site, and also at a location adjacent to a possible site for the proposed disposal facility. In general, the locations of the neutron probe arrays correspond to the pumping and observation well locations. As shown in the detailed enlargement on Figure 2-7, each location will contain an array of three neutron probe infiltration tubes. The tubes will be located 25 feet apart. These three points describe an equilateral triangle. Array 1 (IT-1) is located north of the apparent groundwater divide in the area where relatively high concentrations of nitroaromatic compounds were detected in groundwater samples. Array 2 (IT-2) is located adjacent to a

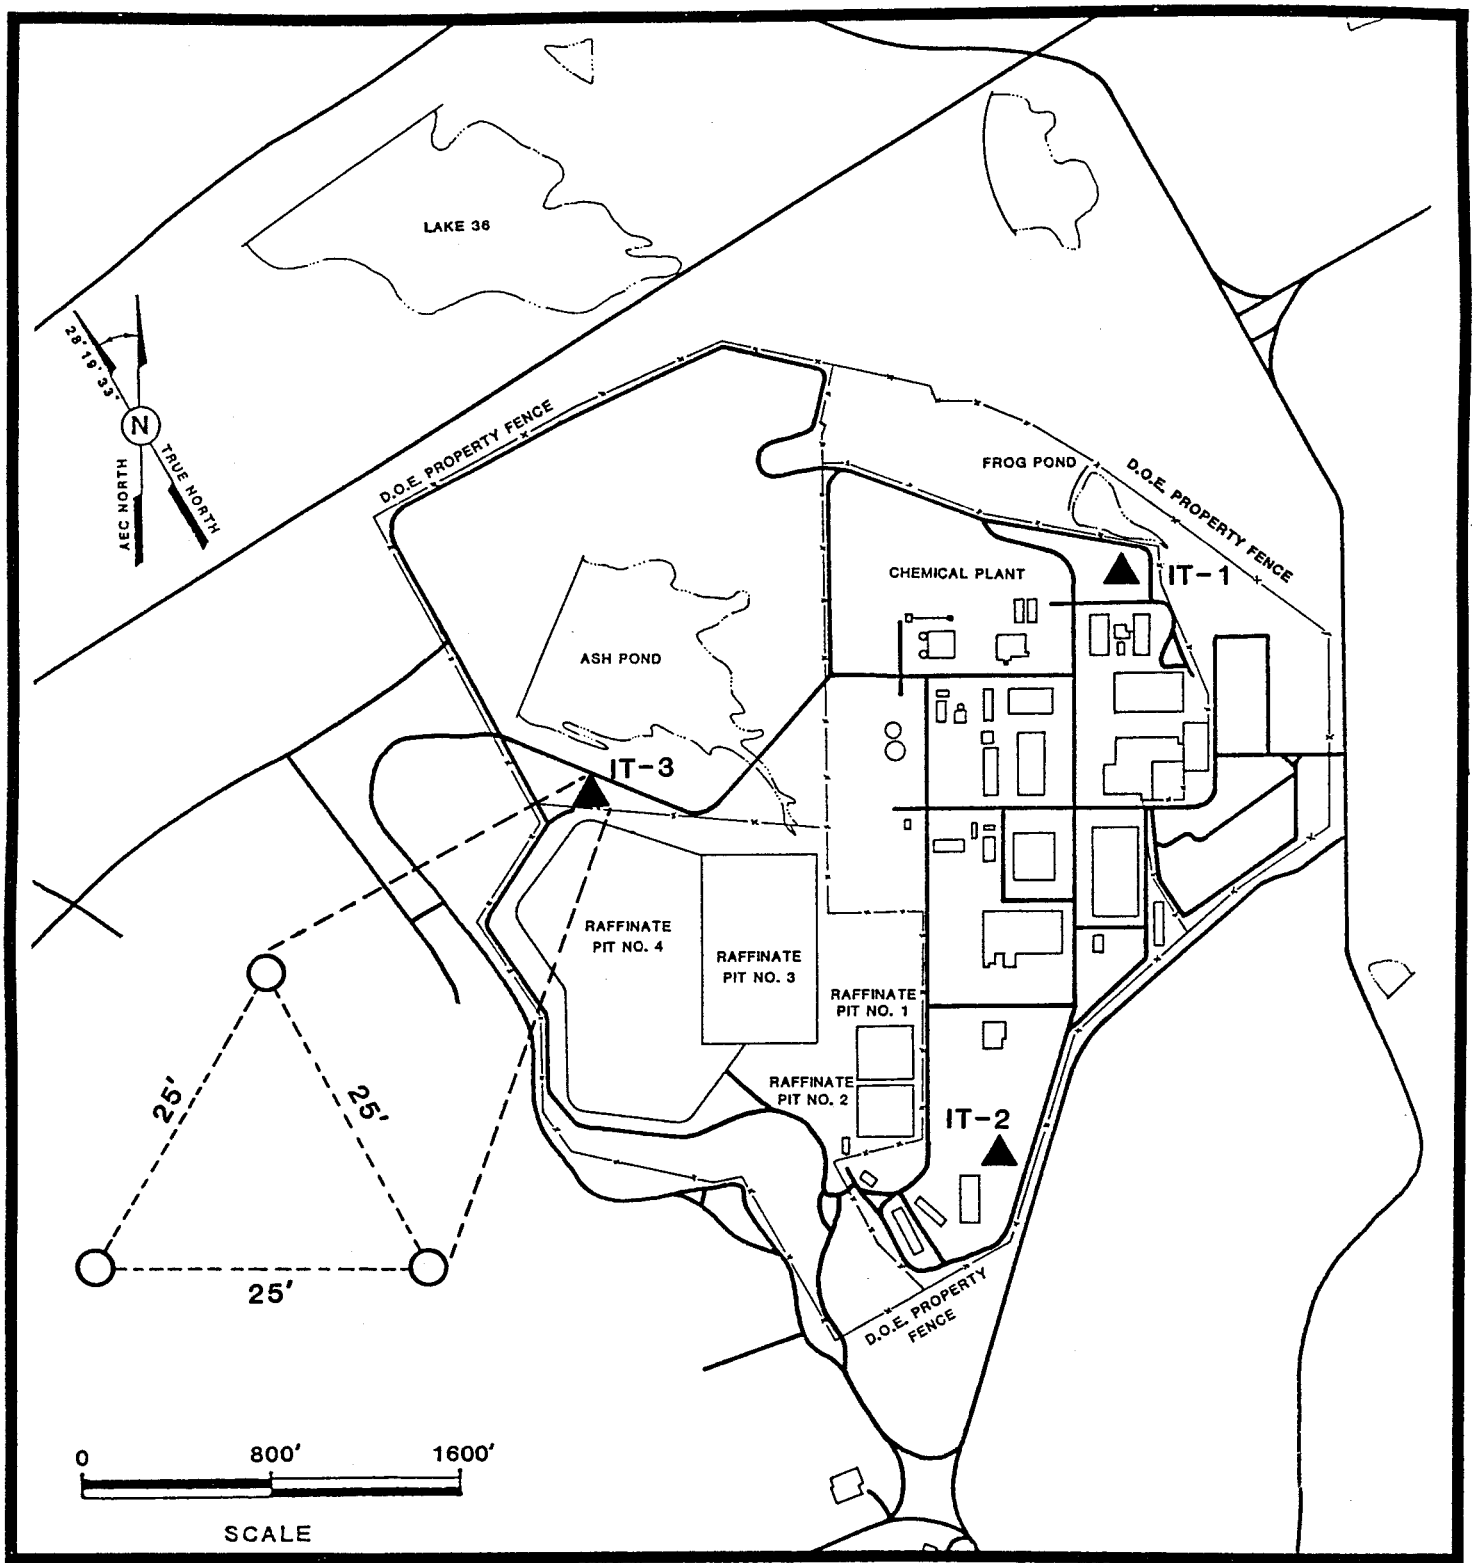

FIGURE 2-7

LOCATION OF INFILTRATION TUBE NETWORK

possible site for a proposed disposal cell area near the southern end of the site. Array 3 (IT-3) is located in the area where the highest nitrate concentrations were detected in groundwater samples from the Phase I Water Quality Assessment. At location IT-2, one array will contain a tensiometer nest containing three tensiometer cups at three different depths.

There may be some variations in correlation between the neutron probe soil moisture measurements and the tensiometer soil suction measurements. This is expected due to hysteresis effects during the wet-dry cycle in unsaturated conditions. To insure that the neutron probe is accurately reflecting field conditions, it will be calibrated at least once yearly using a standardized field installation.

Additional neutron probe monitoring tubes will be installed at each existing and proposed lysimeter location. This will allow localized in-situ soil moisture measurements so that lysimeter sampling can be optimized.

A phased approach to neutron probe monitoring tube/lysimeter installation will be used for the proposed locations. Neutron probe soil moisture measurements will be taken for approximately three months prior to lysimeter installation. Moisture profile data from these measurements will allow more precise depth location of each lysimeter.

2.4.1.5 Drilling and Installation

All drilling activities to be conducted for the installation of the tensiometer nest and neutron moisture logging infiltration tubes will be in accordance with SOPs (WSSRAP procedures manual).

Drilling operations will utilize hollow-stem augers to advance and sample boreholes. Undisturbed samples will be obtained from intervals which will, at a minimum, correspond to the horizons

monitored by the tensiometers (10, 20, and 30 feet). The supervising geologist will maintain a complete log of each soil boring. Sampling intervals will be adjusted to intercept seams of differing soil type and those intervals which appear to contain abundant soil moisture. Thin-walled tube (Shelby Tube) sampling will be used to obtain undisturbed samples of the unconsolidated overburden materials.

Each infiltration tube borehole will be drilled to a depth of 30 feet. The infiltration tube is constructed by hydraulically driving a 2 3/8 inch core barrel into the soil. The core barrel is advanced 4 feet at a time after which the soil sample is removed. When the advancement of the core barrel reaches a depth of 30 feet, a 2 3/8 inch OD aluminum pipe is inserted into the hole. At ground surface bentonite is placed around the tube to prohibit water from percolating into the annular space and affecting the measurements made with the neutron probe. A secure cap with controlled access should be installed over the infiltration tube to prevent entry of debris, water or contaminants (Figure 2-8). The neutron probes will be calibrated by comparison to laboratory measurement of the moisture content of soil samples that were removed during the installation of the infiltration tube.

Tensiometer measurements are effective only in unsaturated soils where soil-water pressures are between -0.8 bar and 0.0 bar. Pressures below -0.8 bar will be correlated to soil moisture content using lab testing and neutron logging.

Tensiometers will be installed in a nest with individual cups terminating at varying depths throughout the region of interest. The tensiometer nest will consist of three tensiometers (Figure 2-9). The A1 tensiometer cup will terminate at the upper or horizon 1 level; the A2 will terminate at the middle or horizon 2 level; and A3 will terminate at the lower or horizon 3 level. These levels correspond to depth intervals of 10, 20, and 30 feet

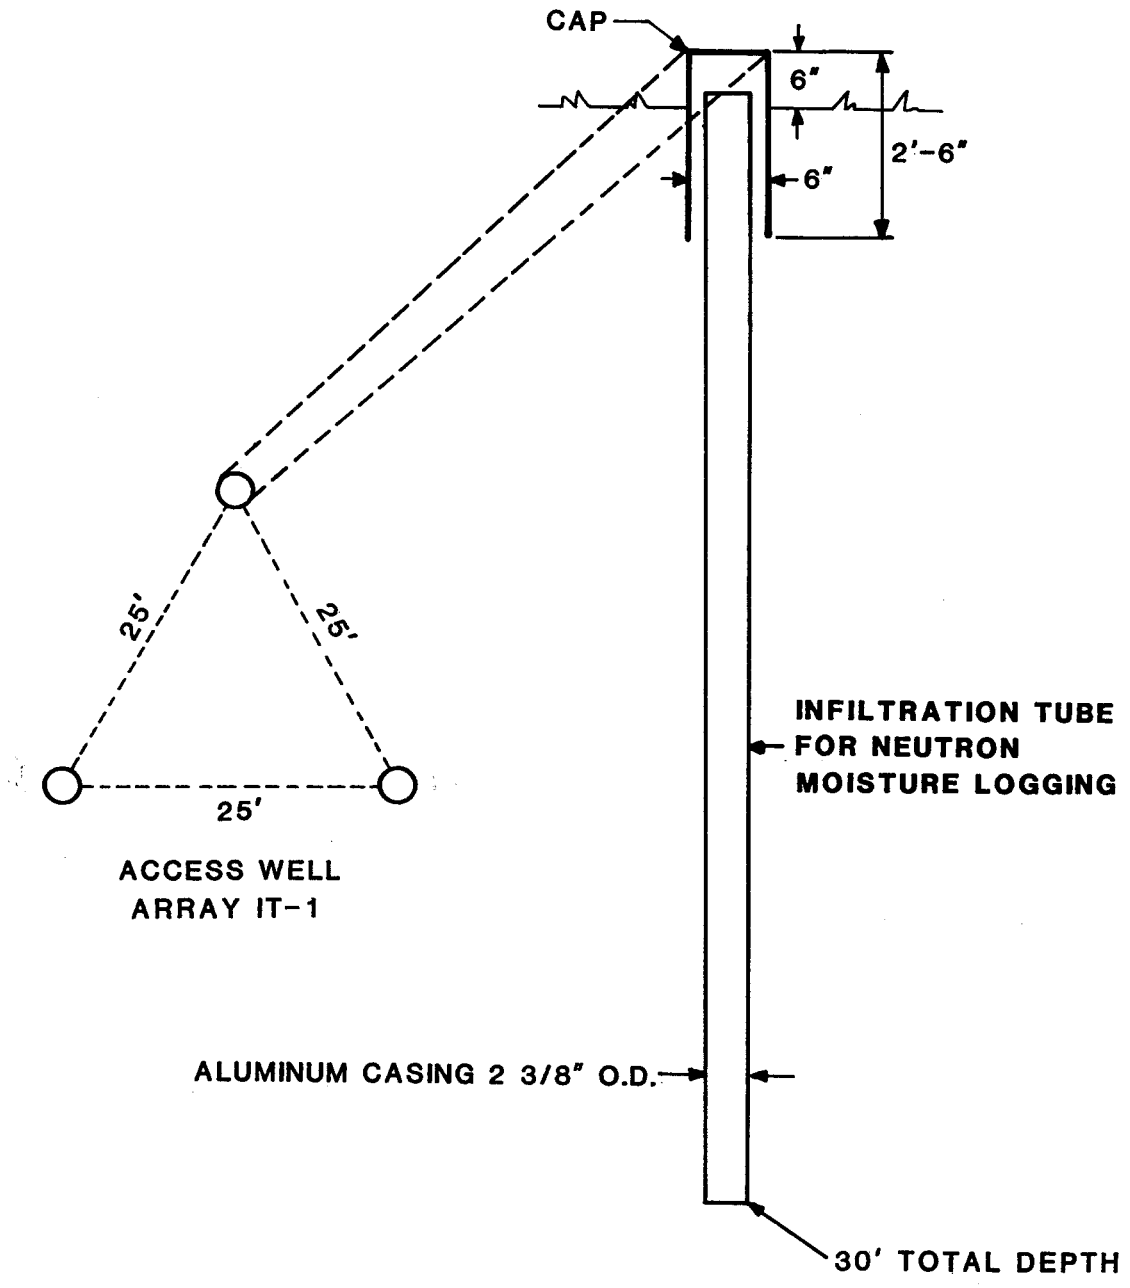

FIGURE 2-8

TYPICAL INFILTRATION TUBE DIAGRAM

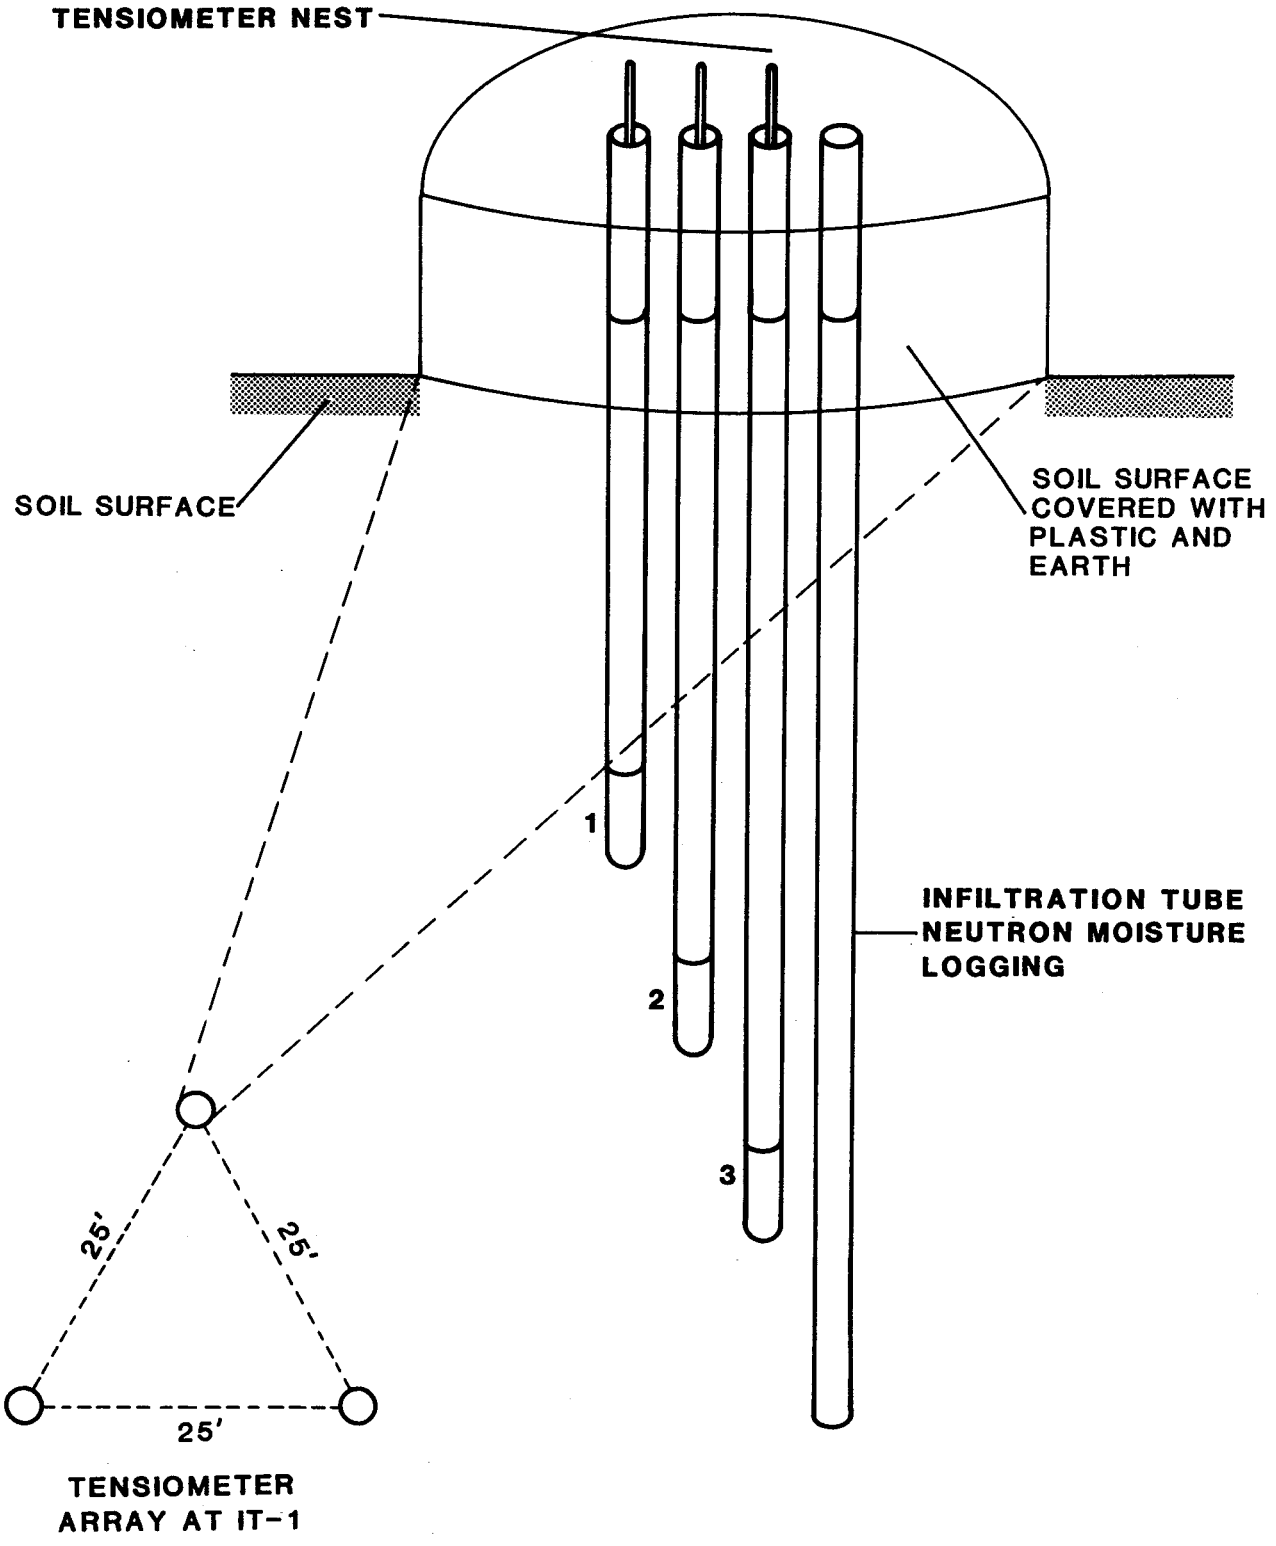

FIGURE 2-9

PROPOSED TENSIOMETER ARRAY DIAGRAM

respectively. The intervals will be adjusted, based on field observations, to intercept zones where moisture is accumulating.

The borings to complete the tensiometer nest will be spaced four feet apart (Figure 2-10). Adjustments in spacing may be necessary to accommodate actual site constraints. Care will be taken to minimize disturbance of adjacent borings when drilling the closely-spaced holes for the tensiometer nest.

Tensiometers will be immersed in water during transport to the field. Silica flour (200 mesh) will be tremmied to the bottom of the hole. The tensiometer cup will then be forced into the silica flour and the tube carefully backfilled with soil to prevent surface water leaking down the tube (Everett et al, 1984).

2.4.2 Contaminant Distribution in the Vadose Zone

Soil pore-liquid sampling will be performed to evaluate the efficiency of the soil processes that degrade wastes, and to detect the migration of hazardous constituents through unsaturated flow.

The sampling of unsaturated soil pore-liquids will utilize vacuum pressure lysimeters. Usually, vacuum lysimeters will collect liquid only at pressures above -0.8 bar, limiting the effective range of soil moisture where samples can be obtained. Soil moisture will be monitored by installing neutron probe access wells in close proximity to each lysimeter location. Figure 2-11 shows a typical single vacuum-pressure lysimeter (EPA, Oct. 1986).

2.4.2.1 Existing Lysimeters

Figure 1-18 presents the location of the existing lysimeter network installed by UNC Geotech in July 1987. Analysis of soil pore water from these lysimeters indicated elevated concentrations of nitrate, calcium, and sodium.

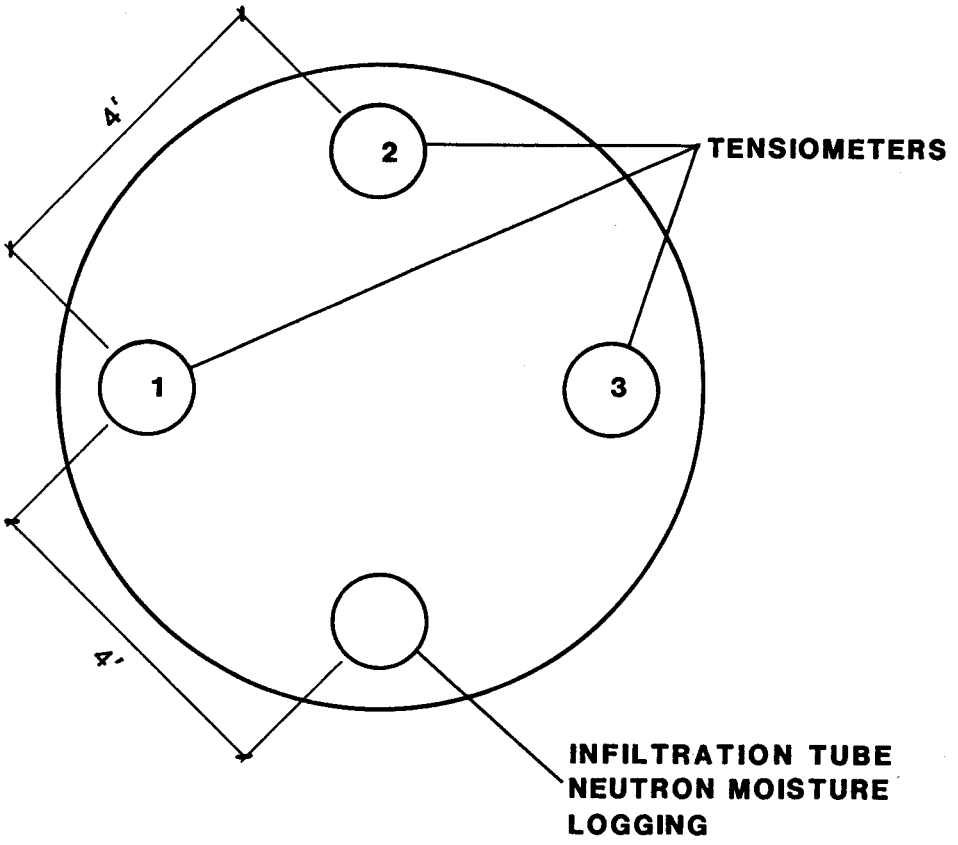

FIGURE 2-10

PROPOSED TENSIOMETER NEST DIAGRAM

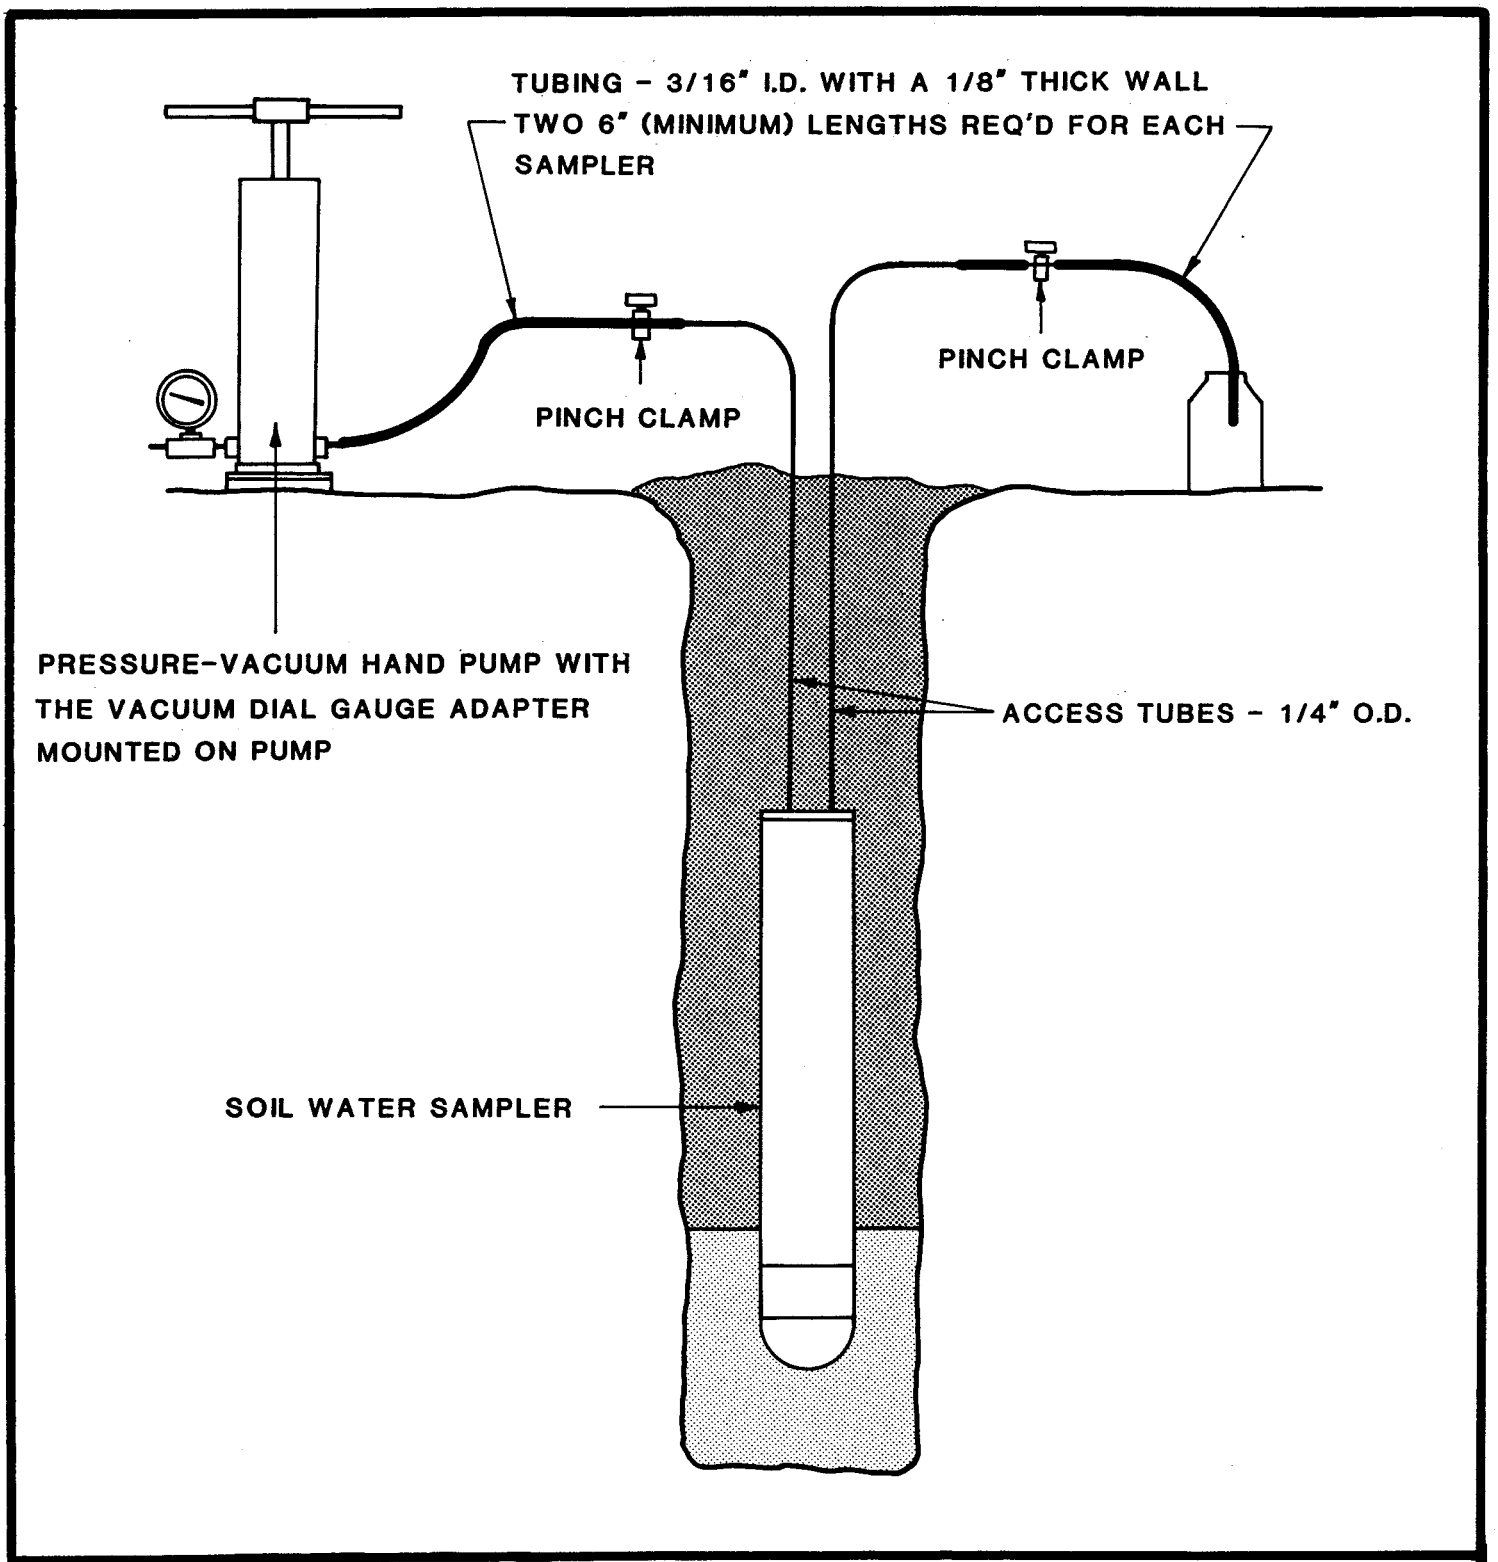

FIGURE 2-11

TYPICAL VACUUM - PRESSURE LYSIMETER

The proposed overburden monitoring program includes installation of neutron probe access wells and continued collection and analysis of samples from these existing lysimeter locations. Also additional neutron probe/lysimeter arrays will be installed and monitored at select locations to evaluate contaminant transport by unsaturated flow.

2.4.2.2 Additional Lysimeters

The location and rationale for additional multiple lysimeter installations were established by reviewing: (1) documented evidence of areas exhibiting soil and/or groundwater contamination, and (2) potential contaminant source areas.

The proposed locations for additional multiple lysimeter installations are shown in Figure 2-12. Table 2-5 lists the rationale for lysimeter placement. The intervals to be monitored at each location are listed in Table 2-6. This table also includes a lithologic description of the interval which is based on the log of the nearest boring. These intervals will be adjusted, based on field observations, in order to intercept zones where moisture is accumulating.

The characteristics of the residuum and unsaturated bedrock will be defined under the geotechnical investigation plan. Lysimeter locations presented on Figure 2-12, supplemented by existing lysimeters, represent a minimal vadose zone monitoring network. This focused operation may be expanded, if necessary, with the acquisition and analysis of data from drilling and sampling programs, including the chemical soils investigation, monitoring, geophysical/geotechnical investigation, waste characterization (e.g. raffinate pit sludge analysis) and the drilling and sampling programs delineated in this plan.

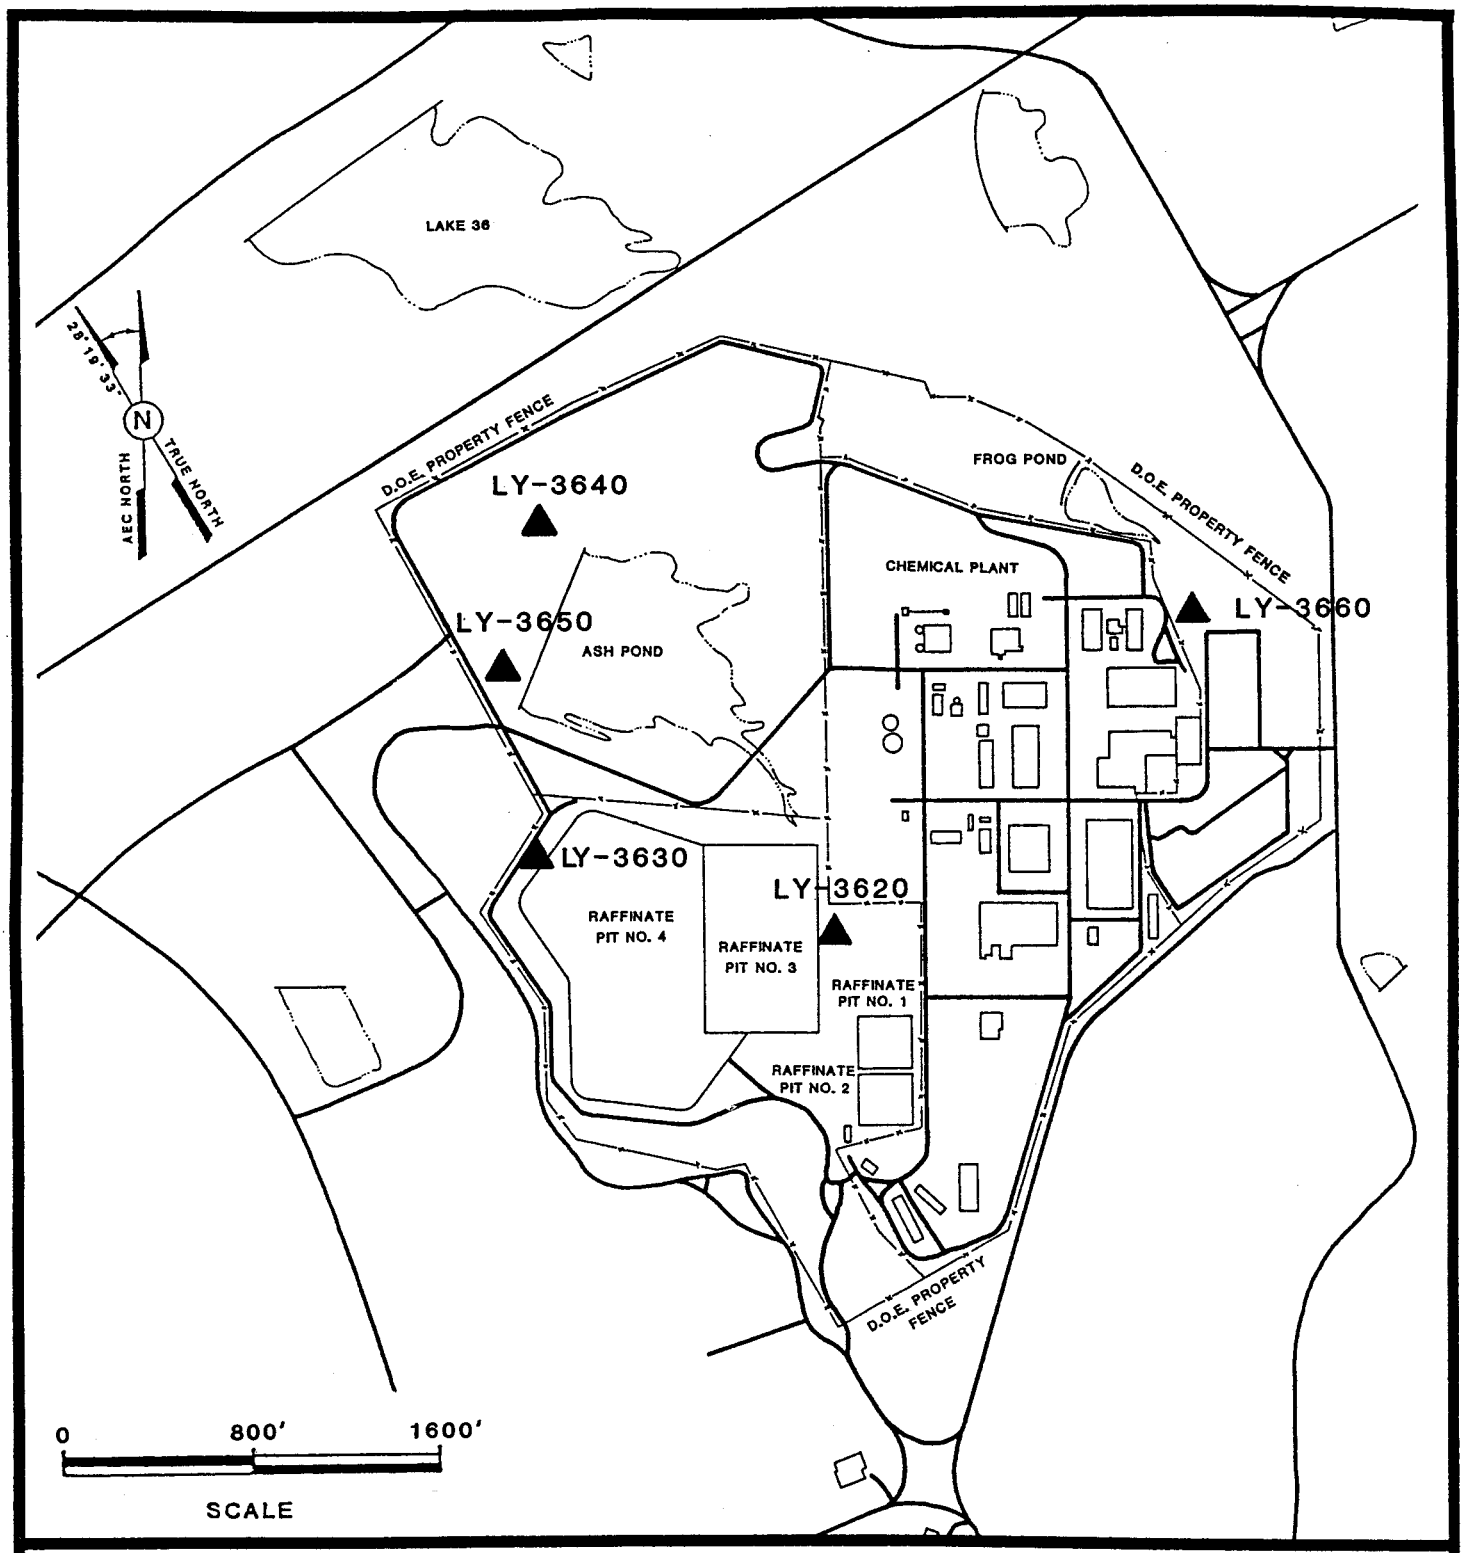

FIGURE 2-12

ADDITIONAL MULTIPLE LYSIMETER INSTALLATION LOCATIONS

T A B L E 2-5

LYSIMETER PLACEMENT RATIONALE

Lysimeter Location Number	Location	Rationale
LY-3620	E. of Raffinate Pit 3	Area of dark green vegetation may indicate leakage from Raffinate Pit 3, or potential migration extending from Raffinate Pit 1.
LY-3630	N.W. of Raffinate Pit 4	Previous drilling in this area encountered very moist zones. Potential seepage from Raffinate Pit 4.
LY-3640	N.W. of Ash Pond near north dump area	Previous drilling operation in this area encountered a very sandy silt. Area delineated as ordnance demolition storage area. Also, saturated materials were encountered during BNI drilling and testing activities.
LY-3650	S.W. of Ash Pond down-stream toe of embankment.	Area of nitrate & sulfate contamination, and ordnance demolition storage area. Area also exhibiting saturated soil during BNI drilling & testing activities.
LY-3660	N. of Bldg.407, near monitoring well MW-2013	Area of 2,6 DNT contamination and area delineated as potential nitroaromatic source from TNT processing. Also area exhibiting saturated soil during BNI drilling & testing activities.

TABLE 2-6
MULTIPLE LYSIMETER INSTALLATION SUMMARY

Lysimeter Location/ Borehole	Depth Interval	Description
LY-3620		
LY-3621	10.0 - 12.0	Clay, silty, brownish-gray to med. gray, moist oxidized zones
LY-3622	18.0 - 20.0	Clay, silty, med. gray, moist, some sub-rounded fine gravel, trace very fine-grain sand, oxidized zones, pyrolusite stringers
LY-3623	23.0 - 25.0	Clay, gravelly, dark yellowish orange, moist, hard, angular chert gravel, pyrolusite lenses, trace very fine-grain sand
LY-3630		
LY-3631	10.0 - 12.0	Clay, silty, gravelly, lt. gray w/orange mottling, some angular chert fragments
LY-3632	17.0 - 19.0	Clay, silty, orange/gray, moist, some chert pebbles
LY-3633	22.0 - 24.0	Clay, silty, gravelly, dk. brown w/orange, moist, red angular chert fragments
LY-3640		
LY-3641	5.0 - 7.0	Silt, orange & greenish gray, some clay, black modules, very stiff
LY-3642	10.0 - 12.0	Clay, silty, mottled orange & gray, very stiff
LY-3643	18.0 - 20.0	Clay, silty, yellowish orange-orange & gray mottled, very stiff to hard, black manganese oxide staining common
LY-3650		
LY-3651	6.0 - 8.0	Silt, clayey, tan to light brown, some black manganese oxide staining
LY-3652	11.0 - 13.0	Clay, mottled orange-brown-gray, stiff, minor manganese oxide staining
LY-3653	18.0 - 20.0	Clay, silty, mottled orange, yellowish-brown and gray w/fine-grain sand & weathered angular chert gravel, black manganese oxide staining & fillings common
LY-3660		
LY-3661	6.5 - 8.5	Silt, clayey, mottled tan & gray, very soft
LY-3662	11.0 - 13.0	Silt, clayey, mottled, stiff, common dark reddish brown iron nodules
LY-3663	18.0 - 20.0	Clay, silty, mottled, very stiff, w/white sand sized chert fragments, occasional black manganese oxide staining and fillings mottled orange & light olive gray

*Descriptions based on nearest logged boring

2.4.2.3 Drilling and Installation

A phased approach to neutron probe infiltration tube/lysimeter installation will be used for the proposed lysimeter locations. Neutron probe soil infiltration tubes will be installed first and moisture measurements will be taken for approximately three months prior to lysimeter installation. Moisture profile data from these measurements will allow more precise depth location of each lysimeter.

All lysimeter drilling and installation activities will be conducted in accordance with the Standard Operating Procedures (SOPs) developed for borehole logging and lysimeter installation and sampling. Drilling operations will utilize hollow-stem auger techniques.

Undisturbed samples will be obtained from the intervals corresponding to the horizons or intervals to be monitored by the lysimeter. Thin-walled tubes will be used to obtain undisturbed samples of the unconsolidated overburden materials. These samples will be retained for possible future chemical analysis. The supervising geologist will maintain a complete log of each soil boring.

In general, lysimeter installation will consist of placing enough silica flour (200 mesh) into a borehole at the proper lysimeter depth interval to form a six- to twelve-inch thick layer. After lowering the sampler into the hole, additional silica flour will be added to cover the sampler to a point at least two inches above the top of the porous cup. The sampler will then be rotated into the silica flour to insure the porous cup is in good contact with the silica flour. The hole will then be backfilled with tamped native soil. A bentonite seal is required above and below each lysimeter in multiple sampler installations (Figure 2-13).

MULTIPLE INSTALLATION

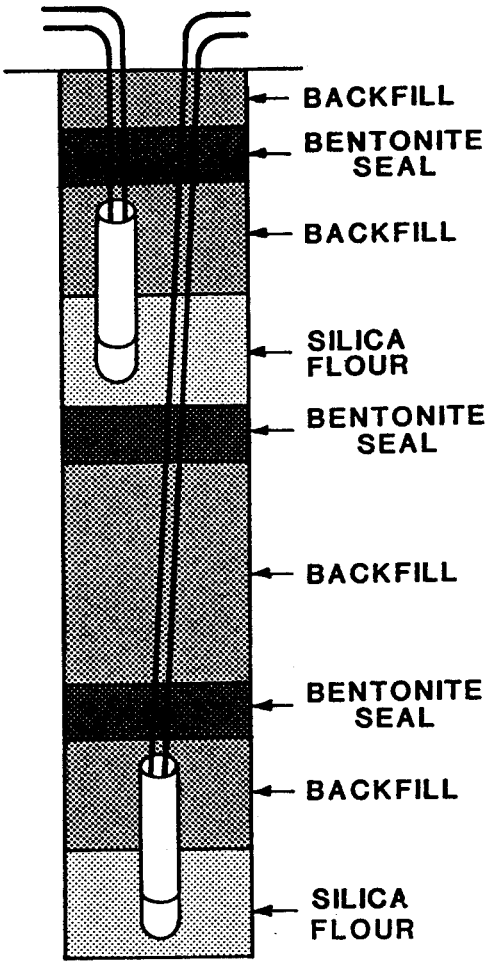

FIGURE 2-13

TYPICAL MULTIPLE LYSIMETER INSTALLATION

2.4.2.4 Soil Water Sampling

Soil water sampling will be performed in conjunction with the quarterly monitoring described in the 1987 Environmental Monitoring Program Plan. Sample collection techniques are described in detail in the WSSRAP Standard Operating Procedures. Repeated sampling over a period of time may be required to collect sufficient sample volume for a complete analysis. The order in which the constituents are analyzed may be prioritized, with analyses for contaminants of greatest concern performed first. Soil water samples will be analyzed for the parameters listed previously in Table 2-3. Analytical results will be entered into a computer data base.

2.4.3 Perched and Mounded Groundwater Zones

The geological environment at the WSS exhibits complex saturated-unsaturated conditions occurring within the vadose zone. Saturated regions within the vadose zone (perched groundwater bodies) result from the presence of a lower permeability layer in a relatively higher permeability formation, or from seepage into a low permeability, poorly drained soil. The result is the formation of discontinuous saturated lenses with unsaturated conditions existing below these lenses and above the water table.

Investigations of perched and mounded zones will focus on the immediate vicinity of the raffinate pits. Previous exploratory drilling investigations conducted at the WSS indicated areas of anomalously high groundwater elevations or perched groundwater (see Section 1.2.6).

Monitoring of perched groundwater at the WSS will be accomplished by the use of overburden monitoring wells. Discrete zones within the overburden are to be monitored.

Previously installed monitoring wells that will be retained in the network are illustrated on Figure 2-14. Overburden monitoring wells OW-3501 and OW-3502 were installed by UNC Geotech in 1987 to allow monitoring of shallow seepage from Raffinate Pits 1 and 3. OW-3503 was installed as a monitoring well in 1983 by BNI and designated B-15A, later designated MW-3005 by WSSRAP staff prior to the development of separate monitoring strategies for saturated overburden and the bedrock aquifer. OW-3504 was installed in 1980 by Lawrence Berkeley Laboratories and designated W-2, later designated MW-3018. The overburden surrounding the screened interval of this well is seasonally unsaturated. OW-3508 was installed in May 1988 incidental to other drilling activities near Raffinate Pit 3. This location will serve to monitor potential mounding from Raffinate Pit 3.

Other monitoring wells installed in the overburden during the course of previous investigations in the raffinate pits area have either remained continuously dry or have been damaged and abandoned.

Additional overburden monitoring wells will be installed in areas previously identified as exhibiting potentially perched or mounded groundwater conditions in the overburden.

2.4.3.1 Location and Rationale

The overburden monitoring network is designed to further investigate the vertical and horizontal extent of contamination in perched groundwater zones and to evaluate leakage from the raffinate pits.

The location and rationale for monitoring well installation were established by reviewing the results from previous subsurface investigations by Bechtel National, Inc. and UNC Geotech. Figure 2-15 presents the proposed overburden monitoring well

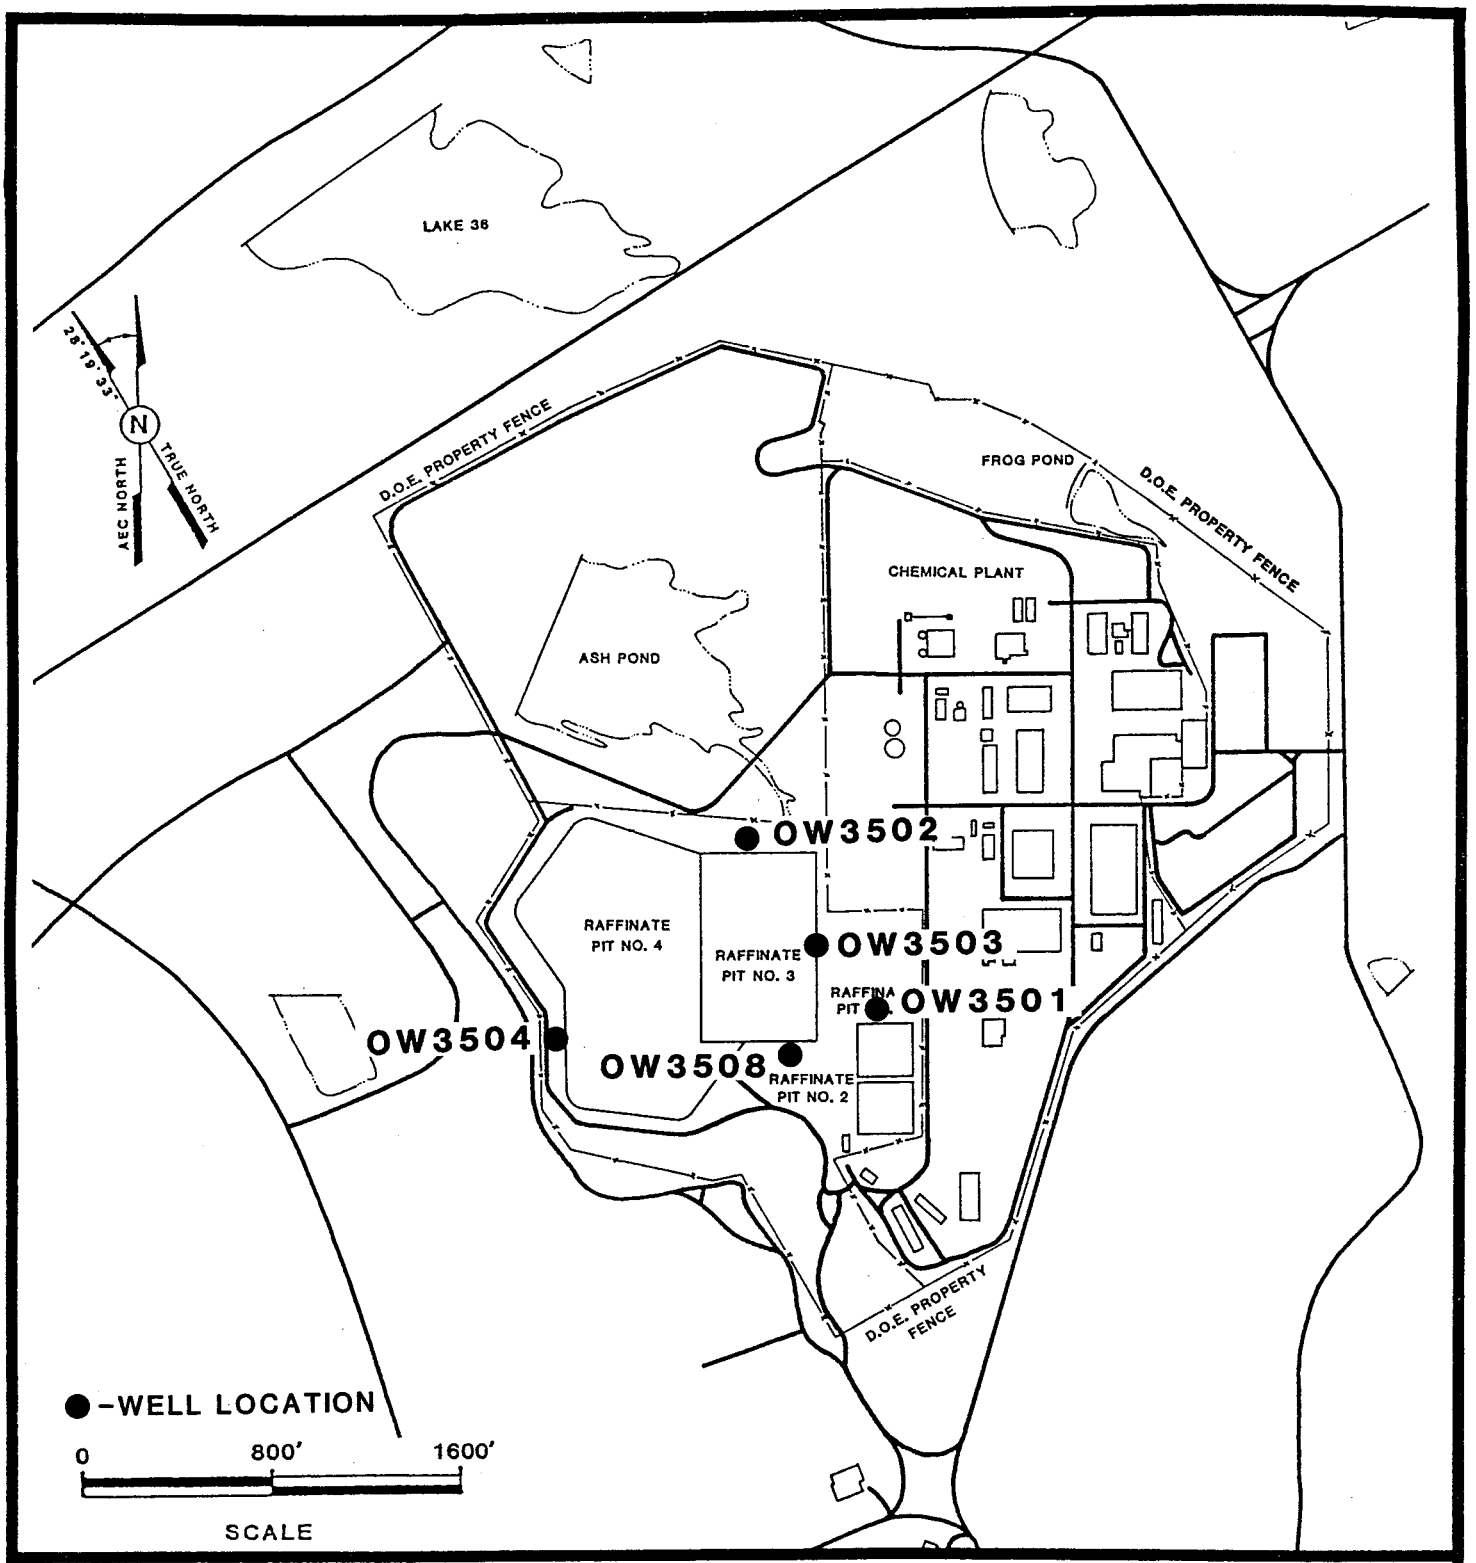

FIGURE 2-14

EXISTING OVERBURDEN MONITORING WELL LOCATIONS

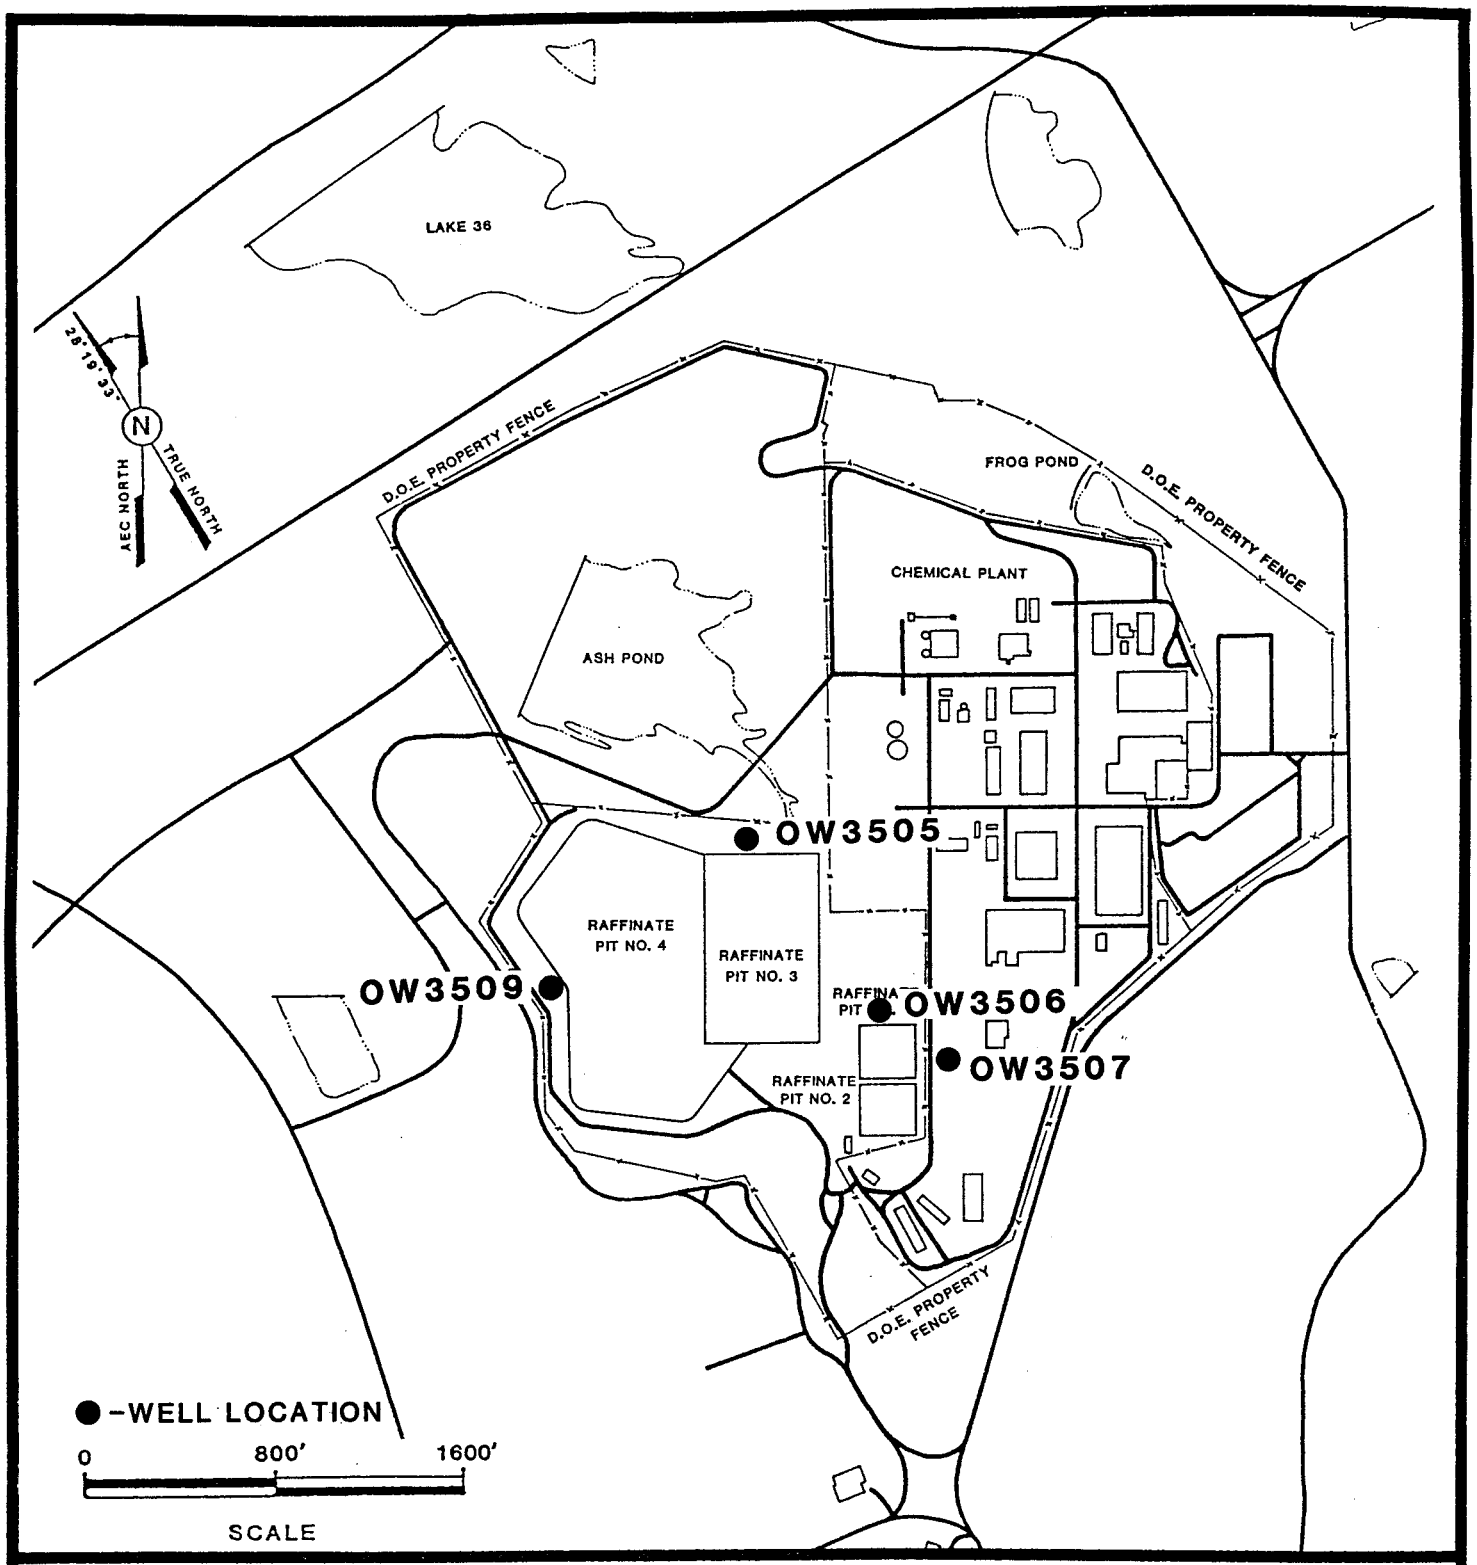

FIGURE 2-15

PROPOSED OVERBURDEN MONITORING WELL INSTALLATION LOCATIONS

installation locations. These areas generally correspond to areas receiving recharge from leaking surface impoundments and/or areas disturbed by previous construction or landfilling activities. Table 2-7 presents a summary of overburden monitoring locations and rationale.

2.4.3.2 Drilling and Installation

Drilling operations for installation of overburden monitoring wells will be performed using hollow-stem augering methods. A supervising geologist will record a lithologic log for each borehole. Split-spoon samples will be collected at intervals of 5 feet, or where cuttings indicate particularly moist zones. Well depths will be adjusted based on field observations.

All drill bits, drill rod, casing, and hand tools will be decontaminated by steam-cleaning prior to beginning drilling and between boreholes. The entire drilling rig will be decontaminated upon arrival on-site.

Wells will be constructed using 2-inch inside diameter (ID) Schedule 40 PVC threaded, flush-jointed screens and casing. Screens will be slotted with 0.010-inch slots. Screen length will be 5 feet to allow sampling of a discrete saturated interval. PVC well materials were selected, since contaminants of concern are not deleterious to PVC and PVC is more readily removable when the wells are abandoned during final remedial action at the site.

Screens and casing will be decontaminated by steam-cleaning and wrapped or covered prior to installation. Screens and casing will be stored above ground to avoid contact with potentially contaminated soils.

The screen and casing will be lowered into the borehole using centralizers to insure that the well is plumb and centered in the

TABLE 2-7
OVERBURDEN MONITORING WELL PLACEMENT RATIONALE

Overburden Monitoring Well	Location	Rationale
OW-3505	North of Raffinate Pit 3, adjacent to OW-3502	Monitor mounding effects from Raffinate Pit 3; OW-3502, installed to monitor shallow seepage, is currently dry
OW-3506	North of Raffinate Pit 1, adjacent to OW-3501	Monitor mounding effects from Raffinate Pit 1; in combination with OW-3501 monitoring shallow seepage
OW-3507	Southeast side of Raffinate Pits 1 and 2	Monitor mounding effects from Raffinate Pits 1 and 2
OW-3509	West of Raffinate Pit 4	Monitor mounding effects from Raffinate Pit 4

borehole. A filter pack of coarse (20-40 mesh) sand will be placed around the screen by tremie pipe to a depth of 2 to 4 feet above the top of the screen.

A bentonite pellet seal will be placed above the filter pack. The minimum thickness will be 3 feet of dry pellets. The pellets will be allowed to set for at least one hour before work continues. The annular space will be sealed to the surface with cement/bentonite grout. A steel protective casing will be set in a concrete pad at the surface. Well construction details were presented previously in Figure 2-3.

2.4.3.3 Overburden Monitoring Well Development

After each well installation is complete and the grout has set for a minimum of 72 hours, each overburden monitoring well will be developed by bailing or pumping. All development equipment will be decontaminated by steam-cleaning before development begins and between wells.

A minimum of five volumes of standing water in the well and filter pack will be removed.

2.4.3.4 Groundwater Sampling

Groundwater sampling of perched and mounded zones will be performed in conjunction with the quarterly monitoring described in the Environmental Monitoring Program Plan. At least two rounds of sampling will be performed for inclusion in final reports and modeling efforts.

Groundwater samples will be collected using submersible bladder pumps and bailers according to WSSRAP Standard Operating Procedures. Measurements of pH, temperature, and specific conductance will be made in the field at the time of sampling.

Groundwater samples will be analyzed for the parameters listed above in Table 2-3.

2.5 SURFACE WATER STUDIES

Results from the Environmental Monitoring Program (EMP) sampling performed in 1987 and 1988 will be incorporated into the overall hydrogeologic characterization and used to determine the impact to surface water bodies of contaminants that may migrate from the WSS through runoff following precipitation or snowmelt. The following sections describe the surface water regime, and present known surface/subsurface connections; sample locations and analytical parameters are also given.

2.5.1 Surface Water Regime - WSCP/WSRP

Surface waters at the WSCP consist of Ash Pond, Frog Pond, and all drainages from both the WSCP and WSRP areas. Surface runoff from approximately 166 acres of the WSCP/WSRP area ultimately flows to the Mississippi River. Twenty-two acres drain toward the Missouri River. Drainages from the WSS are shown on Figure 2-16. The raffinate pits, comprising 27 acres, are impounded within the site, with no discharge.

Surface water from the 166 acres in the Mississippi River drainage is divided into three major drainage basins: Ash Pond area, Frog Pond area and the Raffinate Pits area. Both the Ash Pond area and the west side of Raffinate Pit No. 4 drain to an unnamed tributary to Schote Creek which flows to Lake 35. Both streams lose water to the subsurface. Some of this lost flow resurfaces at Burgermeister Spring (Dean, 1985). (Burgermeister Spring is considered "surface water" in the EMP.) Surface water from the Frog Pond exits the WSCP and flows into Lake 36. Overflow from Lake 36 enters Schote Creek and flows into Lake 35.

Lake 35 has lost water to the subsurface since its construction

SCALE

(Meyer, 1987). Lake 35 overflows to Schote Creek only during extreme precipitation events. Schote Creek joins Dardenne Creek just east of Highway K.

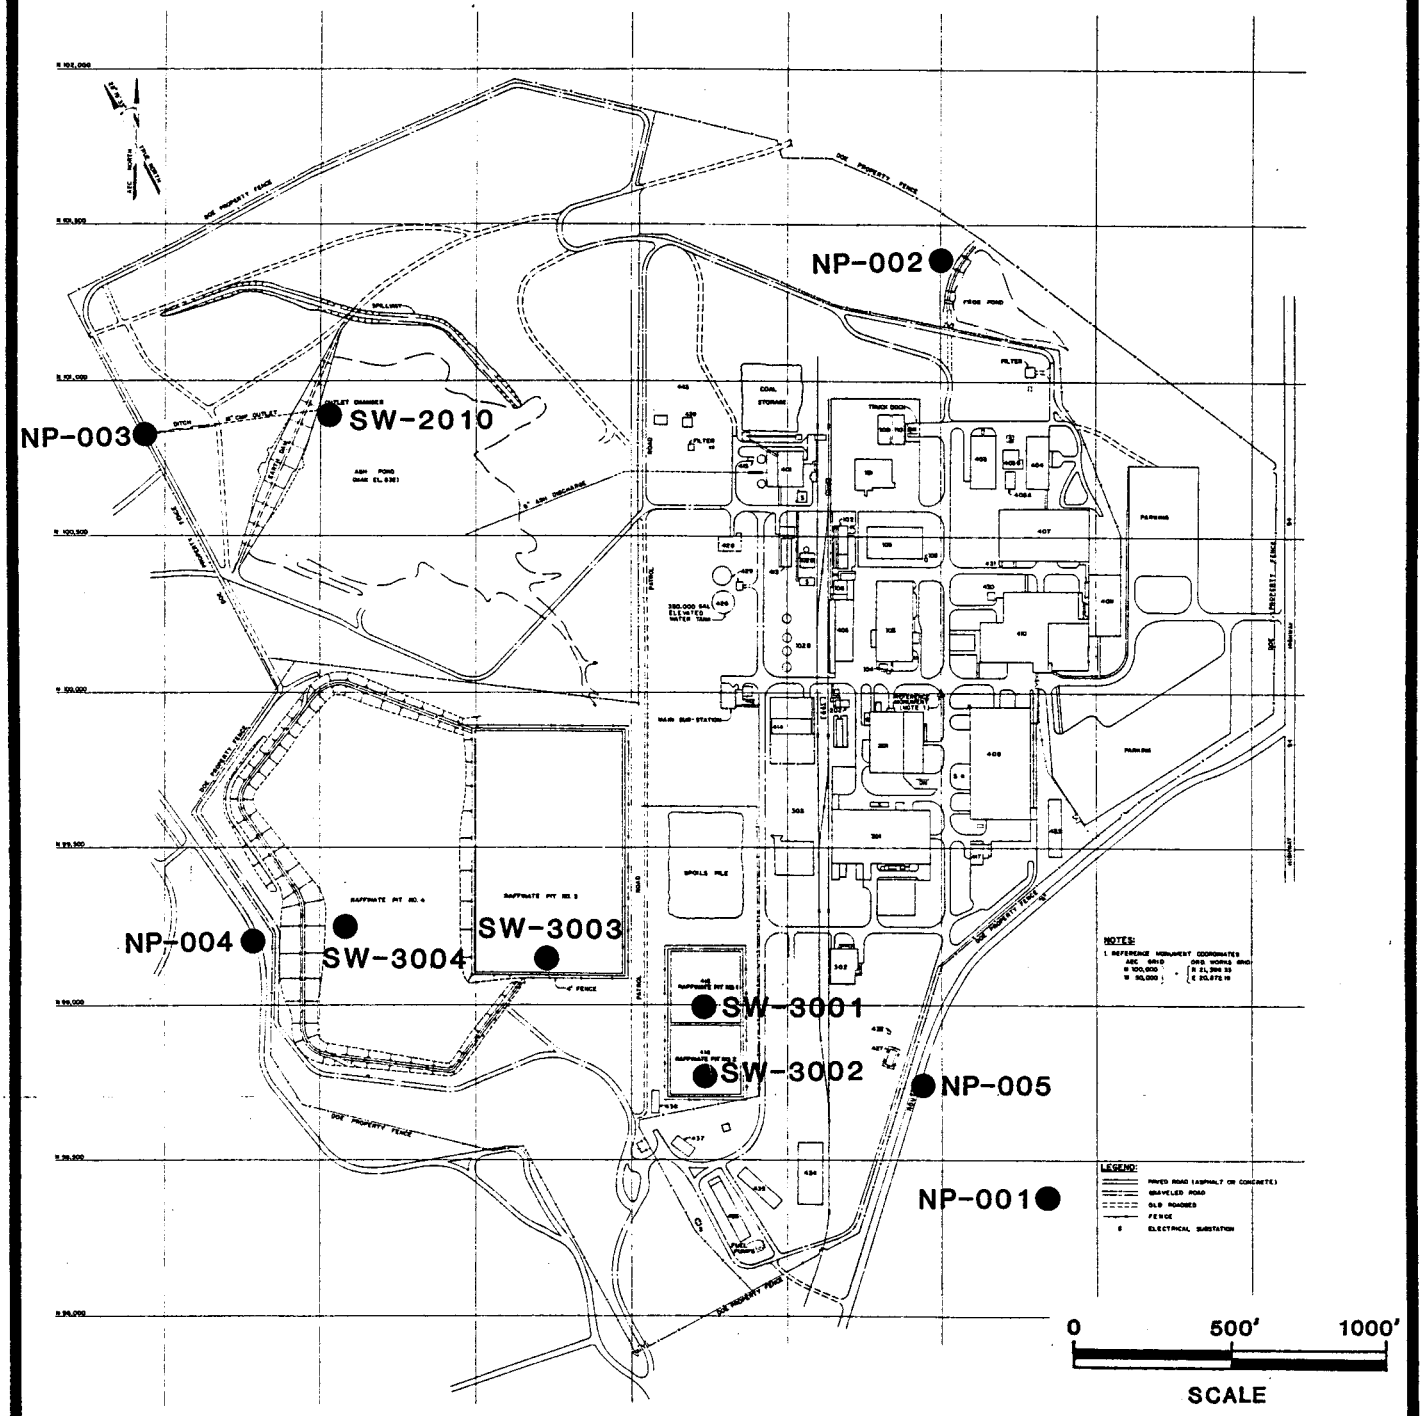
In early 1987, a small swallow hole opened near the headwaters of Lake 35. Missouri Department of Natural Resources dye studies determined that some of the lost water resurfaces in Lake 34 and at a spring just north of Lake 34. Subterranean flow surfacing at Burgermeister Spring flows into Lake 34. Lake 34 outflow enters an unnamed tributary of Dardenne Creek (Figure 2-16). Dardenne Creek flows northeast to the Mississippi River.

The 20 acres of the site that is in the Missouri River drainage is located in the southeast portion of the WSCP. Drainage is via the Southeast Drainage Easement, an intermittent stream valley approximately 1.5 miles long.

Surface water sampling programs have also been performed to support National Pollution Discharge Elimination Standard (NPDES) permits associated with sanitary waste and storm-water runoff. One permit for discharge of sanitary waste through the Imhoff tank expired on December 31, 1986. Sampling consisted of bi-monthly sampling for nitrate, BOD, pH and total suspended solids. In 1986 the DOE applied for a storm-water runoff NPDES permit for the WSCP/WSRP. This permit application is for storm water only; no process waste or other routine discharges occur. Samples collected monthly from five storm-water outfalls are analyzed for gross alpha, natural uranium, nitrate, total suspended solids, total settleable solids and pH. These results are reported to the MDNR according to NPDES procedures. NPDES surface water sampling points are shown on Figure 2-17.

2.5.2 Surface Water Sampling Program

Surface water samples will be collected from 19 locations as shown in Figures 2-17 and 2-18. The rationale for each location



NP - NPDES SAMPLING LOCATION

FIGURE 2-17

ON-SITE SURFACE WATER SAMPLING POINTS

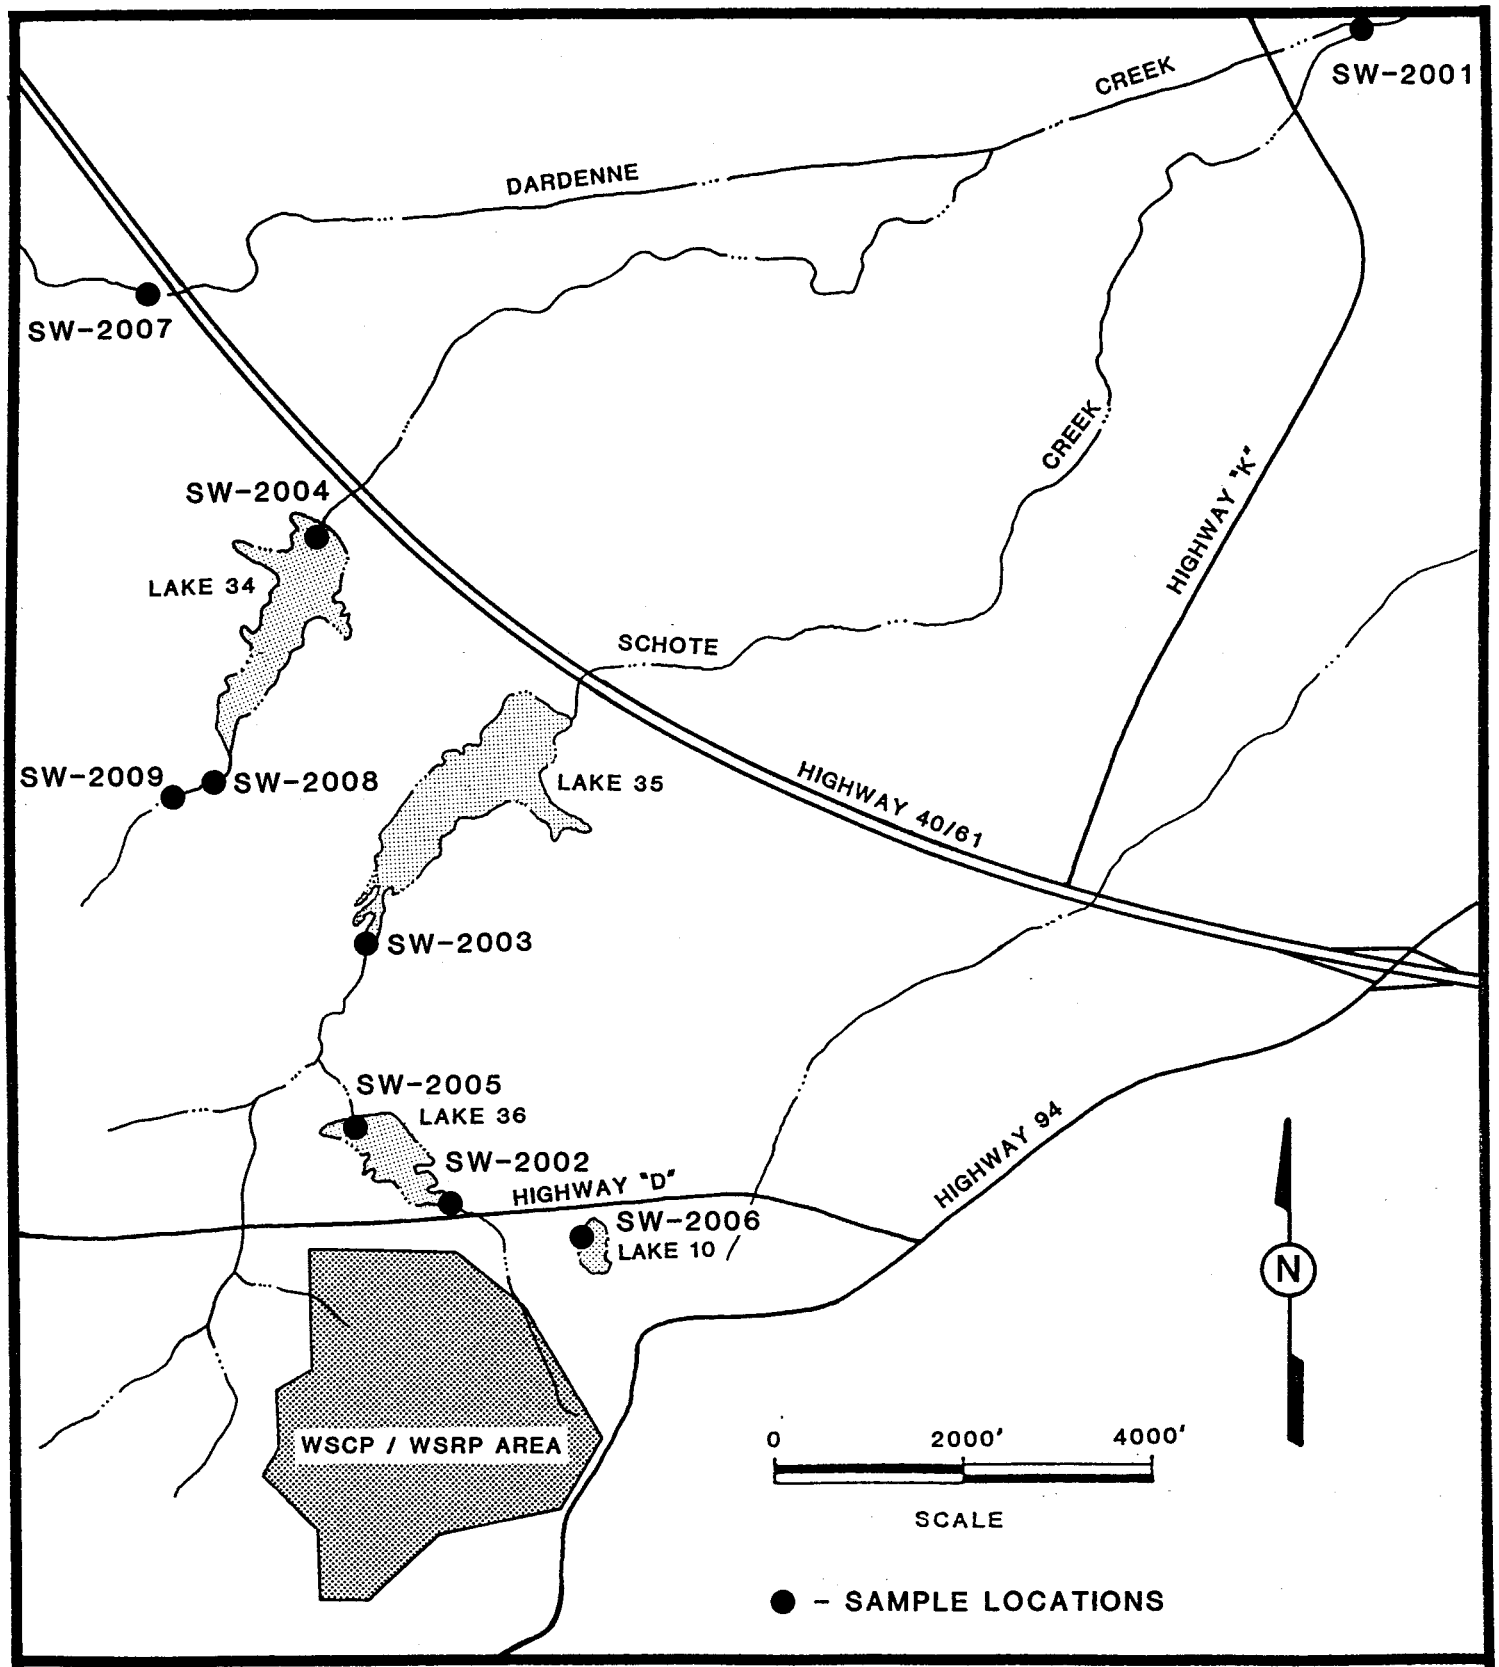


FIGURE 2-18

SURFACE WATER SAMPLING LOCATIONS NEAR THE WSS

is presented in Table 2-8. Samples will be collected concurrently with quarterly groundwater sampling to provide point-in-time comparisons of groundwater and surface water sampling results.

These locations include the five NPDES storm-water discharge points which are currently sampled monthly, nine locations currently sampled under the EMP, the four raffinate pits and Ash Pond. The analytical results will provide water quality information for streams draining the site (some of which lose water to the subsurface), springs discharging potentially contaminated groundwater, and on-site source areas.

Samples will be collected in accordance with procedures outlined in the WSSRAP SOPs.

Analytical parameters for surface water samples include: nitroaromatics, metals, inorganic anions and radionuclides. Parameters were selected based on the results presented in the Phase I Water Quality Assessment, known processes at the WSCP and previously collected data. Complete analytical parameters are presented in Table 2-9.

2.6 REGIONAL HYDROGEOLOGY AND WATER BALANCE

The U.S. Geological Survey (USGS) will perform studies of regional hydrogeology and water balance culminating in the development by the USGS of a three-dimensional regional groundwater flow model. Additional USGS efforts will focus on site-related water quality issues and will serve to provide third-party verification of WSSRAP efforts.

2.6.1 Regional Groundwater Flow and Water Balance

USGS studies will provide further refinement of regional hydrogeology as presented in previous USGS publications and

comprehensive water balance measurements. The USGS will combine these results with WSSRAP data obtained from the field programs outlined in Sections 2.2 through 2.5, to produce a regional groundwater flow model encompassing the shallow aquifer in the Burlington-Keokuk Formation, the leaky confining layer, and deep aquifers in the sequence from the St. Peter Formation through the Potosi Dolomite.

Potentiometric surface maps will be derived from water-level measurements in groundwater monitoring wells installed on-site by WSSRAP, from USGS monitoring wells located on the Busch Wildlife Area to the north of the site, and from various private wells around the site that are suitable for monitoring and sampling. These maps will extend beyond the immediate vicinity of the site covered by the WSSRAP potentiometric surface maps discussed above in Section 2.1.3.

Continuous water level recorders will be installed on six wells near the groundwater flow divide south, east, and northeast of the raffinate pits (Figure 2-19). Daily fluctuations in the groundwater levels will be correlated with precipitation, evapotranspiration, infiltration and barometric fluctuations in order to evaluate and determine the role of each of these factors on the water balance of the plant site. Also, data collected will be used to define the direction of groundwater flow. The locations of the six wells are subject to change as new data are received and analyzed from the drilling program.

Twelve aluminum infiltration tubes (2 3/8 inch OD) will be installed in various soils on the WSS and vicinity properties as shown on Figure 2-20 in order to measure soil moisture content. Use of a neutron probe is a nuclear method of determining moisture content and porosity of soil as described in Sections 2.4.1.2, 2.4.1.3 and 2.4.1.4.

The data that is obtained from neutron probe measurements will be

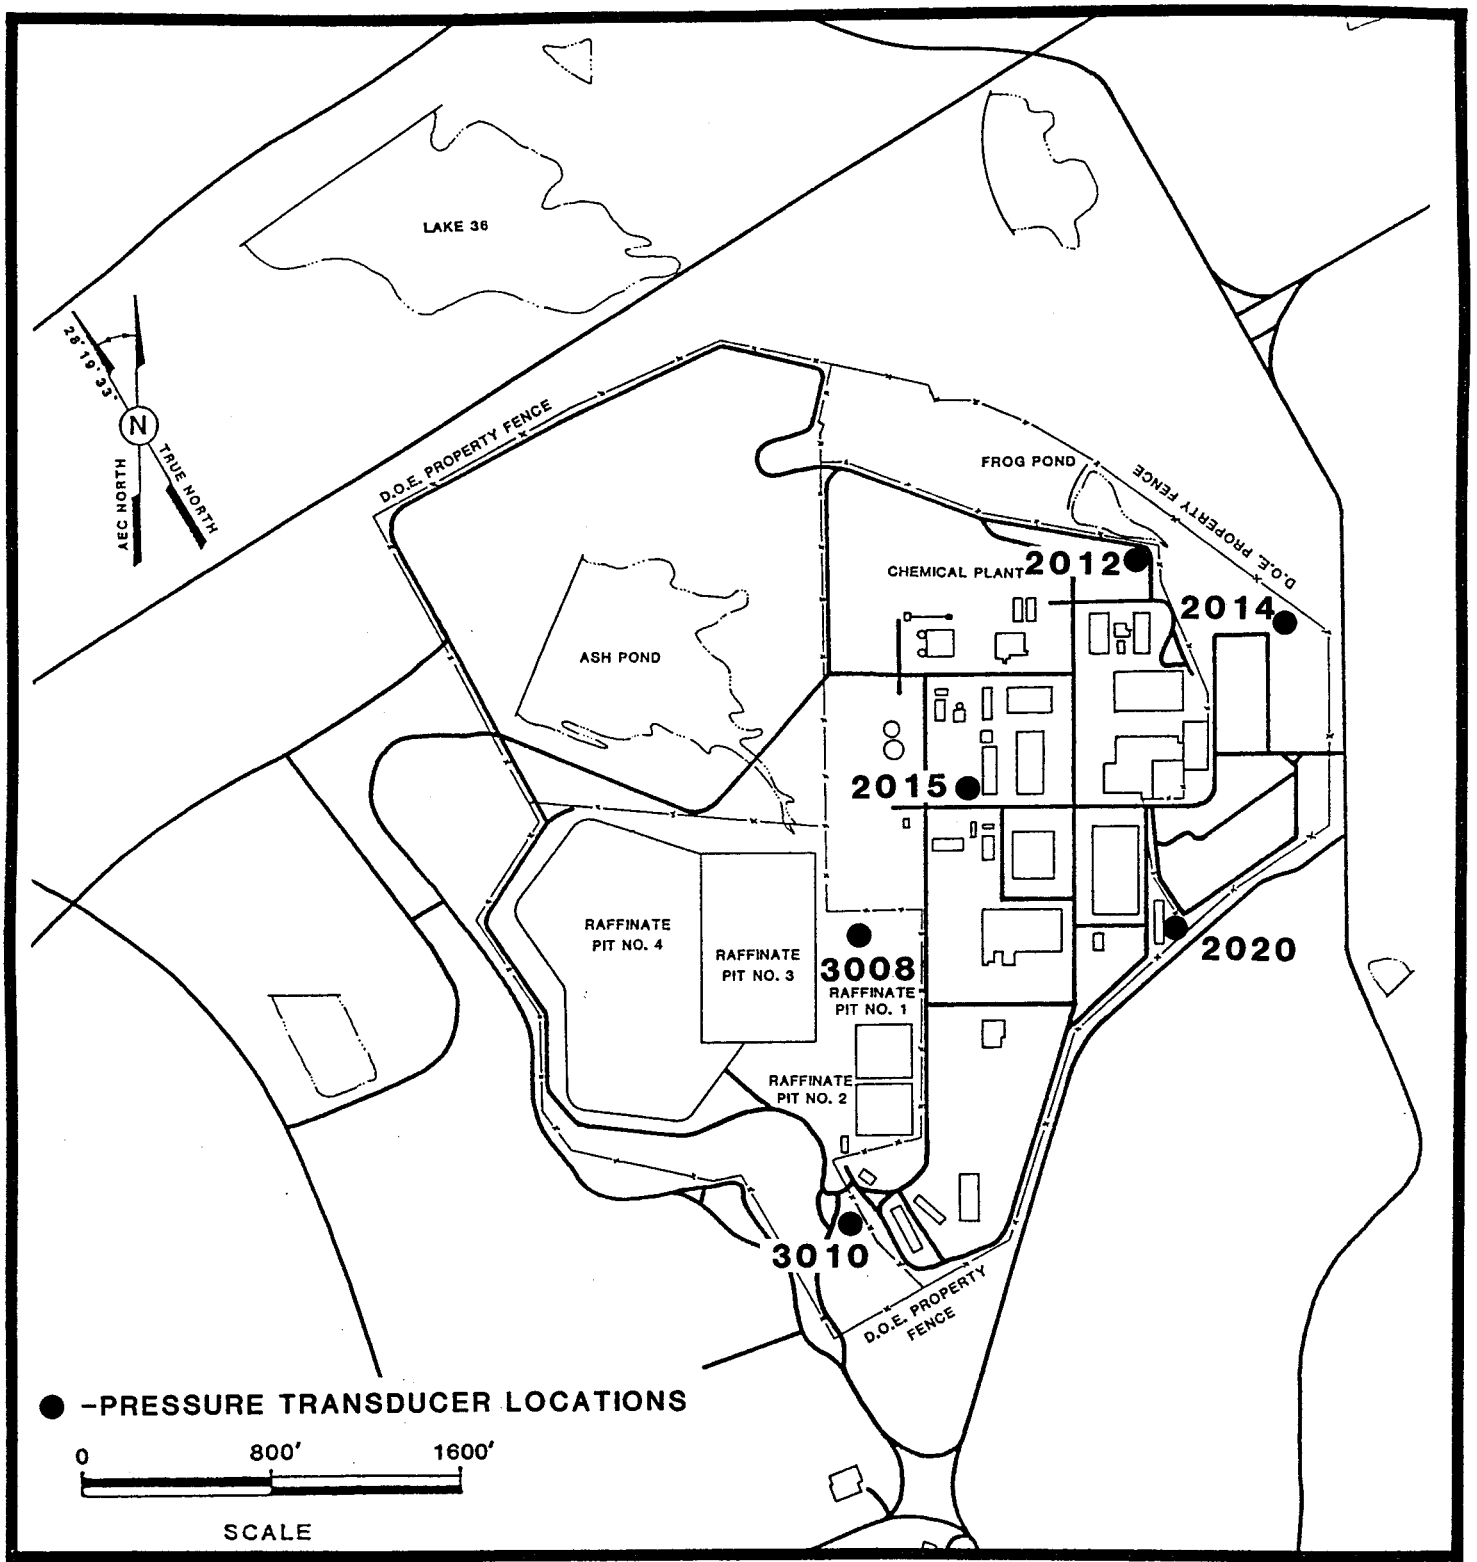

FIGURE 2-19

EXISTING MONITORING WELLS TO BE EQUIPPED WITH CONTINUOUS WATER LEVEL RECORDERS

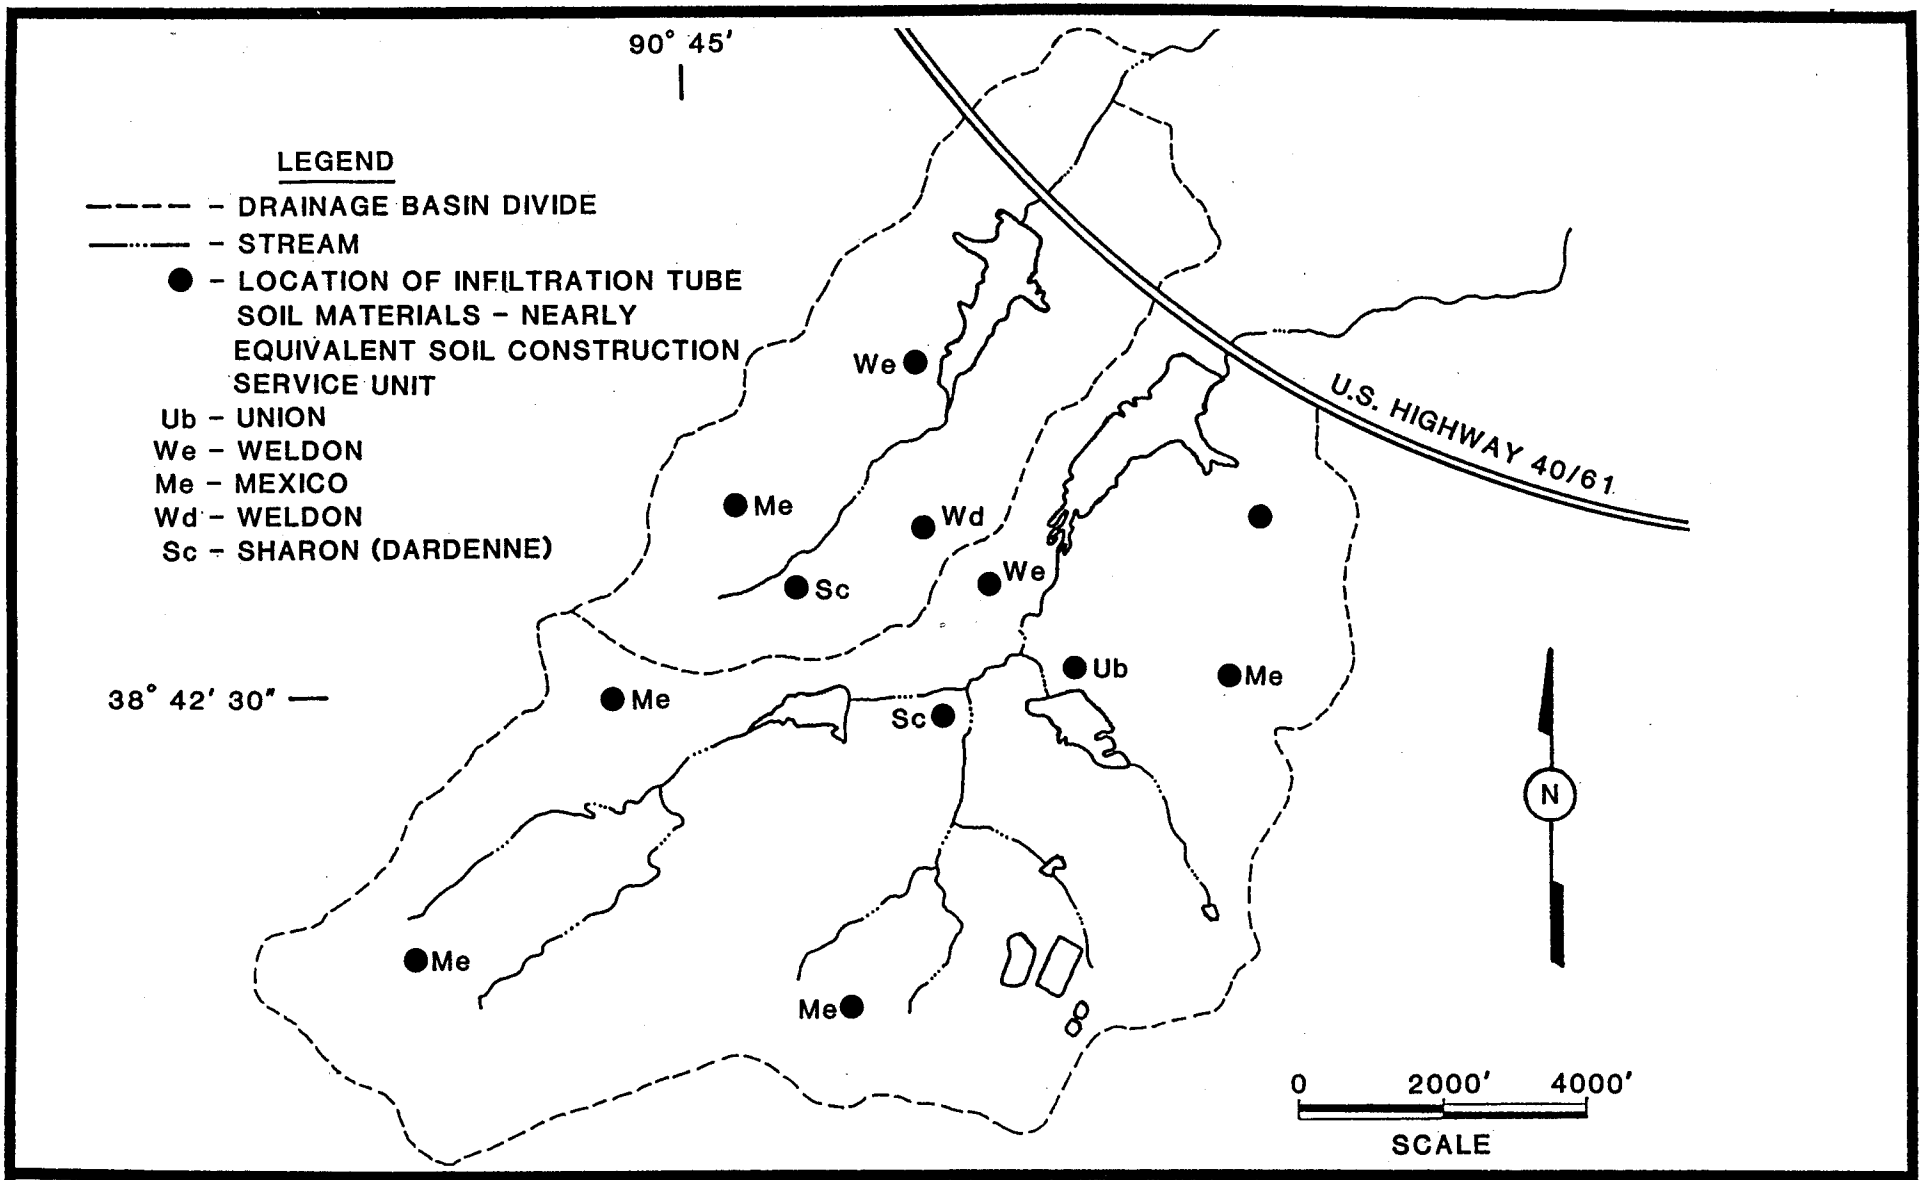

FIGURE 2-20

LOCATION OF INFILTRATION TUBES

used to monitor the saturation of unconsolidated overburden and provide an estimate of evapotranspiration. These data will allow an estimate of the quantity of water that infiltrates into the aquifers and, when compared with precipitation data, will assist with the determination of the water balance.

The regional groundwater flow study will include the installation of two clusters of deep monitoring wells by WSSRAP at the locations shown on Figure 2-21 in order to determine vertical gradients between the shallow and deep aquifers underlying the site. Water samples from various depths and aquifers will be analyzed to determine water quality differences. One well cluster will be located immediately south of the site near the groundwater flow divide. This location was selected to monitor vertical gradients near the groundwater flow divide, which will constitute a no-flow zone (at least in the Burlington-Keokuk Formation) in the regional groundwater model. The second well cluster will be located near Dardenne Creek which is at a lower topographic elevation and is considered to be a hydrogeologic boundary for shallow groundwater flow. Monitoring of vertical gradients at this location will help to determine the depth to which regional groundwater flow in the shallow aquifer, leaky confining layer, and deep aquifer is affected by discharge to Dardenne Creek. Comparison of differences in vertical gradients between the immediate vicinity of the site and Dardenne Creek will allow for accurate calibration of the regional flow model.

Each observation well cluster will consist of one well with the screened sector in the Burlington-Keokuk Limestone Formation at a depth of approximately 100 feet, one well with the screened sector in the Kimmswick Limestone Formation at a depth of approximately 300 feet, and one well with the screened sector in the St. Peter Sandstone Formation at a depth of approximately 700 feet. The cluster immediately south of the site will consist of two deep wells clustered with an existing monitoring well screened in the Burlington-Keokuk Formation (MW-4019). A

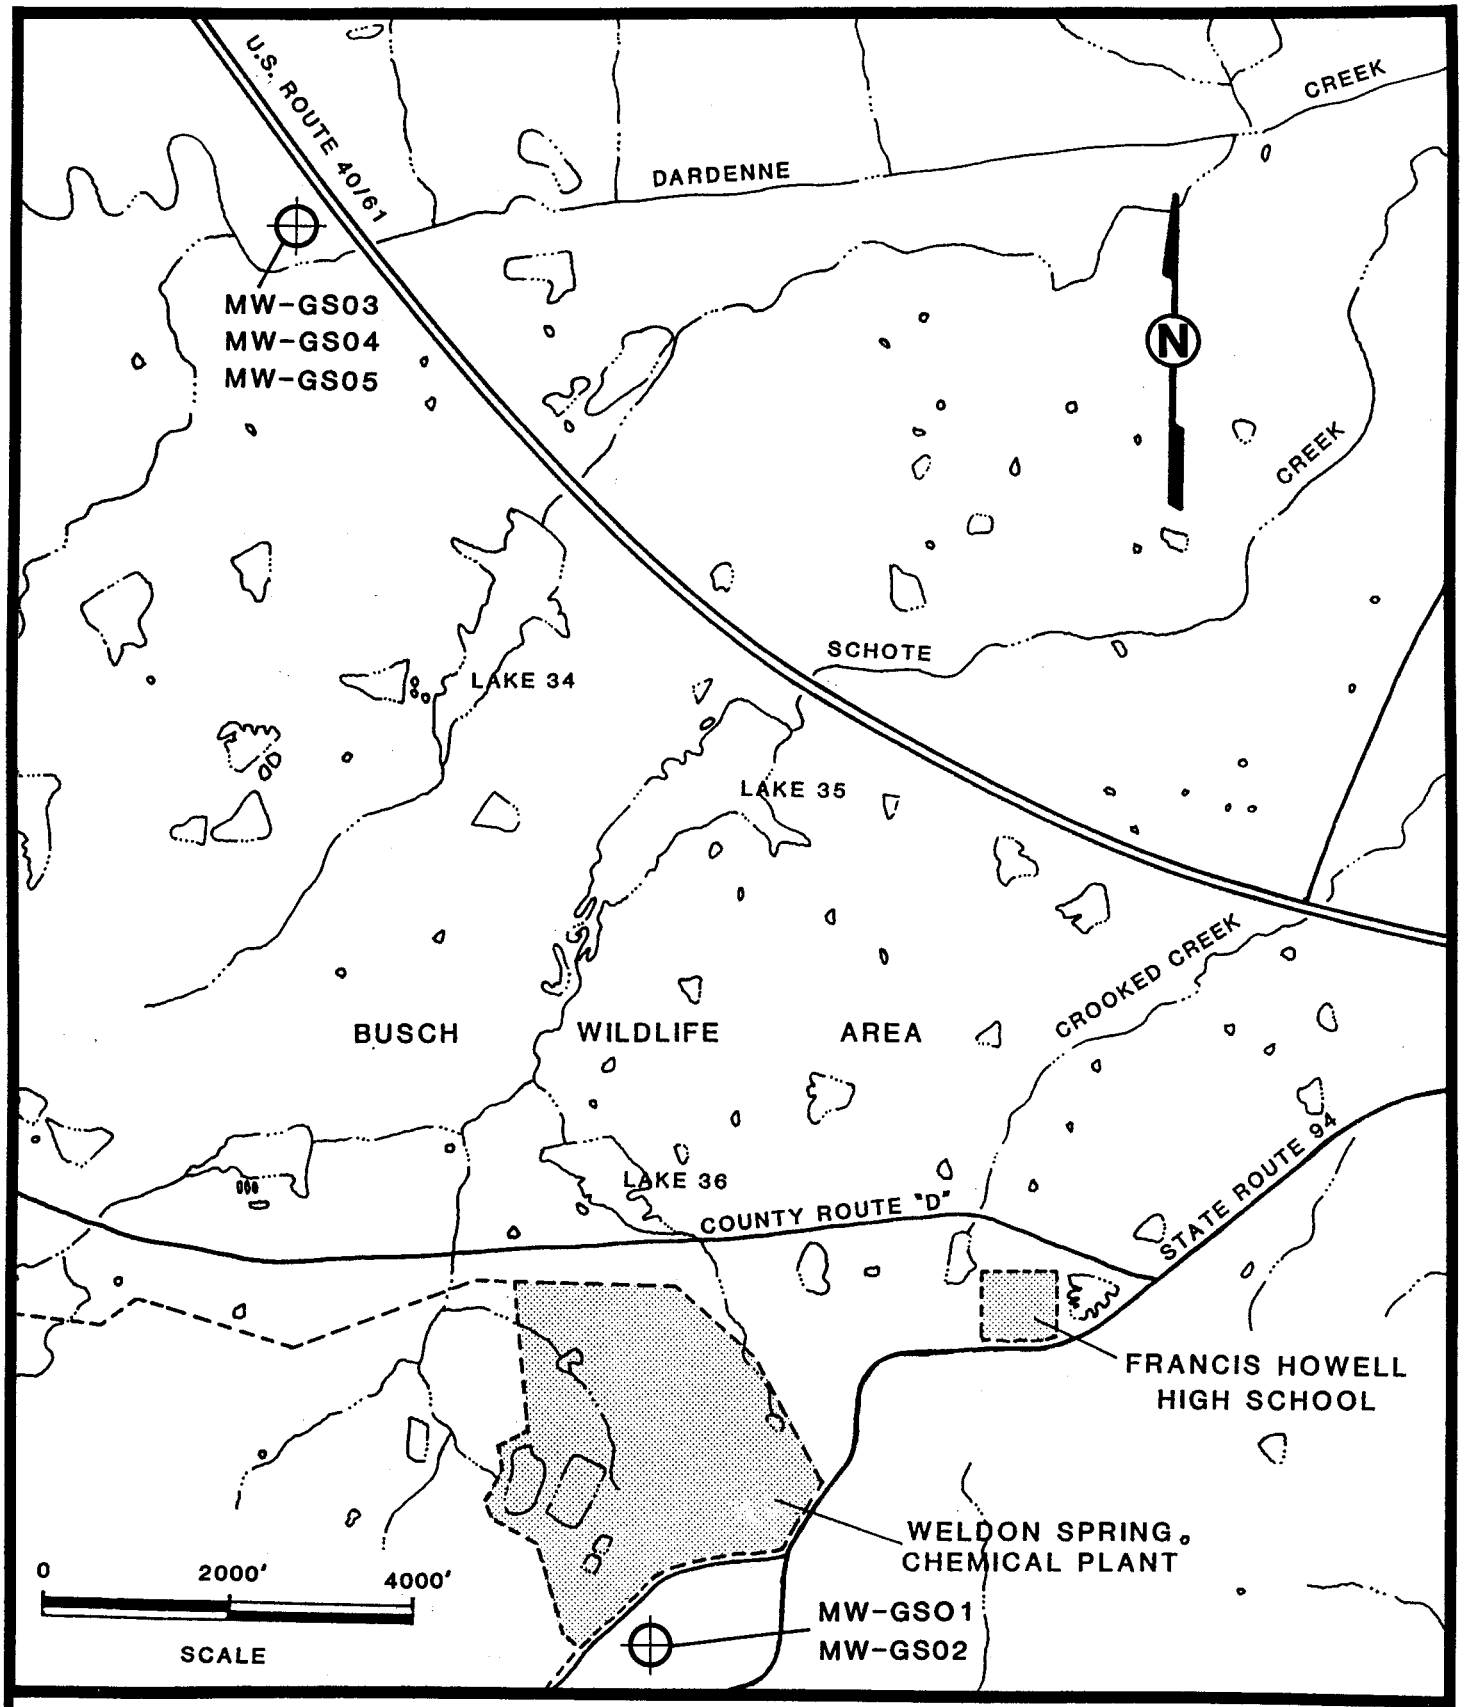

FIGURE 2-21

MONITORING WELL CLUSTER LOCATIONS

geologist will monitor drilling progress, collect rock samples from cores and drill cuttings and ensure compliance with WSSRAP Standard Operating Procedures.

Surface features that relate to groundwater accumulation, movement, or quality will be investigated in depth for the purpose of developing the groundwater flow model. Springs, seeps, losing stream segments, gaining stream segments, karst features in limestone bedrock, fractures, joints, geological structures and any additional phenomena which may become evident during the course of field efforts will be investigated for the purpose of determining effects on water balance and flow characteristics. This portion of the investigation will be performed in cooperation with the Missouri Department of Natural Resources, Division of Geology & Land Survey.

Remote sensing, aerial photographs, side-looking radar, infrared photography and other methods may be employed to delineate surface features. A field reconnaissance program will be conducted in order to locate and define these features and to quantify their effects.

Flow and discharge data from the continuously recording stream gauging stations currently in place on Schote Creek and the unnamed Dardenne Creek tributary which contains Burgermeister Spring will also be used in water balance studies.

Continuous discharge monitoring of Burgermeister Spring will permit comparison of the effects of various weather conditions on spring discharge and chemical quality. Surface water discharge will be compared with other monitored parameters including water table fluctuations, barometric changes, precipitation, temperature, humidity, evapotranspiration and infiltration.

Precipitation amounts will be measured during the spring, summer, and fall months with 19 catch rain gages located in the basins of

Schote Creek and the unnamed tributary that contains Burgermeister Spring (Figure 2-22). The total area of these two basins is about 4.6 square miles. Because of the variability of precipitation during localized thunderstorms during these months, these 19 rain gages are needed. During the winter when storms are regional in nature, the number of rain gages will be reduced to nine. Rainfall amounts will be calculated using both the isohyetal and Thiessen methods. The rainfall data will be used to accurately determine the amount of precipitation within these two basins for utilization in water balance calculation and groundwater flow modeling calibration.

The regional groundwater flow model will be constructed using the USGS 3-Dimensional Groundwater Flow Model (MOD). Vertical extent of the model will be from the surface (Burlington-Keokuk Formation) to the base of the Potosi Dolomite. Tentative horizontal boundaries are constant-head or constant-flow boundaries at the Missouri River and Dardenne Creek to the north and south and no-flow boundaries along major drainage divides to the east and west. Data used to construct the model will include the potentiometric surface and water balance data discussed above and aquifer testing data from WSSRAP efforts discussed above in Section 2.2.

2.6.2 Water Quality

USGS studies include both surface and subsurface water sampling. Water samples will be collected on a quarterly basis from USGS monitoring wells in the Busch Wildlife Area, selected private wells, and selected surface water locations. These data will be combined with WSSRAP data for a regional analysis. The statistical analysis of water quality data will form the data base for the description of the groundwater chemistry. The preliminary list of analytical parameters to be tested is presented on Table 2-10.

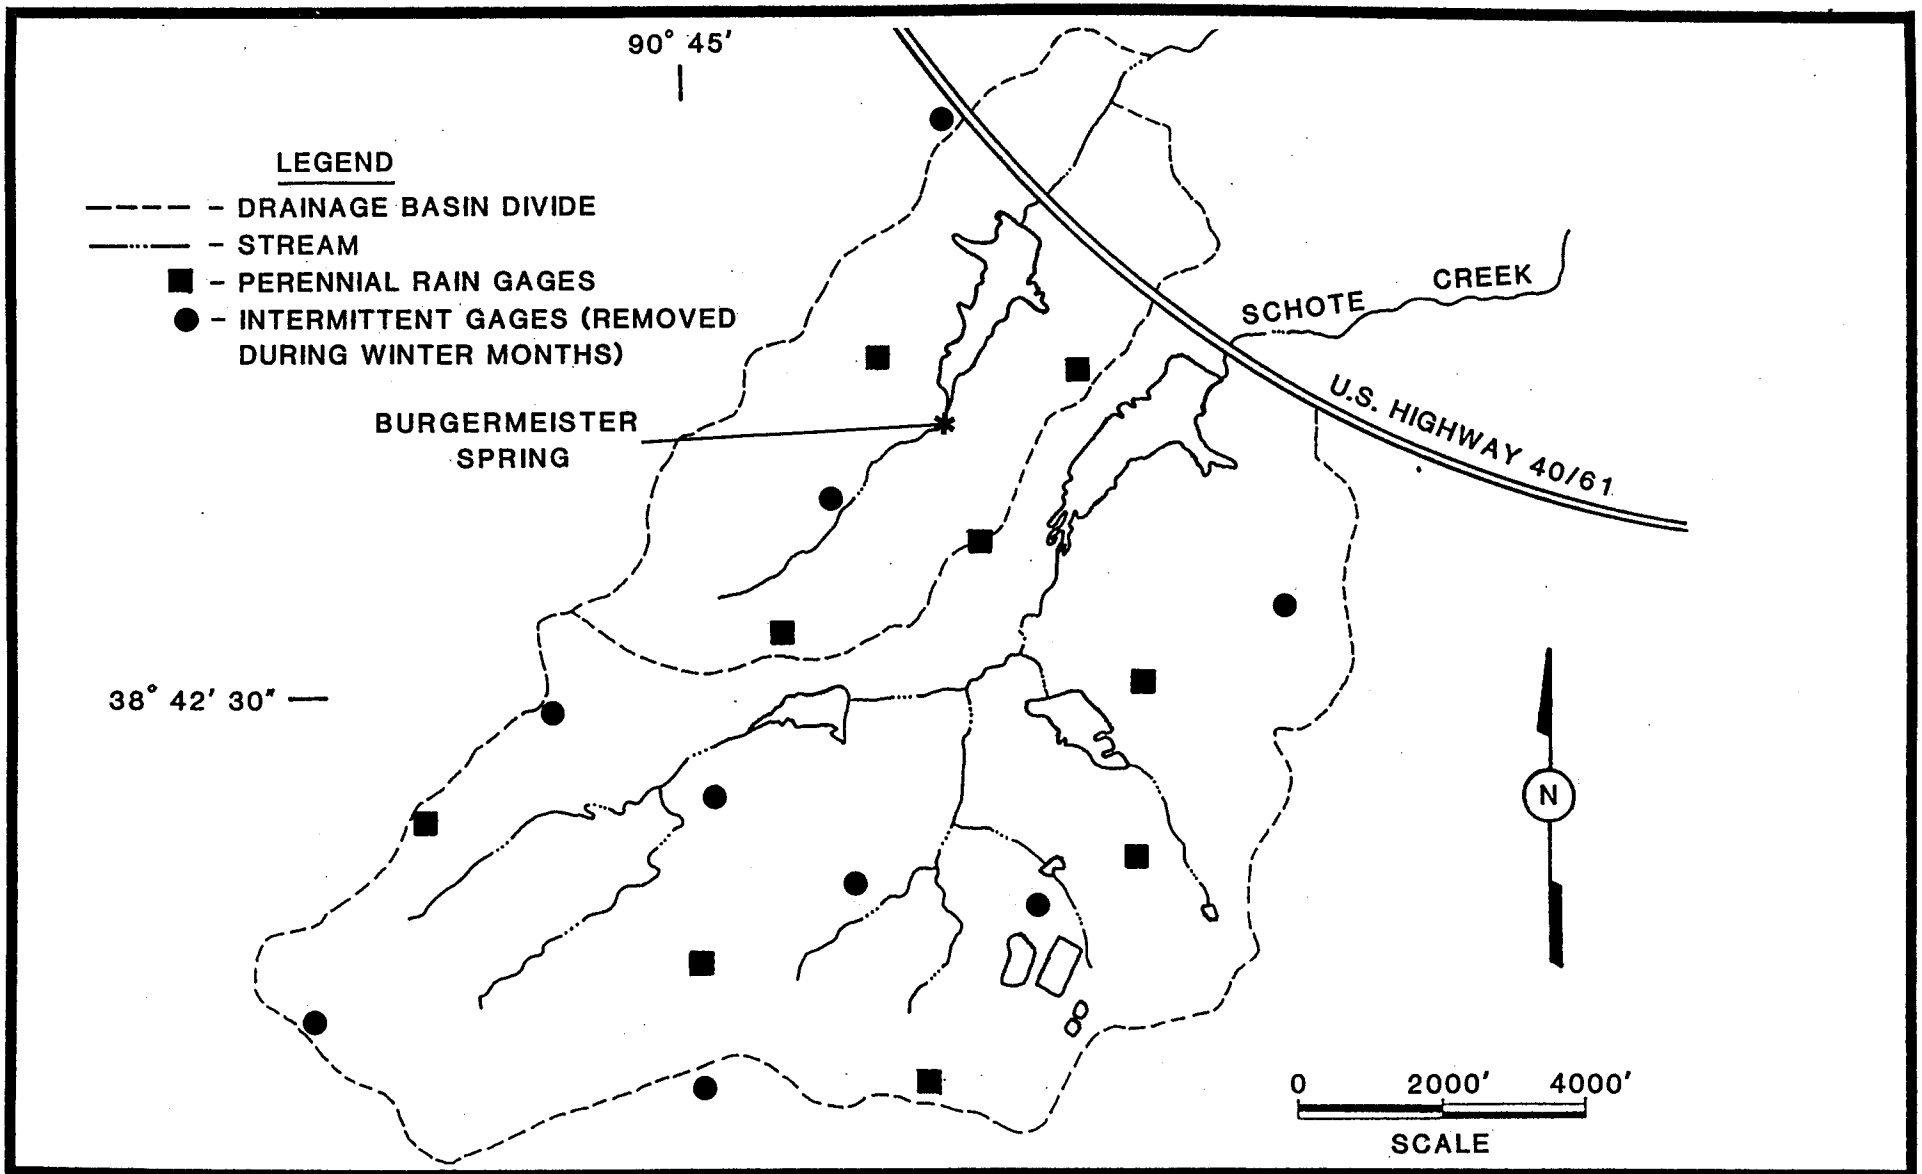

FIGURE 2-22

LOCATION OF USGS RAIN GAGES

TABLE 2-10

ANALYTICAL PARAMETERS FOR USGS WATER QUALITY STUDIES

Specific Conductance
pH
Temperature
Total Organic Carbon
Dissolved:

Calcium	Carbonate
Magnesium	Bicarbonate
Potassium	Sulfate
Lithium	Nitrate
Strontium	Chloride
Uranium	Fluoride
Radium-226	Solids
Sodium	

In addition to the listed parameters, samples will be analyzed for tritium, radium-228 and nitroaromatics on a one-time-only basis unless elevated concentrations are discovered. In the event of the identification of samples containing concentrations above background level, additional sampling and analysis would be conducted in order to further define the extent and concentration of the contaminants in the areas affected.

Continuously recording temperature and specific conductance monitors ("mini-monitors") were installed at Frog Pond, Ash Pond and Burgermeister Spring in 1987 (Figure 2-23). These monitoring sites will continue to be operated to determine how water quality varies with time, climatic conditions and remedial action activities conducted on the site.

The geochemistry of the natural unconsolidated overburden sediments on the site will be investigated in order to determine its effect on contaminant migration. Once the water balance has been determined, these data will be instrumental in determining the locations of contaminant plumes and predicting the direction and rate of plume migration.

2.6.3 Computer Modeling of Chemical and Mineralogical Balance

Geochemical models including WATER and BALANCE will be used in determining the normal chemical balance for groundwater underlying the Weldon Spring Site. WATER calculates the equilibrium distribution of inorganic aqueous species of both major and minor chemical elements. BALANCE defines and quantifies the reactions that will occur between groundwater and naturally occurring minerals in the aquifers.

Data required for these programs include aqueous chemistry and quantitative mineralogy. The aqueous chemical data will be derived from the analysis of the water samples collected from

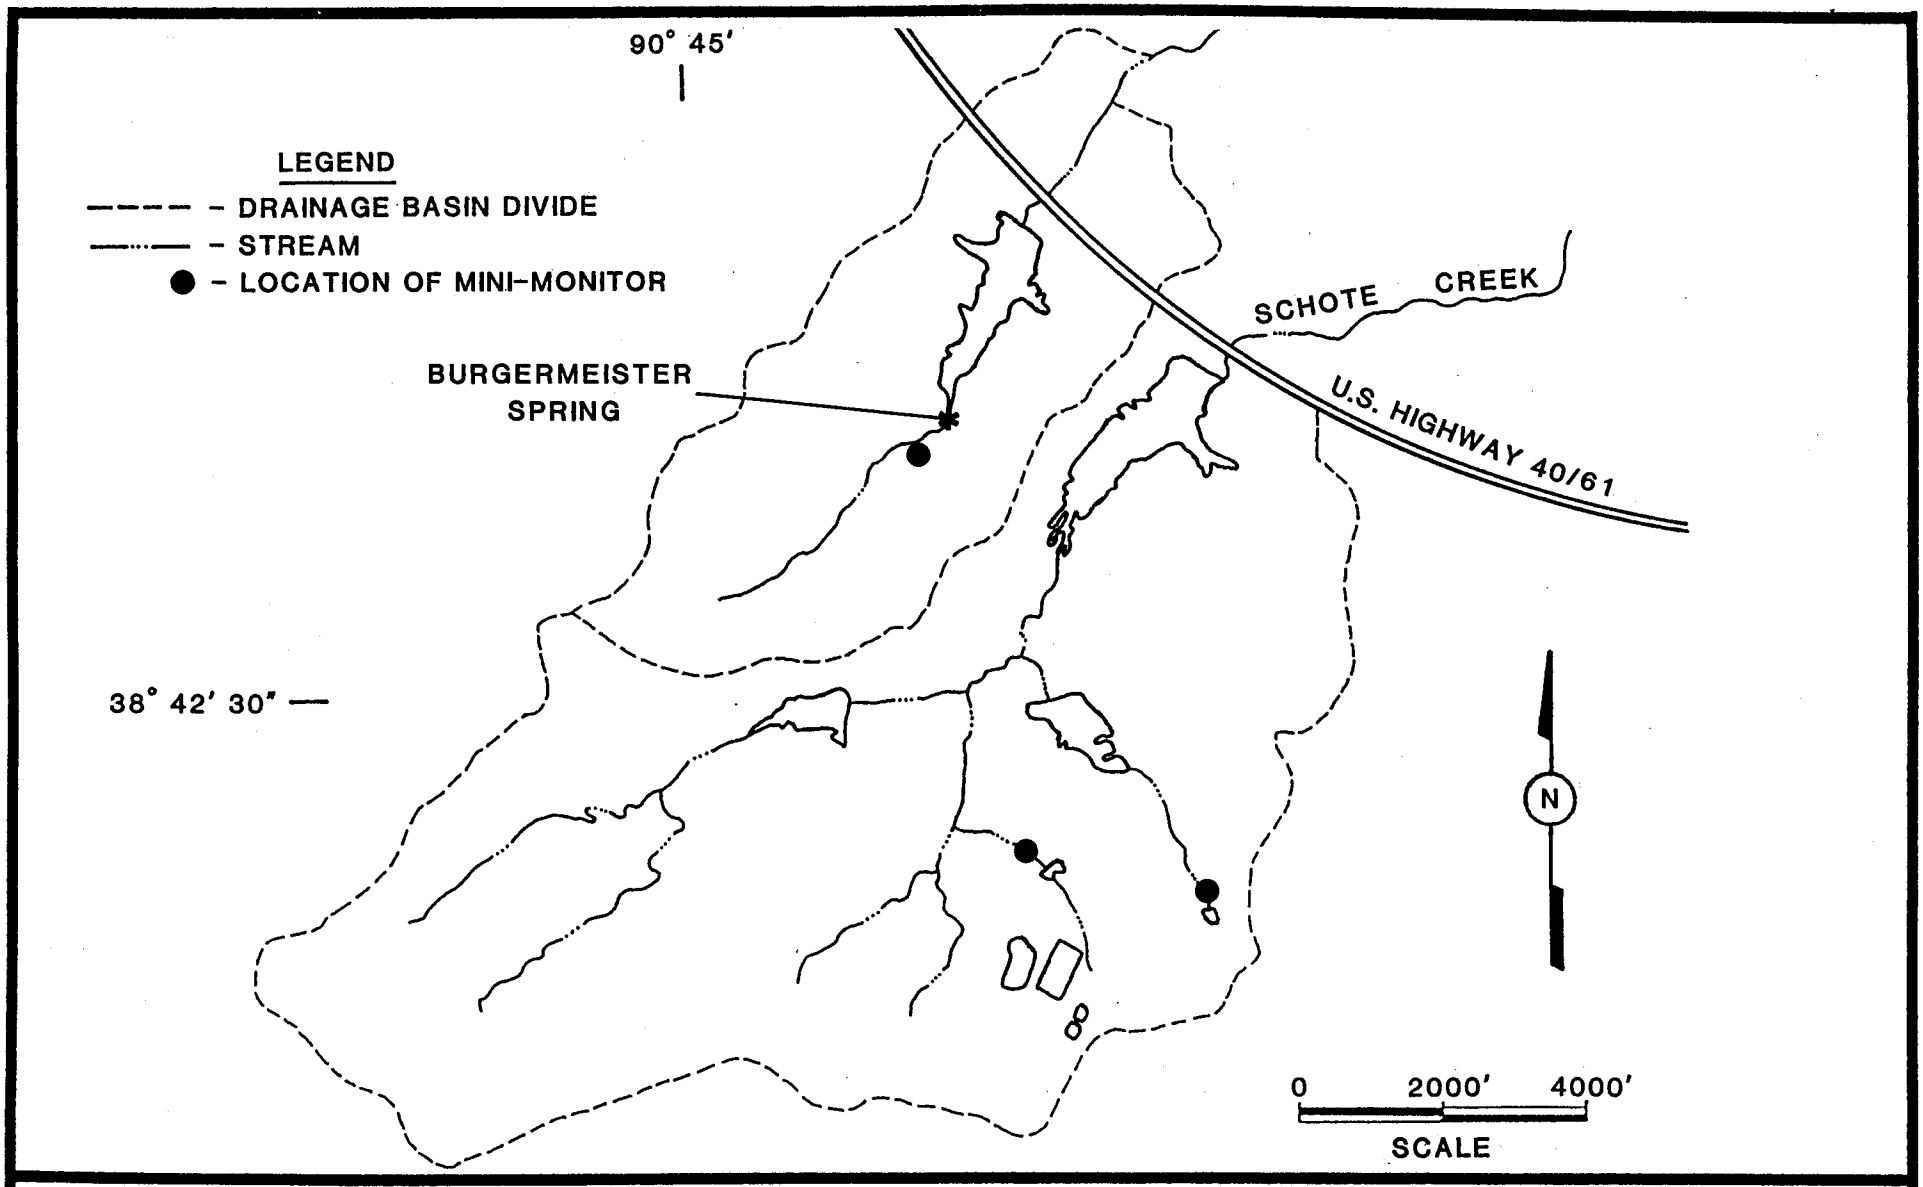

FIGURE 2-23

LOCATION OF USGS MINI-MONITORS

groundwater monitoring wells, and springs and streams on and near the site. The quantitative mineralogy will be determined from cores and overburden samples from wells drilled and trenches cut in both the unconsolidated overburden sediments and the bedrock formations underlying the Weldon Spring Site. The percent of clay minerals and non-clay minerals, as well as the types of clays present at the Weldon Spring Site will be determined. Soil samples will be collected from each of the soil horizons present at approximately a dozen locations distributed throughout the site. Mineralogic analyses will be performed by USGS laboratories.

2.7 COMPUTER MODELING OF GROUNDWATER FLOW SYSTEMS

Groundwater flow models will be developed in order to define and describe the flow regime in the shallow bedrock aquifer underlying the Weldon Spring Site and to predict contaminant migration in this flow regime. These models will be developed by the Department of Geological Engineering of the University of Missouri-Rolla in cooperation with WSSRAP staff. This site-specific modeling is designed to complement the regional modeling performed by USGS.

Models of unsaturated flow, groundwater flow, and contaminant transport will be calibrated to match the field parameters at the Weldon Spring Site. Statistical analyses including probability and uncertainty will be performed to establish reliability of the groundwater flow models.

2.7.1 Computer Programs

Three simulation programs have been chosen for the project because each has certain desirable properties that fit the groundwater flow system at the Weldon Spring Site. Use of these programs will help to identify groundwater flow direction and contaminant transport. The models include the following software:

- o A Modular Three-Dimensional Finite-Difference Groundwater Flow Model (MOD).

- o Saturated and Unsaturated Transport Flow Model (SUTRA).

- o Three-Dimensional Flow and Transport Model (SWIP).

MOD and SWIP are three-dimensional models and SUTRA is a two-dimensional model. Should new parameters arise during the course of field work which are not applicable to MOD, SWIP, or SUTRA, additional software is available to accommodate any additional parameters.

2.7.2 Model Design

Three basic steps are required for the general model design process including: (1) development, (2) calibration, and (3) verification. The development step involves the determination of which parameters are available from the compilation of field studies and which parameters must be derived during the process of calibration and tuning of the program to produce verifiable results.

Calibration is accomplished by modifying and adjusting the undefined parameters until the computed water levels match historical field water levels as measured during a discrete period of time. Unspecified aquifer parameters may include dispersivity, hydraulic conductivity, storativity and others. Field data will not provide perfect definition of all parameters. For some parameters the models will exhibit high sensitivity, while others will have minimal effect on model results. Sensitivity analysis is accomplished by slightly varying a single parameter while all other parameters are held constant. The variation may be repeated over differing typical ranges of a given parameter's value. Models which are essentially insensitive to a given parameter do not require

extensive field data. Models which are very sensitive to a given parameter may ultimately require both extensive and intensive field studies in order to adequately calibrate the computer model.

Verification is accomplished by employing a period of historical water level data which was not used in the model calibration process. The model is verified when the computed and measured water levels match. A poor match requires additional calibration until such time as repeatable verification can be established.

2.7.3 Model Application

Practical application of the computer modeling effort is divided into three separate phases based on the hydrogeologic conditions at the Weldon Spring Chemical Plant and Raffinate Pits sites.

- Phase 1 will focus on the contaminant transport in the shallow unsaturated zone using SUTRA which is a two-dimensional unsaturated transport model. This model will be calibrated and verified and the results will be used to predict recharge rates, which will be used to develop constant flow boundary conditions for use in Phase 2.

- Phase 2 will use MOD, a three-dimensional flow model, to predict contaminant transport in the saturated, fractured bedrock aquifer system. This aquifer will initially be modeled as an equivalent porous medium. The fracture system in this bedrock formation will ultimately be accounted for by imbedding high conductivity zones within the less conductive equivalent porous medium matrix. This model will be calibrated and verified and the results will be used in the development of the Phase 3 model.

- Phase 3 will evaluate contaminant transport along

vertical sections of the fractured and saturated bedrock aquifer using SWIP, a three-dimensional contaminant transport model. Results from Phases 1 and 2 will be used in the development of the Phase 3 model. The Phase 1 model will supply boundary data and the Phase 2 model will provide steady-state flow conditions, which are parameters necessary for the development of the Phase 3 contaminant transport model.

Parameters needed for the purpose of accurate model calibration include:

- o Vertical variation of soil contamination: This will be determined by soil sampling and analysis.

- o Flow characteristics in the unsaturated zone: This will be measured by neutron probes and tensiometers as discussed in Section 2.4.1.

- o Transmissivity in the fractured bedrock aquifer: Field methods for the determination of aquifer transmissivity by pumping tests are discussed in Section 2.2.2.

- o Major conduit forming fractures or fracture zones: The location, orientation and configuration of bedrock fracture systems will be determined through the integration and interpretation of all available subsurface surveys, both direct and indirect.

Open fracture systems will constitute the major controlling geological feature in any groundwater flow system in which they occur and must be incorporated into the flow model. The size and extent of such features should be mapped as accurately as possible. Aperture width, fracture spacing and the nature of any filling materials should be measured as accurately as practicable

within the limitations of the current prevailing field technology.

The final verified models will be used to evaluate the potential for significant contaminant migration in the shallow bedrock aquifer from the Weldon Spring Chemical Plant and Raffinate Pits sites to adjacent areas of beneficial use. The models will also be utilized in the planning, evaluation and development of various subsurface restoration/mitigation options that may be considered in future site remediation plans.

2.7.4 Model Uncertainty

Model uncertainty is an inherent quality that is directly related to the sophistication of the model design. The more variable parameters that are properly recognized, treated and manipulated in the model design, development and calibration, the more accurately the model will imitate the natural phenomena under investigation.

An important aspect of model uncertainty is the quality of the raw field data used as input to the modeling process. It is imperative that as many variable parameters as possible be identified and accurately measured in the field. Field investigations are an integral aspect of the program in progress at the site. Field research includes soil and water quality sampling from groundwater monitoring wells, water quality and discharge measurement from several surface streams and springs and continuous recording of water levels in several ponds and streams.

The additional groundwater monitoring wells installed during 1988 will better define areas of contamination and flow patterns (Section 2.1.1.2). Slug tests (Section 2.2) and pumping tests (Section 2.2.2) will be employed in the determination of hydraulic conductivity, transmissivity, storativity and anisotropy--parameters which will be utilized in the process of

calibrating the computer models.

A site-specific investigation of the fractured limestone bedrock aquifer will include the identification of controlling fractures, fracture zones and fracture systems. The fracture system will be studied by means of field identification, measurement and mapping, and analysis of aerial photographs and topographic maps. The effect of fractures on the groundwater flow regime will be determined by comparing the configuration of the piezometric surface of the shallow bedrock aquifer to the orientation of the individual components of the integrated fracture system. Direct comparisons of these parameters will help to clarify their relationship and interdependence within the shallow groundwater aquifer.

Statistical analysis of the field and laboratory data used as input to the models will give some quantification of parameter uncertainty. Simple analytical and numerical approaches may be used to evaluate the uncertainty of predictions of groundwater flow and contaminant transport predictions. The statistical analyses of input parameters (i.e., groundwater velocity, initial source concentration, etc.) will be used to qualitatively and quantitatively evaluate the reliability of predicted flow and concentrations at a particular location and time. These measures of uncertainty, though based on simplified solution models, will provide additional information for utilization in field data acquisition and planning of remedial actions.

3.0 DOCUMENTATION

All field activities performed by WSSRAP staff and subcontractors will be thoroughly documented by a combination of chronological field notes encompassing all field activities, photographs of field activities, and data forms for drilling, well installation, specific sampling activities and field measurements. Field activities performed by other governmental agencies (Missouri Department of Natural Resources--Division of Geology and Land Survey and U.S. Geological Survey) will be documented under procedures established by those agencies.

3.1 FIELD NOTEBOOKS

During the course of monitoring-well installation and development, pumping-test-well installation and development, field implementation of unsaturated zone monitoring instruments, and aquifer testing, a designated field geologist or engineer will record daily activities in a permanently bound, waterproof and paginated notebook. Entries in this notebook will include:

- The date
- Weather conditions
- All personnel involved, including subcontractor and governmental agency personnel
- Chronological record of the day's activities. A description of each activity, and the time (24-hour clock) will be entered. Any measurements or other information that are not recorded on designated field forms will be recorded in the field notebook.

All entries will be made in waterproof ink. When errors are made, they shall be crossed out with a single line and initialed by the designated field geologist or engineer. The field geologist or engineer will sign the notebook at the end of each day.

3.2 PHOTOGRAPHS

Photographs will be taken of representative activities for each hydrogeologic subtask. Photographs will be taken of activities at each stage of each subtask: installation, sampling, logging of core, testing, measurements, etc. Log entries will be made in the field notebook that identify the location and activity depicted in each photograph. Each entry into the field notebook photographic log will include the name of the photographer, the date, the location, description of activities, and identity of each person in the photograph. Photographs will be retained in WSSRAP Document Control.

3.3 FIELD FORMS

Field data forms have been developed for borehole logging, well installations, well development, and sampling activities under this Hydrogeologic Sampling Plan. Instructions for completing each form are included in the WSSRAP Standard Operating Procedure (SOP) for each activity. A brief description of the information to be documented on each form is presented below.

3.3.1 Borehole Logging

This subsection presents a description of the documentation procedures for borehole logging activities at the WSSRAP. Borehole logs are used to keep a detailed record of drilling and exploratory excavations on a prepared form, and include geological descriptions of both soil and rock.

A borehole log form (Figure 3-1) will be used when drilling in both soils and rock. The following information will be entered on the heading of each log sheet:

- Boring or well number
- Location

WELDON SPRING SITE REMEDIAL ACTION PROJECT

- Elevation
- Name of drilling contractor
- Drilling method and equipment
- Water levels
- Start and finish (time and date)
- Name of geologist/engineer responsible for logging
- Description of site conditions

The following technical information is recorded on the logs:

- Depth of sample below surface
- Sample/core interval
- Length of sample recovered
- Counts per minute (cpm) as recorded by a Geiger-Mueller Pancake Detector (optional - used in areas with potential radiological contamination)
- Standard Penetration Test (ASTM-D1586) results as applicable
- Visual classification containing a soil or lithologic description
- Total depth of the borehole

All pertinent observations about drilling rate, equipment operation, or unusual conditions will be recorded.

Soil descriptions will be in accordance with the Unified Soil Classification System (USCS) as described in ASTM D 2487-69 (1975) and should stress major constituents and characteristics. The following format for soil descriptions will be used:

1. Soil name
2. Gradation or plasticity
3. Particle size distribution
4. Color
5. Moisture content

6. Relative density or consistency
7. Soil texture and structure
8. Relative permeability
9. Local geologic name
10. USCS classification

Rock descriptions will include the following:

1. Lithology and texture
2. Color
3. Hardness
4. Weathering
5. Grain size
6. Description of bedding and/or jointing
7. Discontinuity descriptions
8. Local geologic name
9. Percent recovery of core
10. RQD of core samples

3.3.2 Well Completion Diagrams

A monitoring-well completion diagram (Figure 3-2) will accompany each monitoring well installed. The form will contain the following information:

- Well number
- Location
- Geologist or engineer
- Well installation date
- Drilling contractor

Monitoring-well construction details to be included on the diagram are as follows:

- Borehole diameter
- Casing dimensions and type

3.3.3 Well Development

Well development entails surging, pumping, and/or bailing of wells in order to restore the natural hydraulic conductivity, remove foreign sediment and fluids introduced during drilling, and to assure collection of representative groundwater samples for water quality analyses.

A well development form (Figure 3-3) will be filled out upon completion of development for each well. The form will contain the following information:

- Water levels (static and final) measured to the nearest one-hundredth foot (0.01')
- Well depth measured to the nearest one-tenth foot (0.10')
- Well volume (casing and filter pack)
- Beginning and ending times recorded in a 24-hour clock format
- Description of water conditions (i.e., clarity, color, and description of sediments)
- pH
- Water temperature
- Specific conductance
- Comments (e.g. pumping rates, duration of surge and pump sequences, variations in flow/recharge rates, etc.)
- Total volume removed

The completed well development forms will be given to the project hydrogeologist or designee who will maintain a file on each monitoring well.

3.3.4 Sample Documentation

Standard sample handling and chain-of-custody documentation will be employed and maintained for all surface, vadose zone and groundwater samples collected for WSSRAP.

Sample documentation will include field data sheets (Figures 3-4 thru 3-6) and preprinted container labels (Figure 3-7).

The sampling team leader (WSSRAP environmental technican) will be responsible for all documentation. All documentation will be filled out with pens containing waterproof ink. The field data sheets will be completed at the time of sample collection. The field data form for groundwater sampling will include the following information:

- Monitoring well number/Sample number
- Date
- Sampling personnel
- Static water level
- Well volumes purged
- Water conditions
- Temperature
- pH
- Conductivity
- Time of sample collection
- Fractions collected

All original field data forms will be retained in the project files.

3.3.5 Sample Packaging, Labeling and Preservation

All samples will be transferred into the appropriate bottles (Table 2-3) with Teflon-lined caps. Bottles and caps are supplied and decontaminated prior to use by an approved laboratory. Each container will have a preprinted label. The label is marked with a unique serialized number and the parameter(s) to be analyzed are identified on it. After labeling, the sample containers will be placed on ice in a secured cooler.

All samples will be packaged, labeled and preserved according to standard U.S. EPA Region VII procedures and Department of Transportation regulations as required in 49CFR.

3.3.6 Chain-of-Custody

The WSSRAP standard Chain-of-Custody form (Figure 3-8) will accompany a sample or group of samples as custody of the sample(s) is transferred from the original custodian to subsequent custodians. The custody record will provide the necessary information to cross-reference the sample number to the specific sampling location and will provide the date of collection as well as documentation of custody. Detailed components and procedures are described in the Groundwater Sampling SOP (ES&H SOP #4.01.01). The samples obtained by the field sampling team will be picked up by a laboratory courier on a daily basis. The field sampling team will offer a completed chain-of-custody form for signature to the sample receiver and will retain a copy of the completed form. Chain-of-custody procedures are applied to all samples collected for site characterization as described in Section 6.0 of the QAPP. Copies

3.4 COMPUTER DATA BASE

A large amount of data will be generated during site characterization. Those field measurements and other data collected and analyzed during the hydrogeologic investigation will be reduced for input into the computerized data base maintained by the WSSRAP Environmental, Safety, and Health Department. The data will include logs, tracking forms, and results of laboratory analyses. Computer software is protected and documentable.

4.0 DATA ANALYSIS

4.1 INTRODUCTION

All data collection activities are in accordance with the Data Quality Objective (DQO) process as defined in EPA 540/G-87/003. The three-stage DQO process ensures that data collected are sufficient and of adequate quality for their intended uses. A major component in the Stage 1 DQO process will be the review and analysis of measurement data collected in the RI and those data collected during prior investigations.

A conceptual model has been constructed, with the utilization of existing data, in accordance with the Stage 1 DQO development process. This model, with known and potential sources, migration pathways, and receptors, has been described in Section 1.3 of this sampling plan. The Stage 1 process also recommends the delineation of specific objectives and goals of the investigative program. These are presented in Section 1.0.

Other sections in this plan address the subsequent stages of the DQO process. For example, Stage 2 components include:

- Delineation of specific objectives (Section 1.0)
- Identification of data uses and needs (Section 1.4)
- Identification of data quantity and quality needs (Section 2.0)
- Approach to sampling and analysis, including testing devices and procedures (Section 2.0 of this plan; WSSRAP and laboratory procedures manuals

Stage 3, the data collection process, is described in detail in Section 2.0.

Precision, accuracy, representativeness, completeness, and comparability (PARCC) parameters are major considerations of the

DQO process for: reviewing and evaluating data (Stage 1); defining sampling options (Stage 2); and establishing goals for the Stage 3 data collection or sampling program.

Data adequacy, i.e. data validity and data sufficiency, then, is established after consideration of PARCC parameters. The quality of data is assured for PARCC by adherence to SOPs and utilizing external measures of quality. Data validation work tasks are considered by EPA to be a component of the sample analysis. EPA approved and/or best available methodology is used for data quality assessment.

Data collected under Stage 3 of the DQO process will be compiled, subjected to the Quality Assurance/Quality Control (QA/QC) element evaluations, incorporated initially into the conceptual model and ultimately to meet remedial action objectives of the study, into computer models. With the input of detailed chemical and physical hydrogeologic data, the models will allow for an evaluation of contaminant flow and transport mechanisms, and will permit a definition of the extent of contaminant plume migration as a function of time.

4.2 QUALITY ASSURANCE/QUALITY CONTROL

Quality assurance (QA) on the Weldon Spring project is in accordance with EPA guidelines and is defined as the total integrated program for assuring the reliability of monitoring data. Quality control (QC) is the routine application of procedures for obtaining prescribed standards of performance in the monitoring and measurement process (U.S. EPA, 1980). The DQO process developed by EPA (March 1987) stipulates requirements for the preparation of a Quality Assurance Project Plan (QAPP). The process relies upon the incorporation of the 16 QA elements in the QAPP, Standard Operating Procedures (SOPs) and other documents, e.g., laboratory analytical methods and CLP procedures. Table 4-1 presents, in accordance with the DQO

guidelines, the 16 QA elements and a reference to those documents that address QA issues which are applicable to this plan.

The DQO staged process has been addressed in the QAPP (Section 2.0). The overall objective of the data collection stage is to ensure that all data used to support decisions made by DOE meet the requirements imposed by federal and state agencies.

The quality assurance (QA) program is conducted for both routine environmental monitoring and characterization activities and is composed of two components: field and analytical QA evaluations.

The field QA program for field activities includes the following:

- Preparation of site-specific sampling plans and sampling procedures for collection of all environmental samples
- Annual audit of all field procedures with follow-up corrective action programs, if required
- Proper documentation of sample collection including sample collection forms, field notebooks and chain of custody records
- The routine collection and analysis of QC blanks including trip blanks and equipment blanks

The analytical QA program for laboratory analyses makes use of a number of different types of quality control samples to document the validity of the data generated. These samples include:

QUALITY ASSURANCE PROJECT PLAN ELEMENTS

QAPP Elements	Information Provided In
13. Preventive Maintenance	QAPP SOPs Analytical Limits/ Detection Methods
14. Specific Routine Measures Used to Assess Data Precision	SOPs HISP QAPP
15. Corrective Action	QAPP
16. Quality Assurance Reports to Management	QAPP

- Method Blanks (one per batch, batch not to exceed 20 samples). Method blanks contain all the reagents used in the preparation and analysis of samples to assess contamination rising from reagents, glassware and other materials used in the analysis.

- Laboratory Control Samples/Spiked Blanks (LCS - one per batch, batch not to exceed 20 samples). These samples are prepared by adding known quantities of compounds of interest to deionized water and are used to establish that an instrument or procedures were controlled.

- Calibration Check Samples (as needed, or per method). Calibration standards are periodically used to verify that the original calibration is still valid.

- Duplicate and Spike Samples (5% duplicate; 5% spike). Analysis of duplicate samples is performed to enable an estimate of the precision of the analytical procedures. Spike samples are measured to determine the accuracy of the analytical procedure and access matrix effects. For analyses conducted according to the Contract Laboratory Program (CLP) methodology, these controls are termed matrix spike and matrix spike duplicate samples.

- Blind QC Samples (one per 20 samples). Blind QC samples are inserted into the sample load in a fashion unrecognizable to the laboratory analyst. These samples, in addition to the standard duplicate sample analysis discussed above, are used to assess analytical precision.

- EPA Laboratory Performance Evaluation (PE) (Annually). In order to assess overall performance of the primary analytical laboratory, spike samples are submitted annually by EPA Region VII to the PMC primary laboratory.

- o Interlaboratory Evaluation (Annually). In order to assess comparability of data, sample splits are shipped to different laboratories to provide a measure of analytical or method bias.

The specific monitoring activities include surface water and groundwater analyses for various organic, inorganic, and radioactive species.

These quality control measures are to assure that data collected from project sampling tasks are valid and meet the highest practical attainable level of precision and accuracy. These criteria, combined with the adherence to representativeness, completeness, and comparability requirements and guidelines (Section 4, QAPP) will allow for an accurate characterization of the site and the evaluation and delineation of remedial measures. The QA objectives for the hydrogeological characterization program will be met, in part, by the use of periodic audits of field sampling and laboratory analysis activities. The results of audits and technical quality control procedures, as well as other program QA documentation and reports described in this plan will be maintained to meet DOE and EPA requirements.

4.3 RI PLAN ELEMENTS

4.3.1 Groundwater Monitoring Well Network

Monitoring data gathered to date indicate the presence of a groundwater divide beneath the site. Sulfate, nitrate, nitroaromatics and uranium contaminant plumes have been identified. Data gathered in the future from monitoring wells will be used to refine the conceptual model, and the groundwater contour, contaminant plume, and isopleth maps of the WSS. Additional monitoring data will further define contaminant source and recharge areas and flow directions, and will delineate the

extent of vertical and horizontal migration of contaminants.

4.3.2 Aquifer Testing

Data generated from the aquifer testing program described in Section 2.2 of this sampling plan will be analyzed by the use of commonly applied analytical formulae and computer programs. These data, displayed on a series of matching curves, graphs, tabulations and computer print-outs will be incorporated into conceptual and computer models, superimposed on or compared with groundwater contour and contaminant plume maps to determine the degree, extent, and impact of groundwater contamination. The data interpretation process will likely include the preparation of maps and cross-sections to depict anisotropy, zones of primary and secondary hydraulic conductivity, and other aquifer characteristics.

4.3.3 Bedrock Hydrogeology

Data gathered during the aquifer testing program will be expanded with the inclusion of hydrogeologic data gleaned from published geologic and environmental reports and maps from federal, state, and local agencies (e.g. USGS, MDNR, St. Charles County, and others) and from previous site studies. These data, and additional information gathered from planned soils, geological, geophysical, and hydrogeological investigations, will be reduced and compiled in the form of tabulations, maps, stratigraphic sections, cross-sections and drawings. These data will be used as additional components of the models to illustrate the extent and nature of fractures and jointing, weathering, structural and lithologic features, solution channels and other bedrock characteristics common to a karstic environment, and to define recharge and source areas.

4.3.4 Overburden Hydrogeology

This sampling plan describes the methods to be implemented to further characterize these zones. The vadose-zone monitoring operations in the overburden, sampling of soil for chemical and physical parameters, definition of perched groundwater zones, and soil attenuation studies will provide data which, upon analysis, will allow for the description of: 1) contaminant source areas; 2) the extent of overburden contamination migration routes; and 3) the rate of contaminant migration. Also the ultimate fate of contaminants can be predicted and possible remedial measures can be assessed. This characterization effort will also provide data for the determination of a suitable site for a disposal cell--a remedial action under consideration at the WSS.

4.3.5 Surface Water

Groundwater recharge and contaminant source studies coupled with a detailed hydrological and climatological study will provide data for conceptual and computer models. These models will allow for a better understanding of the water balance, description of surface water and contaminant flow from the site and area drainageways, and the identification of potential receptors of contaminants, e.g. Busch Wildlife Lakes, area ponds and streams, and springs and seeps resulting from the interaction of surface and groundwater flow mechanisms. Surface drainage features and facilities plotted on topographic and geologic maps will also allow for the consideration of ERA's (IRA's) to preclude further contaminant migration. Sludge and sediment samples collected from lakes, creeks and ponds can, upon analysis, provide a further understanding of source areas.

4.3.6 Other Analyses

Supplemental hydrogeological studies may include biological, chemical and geochemical, climatological and meteorological and

other research or field studies necessary to fulfill the objectives of the RI. The DQO process provides a framework for data collection under the RI program and evaluation of data in accordance with Stage 1 DQO guidelines. The field data collection program delineated in Section 2.0 is intended to provide sufficient, valid hydrogeologic data to characterize the site and meet stated objectives.

4.4 DATA SYNTHESIS

All data analysis efforts are directed to the development and refinement of the site conceptual model. These data will include source characteristics, the nature and extent of contamination, contaminant migration and transport mechanisms, and environmental and health impact. In this process, quantitative results will be applied to the conceptual model.

The models, with accompanying maps, tabulations, cross-sections, graphs, logs and other back-up data will, in accordance with EPA's RI/FS guidelines, allow for the description of: 1) the environmental setting of the site, e.g., surface features, soils, geology, hydrology, meteorology, and ecology; 2) source location, types, quantities, and concentrations of contaminants; 3) the nature and extent of contamination; and 4) an analysis of contaminant fate and transport.

The type of models to be used will be ascertained upon receipt of data and after its incorporation into existing simplified models which will dictate the need for, and the selection of, more complex analytical or numerical models.

With the acquisition, analysis, and synthesis of additional data gathered under this and other work plans, the concurrent FS will proceed with the development and refinement of remedial measures in accordance with the phased RI/FS approach as mandated by CERCLA/SARA.

4.5 HYDROGEOLOGIC CHARACTERIZATION REPORTING

The results of analyses of the hydrogeologic data described above will be compiled into a report or reports, components of which can be extracted for the overall RI/FS-EIS process. Information from the hydrogeologic characterization study along with information from reports produced by the MDNR and the USGS will be incorporated into the site RI report.

APPENDIX

TABLE A
WATER TRACING SAMPLE LOCATIONS

ITEM	SAMPLE NUMBER	LOCATION TYPE	LOCATION NAME	LOCATION DESCRIPTION	LATITUDE	LONGITUDE	APPROXIMATE ELEVATION (FEET MSL)
1	SP5101	Spring	Boys Town Camp Spring	About 1 mile south of Weldon Spring Heights; near the mouth of drainage 5100; flows from a concrete basin.	38° 41'58"	90° 40'58"	465
2	SP5102	Spring	West Tributary Junction Spring	In southeast draining branch of drainage 5100; just above mouth of east draining tributary about 1/4 mile upstream of Missouri River; spring rises from the bed or the creek.	38° 41'14"	90° 41'15"	470
3	SP5201	Spring	Rock Ledge Spring	About 1 mile south of Francis Howell High School and 3/4 mile upstream of the mouth of drainage 5200; spring flows from bedrock and cascades from a rock ledge.	38° 41'09"	90° 42'52"	490
4	SP5205	Spring	Peter's Spring	About 1/3 mile east-northeast of Weldon Spring Chemical Plant entrance; flows from west valley wall on top of alluvial terrace.	38° 41'48"	90° 43"'02"	565
5	SP5301	Spring	Highway 94 Spring	About 1/2 mile south of Weldon Spring Chemical Plant; flows from east side of drainage 5300 about 100 yards downstream of Hwy 94.	38° 41' 23"	90° 43'36"	570

TABLE A (CONTINUED)
WATER TRACING SAMPLE LOCATIONS

ITEM	SAMPLE NUMBER	LOCATION TYPE	LOCATION NAME	LOCATION DESCRIPTION	LATITUDE	LONGITUDE	APPROXIMATE ELEVATION (FEET MSL)
6	SP5303	Spring	Southeast Drainage Perennal Spring	About 1 mile south-southeast of Weldon Spring Chemical Plant; flows from east valley wall and across alluvial terrace via a 50 yard long spring branch.	38° 41'03"	90° 43'22"	520
7	SP5402	Spring	Natural Bridge Spring	About 1 mile south of Weldon Spring Chemical Plant; flows from east edge of valley 5400; spring branch is interrupted by a very small "natural bridge".	38° 40'24"	90° 43'51"	560
8	ST5401	Stream	Hamburg Quarry	About 1 1/2 miles south of Weldon Spring Chemical Plant; stream channel just below spring fed pond and upstream of quarry (just downstream of Springs SP5401 and SP5406).	38° 40'27"	90° 43'32"	475
9	SP5501	Spring	Deer Spring	About 1 1/2 miles south-southwest of Weldon Spring Chemical Plant; flows from creek bed adjacent to east valley wall; frequented by deer during dry times.	38° 40'37"	90° 44'24"	515
10	ST6001	Stream	Dardenne Creek	Dardenne Creek at bridge for Highways I-64, US 40, and US 61.	38° 44'05"	90° 44'23"	470

TABLE A (CONTINUED)
WATER TRACING SAMPLE LOCATIONS

ITEM	SAMPLE NUMBER	HORIZONTAL DISTANCE FROM SITE* (MILES)	VERTICAL DISTANCE FROM SITE* (FEET)	GRADIENT FROM SITE* (FT/MI)	ESTIMATED FLOW RATE (GPM) MAXIMUM	MINIMUM	GEOLOGIC FORMATION	RATIONALE
6	SP5303	0.85	90	106	200+	1	Burlington Limestone	Perennial spring partially supplied by losing stream segment 300 to 500 yards upstream; only perennial spring in drainage 5300.
7	SP5402	1.00	50	50	50+	?	Burlington Limestone	Closest moderate flow spring to the site in drainage 5400.
8	ST5401	1.50	135	90	200+	?	Fern Glen Formation (Limestone)	Combined flow of a large flow spring, a moderate flow spring, and moderate surface flow near the mouth of drainage 5400.
9	SP5501	1.45	95	66	200+	100+	Fern Glen Formation (Limestone)	Spring with largest flow in drainage 5500.
10	ST6001	2.75	140	51	Enormous	Large	Burlington Limestone	Combined surface water drainage and groundwater discharge from a large area north and west of site.

* Measured from the groundwater divide location at elevation 610 under Building 408.

TABLE A (CONTINUED)
WATER TRACING SAMPLE LOCATIONS

ITEM	SAMPLE NUMBER	HORIZONTAL DISTANCE FROM SITE* (MILES)	VERTICAL DISTANCE FROM SITE* (FEET)	GRADIENT FROM SITE* (FT/MI)	ESTIMATED FLOW RATE (GPM) MAXIMUM	MINIMUM	GEOLOGIC FORMATION	RATIONALE
1	SP5101	2.45	145	59	1000+	?	Burlington Limestone	Large flow perennial spring; major source of flow in drainage 5100.

ABSTRACT

During the course of the Weldon Spring Site Remedial Action Project (WSSRAP) radionuclides may be emitted to the air. Emissions of radionuclides are regulated by the U.S. Environmental Protection Agency in 40 CFR 61. It is clear in 40 CFR 61 that, for sites being remediated according to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), no monitoring or reporting of radon emissions is required prior to completion of temporary or permanent disposal sites, other than that already required under CERCLA. For radionuclides other than radon, however, it is not clear whether 40 CFR 61 requires sites being remediated according to CERCLA to implement additional monitoring and reporting prior to completion of disposal facilities. Because the U.S. Department of Energy is committed to protection of the public and environment, a plan has been formulated which defines how the WSSRAP will implement a monitoring program for radionuclides other than radon. This plan adheres to the specifications contained in 40 CFR 61.

1 INTRODUCTION

1.1 SITE HISTORY

The Weldon Spring Site is located in St. Charles County, Missouri, about 30 miles west of St. Louis on land formerly used by the Department of Army (DA) as a trinitrotoluene (TNT) and dinitrotoluene (DNT) ordnance works. The site consists of a 9-acre former limestone quarry; a 51-acre raffinate disposal area; and a 166-acre uranium feed materials plant. The feed materials plant was built in 1955-1957 by the Atomic Energy Commission (AEC), the predecessor to the U.S. Department of Energy (DOE), and operated by Mallinckrodt Chemical Works for the AEC from 1957 through 1966. The plant processed uranium ore concentrates and recycled scrap to pure uranium trioxide, uranium tetrafluoride, and uranium metal. Thorium ore concentrates were also processed. The raffinate residues from this processing were disposed of in four large open pits. During the plant's operational period, the buildings, the equipment, the immediate terrain, the process sewer system, and the drainage easement to the Missouri River became contaminated with uranium, thorium, and their decay products.

During the period 1943-1957, the DA disposed of rubble and soils contaminated with TNT and DNT in a former limestone quarry about 4 miles from the ordnance works. Later, from 1959 through 1966, the AEC disposed of building rubble and soils contaminated with thorium and uranium and their decay products in the same quarry. The quarry now contains about 95,000 cubic yards of contaminated materials, including quarry materials contaminated by this radioactive waste.

In 1967, the feed materials plant site was selected to be converted to a herbicide production facility. Except for the materials stored in the raffinate pits, the site was transferred

back to the DA and renamed the Weldon Spring Chemical Plant (WSCP). The DA began a major effort to decontaminate three process buildings for herbicide production. The cleanup was not totally successful, and in 1969, reduced requirements for the herbicide and increased cleanup costs resulted in cancellation of the project. The 51 acres encompassing the Weldon Spring Raffinate Pits (WSRP) were transferred back to the AEC in 1971.

On November 27, 1984, the DOE was directed by the Office of Management and Budget to assume responsibility for the decontamination of the WSCP and to integrate work with other DOE remedial actions proposed for the Weldon Spring Quarry (WSQ), and the WSRP. In 1987 the WSQ was placed on the National Priorities List (NPL). The WSCP/WSRP were placed on the NPL in 1989. These NPL sites are being remediated according to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Environmental Policy Act (NEPA).

During cleanup of the Weldon Spring Site (WSS) a temporary storage area (TSA) for wastes from the WSQ is proposed. In addition, the DOE-preferred alternative for all wastes at the WSQ and WSCP/WSRP is to build a permanent disposal site at the WSCP/WSRP.

1.2 REGULATIONS PERTAINING TO RADIOACTIVE EMISSIONS

Because of the radioactive materials present at the WSCP/WSRP and WSQ, radon is emitted to the atmosphere as are other radionuclides from the U-238, U-235, and Th-232 natural decay series. Atmospheric emissions of radon and radionuclides other than radon are regulated by the U.S. Environmental Protection Agency (EPA). The regulations are contained in 40 CFR 61 which was updated and became effective on December 15, 1989. It is clear in Section G of 40 CFR 61 that, for DOE

facilities being remediated according to CERCLA, radon monitoring or reporting programs required through the CERCLA program are sufficient to protect the public health until temporary or permanent storage facilities for Ra-226-containing byproduct material are completed. Once all wastes have been placed and completely covered at the TSA, radon flux monitoring will be performed at the TSA. If a permanent disposal site is constructed at the WSCP/WSRP, radon flux monitoring will be performed after construction of the disposal site is completed. Radon flux monitoring will be performed according to 40 CFR 61, Appendix B, Method 115.

However, it is not clear in those sections of 40 CFR 61 that pertain to radionuclide emissions other than radon whether DOE sites being remediated according to CERCLA are required to monitor and report emissions prior to completion of temporary or permanent storage facilities.

1.3 MONITORING RADIONUCLIDE EMISSIONS OTHER THAN RADON

The DOE is currently determining through discussions with EPA whether the monitoring and reporting requirements for radionuclide emissions other than radon contained in 40 CFR 61, Subpart H apply to CERCLA sites prior to completion of permanent or temporary storage facilities. Regardless of whether 40 CFR 61, Subpart H applies to the WSS during remediation, the DOE is committed to protection of the public and environment. Therefore, a monitoring and quality assurance program sensitive enough to detect concentrations of radionuclides other than radon at levels specified in 40 CFR 61 will be initiated at the WSS.

Results of the monitoring will be reported in annual site environmental reports. These reports are intended to allow EPA

oversight of radionuclide emissions during remediation according to CERCLA/NEPA. The monitoring, reporting, and quality assurance program is discussed below.

2 METHODS OF EMISSION EVALUATION

The national emission standard for radionuclides other than radon is set so that no member of the general public receives an effective dose equivalent greater than 0.10 mSv (10 mrem) per year. 40 CFR 61 Subpart H requires that radionuclide emissions other than radon be measured and effective dose equivalents estimated by computer models. If the emission monitoring and modeling specified in Subpart H is impractical, alternate procedures may be acceptable. As an alternate to modeling dose equivalents, air concentrations can be monitored at critical receptors.

After evaluating the methods of assessing effective dose equivalents from radionuclides other than radon, it was determined that monitoring air concentrations at critical receptors was the most accurate means of assessing effective dose equivalents to maximally exposed individuals. This plan describes how the Weldon Spring Site Remedial Action Project will use monitoring results to estimate effective dose equivalents to members of the public resulting from emissions of radionuclides other than radon.

3 SCOPE

This plan discusses the monitoring, reporting, and quality assurance program requirements that will be used to estimate and document the effective dose equivalent from airborne emissions of radionuclides other than radon at locations of highest potential offsite exposure. The monitoring plan, including rationale for the monitoring program as well as sampler location, description, analytical methods, and frequency is discussed in Section 4. This monitoring program meets the specifications in 40 CFR 61, Subpart H. Also contained in Section 4 is a description of the annual reporting system.

Section 5 contains the quality assurance plan. This plan meets the requirements of 40 CFR 61, Appendix B.

4 PLAN

The Weldon Spring Site (WSS) is currently being remediated according to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Environmental Policy Act (NEPA). It no longer operates as a uranium and thorium processing plant and has been in mothball status since about 1966. Therefore, radionuclides are no longer emitted from the types of sources (i.e. stacks, vents, or pipes) described in 40 CFR 61, Subpart H.

Airborne emissions of radionuclides at the WSS result from wind dispersal of surface soils or dust and dirt within deteriorating buildings and from fugitive dust generated during remedial actions. Monitoring these types of emission sources is not practical because of the inability to adequately characterize the emission inventory. The amount of entrainment can be estimated from fugitive dust emission factors developed by the U.S. Environmental Protection Agency (EPA) for various materials handling activities, but it is generally recognized that those estimates contain gross uncertainties. Measurement of the entrainment and emissions inventory is also extremely difficult and results are uncertain at best, because the emissions are highly variable both over time and location. Accurate measurements of area or volumetric fugitive emissions can only be made with complete knowledge of the micro-meteorology in and around the source and the use of many (usually greater than 10) concentration or measurement locations. Therefore, modeling of downwind dispersion and subsequent dose calculations using either assumed or measured emission rates leads to extremely uncertain results. The most accurate method of dose calculation at nearby receptor points is through the use of actual concentration measurements at these locations.

An assessment of the effective dose equivalents at critical receptors will be documented by environmental measurements of radionuclide air concentrations. Critical receptors are defined as those locations at which individuals abide or reside where the highest potential offsite concentrations of radionuclides other than radon are likely to occur during remediation of the Weldon Spring Site (WSS). The proposed monitoring and sample analysis plan is presented in Section 4.1. Section 4.2 describes how the monitoring meets the specifications in 40 CFR 61.

4.1 MONITORING PLAN

This section describes sampler locations, discusses rationale for selecting critical receptor locations, establishes occupancy times at critical receptor locations, describes the samplers, presents sampling frequency, and presents sample analytical techniques. Also included in Section 4.1.4 is a discussion of how the monitoring results will be reported.

4.1.1 Sampler Locations

The WSS includes the Weldon Spring Raffinate Pits (WSRP), the Weldon Spring Chemical Plant (WSCP), and the Weldon Spring Quarry (WSQ). Eleven air particulate samplers are in use at the WSS. Five samplers are located on the WSCP/WSRP perimeter. Four are located offsite, one of which measures background air. Two are at the WSQ perimeter. Sampler locations with respect to the WSCP/WSRP and WSQ are shown on Figures 4-1 through 4-3.

Sampler location AP-4007 at the Busch Wildlife Area office measures background concentrations for the WSS. This station is located 1.1 km (0.7 mile) from the WSCP perimeter. The forested and gently rolling terrain between the WSCP and this sampling

station provides a significant physical barrier to airborne particulates originating from the site.

As shown in Figure 4-1, sampler stations AP-2001, AP-4006, AP-4008, and AP-2005 are strategically located to measure radioactive air particulate concentrations around the WSCP/WSRP at the point where a maximally exposed individual resides or abides. Station AP-2001 is at the common boundary of the WSCP and Missouri Highway Maintenance Facility. Station AP-4006 is located at the Francis Howell High School. Station AP-4008 is on the Weldon Spring Army Reserve Training Area. Station AP-2005 is located between the WSCP and the Weldon Spring Site Remedial Action Project (WSSRAP) Administration Building.

Located 0.8 km (0.5 mi) west of the quarry is a residence. This residence is within 150 meters (0.1 mi) and directly in line with the quarry monitoring station (Figure 4-3).

These sites were selected as critical receptor locations because they are located within 1.0 km (0.62 mile) of the WSS where members of the public may spend at least eight hours per day for a significant fraction of a year. Other facilities (for example the St. Charles County Water Treatment Plant and the Weldon Spring Heights Subdivision) are located near the WSS; however, no other facility is closer than 2.5 km (1.6 mile) from the WSS. Because of this greater distance these facilities were not considered critical receptors.

At the one critical receptor that is a residence, occupancy will be assumed to be continuous. The number of individuals at the other receptors and typical occupancy patterns are discussed below.

There are nine workers at the highway maintenance facility. A typical worker is at the facility less than 40 hours per week, 50 weeks per year.

There are approximately 1,800 students, faculty and staff members at the high school. Faculty and staff generally spend more time at the school than do students. A typical employee spends 45 hours per week, 50 weeks per year at the school. One janitor lives on the school grounds. Occupancy for this person will be assumed to be continuous.

A remedial investigation is being conducted at the Army Reserve Training area. Subcontract workers perform site characterization tasks intermittently. One employee of the Department of the Army works at most 40 hours a week, 50 weeks per year at the office on the Army Reserve property.

Currently there are approximately 110 workers at the WSSRAP Administration Building. Workers typically spend less than 50 hours per week, for 50 weeks per year, at the facility.

4.1.2 Sampler Description and Sampling Frequency

Air particulate samplers are low volume, self adjusting carbon-vaned, oil-less air pumps at the three quarry locations, and low volume, self-adjusting, twin diaphragm, oil-less air pumps at the five WSCP/WSRP site perimeter locations and at the other three offsite locations. Each sampler is mounted in a weather-protective housing with a 110-volt outlet and a thermostat-controlled fan for cooling. Each sampler will have a timer to document the operational periods. Samplers also have a flow meter and vacuum gages to automatically maintain constant flow.

Air filters are mounted approximately 1 meter (3 feet) above ground surface. The sampling head is on the side of the protective housing opposite the cooling fan exhaust. This prevents the cooling fan exhaust from disturbing the air being drawn through the filter.

All air samplers will run continuously at a flow rate of approximately 40 liters per minute. Samples are collected on 47 millimeter diameter 0.8 micron pore size mixed ester cellulose filter paper. Filters are exchanged weekly.

4.1.3 Sample Analysis

Air samples obtained at the common perimeter of the WSCP and the highway department, the high school, the Army training area, near the WSSRAP Administration Building, by the nearest WSQ resident, and at the Busch Wildlife Area Headquarters will be used to assess effective dose equivalents to a maximally exposed individual. Other sampling locations do not represent potential locations for maximum public exposure because public occupancy times at these locations is negligible.

Each filter, representative of approximately 403,200 liters of air (40 liters per minute times 10,080 minutes per week) will be analyzed for gross alpha concentration. Following gross alpha analysis filters will be cut into three equal sections, with each section placed in an individual envelope. The filters will be cut in thirds for quality assurance. This will allow an evaluation of analytical precision. Three pieces are used because, if an error caused a difference in analytical results between two filter portions, the third portion will allow a determination of which result was erroneous.

In January of each year the three sections of 52 weekly filters will form three composite samples for each of the five

critical receptor locations and the Busch Wildlife Area background station. The 18 composite samples (filter thirds from six sampler locations) will be analyzed for isotopic thorium, isotopic uranium, Ra-228, and Ra-226. Analysis for this suite of radionuclides allows a determination of the concentration of all radionuclides at the Weldon Spring Site which could contribute more than 10 percent of the total effective dose equivalent. Radon and daughters are not included because they are not regulated by 40 CFR 61, Subpart H.

Yearly analyses of the filters is considered acceptable because it meets the intent of 40 CFR 61. The primary method given in 40 CFR 61 of determining effective dose equivalents is through computer modeling. The computer modeling exercise is to be performed and reported annually. Monitoring of airborne concentrations is also allowable. Therefore, a yearly determination of the airborne concentrations and associated effective dose equivalent at critical receptors meets the specifications of 40 CFR 61.

4.1.4 Reports

Reports of environmental monitoring for radionuclide emissions other than radon have been made for calendar years 1986 through 1988 in Annual Environmental Monitoring Reports (DOE, 1986; DOE, 1987a; DOE, 1988). These monitoring reports were transmitted to EPA Region VII. Although the monitoring at critical receptor locations was not sensitive enough to distinguish an annual effective dose equivalent of 0.10 mSv (10 mrem) above natural background, results for years 1986 through 1988 detected no significant difference at the 95 percent confidence level between gross alpha concentrations at critical receptors and the background monitoring station. This was as expected because no significant activities occurred at

the WSS during these years that generated airborne radionuclide emissions.

Beginning with air samples collected during calendar year 1990, results of the monitoring performed as specified in Section 4.1 of this plan and an assessment of the effective dose equivalent at critical receptor locations will be reported in the 1990 Annual Site Environmental Report. These annual reports meet the requirements of 40 CFR 61 because the WSS is being remediated according to CERCLA. This allows EPA oversight which is sufficient to protect the public health by providing EPA Regional Office VII with all the information it needs to assess potential impacts on public health as a result of remediating the WSS.

4.2 COMPARISON TO 40 CFR 61 SPECIFICATIONS

In order to satisfy the sensitivity requirements of 40 CFR 61 through environmental monitoring the following must be met:

1. The air at the point of measurement must be continuously sampled for collection of radionuclides.

2. Those radionuclides released from the facility that are major contributors to the effective dose equivalent must be collected and measured as part of the environmental measurement program.

3. Radionuclide concentrations which would cause an effective dose equivalent of 10% of the standard must be readily detectable and distinguishable from background.

4. Net measured radionuclide concentrations must be compared to the concentration levels in Table 2,

Appendix E of 40 CFR 61. In the case of multiple radionuclides being released from a facility, it must be demonstrated that the value for all radionuclides is less than the concentration level in Table 2, and the sum of the fractions that result when each measured concentration value is divided by the value in Table 2 for each radionuclide is less than 1.

5. A quality assurance program must be conducted that meets the performance requirements described in Appendix B, Method 114 of 40 CFR 61.

This subsection describes how the monitoring program at the WSS will satisfy items 1 through 4. Item 5 is addressed in Section 5.

Items 1 and 2 have been addressed previously. Samplers will run continuously and all major contributors to effective dose equivalent will be collected and measured.

Regarding Item 3, the sampling protocol at the critical receptor locations will be followed at the background monitoring station. Assuming typical Th-232 soil concentrations of 40 Bq/kg (1 pCi/g) and a typical rural airborne dust loading of 16 $\mu g/m^3$ (EPA, 1980), airborne Th-232 concentrations in background air would be 6×10^{-13} MBq/m^3 (2×10^{-17} Ci/m^3). (Th-232 was chosen for this example because it is the greatest contributor to effective dose equivalent.) Assuming continuous inhalation at 20 m^3/day (Cember, 1983) for 365 days/year and using a committed effective dose equivalent conversion factor of 4.43×10^{-4} Sv/Bq (EPA, 1988), a committed effective dose equivalent of 2×10^{-3} mSv (0.2 mrem) is predicted. Since the committed effective dose equivalent for Th-232 is received over a 50-year period the effective dose equivalent received in any single year would be at least a factor of ten lower. For these

TABLE 4-1 Sensitivity Analysis

Radionuclide	Required Sensitivity MBq/m³	(Ci/m³)	Ratio
U-238	3.1E-10	(8.3E-15)	0.018
U-234	2.9E-10	(7.7E-15)	0.020
Th-230	1.3E-10	(3.4E-15)	0.044
Ra-226	1.2E-10	(3.3E-15)	0.045
Th-232	2.3E-11	(6.2E-16)	0.242
Th-228	1.2E-10	(3.1E-15)	0.048
Ra-228	2.2E-10	(5.9E-15)	0.025
		SUM	0.442

reasons the annual effective dose equivalents for each radionuclide in background air is much less than 1×10^{-2} mSv (1 mrem). Monitoring results which attain the sensitivity requirements of Item 4 would, therefore, be readily detectable and distinguishable above background.

The sensitivity of the monitoring method meets the criteria in Item 4. A radiochemical detection limit for each radionuclide of 40 mBq (1 pCi) can be attained (Horton, 1990). By dividing this detection level by the 700 m³ drawn through the filter thirds in each composite sample, an airborne concentration of 5.28×10^{-12} MBq/m³ (1.5×10^{-16} Ci/m³) can be detected. Listed in Table 4-1 are the radionuclides for which monitoring will be performed, the analytical sensitivity specified in Table 2, Appendix E of 40 CFR 61, and the ratio of achievable sensitivity to the required sensitivity. Since the

ratio of the sensitivities for each radionuclide is less than 1.0 and the sum of the ratios is less than 1.0, the proposed analytical method meets the requirements of 40 CFR 61.

5 QUALITY ASSURANCE

This section discusses the quality assurance program that will be conducted to ensure that emission measurements are representative and are of known precision and accuracy. Also included are administrative controls to assure prompt response when measurements indicate unexpectedly large emissions. In addition to complying with all requirements contained in this section, this monitoring program will also comply with the Weldon Spring Site Quality Assurance Program Plan (QAPP) (DOE, 1987b).

5.1 ORGANIZATIONAL STRUCTURE

The responsibility for implementing the emission monitoring program lies within the Environmental, Safety and Health (ES&H) Department. As such, the ES&H Manager has overall responsibility. Actual sampling protocol will be carried out within the Radiation Protection Group under the guidance of the Radiation Protection Manager. Audits will be conducted by the Quality Assurance Department which reports directly to the MK-Ferguson Company Quality Assurance Director. Any corrective actions which require modifications in the way remedial actions are performed at the Weldon Spring Site (WSS) are the responsibility of the Operations Department Manager. The lines of responsibility are shown in Figure 5-1.

5.2 SAMPLE COLLECTION AND ANALYSIS PROCEDURES

Project procedures exist for all phases of sample collection and analysis except for the method of dividing individual filters in thirds and the means of compositing samples. This procedure is currently being drafted and will be forwarded upon completion.

FIGURE 5-1 Lines of Authority

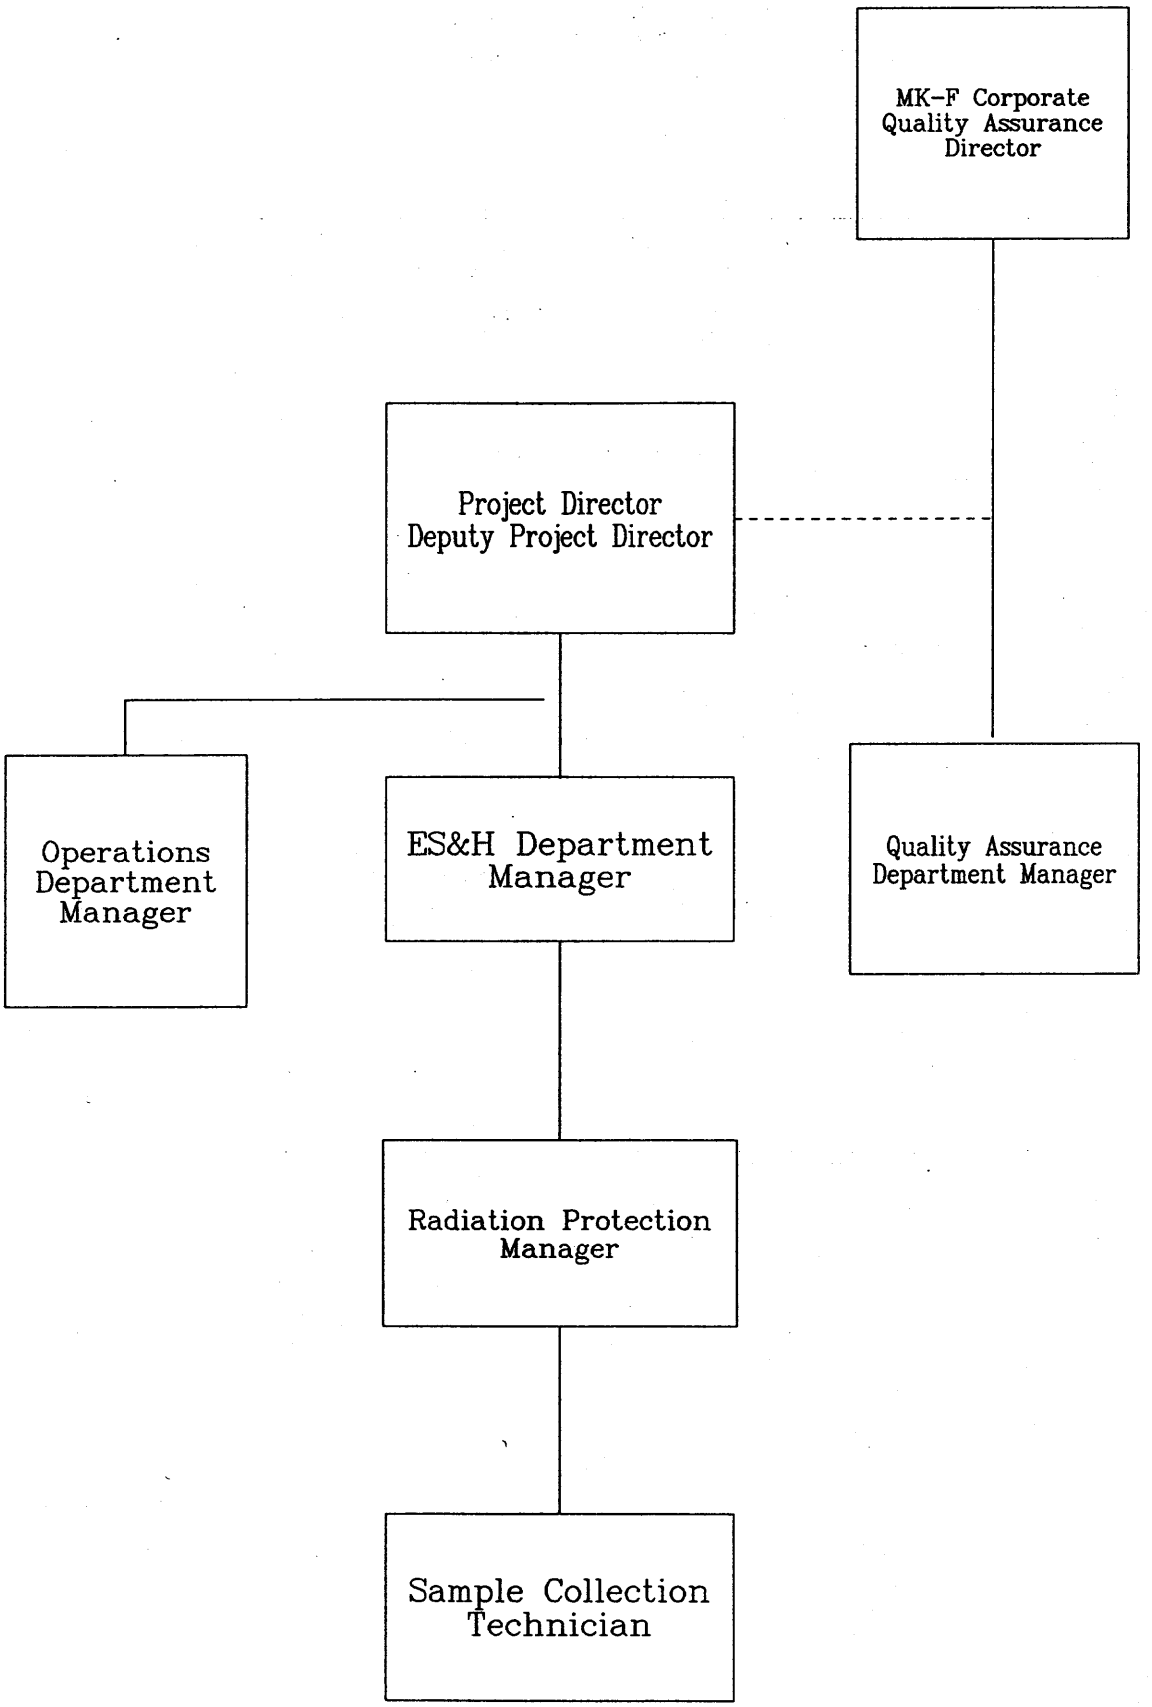

Table 5-1 presents a list of procedures and aspects of the sampling program which they govern. Each procedure is attached to this plan for reference.

Actual radioanalytical procedures are not performed at the site but at a subcontractor laboratory. The radioanalytical procedures used are specified in Table 5-2.

TABLE 5-1 Sampling Procedures

5.3 ADMINISTRATIVE CONTROLS

Assurance that increased radionuclide emissions due to unplanned or unforeseen circumstances can be detected and controlled is achieved through weekly gross alpha analyses of each filter. Isotopes of thorium are the alpha-emitters at the WSS that have the highest potential to cause radiation dose at critical receptor locations. Isotopes of thorium are most prevalent in the quarry and in the raffinate pits. For other site areas such as Weldon Spring Chemical Plant (WSCP) buildings, uranium is the primary contaminant. At the quarry, Th-230 comprises, on average, 33 percent of the total alpha activity contributed by those radionuclides that will be measured at critical receptor locations. At the raffinate pits, Th-230 comprises, on average, 87 percent of the total alpha activity contributed by those radionuclides that will be

measured at critical receptor locations. Clearly, Th-230 has the highest potential to cause a radiation dose at critical receptor locations.

If the potential for a person to receive a yearly effective dose in excess of 0.10 mSv (10 mrem) can be detected on a weekly basis, sufficient control over radionuclide emissions can be attained. This is achieved if a dose equivalent rate of 0.002 mSv (0.2 mrem) per week can be detected. Given a typical weekly occupancy time of five 8-hour days for persons closest to the site where the highest potential airborne concentrations are expected to occur, a quantity of air inhaled during eight hours at work of 10 m^3 (Cember, 1983), and a Th-230 committed effective dose equivalent conversion factor of 8.8×10^{-5} Sv/Bq (EPA, 1989), a dose equivalent of 0.002 mSv/week (0.2 mrem/week) corresponds to an airborne concentration of 4.4×10^{-10} MBq/m^3 (1.2×10^{-14} Ci/m^3).

A natural background gross alpha concentration of $2 \times 10^{-10} \pm 1.2 \times 10^{-10}$ MBq/m^3 at two standard deviations ($5 \times 10^{-15} \pm 3.26 \times 10^{-15}$ Ci/m^3) has been documented at the site (DOE, 1988). It can be seen that a committed effective dose equivalent rate due entirely to Th-230 of 0.002 mSv/week (0.2 mrem/week) can be resolved above natural background gross alpha concentrations. In fact, an effective dose equivalent rate much lower than 0.002 mSv/week (0.2 mrem/week) can be resolved above natural background gross alpha concentrations.

The wastes at the WSS contain a mixture of alpha emitters. Although some of the detected alpha activity will be due to Th-232 and Th-228, which have a higher potential to cause internal dose, a larger percentage of alpha emitters with lower internal dose delivery potential will also be present. This is based on measured radionuclide concentrations in waste

materials. In addition, a Th-230 concentration of 4.4×10^{-10} MBq/m^3 (1.2×10^{-14} Ci/m^3) would result in a committed effective dose equivalent of 0.002 mSv/week (0.2 mrem/week). The effective dose equivalent would be much less because the dose equivalent from inhalation of Th-230 in any given year is spread out over a period of more than 10 years.

To ensure that remedial actions do not result in unplanned or unforeseen airborne radionuclide concentrations at critical receptor locations, a "sliding weekly average" gross alpha concentration will be computed for each critical receptor monitoring station. The sliding weekly average gross alpha concentration will be computed by summing all weekly gross alpha concentrations and dividing by the number of weeks of sampling during a calendar year. As successive weekly samples are analyzed, the results will be used to recompute the sliding weekly average concentration. If a sliding weekly average gross alpha concentration at critical receptor locations in excess of natural background is detected with 95 percent confidence, site operations which may have caused the elevated concentration will be evaluated to determine whether all reasonably achievable dust control measures have been implemented.

A weekly sampling frequency is adequate to control radiation exposures because the 0.10 mSv (10 mrem) level specified in 40 CFR 61 is a long-term standard (i.e. yearly). A response time of one week to control unplanned or unforeseen emissions will be adequate to maintain control over emissions.

5.4 QUALITY CONTROL

The quality control program will include spikes, duplicates, blanks, and control charts. This program is designed to meet the requirements of 40 CFR 61, Appendix B.

With each group of filters sent for radiochemical analysis, two filters will be spiked with known activities of Th-230 and two filters will be spiked with known activities of natural uranium (U-238, U-235, and U-234 in natural activity ratios).

Since each filter composite collected at critical receptor locations is cut into thirds, these filter thirds will serve as duplicates. Five percent of all gross alpha analyses are repeated to verify detector performance.

Field blanks are used each week when air filters are exchanged. These will be composited and analyzed radiochemically following analysis for gross alpha activity. In addition, each week an unused filter is analyzed for gross alpha activity. These filters will be composited and analyzed radiochemically.

Control charts are maintained to verify gross alpha detector performance. A control chart is generated to track daily detector background and daily certified standard source checks. Daily background and source counts must fall within three standard deviations of values posted when the detectors undergo semiannual calibration (MKF and JEG, 1989).

In addition to the system of spikes, duplicates, blanks, and control charts the radioanalytical analyses will be evaluated for internal consistency. At the WSS, U-238 and U-234 are in secular equilibrium. Uranium concentrations on air filters should also be in equilibrium. When radioanalytical results are provided, the degree of equilibrium will be evaluated. In most cases, Th-228 and Ra-228 are also in equilibrium. Equality between these radionuclides will also be evaluated.

5.5 DATA QUALITY OBJECTIVES

Accuracy and precision of radiochemical analyses will be measured at the 85 percent confidence level. Accuracy, as determined with the results of spiked samples, will be considered acceptable if analytical results of spiked samples are within $\pm$50 percent of known values for 85 percent of all samples. Precision will be determined by averaging the results of the three duplicate analyses. Precision will be considered acceptable if the standard deviation of duplicate analyses is within $\pm$50 percent of the average for 85 percent of the duplicate data sets. Analytical precision will also be calculated for U-238/U-234 for each composite sample. Precision will be considered acceptable if the standard deviation of the U-238/U-234 results for each composite sample are within $\pm$ 50 percent of the average for 85 percent of all samples.

Accuracy and precision of gross alpha analyses will be measured at the 95 percent confidence level. Accuracy, as determined by the daily source counts, will be considered acceptable if 95 percent of all daily values fall within three standard deviations of the certified standard source. Precision, as determined by the results of duplicate analyses, will be considered acceptable if 95 percent of the duplicate counts are within three standard deviations of the original count.

5.6 AUDITS

Internal audits will be conducted yearly by the WSSRAP Quality Assurance Department in accordance with the WSSRAP QAPP. The primary purpose of the audits will be to assure that sample collection, sample compositing, gross alpha analyses, and sample chain of custody are performed according to standard operating procedures. The internal audits will also ensure

conformance with this overall "Plan for Monitoring Radionuclide Emissions Other Than Radon at Weldon Spring Site Critical Receptors."

External audits of the radioanalytical laboratory will also be performed annually by the WSSRAP Quality Assurance Department. These audits will ensure conformance of the radioanalytical laboratory to standard operating procedures.

5.7 CORRECTIVE ACTIONS

If data quality objectives are not met, the Radiation Protection Manager will provide a report evaluating the reasons for noncompliance and providing a statement of required corrective actions. The Environmental Safety and Health Manager will ensure the appropriateness of the recommended corrective actions and ensure that corrective actions are implemented in a timely manner.

If results of gross alpha analyses indicate detectable emissions of radioactive particulates at critical receptor locations the Radiation Protection Manager shall inform the Operations Department Manager. The Operations Department Manager will be responsible for ensuring that emissions are controlled to a level which is as low as reasonably achievable.

5.8 REPORTS

Emissions measurement program results including assessment of data quality, results of internal audits and corrective actions, if any, shall be prepared annually.

ENVIRONMENTAL DATA ADMINISTRATION PLAN

Enclosed for your review and comment are two copies of the above plan. The Environmental Data Administration Plan (EDAP) identifies the approach and conduct of all activities related to the collection, analysis and administration of documentation of all data gathered at the Weldon Spring Site. The EDAP discusses methods used for acquiring data, programs for quality assurance, and maintenance of the data. This includes sampling plan preparation, data verification and validation, data base administration and data archiving.

Please provide any comments by July 6, 1990.

EDAP/TXTJOANN

ABSTRACT

Environmental monitoring and surveillance activities at Weldon Spring Site Remedial Action Project (WSSRAP) result in data and documentation that is used to develop remedial action alternatives and demonstrate compliance with U.S. Department of Energy (DOE) environmental protection policies.

This Environmental Data Administration Plan (EDAP) summarizes standard operating procedures and data quality objectives developed for use in the collection and analysis of environmental data. Data quality review programs are conducted to ensure data integrity and validity. The EDAP describes administration procedures adopted at WSSRAP to manage the use of environmental data.

1 INTRODUCTION

Environmental monitoring, surveillance, and characterization activities are conducted at the Weldon Spring Site (WSS) as part of the Weldon Spring Site Remedial Action Project (WSSRAP). These activities are described in detail in numerous sampling plans, monitoring programs, and permits. Environmental monitoring activities are conducted at the WSS to ensure that any potential public exposure is documented and quantified in an effort to protect the health and safety of the public. These activities are also required to demonstrate compliance with regulatory requirements and U.S. Department of Energy (DOE) environmental protection policies (MKF and JEG, 1990a).

Two major types of information are collected and evaluated during the environmental monitoring activities: documentation (field notes, data quality reviews) and data (analytical). The information collected is used to support an evaluation of alternative remedial actions. Future environmental sampling activities will provide data on which to evaluate remedial efforts, public and worker safety and protection of the environment.

Data quality objectives (DQOs) have been established in accordance with Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) guidelines for environmental data. DQOs are qualitative and quantitative statements which specify characteristics of the data required to support U.S. Environmental Protection Agency (EPA) decisions during remedial action activities (EPA, 1987). The DQOs identify specific goals for WSSRAP data which include Precision, Accuracy, Representativeness, Completeness and Comparability (PARCC). The DQO plan reviews these goals and is presented in Appendix A. The WSSRAP DQOs are standard in their application and are used as a guideline for WSSRAP.

Standard Operating Procedures (SOPs) have been developed to provide consistency in methodology, reporting of data, and documentation of environmental activities. SOPs include procedures for sample collection and identification and for data quality review. SOPs are detailed in controlled copies of the WSSRAP Procedures Manual (MKF and JEG, 1989). The procedures are reviewed periodically and updated as necessary to record changes in procedures. All manuals are updated and distributed as changes are made.

1.1 PURPOSE

The purpose of this Environmental Data Administration Plan (EDAP) is to identify the approach and conduct of all activities related to the collection, analysis and administration of documentation and data gathered to make environmental decisions at WSSRAP.

The EDAP discusses methods used for acquiring technical data, programs for quality assurance and maintenance of documents and data. The plan establishes a foundation for gathering and examining data prior to its incorporation for use at WSSRAP.

1.2 SCOPE

The EDAP provides guidance on the management of environmental documentation and data resulting from monitoring, surveillance, and characterization at the WSSRAP. All phases of data collection, analysis, and quality are performed as detailed in this plan. This includes sampling plan preparation, data verification and validation, database administration, and data archiving. This plan does not govern worker protection monitoring activities or the quality of data as a result of these activities.

1.3 HISTORICAL OVERVIEW

Analytical data collected from 1987 to 1989 by the Project Management Contractor (PMC) have been managed on an investigation-by-investigation basis. Sampling plans included quality control measures to ensure data integrity. Under the DQO program, data were examined by PMC personnel to test their adherence to PARCC requirements. This review provided a first step to addressing data quality under the DQO program.

While data from 1987 to 1989 were reviewed for PARCC compliance, a separate effort to assess and document the validity of analytical results was also made. The results of this effort are currently being presented in a document scheduled for issue in October 1990: "Data Validation Review."

Data verification and validation programs described in this EDAP were initiated in 1989 for environmental sampling activities. These programs establish additional quality control measures and are detailed in this plan.

1.4 MAINTENANCE

The EDAP will be reviewed annually and revised as necessary to ensure compliance with DOE orders and the overall mission of the WSSRAP. All documents and data will be maintained in accordance with procedures described in Section 4.0 of this plan.

2 DATA COLLECTION

2.1 SAMPLING AND ANALYSIS PLANS

Sampling and analysis plans are developed and prepared for all site activities requiring field collection and laboratory analysis of samples. These plans range in size from one-page memos to multi-paged, self-supporting documents. The plans are activity-specific, describing the objectives and details of the individual sampling efforts and the ultimate uses of the data generated. Sampling and analysis plans specify the types, locations, and frequency of samples to be collected, as well as the sampling protocol and procedures. The plans also detail the specific QA/QC measures to be taken during sampling and analysis effort and reference the requirements of the Quality Assurance Program Plan (QAPP) for the Weldon Spring Site Remedial Action Project (WSSRAP). Sampling plans specify detailed Data Quality Objectives (DQOs) which may take precedence over the standard DQOs.

2.2 SAMPLE COLLECTION AND DOCUMENTATION

Samples are collected using standard operating procedures (SOP) from specific, preplanned locations as detailed in the WSSRAP sampling plans.

Two forms of documentation are used during sample collection to define data reporting requirements that characterize sampling efforts and ensure consistent data records. The field log books are maintained by the field sampling personnel to record details such as dates, times, personnel, weather conditions, deviations from sampling protocol or any other information potentially impacting the specific sampling event. The level of detail should be sufficient to

understand and re-create the activity at a later date, even in the absence of the field personnel.

The sampling field data form is completed for each sample location at the time of sample collection. These forms are specific to the common types of samples collected at the WSSRAP, i.e., soils, groundwater, surface water, etc. The field sampling forms record the sample identification numbers assigned to the sample collected based on location and date (SOP ES&H 4.1.1). This unique ID number is used throughout documentation and reporting of data. The forms also initiate the tracking of laboratory performance and evaluation of data quality. Additionally, these forms document that field personnel collected samples in accordance with WSSRAP procedures, preserved samples properly, and collected QA/QC samples, and other vital information. An example of a typical sampling field data form is shown in Figure 2-1.

2.3 CHAIN-OF-CUSTODY

Sample custody is an integral part of quality and field laboratory operations. Sample possession must be traceable from the time each is collected until it is disposed of or placed in final storage. A sample is under custody if one or more of the following criteria are met:

- the sample is in the actual possession of the responsible party

- the sample is in the view of the responsible party, after being in possession

- the sample was in the responsible party's possession and then that person locked it up or sealed it to prevent tampering

- o the sample is in a designated and identified secure area under control of the ES&H Department.

All samples are collected according to SOPs for the particular sample type. The field personnel are responsible for the collection, care and custody of the sample until the sample is properly transferred or dispatched. An Environmental Chain-of-Custody form (Figure 2-2) is completed for each sample or group of samples. The Chain-of-Custody (COC) form includes sample identification numbers, number of containers, sample matrix, analytical parameters requested, turnaround time required, samplers' signatures and a section for tracking sample possession.

When the samples are shipped to the lab for analysis the individuals relinquishing and receiving the samples sign, date, and note the time and reason for transfer on the COC. The completed original form is then placed inside the shipping container. The laboratory documents receipt of the samples on the COC and notify the shipper and the WSSRAP in the event that samples are damaged, tampered with, or missing.

Corrections necessary in completing COC forms are made by a single strike-mark through the error. The person making the correction initials and dates each correction.

2.4 REQUEST FOR ANALYSIS

Samples collected in the field commonly require analysis by an off-site laboratory subcontracted by the WSSRAP. In order to authorize testing on the samples, PMC personnel complete a Laboratory Services Authorization Form. These forms are specific to each sample matrix (i.e., water, soil, etc.). They include such information as laboratory name, sample identification numbers, number of containers, analytical

parameters, turnaround time requested and required number. The Laboratory Services Authorization Forms authorize analytical service and provide a mechanism for tracking analytical laboratory budgets and performance. An example form is presented in Figure 2-3.

2.5 SAMPLE SHIPMENT

Samples are packaged and shipped to analytical laboratories in accordance with WSSRAP standard operating procedures. These procedures detail the requirements of packaging and shipping for common types of samples in order to protect the samples during shipment. All samples shipped off-site are accompanied by a Shipping Order Form (Figure 2-4). This form is completed by the Subcontract Administrator when the Chain-of-Custody and Laboratory Services Authorization Forms are reviewed and approved. These three forms are combined, placed in a plastic bag, and accompany the sample being shipped.

2.6 SAMPLE TRACKING

Sample shipments to analytical laboratories are inventoried and controlled by the use of a laboratory contract request number. When a sample shipment is made, sample information from the documentation is entered into a computerized database, the Environmental Sample Tracking (EST) system.

EST allows timely inventory of the status of analytical samples from collection through receipt of data results. The EST system also serves an accounting function by calculating analytical costs, assists in invoice payment authorization and provides budget reporting.

3 DATA QUALITY

All data and documentation from sampling activities are reviewed under Environmental Data Administration Plan (EDAP) data quality programs. Data received from analytical laboratories are also reviewed for completeness and quality. The data quality programs, data verification and data validation examine documents and data prior to its use at WSSRAP.

3.1 DATA VERIFICATION PROGRAM

The verification program is primarily designed to ensure that documentation and data are reported in compliance with established Data Quality Objectives (DQOs) and Standard Operating Procedures (SOPs) and to evaluate the completeness of data. The Data Verification Program consists of six verification tests Two tests are associated with data delivery and analytical costing. Four tests compare actual procedures to Weldon Spring Site Remedial Action Project (WSSRAP) DQOs, analytical protocol and SOPs. Elements reviewed are sample preservation and identification, Chain-of-Custody (COC) completion, analytical hold times, and data review. The results of the verification tests are documented with a verification checklist (Figure 3-1).

3.1.1 Data Delivery

Delivery of analytical data is tracked to ensure that the requested laboratory services are performed in an accurate and timely manner.

Analytical results are delivered in two formats: a formal report with QA/QC paperwork and an electronic copy. Current contracts with two analytical laboratories require delivery only

of formal analytical reports. Future laboratory service contracts will require delivery of data in both formats.

Analytical results from subcontract laboratories are received at WSSRAP and are logged and dated by the Project Management Contractor (PMC) Subcontract Administrator. All analytical results are forwarded to the PMC Data Administration Section. The receipt of data is recorded in a manual sample tracking log.

The data formats are reviewed to determine if all formats have been received according to contract requirements. In addition, data are reviewed to confirm that all parameters are received for the analytical tests. If additional data are required to complete the laboratory request, a discrepancy form (Figure 3-2) is completed and sent to the Subcontract Administrator for handling.

As discussed in Section 2.4, when samples are shipped, a lab authorization form is completed. The laboratory authorization form indicates a turnaround time for delivery of analytical results. The standard turnaround time is 28 calendar days.

Analytical services are also available within premium turnaround times ranging from 48 hours to 2 weeks. These services are usually reserved for special sampling events or National Pollutant Discharge Elimination System (NPDES) monthly reports.

When the data are received by the PMC, the date is recorded on the laboratory report. This date is compared with the shipping date for the sample to determine a total turnaround time. If a turnaround time is greater than the requested time, a verification discrepancy form is completed to record the

ORIGINATOR: JMH		DRAWN BY: GLN		DATE: 4/90	

turnaround time. The potential effects of negligence in meeting turnaround times may include failure to comply with analytical hold times on analyses.

3.1.2 Sample Preservation and Identification

Documents prepared during sample collection are reviewed to verify compliance in identification and preservation of samples. According to procedures, consistent numbering of sample location is necessary for sample identification. Sample IDs are checked for proper use of sample type identifiers, location number/coordinates, date codes and QA/QC coding.

Preservation of samples is required under certain analytical methods. Sample preservation required prior to shipment is documented on field data forms. The forms are reviewed for completeness and accuracy in preservation during the verification tests.

3.1.3 Chain-of-Custody

Copies of COC records are returned to the PMC with the analytical results. The COC records are reviewed for compliance with procedures as described in EDAP Section 2.3 and WSSRAP SOPs. The COC is reviewed for possession and signatures status of the samples, for any samples that may have been damaged, and for clarity of information provided on the COC form.

3.1.4 Analytical Holding Times

WSSRAP DQOs incorporate analytical methods under U.S. Environmental Protection Agency (EPA) Contract Laboratory Program (CLP) protocol. These methods designate maximum analytical holding times, the period between sample collection

and analysis. Some methods also specify extraction procedures and extraction holding times.

When analytical results are received, the date of extraction and date of analysis for each analyte is reported. The extraction and analysis dates are compared with the sample collection date to determine total holding time for the sample. The sample's holding time is compared to the holding time for the analytical method as defined by the WSSRAP DQOs. Holding times are recorded for each analysis. A discrepancy form is completed for sample holding times that exceed DQO protocol.

3.1.5 Data Review

All analytical data are reviewed as a final verification test. The data review process evaluates comparability of sample data with other previously reported concentrations for the sample location. Sample data is also compared to the QA/QC samples, field blanks, and laboratory duplicate samples collected on the same sample date. The data review reports inconsistencies in concentrations, sampling procedure, sample identification, etc.

The data review form (Figure 3-3) is completed by the PMC personnel. The data reviewer will designate the data as "acceptable" or "unacceptable" and include qualifying comments on the data review sheet for all data designated as unacceptable. Unacceptable data will be considered for data validation activities as presented in Section 3.2.

3.1.6 Verification Documentation

The verification checklist is completed by the Data Administration Section based on results of each verification

ORIGINATOR: JMH		DRAWN BY: GLN		DATE: 4/90	

test. Overall integrity of the data is measured and documented with the verification checklist.

All data will be assigned a verification status code of A (approved) or S (significant). If no discrepancies exist from the verification review, a status of A, approved will be assigned to the data. If significant discrepancies exist, such as samples that exceed holding times, a status code of S will be assigned to the data. Data with a status code of S will be considered for validation review as part of the non-random data validation program that is further detailed in Section 3.2.

All data regardless of status code will be considered available for use by WSSRAP. The verification status does not disqualify data from use. The verification tests are used to determine compliance with WSSRAP DQOs and SOPs and prequalify sample data for data validation review.

3.2 DATA VALIDATION

Data validation is the process of reviewing the analytical data, using laboratory records, to assess laboratory performance as compared to quality control (QC) criteria, data quality objectives, and procedural requirements. The purpose of validation is to document the quality and usefulness of the data and documentation developed during sample analysis.

The validation of data is divided into the following three tasks: (1) identification of data to be validated, (2) actual validation, and (3) documentation. These tasks are discussed in the following sections.

3.2.1 Identification

The identification of data to be validated is accomplished in two ways. The first consists of routine validation. Approximately 5% of the samples collected will be validated as soon as the analytical data is received from the lab. These data points are identified in the sampling plans that detail their collection. An additional 5% of the data will be selected following completion of the data review portion of the verification process. Additional data points may be identified for validation based on the criticality and sensitivity of the data. For example, data that contribute to risk assessments or final remedial action decisions may be identified for validation. Requests for validation are made on data validation request and tracking log forms (Figure 3-4).

3.2.2 Validation

The actual data validation process is detailed in an Engineering SOP (ENG-9). This process consists of reviewing and evaluating the data resulting from laboratory analyses. The review consists of two phases. The first deals with the analytical process itself. Laboratory analytical records are reviewed and evaluated to assure compliance with the procedures governing the analysis. These records may include but are not limited to: sample custody records, sample preparation logs, instrument printouts, calibration checks, initial calibration data, etc.

The second phase of the data validation process consists of evaluating the data for precision, accuracy, and completeness. Precision, accuracy and completeness are evaluated by comparing the data to data quality objectives in sampling plans.

The primary end result of the validation process is a qualifier which denotes the quality of the data point. These qualifiers range from "acceptable with no limitations" to not acceptable. This qualifier enables data evaluation personnel to incorporate data quality into interpretations. A list of data qualifiers is shown in Figure 3-5.

3.2.3 Documentation

Data validation activities will be recorded in several documents. These documents include a detailed validation checklists specific to analysis. An example of validation documentation for a semi-volatiles analysis is shown in Appendix B. Data validation summary reports will be generated for each validation request and will provide information substantiating the assignment of qualifiers.

As a result of validation activities, at least 10% of the WSSRAP data will be directly validated (validation that results out of a specific request from data users). However, for some analyses, a portion of the database will also be validated indirectly (or "by association") as a consequence of the "sample batching" nature of most analytical procedures. Such indirect validation is possible for most metals analyses, most miscellaneous inorganic analyses, some anions, and some radiological procedures since the data documentation for these analyses is typically presented for the entire analytical batch or lot (which may include WSSRAP samples that were not specifically requested for validation).

DATA VALIDATION QUALIFIER LIST

QUALIFIER	PURPOSE
Primary	
N	Sample not scheduled for data validation
P	Data validation in Progress (Pending)
A+	Data useable; no further qualifiers
A[*]	Data useable; with qualifiers
R[*]	Data Rejected; with explanation
O[**]	Data validation ON-HOLD (additional info requested from lab)
Secondary *	
>	high bias
<	low bias
L	Lab Control Sample (LCS) outside acceptance range (accuracy)
B	Blank contamination (integrity)
M	MS/MSD outside acceptance range (accuracy/precision)
D	Dup. Relative % Difference outside acceptance range (precision)
S	Surrogates outside acceptance range (accuracy)
I	Internal Standards (GC/MS) outside acceptance range (quantification)
H(#/#)	Holding times exceeded (integrity)
C	Calibration criteria not met (quantification)
T	GC/MS Tune criteria not met (qualification)
F	Interferences present (matrix related)
?	Other (see data validation notes)
J	Estimated value
Y	Shipping delay to lab (greater than 1 day)
G	Typographical error (significant)

Tertiary **

c	calibration	i	instrument printouts
s	sample preparation	l	control charts
t	tune	d	data summary sheets
q	QC samples/information	n	notebook entries
u	custody transfer record	e	corr. action/exception reports
p	standards preparation	?	other (see data validation notes)
m	mass spectra		

EXAMPLES:

A[L>,H(5)] - means the data point is useable, but the value may be slightly high (per the LCS); and the holding time was exceeded by 5 days.

A[F,J] - means the data point appears useable, but there are sample-related interferences present that resulted in an estimated value.

R[S<] - means the data are not useable because the surrogate recoveries were too low to rely on the value.

P - means this sample/analyte is scheduled for data validation, but the validation tasks are not yet complete.

DATA VALIDATION QUALIFIERS

4 DATA ADMINISTRATION

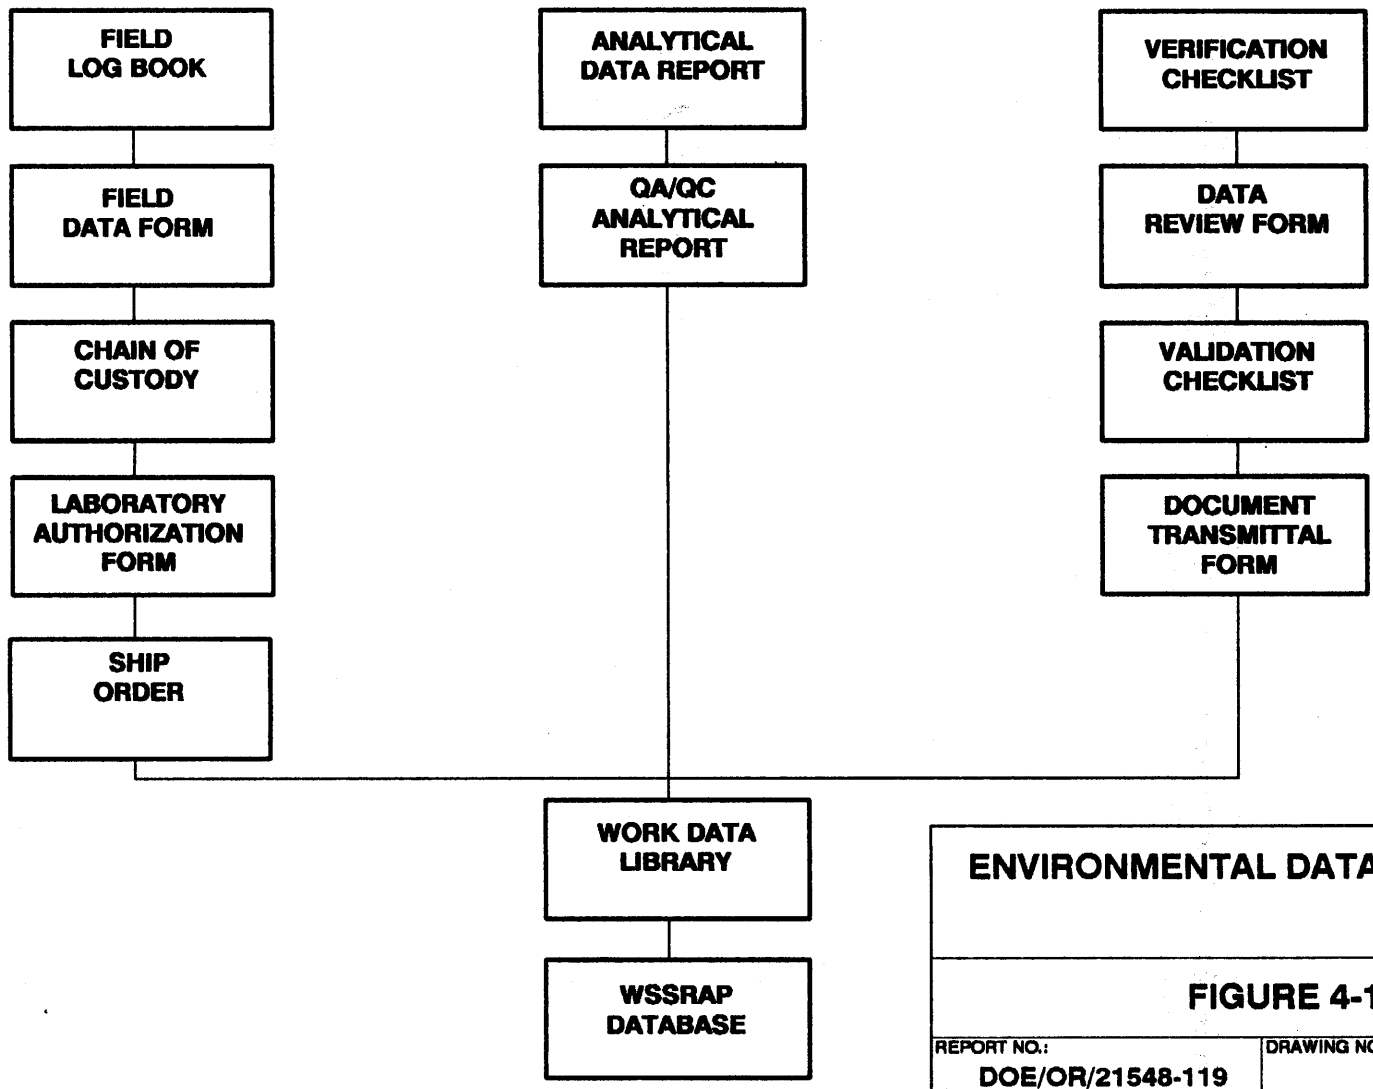
All documentation and data generated through the environmental monitoring activities are managed and maintained by the data administration plan of the Environmental Data Administration Plan (EDAP). Each document created from sampling to data quality review provides information and support for environmental decisions at Weldon Spring Site Remedial Action Project (WSSRAP). The standardization of forms and documents as directed by Standard Operating Procedures (SOPs) provides a source of information that is complete yet unique for each sample. The full set of data and documents is termed the data audit trail. Figure 4-1 summarizes the data and documentation in the audit trail. The administration of data includes the maintenance of all documents and data in the audit trail, providing the information to WSSRAP in an organized, flexible manner and incorporating a system to archive data.

In this discussion of data administration plans, all environmental data and documentation from sampling, analysis and quality review programs are collectively referred to as records.

4.1 RECORD MAINTENANCE

Environmental records are maintained in two formats: hard copy records and electronic records. Hard copy records include all documents and data preserved in written, typed or instrument-printed form. All environmental records originate in hard copy format.

Electronic records are defined as computerized records of environmental data. Currently, only analytical data are maintained in electronic format. Approximately 60% of the subcontract laboratories transcribe analytical reports into electronic format. Analytical results not reported in



ENVIRONMENTAL DATA AUDIT TRAIL

FIGURE 4-1

electronic format are transcribed to electronic records by the Project Management Contractor (PMC).

4.1.1 Hard Copy Records

All original records are received by the PMC. When the original is received, a copy of the document is made. A copy of the record is filed in the Work Data Library.

The Work Data Library is a centralized library system that contains all documents and data from environmental monitoring activities. The library is primarily organized by record type: data or documentation. Each record type is then classified and filed according to sample type. Sample types were mentioned in Section 2.1 as a manner in which to assign sample identification numbers. Functionally, sample types also form the basis for data interpretation and, therefore, sample types are used in record management. Table 4-1 lists the sample type categories in use.

When a record is submitted to the library files, it is assigned an index number based on record and sample type number. An example of the index record number is ES-19-01-02. The first four characters (ES-19) identify the document as an environmental record. The fifth and sixth digits (01) designate the record as analytical data. The seventh and eighth digits (02) designate the sample type as surface water. A current Work Data Library index is presented in Table 4-2. The index is updated periodically to incorporate new records.

When record copies are made for the Work Data Library, the originals are forwarded to Quality Assurance for secured storage. An internal document transmittal form is completed to accompany the document transfer (Figure 4-2). All original

documents are inventoried by Quality Assurance and stored in fireproof safes at the WSS.

4.1.2 Electronic Records

Electronic records are maintained in a computerized database system termed the WSSRAP database. The WSSRAP database is a microcomputer based system utilizing dBASE III Plus software. Analytical records are organized into database files by sample type such as groundwater. The database files contain in database fields specific information on the sample. The fields maintained in the WSSRAP database include sample identification number, sample date, analytical date, parameter, etc. The list of all database fields and a description of field information is presented in Table 4-3.

Analytical results reported by the subcontract laboratory in electronic format are submitted on a 5 1/4" floppy diskette. Each diskette contains a dBASE III Plus file recording specific sampling information. The diskette is received by the PMC and copied to the WSSRAP database during verification tests. After the disk transfer is completed, a control number is assigned to each diskette and recorded on a disk record log maintained by the PMC. All diskettes are filed in a fireproof safe located at the WSS.

4.2 RECORD USE

The Work Data Library and the WSSRAP database provide an centralized source for information to be used in preparing environmental reports and remedial action alternatives. The environmental records are organized to provide data that are readily retrievable and convenient for use. Environmental records are required for use by on-site and off-site personnel.

TABLE 4-3 WSSRAP Environmental Database Fields

Field	Description of Information
WSSRAP ID	Sample identification number
Lab ID	Analytical laboratory identification number
Sample Date	Date of sample collection
Matrix	Sample type
Category	Compound or group of parameters analyzed
Parameter	Compound analyzed - chemical or radiological
Concentration	Identified amount of parameter
Units	Standard of measurement of parameter analyzed
Error	Range of error in measurement of concentration. Used mainly in radiological analyses.
Analysis Date	Date of analysis of sample
Extraction Date	Date of sample extraction if applicable under analytical method
Method	Analytical method used by laboratory in analysis of sample
Detection Limit	Minimum reportable concentration of compound defined by data quality objectives
Verification	Verification code assigned reflecting analytical status of sample
Qualifier	Validation code assigned to sample reflecting usability of data

4.2.1 Use of Work Data Library

The Work Data Library is located at the WSS. All personnel have full access to records in the library for use and/or copying. Personnel requiring use of records must sign the documents out on a library log maintained by the PMC to record such use of records. A maximum check-out period of one day is allowed and only on-site use of records is permitted. The Data Administration Section manages the use of the Work Data Library.

4.2.2 Use of WSSRAP Database

The electronic record database is more widely used for review of analytical data by WSSRAP personnel. Database use is managed by a customized software program called the Generic Universal Report Utility (GURU). The GURU program was developed by the PMC for use in accessing the WSSRAP database. GURU is a compiled dBASE program written for the IBM PC network system.

The GURU program provides a tool for easy and flexible access to data records. The GURU is also defined as a data extraction program since data can be selected and sorted based on sample identification number, parameter or any other field definition. Selected data can be extracted or copied to other computerized formats or as a printed report.

The GURU program also provides a method to secure data contained in the WSSRAP database. Data are made available to the user without risking the integrity of the data. Users are allowed to view or copy records, but records cannot be modified or deleted within the GURU system.

On-site use of the WSSRAP database is provided by accessing the WSSRAP local area network system. Users requiring access to the database must complete a user registration form with the PMC

Management Information System (MIS) Coordinator. A user name and password is assigned to each user and specifies access to the WSSRAP database and GURU system.

Off-site use of the WSSRAP database and the GURU system is available for WSSRAP participants. Access to the database will be provided by a modem connection. The modem capability allows off-site users to dial in on standard phone lines and connect to a computer at the WSS. The modem connection allows the same convenience and security features of on-site use. Off-site users requiring access to the database must complete a users' registration form with the PMC MIS Coordinator. A user name and password is assigned to each user and off-site access may be specified.

4.3 DATA ARCHIVING

A system of archiving environmental data is necessary due to the volume of data and duration of WSSRAP. Formats of data documentation -- hard copy, originals, and electronic -- will be archived. Archiving of data will be allowed only after all EDAP data quality activities have been completed on the data to be archived. Specifically the data must be verified and validated under the EDAP program.

All original documents are transferred to Quality Assurance and are archived under DOE contract requirements. The original documents are stored in the WSSRAP Quality Control area in a fireproof safe. The original documents will be maintained by Quality Control for the duration of the project. Work Data Library and Electronic data records are maintained by the Data Administration sections. These records will be archived. Archival of records is performed annually.

Work Data Library documents will be inventoried and will be boxed and stored at WSSRAP for a one-year period in archive status. After one year in archive, the Work Data Library documents will be destroyed.

Electronic data records will also be archived after five years. All archive data will be transferred to new historic data record files. The archive files will be backed up with magnetic tapes and stored in the fireproof safe in Quality Assurance. The archive data files will be available for use by the WSSRAP GURU program but not in conjunction with active data files. Original electronic data reporting disks from the laboratory will be destroyed after five years.

APPENDIX A
Data Quality Objectives

Specific Data Quality Objectives (DQOs) for the Weldon Spring Site Remedial Action Project (WSSRAP) have been developed according to the U.S. Environmental Protection Agency (EPA) Guidance Document. These site-specific DQOs include Precision, Accuracy, Representativeness, Completeness and Comparability (PARCC) goals for future data collection activities. Each of these goals is discussed in the following paragraphs.

PRECISION AND ACCURACY

Precision and accuracy goals for analytical data are presented in the following table. Analytical methods, detection limits and precision and accuracy goals are presented by analytical parameter and media for both soil and water. Generic precision and accuracy goals are also presented.

REPRESENTATIVENESS

The representativeness of data collected will be ensured by proper selection of sampling locations and by ensuring that Standard Operating Procedures are followed during sample collection.

COMPLETENESS

Completeness is the percentage of measurements that are valid. The goal for completeness at the WSSRAP is 85%.

COMPARABILITY

By establishing precision and accuracy goals and monitoring analytical performance, comparability evaluations can be made with previous data for which precision and accuracy data are available.

The DQOs presented herein are to be used for future monitoring and characterization activities. As future characterization activities are identified, these DQOs will be reviewed. If the existing DQOs are acceptable and appropriate, they will be applied. If not, new DQOs will be developed. The DQOs presented in this summary will be reviewed annually and updated as appropriate.

Jefferson City, Missouri 65102

Dear Dr. Bedan:

In response to your November 22, 1989 memo, we have reviewed the Draft Remedial Investigation Report for the Weldon Spring Site Remedial Action Project prepared by the U. S. Department of Energy. As usual the document is well done. One question that prevailed as I reviewed the document was whether this was a document that decided action or one that simply laid out the situation. I found some indications of both.

Several questions related to our Busch and Weldon Spring Wildlife Areas came to light. They are:

1. Page 5-112 through 5-122. It appears that the Department of Conservation sites 1, 3, 4, 5, 7 and 9 require remediation while sites 2, 6, 8 and 10 apparently do not require remediation. Sites 1, 2 and 10 apparently have been cleared up. Site 6 is recommended to be remediated during quarry cleanup. Why not include site 8 in the remediation of quarry cleanup?

2. Page 5-123. We concur in the need for cleanup of Southeast Drainage.

3. Page 5-132. Sediment samples from Site SD-4001, Lake 36, SD-4007 and Lake 35 have mean uranium levels of 31 pCi/g, 30 pCi/g, 26 pCi/g and 23.6 pCi/g. The reference level for uranium indicated on page 5 of the Executive Summary is 15 pCi/g. Would it follow that remediation on these sites is warranted since they exceed the reference level?

4. Page 5-155 and 5-157. Data are puzzling to us. We have collected a set of fish flesh samples for lead analyses. We would hope that as more data become available a decision can

be made on appropriate action to respond to elevated lead levels. With very high lead levels in Ash Pond and upstream of Lake 36, how will the Department of Energy interact with the Department of Army on cleanup activities?

We appreciate your patience in soliciting our comments. If you have questions or wish to discuss these comments, please call me.

Sincerely,

W. H. Dieffenbach

St. Charles, Missouri 63303

Dear Mr. McCracken:

We have completed our review of the draft Remedial Investigation Report for the Chemical Plant and Raffinate Pit Area dated September 1989. Overall, the report presents a good summarization and evaluation of the various data collection efforts. Our comments and suggested revisions are enclosed with this letter.

Please call if you have any questions.

Sincerely yours,

Robert L. Morby
Chief, Superfund Branch
Waste Management Division

1/29/90

REVIEW COMMENTS ON THE DRAFT REMEDIAL
INVESTIGATION REPORT FOR THE WELDON SPRING SITE

January 1990

General Comments:

1. The scope of the remedial investigation needs to be more fully defined. It may not be clear to the reader that the report is only intended to examine the contamination from the uranium processing plant, and the contamination from explosives production which is inside the DOE property lines. The rationale for this definition needs to be presented, since property lines are generally not relevent to the definition of the extent of contamination. It remains EPA's position that the DOE's and the U.S. Army's respective responsibilities must be defined in a written agreement to ensure that all needed investigation will be completed in an efficient manner. The adequacy of the scope of the RI needs to be evaluated in the context of such an agreement.

2. The field sampling plans which were developed and implemented to form the basis of the RI report are described in the report; however, the reader is not clearly directed to the respective sampling investigation reports which presumably contain more focused and thorough analysis than the summaries contained in the RI report.

3. A useful summary of data gap analyses and general plans for additional data collection is not presented.

4. The data available for analysis of ecological impacts appears to be limited. The impacts of contamination on the wildlife is presented only in the context of the implications to human health. A complete baseline risk assessment must consider environmental effects as well as public health effects. Information on the numbers of species using the contaminated area, their reproductive success, and any evidence that the contamination is affecting the viability of local wildlife populations should be presented.

Detailed Comments:

1. The Table of Contents should be expanded to include a list of plates.

2. In the Executive Summary (page 1), there is a statement which refers to the percentage of land transferred to the U.S. Atomic Energy Commission (AEC) versus the amount of land originally used

for ordnance production. Ten percent is the amount quoted; whereas, the actual amount is closer to one percent as explained in Appendix H. The original site covered 17,232 acres compared to 205 acres transferred from the Department of Army (DA) to AEC.

3. In the third paragraph of the Executive Summary, there are statements which are contradictory. It is stated first that the Weldon Spring Raffinate Pit (WSRP) and the Weldon Spring Chemical Plant (WSCP) areas are on the National Priorities List. The next sentence states that they have been nominated to be on the list.

4. On page 8 in the third paragraph, the reference to Figure 7 should be to Figure 6.

5. The first sentence of the first paragraph on page 10 should be rewritten. It appears that nitroaromatics precipitate in the unsaturated zone before reaching the saturated zone.

6. Several conflicting statements were found. As an example, on page 10 in the Executive Summary, the following statement is made: "Nitroaromatic compounds quickly degrade upon exposure to sunlight and therefore are not transported in surface waters." It is noted on page 6-16, Vol. I that the nitroaromatics TNB and DNB are not subject to photolytic degradation. Also, on page 1-4, the Army Reserve is 1,843 acres, while on page 3-13, Vol. I, it is approximately 1,660 acres.

7. On page 1-5 in the second paragraph, the text states that the Weldon Spring Wildlife Area is located across Missouri Highway 94. Figure 1.2-2, which is referenced, shows the site and the wildlife area on the same side of the highway.

8. Numerous abbreviations labeling buildings, water towers, etc., are shown on Plate 1. A legend should be provided to identify the structures.

9. Table 3.7-1 should indicate what the numbers on the table represent such as the number of samples taken.

10. In Section 4.5.11, page 4-33, second paragraph, it is concluded that the observed net infiltration in the raffinate ponds is "closely related" to the measured hydraulic conductivities of the underlying material. In fact, those hydraulic conductivities span four orders of magnitude. The magnitude of the measured net infiltration lies in the middle of that range. While this is to be expected, it may be misleading to use the term "closely related" to characterize this agreement.

11. The discussion on stratigraphy is good; however, we suggest that the surface soils be addressed in terms of the Department of Agriculture's soil series and descriptions.

12. Page 4-1 references Figure 4.1-2 for site elevations, but it only shows elevations for the surrounding area.

13. The term "normal" is also used incorrectly. In meteorology, "normal" refers to averages of climatological data for the 30-year period from 1951 through 1980. In the context used in the report, either the term "average" or "mean" is more appropriate.

14. The legend on Figure 4.3-2 should include a description of the well, trench and borehole numbering system.

15. In the first paragraph on page 4-21, the last sentence indicates that the four raffinate pits do not contribute to direct runoff; however, Figure 4.4-2 seems to show flow out of pit number 4. Table 4.4-2 also indicates the raffinate pits are closed basins, but Figure 4.4-3 seems to show a stream gage that measures the outflow from pit 4.

16. The term "swallow holes" appears occasionally. Pages 4-26, 4-30 and 4-31 refer to "swallow holes" and Figures 4.4-4 and 4.4-11 refer to "shallow holes." Definitions should be provided since it is not clear what these holes are.

17. The method used for estimating surface runoff on page 4-24 is not a very reliable one. A better approach would have been to calibrate a model to the measured events, then use a historical sequence of precipitation events to determine average runoff conditions. An alternative approach would be to examine records from similar gaged watersheds in the area.

18. On page 4-31, the definition of the vadose zone is misleading. The vadose zone may be temporarily saturated due to surface ponding and may have perched water tables. Perched water tables are mentioned on page 6-4. A possible definition is the zone between the soil surface and the permanently saturated zone.

19. On page 4-33, there is a discussion about lysimeters and that they were installed to determine possible contaminant migration. More explanation is needed to explain how a lysimeter would show contaminant migration. The discussion on page 5-141 about lysimeters is even more confusing on just how the lysimeters are being used. On Table 5.4-1, lysimeter LYS3506 should be LYS3606.

How does the comparison of the two figures lead to the conclusion of a deep "trough"? The discussion which continues onto page 6-B appears to contradict this conclusion. This paragraph is confusing and needs clarification.

29. The discussion on the factors affecting the persistence and attenuation of organic compounds should be expanded. Sometimes degradation products are more toxic than the parents. Were the degradation products adequately sampled and analyzed?

30. On page 6-16 in the first sentence of Section 6.2.7.2, change "deleted" to "detected".

31. From January 1967 to February 1969, the Department of the Army prepared plans to design and construct a plant at the site to produce the herbicide "agent orange". This fact is mentioned in the appendix, but the appendix does not indicate that there was no actual production of the herbicide at the Weldon Spring site during that two-year period.

32. Important information appears missing from the appendices. Descriptions of the monitoring well construction and sampling techniques should have been included.

20. The second paragraph on page 4-35 refers to Figure 4.5-5 when it should really be 4.5-6.

21. On page 4-40 in the third paragraph, briefly explain why the Bouwer and Rice method is believed to be the more reliable method.

22. The loss by seepage from the raffinate pits should be reported as a volume per unit of time. The second paragraph on page 4-47 only specifies an apparent velocity.

23. In Chapter 5, many concentrations are discussed in various samples. Generally, these concentrations are not referenced with any standard to indicate if the concentration is significant in terms of human health or the environment. Page 5-16 has numerous examples of this. Page 5-22, last paragraph, provides the kind of comparison to an established standard that would be helpful throughout the document.

24. An inconsistency was noted in Section 5.1.2.3, page 5-14, second paragraph. The report indicates that the evaporation of all water from raffinate pits 1 and 2 has not happened since 1980; however, Table 5.1-16 indicates a dry surface in 1987. A clarification is needed.

25. Tables 5.1-6 and 5.1-7 have the same title. One of them should be changed to reflect the differences in the data presented.

26. Section 3 of the report describes the investigations conducted at the site. To keep the report consistent, we suggest that the radiological investigations be described in that section as well, rather than in Section 5.

27. On Tables 5.2-2 through 5.2-31, there does not appear to be any difference between the constituents labeled "Other contaminants at levels above two times their upper background limit" and those labeled "...above their upper background limit."

28. The last paragraph on page 6-7 uses a comparison of Figures 4.6-3 and 4.6-4 to indicate a deep ground water "trough" extending from the Weldon Spring site to the Burgermeister Spring. It is suggested that conduit flow velocities in this "trough" are on the order of two feet per minute. This velocity is several orders of magnitude greater than any other reported velocities in the area. Because of this and the potential for very rapid offsite migration of contaminants, there should be more discussion about this "trough." How were these velocities calculated?

FROM: Peter Price, Geologist, DGLS

SUBJECT: Comments on Draft Remedial Investigation Report for the Weldon Spring Site Remedial Action Project, Rev. B

General Comments

Please reference MDNR's First Annual Report on the Shallow Groundwater Investigations at Weldon Spring, Missouri as MDNR, 1989 rather than Hoffman, 1989. Citations occur on pages 4-24, 26, 46, 50 and 51, on Table 4.6-9, and perhaps elsewhere.

Figure 4.1-2 presents a topographic map of the Weldon Spring area but is not detailed with respect to the site. Nowhere else is there a topographic map of the site. We would suggest adding a topographic map of the site at the same general scale as many of the other site maps in the report. Drainage patterns and surface features would be much more obvious with such a map in combination with the text descriptions.

Specific Comments

Table 4.6-1 - footnote (d) is not explained

P. 3-22 MDNR Dye Tracing Studies - this section does not report MDNR-DGLS dye tracing experiments correctly. Only two borehole dye traces were attempted in 1983 (MW 2020, March 9; MW 3007, April 7) by Dean. The report only mentions one losing stream dye trace (from West Raffinate Pit Drainage, Feb. 1984) of three conducted. The other two were from the head of the Southeast Drainage (June 1984) and from Ash Pond Drainage (March 1985). The 1988 attempted borehole traces are adequately described. Fig. 3.4-4, Water Tracing Sample Locations, appears to be a modified version of a map produced by MDNR-DGLS (MDNR, 1989).

P. 3-29, Section 3.7.1.6 - This section mentions recent (1988-1989) exploration programs, to help describe site geology, conducted by the PMC. Some information from these programs is presented in tabular form (Table 4.3-1) but drilling logs are not presented in the RI Report. Are drilling logs from these recent programs presented in another document?

P. 4-9, Section 4.3.1.1 - The Bushberg Sandstone has been reported in the literature as a Devonian age formation (Kleeschulte and Emmett, 1987; Miller, et al, 1974; Koenig, 1961). However, more recently the Bushberg has been assigned to the Mississippian System (Thompson, 1986). The text and Figure 4.3-1 should reflect current understanding.

The term "unit" is not customarily capitalized since it is not part of the formal name of a formation. Unit is capitalized several places on this page.

The thickness figures given for the Warsaw and Salem formations do not agree with those given in Figure 4.3-1. The thickness figures in the text refer to the site area for most formations. The descriptions of the Warsaw and Salem do not, and may mislead the reader.

P. 4-10, paragraph 2 - Alluvium overlies units other than glacial drift and loess in the vicinity of the site. The last sentence of this paragraph is incorrect.

P. 4-10, Section 4.3.1.2 - This section presents several isopach and contour maps of the site presumably generated from the geologic database. A check of several data points against geologic logs, particularly on Figure 4.3-19, reveals several points in disagreement with plotted contours or isopachs. Many data points cannot be checked because geologic logs have not been presented in this document or elsewhere. Is there an explanation for these apparent conflicts?

P. 4-13 - The residuum unit is described as an individual stratigraphic unit in the text but is not represented as such in the Generalized Stratigraphic Column (Figure 4.3-1). There is a problem in assigning it an age but it should be represented, perhaps as "Quaternary or pre-Quaternary" may be most appropriate.

P. 4-14 - MDNR-DGLS does not consider a hydraulic conductivity of 5 x 10^{-8} cm/sec. to be representative of the residuum unit. Our experience indicates that it has a much higher permeability. We support further sampling and testing of this unit, as mentioned.

P. 4-28 - The descriptions of gaining and losing reaches, particularly in paragraphs 2 and 3, are not clear because mentioned landmarks are incorrectly named and not represented on the reference maps. Road DD is maintained by the State and might better be referred to as State Road DD. Road C and B are Busch Wildlife Area roads and are not shown on Figure 4.4-9.

P. 4-30 - The March 1985 injection of dye was detected only at Burgermeister and its wet weather springs (SP 6301 and SP 6302). Dye was not recovered at SP 6303 (Dean, 1985; MDNR, 1989).

P. 4-35 - Second paragraph refers to Figure 4.5-5 but should probably be 4.5-4.

P. 4-44 - Section 4.6.2.5 Are final pump test results available? If available, the results should be presented and their significance explained.

Mr. Steve McCracken
U.S. Department of Energy
Weldon Spring Remedial
Action Project
Route 2, Highway 94 South
St. Charles, Missouri 63303

Dear Mr. McCracken:

The Missouri Department of Natural Resources (DNR) has reviewed the draft Remedial Investigation Report for the Weldon Spring Site Remedial Action Project (DOE/OR/21548, September 1989). In general, the report presents a good summary of the characterization data on the Weldon Spring site.

Attached are comments from DNR's Waste Management Program, DNR's Division of Geology and Land Survey, and the Missouri Department of Conservation. No comments were received from the Missouri Department of Health.

Some additional specific comments are:

VOLUME I: Page 3-23, Section 3.4.5, Domestic Well Sampling: This section references the private well information received from the St. Charles Countians Against Hazardous Waste and the U.S. Geological Survey. Figure 3.4-5 is a preliminary map of the private well locations. The report does not discuss the extensive sampling data on these and other wells obtained by the Missouri Department of Health (MDOH) from 1982 to 1989. Attached is the MDOH data on these wells.

I suggest that you summarize this data and discuss its significance in demonstrating the limits of the groundwater contamination. This information may also be relevant to the baseline risk assessment in that it shows that private wells are not being affected by the uranium processing that occurred at the site. To protect the privacy of individuals, well owner names should not be used in the RI report.

DEQ ADMIN

DATE: January 30, 1990

TO: Mr. Dave Bedan, Radioactive Waste Site Coordinator, DEQ Admin.

THROUGH: Mr. John Doyle, P.E., Chief, HWS, WMP

FROM: Mr. Dave Freise, P.E., EE, HWPU, HWS, WMP

SUBJECT: Comments on Draft RI (September 1989) for WSCP site

This RI primarily addresses the Weldon Spring Chemical Plant, however, the report, to a minor degree, discusses the Quarry Site. Presumably this is because it is planned for the Quarry Site wastes to be stored at the Chemical Plant Site. Appendix B of the report contains ARAR's which deal with both the Chemical Plant and Quarry wastes. The Appendix deals to a large degree with the Quarry wastes since there are potentially many more ARAR's for the Quarry wastes.

Since this is a first attempt, please don't spare the red pen if I'm to learn what's needed of me. If you have any questions, please contact me at 751-5942.

JDD:dfr

REVIEW COMMENTS ON DRAFT RI/FS AND ARARS FOR WSCP SITE

GENERAL COMMENTS

1. Although much of the TNT operations formerly located at the Chemical Plant were possibly taken care of at the "burn" sites, I would like to see some discussion of the leveling of the site to construct the Chemical Plant. From Plate #1 it appears TNT plants/lines 1 through 4 were located in areas extensively changed by construction of the chemical plant. It would seem logical that some TNT and DNT contaminated wastes were buried or disposed of on site or elsewhere during the construction of the chemical plant.

2. Some of the Interim Response Actions listed in Table 1.2-2 would appear to require a relatively long time to accomplish. ARAR's for these actions are not discussed. EPA policy has stated ARAR's would be followed at "removal actions" to the extent practicable.

3. The fish sampling for the biological contamination portion of the report did not include any bottom feeders. Since the contaminants could be in the sediments, bottom feeders would more likely be contaminated.

4. Were the soil samples analyzed by depth interval (relates to comment 1 above)? It was difficult to tell from the report.

5. Shouldn't Figure 7 of the report show the Twin Lakes development as a receptor?

6. Were the soils selected for background soil sampling of the same toxinomic units as those found at the WSCP site? In some instances the existing chemical plant surface soil may be a subsurface horizon due to the site grading which occurred.

7. Please keep in mind that those IRA's which call for off site disposal will probably require special solid waste permits.

8. Has there been any effort to explain the differences in concentrations between Table 5.1-11 (BNI samples) and Table 5.1-19 (PMC samples)? The BNI results are considerably higher on average.

9. Appendix F and other portions of the report make reference to evaporating the red and yellow waters. This appears unlikely given the flow rates of 40 to 50 mgd.

10. Appendix H makes at least 3 references to the disposal of red water sludges or TNT contaminated material. What efforts have been made to trace the ultimate fate of these materials? Can it definitely be stated they are not buried below the WSCP site or at the Quarry?

11. Has any effort been made to characterize the materials which were dumped into Pit Number 4 in December 1966?

RCRA ARAR - Comments (See Vol. III Appendix B)

1. General - The ARAR's tables did not address the chemically contaminated portions of the buildings, process equipment, or storage tanks. In certain instances portions of the WSCP buildings and equipment may be considered hazardous waste.

2. Table 3 - Has the EPA text; Permit Writers Guidance Manual for the Location of Hazardous Land Storage and Disposal Facilities: Phase I. Criteria for Location Acceptability and Existing Regulations for Evaluating Locations (Feb. 1985), been evaluated for "To be considered" ARAR's?

3. Table 4 - Airborne particulates from handling of RCRA waste must be controlled (264.251,.273,.301).

4. Table 5A, Removal Criteria, does not address RCRA materials which are radiologically contaminated. The treatment, storage, and disposal, of these materials will need to meet RCRA requirements.

5. Table 5B - Tank storage for some period of time in existing tanks appears to be a possibility. If so then 40 CFR 264.191 would be relevant and appropriate.

6. Table 5B, page 3 - Some sections of 40 CFR 264.193 and 194 may not be substantive [eg. (g), (h), (i)].

7. Table 5B, page 4 - Inspections of storage tanks should be relevant and appropriate (40 CFR 264.195).

8. Table 5B, page 8 - Inspection of containers would appear to be relevant and appropriate (40 CFR 264.174).

9. Table 5B, Page 11 and 12 - Although 40 CFR 264.341,.342, and .344 are directly related to permit requirements they would appear to be substantive since the incinerator efficiency or operating limits cannot be determined by the operator with out the required analysis.

10. Table 5B, page 12 - The monitoring requirements of 40 CFR 264.347 appear to be substantive to operate an incinerator.

11. Table 5B - Closure requirements of 40 CFR 264.351 appear to be substantive.

12. Table 5B, page 15 - It would appear that more of 40 CFR 265 subpart P would be relevant and appropriate since it is parallel to 40 CFR 264 subpart O.

13. Table 5C - Wouldn't 40 CFR 265.400 be a "to be considered"?

14. Table 5G - This table should include the Land Ban (40 CFR 268) since any land filled RCRA materials will have to be in compliance with the treatability standards.

15. Table 5G - Page 5, Section 315 of 40 CFR 264 would appear to be substantive.

16. The proposed rules of 40 CFR 269 would appear to be "to be considereds". Part of these rules were proposed on February 5, 1987 (52 FR 3748).

17. Subpart F of 40 CFR Part 264 would appear to be relevant and appropriate to the Quarry site itself.

STATE RCRA ARARS

1. Table 3 - MO. Hazardous Waste Regulations chapter 13 (PCB's) incorporate the chapter 7 (TSDF's) requirements. Locations of commercial facilities handling wastes which come under the PCB rules must comply with MO-RCRA location standards. This may be relevant and appropriate at the site.

2. Table 4, page 1 - Missouri PCB Treatment, Storage, Disposal facilities must meet the MO. Hazardous waste regulations chapter 13 and 7.

3. Tank systems should consider the location standards of 40 CFR 264 subpart N in accordance with 10 CSR 25-7.264(2)(J)4, pages 12 and 13.

4. Sampling methods for incineration should comply with 10 CSR 25-7.264(2)(0), page 24, where more restrictive than 40 CFR 264.343.

5. The requirements of 10 CSR 25-7.264(P) & (Q), pages 24 through 28, would be applicable to treatment or disposal facilities.

6. Leak detection and leachate collection systems must have a permeability of at least 0.01 cm/sec. [See 10 CSR 25-7.264(2)(N)2.A.(II), page 23].

7. The compliance monitoring point of 40 CFR 264.95 is modified by 10 CSR 25-7.264(2)(F)2, page 5. The establishment of this point is referenced in 40 CFR 264 subpart F (See Table 5G, page 5 and 6).

RESPONSIVENESS SUMMARY FOR THE RI REPORT

Enclosed are two copies of the Responsiveness Summary for the Weldon Spring Chemical Plant/Raffinate Pit Remedial Investigation (RI) Report (Rev. B). The Responsiveness Summary addresses RI Report review comments from the U. S. Environmental Protection Agency (EPA), the Missouri Department of Natural Resources (MDNR), and the Missouri Department of Conservation (MDOC).

The following responses were modified to reflect the comments discussed in the March 28, 1990 meeting.

- EPA RI Report Review Comments (Enclosure A)
  - General comments 1 and 4
  - Detailed comments 17 and 28
- MDOC RI Report Review Comments (Enclosure B)
  - No change to Responsiveness Summary
- MDNR RI Report Review Comments (Enclosure C)
  - Detailed comment 10
- MDNR RI Report Review Comments (Enclosure D)
  - General comments 5 and 12

The RI will be revised to reflect conclusions of the comment responses. However, a revision to the RI will not be available until September 1990, because some minor changes may be necessary in order to assure that the RI is compatible with other environmental documents.

If you have any comments on the responsiveness summary, please respond by July 20, 1990.

Sincerely,

Stephen H. McCracken
Project Manager
Weldon Spring Site
Remedial Action Project

SUBJECT: Contract No. DE-AC05-86OR21548
DRAFT RESPONSIVENESS SUMMARY FOR THE RI REPORT

REFERENCE: Letter from S. H. McCracken to R. E. Hlavacek, EPA & MDNR Comments on the Draft Remedial Investigation (RI) Report for the Weldon Spring Chemical Plant/Raffinate Pit Area, March 1, 1990

Dear Mr. McCracken:

Attached please find twenty copies of the Responsiveness Summary for the Weldon Spring Chemical Plant/Raffinate Pit Remedial Investigation (RI) Report (Rev. B) for your review and comment. The Responsiveness Summary addresses RI Report review comments from the U. S. Environmental Protection Agency (EPA), the Missouri Department of Natural Resources (MDNR), and the Missouri Department of Conservation (MDOC).

As requested in your letter of March 1, 1990, the Responsiveness Summary was prepared for transmittal to EPA and MDNR/MDOC. This document was reviewed by ANL and members of the site DOE and PMC staff.

Please direct your comments to Mr. Doug Steffen of my staff.

Sincerely,

R. E. Hlavacek
Project Director

LETTER5.LGO/TXTMMW

ATTACHMENT A

Comments of the U. S. Environmental Protection Agency

GENERAL COMMENTS

Comment 1:

The scope of the remedial investigation needs to be more fully defined. It may not be clear to the reader that the report is only intended to examine the contamination from the uranium processing plant, and the contamination from explosives production which is inside the DOE property lines. The rationale for this definition needs to be presented, since property lines are generally not relevent to the definition of the extent of contamination. It remains EPA's position that the DOE's and the U.S. Army's respective responsibilities must be defined in a written agreement to ensure that all needed investigation will be completed in an efficient manner. The adequacy of the scope of the RI needs to be evaluated in the context of such an agreement.

Response to Comment 1:

The scope of the Weldon Spring Site remedial investigation is presented in Section 1.1.1 where it is stated that the RI focused on both the on-site contamination associated with the chemical plant and raffinate pits, and the off-site areas also contaminated by these sources. Extensive efforts have been devoted to determining the extent of on-site and off-site contamination. DOE work has included characterization of various off-site media that may contain WSS contaminants. Data from this characterization work are presented either directly in the RI Report or in referenced documents.

DOE has assumed responsibility for investigation and remediation of all on-site soil contamination and any off-site soil contamination that is associated with a radiological source. DOE has also assumed responsibility for remediation, as required, of radiologically contaminated groundwater whether on- or off-site.

Comment 2:

The field sampling plans which were developed and implemented to form the basis of the RI Report are described in the report; however, the reader is not clearly directed to the respective sampling investigation reports which presumably contain more focused and thorough analyses than the summaries contained in the RI Report.

Response to Comment 2:

Agree. The field sampling plans are described in Section 2.2.1. The following specific references will be added to more clearly define the descriptions in Section 2.2.1:

Page 2-3, Paragraph 3, Line 1
Insert "(MKF and JEG, 1988j)"

Page 2-4, Paragraph 1, Line 2
Insert "(MKF and JEG, 1988t)"

Page 2-4, Paragraph 2, Line 1
Insert "(MKF and JEG, 1988i)"

Page 2-4, Paragraph 3, Line 2
Insert "(MKF and JEG, 1988n)"

Page 2-4, Paragraph 4, Line 1
Insert "(MKF and JEG, 1988o)"

Page 2-4, Paragraph 5, Line 3
Insert "(MKF and JEG, 1987l)"

Page 2-4, Paragraph 5, Line 3
Insert "(MKF and JEG, 1987b)"

The references discussed in Section 3, Weldon Springs Study Area Investigtions, are the investigation reports that form the basis for the RI Report. The reader will be directed to these reports by adding the following statement to Section 2.2, page 2-3, paragraph 1: "Results of these sampling programs are summarized in Section 3."

Comment 3:

A useful summary of data gap analyses and general plans for additional data collection is not presented.

Response to Comment 3:

Agree. The RI database is presently being evaluated relative to the alternative analysis for the feasibility study. Potential data gaps identified by this analysis will be summarized in the RI and general plans for additional data will be presented. DOE does anticipate collecting additional data in the following areas:

- o Soil contamination: Extent of soil contamination under the buildings, raffinate pits and Ash Pond.
- o Overburden physical characteristics: Field tests to verify hydraulic conductivity values in the vadose zone.
- o Contaminant transport and attenuation: Studies are currently being conducted by USGS/UMR to evaluate geochemical aspects of contaminant transport and attenuation.
- o Ecological studies: Studies are currently being planned to assess potential impacts to species using contaminated areas of the WSS. Data from these

studies will augment existing data from the MDOC (Busch Wildlife Area) and WSSRAP characterization programs.

Comment 4:

The data available for analysis of ecological impacts appears to be limited. The impacts of contamination on the wildlife is presented only in the context of the implications to human health. A complete baseline risk assessment must consider environmental effects as well as public health effects. Information on the numbers of species using the contaminated area, their reproductive success, and any evidence that the contamination is affecting the viability of local wildlife populations should be presented.

Response to Comment 4:

Agree. Although site-specific data are limited, extensive data exist on a regional scale related to the ecological character in the general site vicinity. The 217 acre WSS is adjacent to the 1,843 acre U.S. Army Reserve Training Area, the 6,919 acre Busch Wildlife Area, and the 7,200 acre Weldon Spring Wildlife Area. It has been our approach to utilize the local and regional data derived from these surrounding areas as the base for ecological information. This database may be augmented as a result of the data gap analyses. Planning for additional data collection both on- and off-site is currently underway.

DETAILED COMMENTS

Comment 1:

The Table of Contents should be expanded to include a list of plates.

Response to Comment 1:

Agree. This change will be made in the Table of Contents.

Comment 2:

In the Executive Summary (page 1), there is a statement which refers to the percentage of land transferred to the U.S. Atomic Energy Commission (AEC) versus the amount of land originally used for ordnance production. Ten percent is the amount quoted; whereas, the actual amount is closer to one percent as explained in Appendix H. The original site covered 17,232 acres compared to 205 acres transferred from the Department of Army (DA) to AEC.

Reponse to Comment 2:

Agree. Text in the Executive Summary (page 1, second paragraph, fifth sentence) will be changed to read: "The portion of the Weldon Spring Ordnance Works transferred to U.S. Atomic Energy Commission is about one percent..."

Comment 3:

In the third paragraph of the Executive Summary, there are statements which are contradictory. It is stated first that the Weldon Spring Raffinate Pit (WSRP) and the Weldon Spring Chemical Plant (WSCP) areas are on the National Priorities List. The next sentence states that they have been nominated to be on the List.

Response to Comment 3:

Agree. The Weldon Spring Raffinate Pit/Chemical Plant areas and the Weldon Spring Quarry area are all included on the National Priorities List. The text in the Executive Summary (page 1, third paragraph) will be changed by deleting the third sentence ("The remainder of the Weldon Spring Site, the Weldon Spring Chemical Plant and Raffinate Pit area, has been nominated to be included on the National Priorities List").

Comment 4:

On page 8 in the third paragraph, the reference to Figure 7 should be to Figure 6.

Response to Comment 4:

Agree. Figure reference in the Executive Summary (page 8, third paragraph, first sentence) will be changed to Figure 6.

Comment 5:

The first sentence of the first paragraph on page 10 should be rewritten. It appears that nitroaromatics precipitate in the unsaturated zone before reaching the saturated zone.

Response to Comment 5:

Agree. This sentence will be rewritten to read: "Nitroaromatic compounds in the groundwater are believed to enter the saturated zone by leaching from contaminated soils."

Comment 6:

Several conflicting statements were found. As an example, on page 10 in the Executive Summary, the following statement is made "Nitroaromatic compounds quickly degrade upon exposure to sunlight and therefore are not transported in surface waters." It is noted on page 6-16, Vol. I that the nitroaromatics TNB and DNB are not subject to photolytic degradation. Also, on page 1-4, the Army Reserve is 1,843 acres, while on page 3-13, Vol. I, it is approximately 1,660 acres.

Response to Comment 6:

Agree. Text will be revised by deleting the statement in the Executive Summary, page 10, that reads: "Nitroaromatic compounds quickly degrade upon exposure to sunlight and therefore are not transported in surface waters." This statement is too general in nature and is not correct as written.

Agree. Statement in Section 1.2.1, page 1-4, that presents the size of the Army Reserve property as 1,843 acres is incorrect. This figure will be changed to 1,660 acres as correctly shown in Section 3.2.3, page 3-13.

Comment 7:

On page 1-5 in the second paragraph, the text states that the Weldon Spring Wildlife Area is located across Missouri Highway 94. Figure 1.2-2, which is referenced, shows the site and the wildlife area on the same side of the highway.

Response to Comment 7:

Agree. Figure 1.2-2 is correct. The text describing the location of the Weldon Spring Wildlife Area (Section 1.2.1, page 1-5, second paragraph, first sentence) will be revised as follows: "The Weldon Spring Wildlife Area (Weldon Area) is located to the south of the WSS (Figure 1.2-2) and consists of approximately 2,900 ha (7,200 ac)."

Comment 8:

Numerous abbreviations labeling buildings, water towers, etc., are shown on Plate 1. A legend should be provided to identify the structures.

Response to Comment 8:

Agree. A legend will be provided on Plate 1 to identify these structures.

Comment 9:

Table 3.7-1 should indicate what the numbers on the table represent such as the number of samples taken.

Response to Comment 9:

Agree. The numbers in Table 3.7-1 indicate how many geotechnical tests of a given type were performed by each organization at WSSRAP. A heading "Number of Tests Performed", will be added within Table 3.7-1 to more clearly indicate the meaning of the data.

Comment 10:

In Section 4.5.1, page 4-33, second paragraph, it is concluded that the observed net infiltration in the raffinate ponds is "closely related" to the measured hydraulic conductivities of the underlying material. In fact, those hydraulic conductivities span four orders of magnitude. The magnitude of the measured net infiltration lies in the middle of that range. While this is to be expected, it may be misleading to use the term "closely related" to characterize this agreement.

Response to Comment 10:

Agree. Text on page 4-33, Section 4.5.1, second paragraph, last sentence, will be reworded to read: "The magnitude of the measured losses from the pits corresponds to a soil permeability of approximately 1.0×10^{-6} cm/sec which is an order of magnitude greater than the median laboratory value for saturated hyraulic conductivities at the site. Laboratory values for saturated overburden hydraulic conductivity range from 1.6×10^{-9} to 2.0×10^{-5} cm/sec (4.5×10^{-6} ft/day to 5.7×10^{-2} ft/day) (BNI, 1986a)."

Comment 11:

The discussion on stratigraphy is good; however, we suggest that the surface soils be addressed in terms of the Department of Agriculture's soil series and descriptions.

Response to Comment 11:

Field logging and laboratory classification was based on the Unified Soil Classification System which is more commonly used in performing engineering studies. Use of the USDA classification system will be considered for future studies.

Comment 12:

Page 4-1 references Figure 4.1-2 for site elevations, but it only shows elevations for the surrounding area.

Response to Comment 12:

Agree. A new Figure 4.1-3 will be drafted which will show site elevations. The reference in Section 4.1, page 4-1, paragraph 3, first sentence will be changed to Figure 4.1-3.

Comment 13:

The term "normal" is also used incorrectly. In meteorology, "normal" refers to averages of climatological data for the 30-year period from 1951 through 1980. In the context used in the report, either the term "average" or "mean" is more appropriate.

Response to Comment 13:

Agree. The text will be revised to strike the term "normal" and use "average" instead (Section 4.2, page 4-3, paragraph 4, second sentence).

Comment 14:

The legend on Figure 4.3-2 should include a description of the well, trench and borehole numbering system.

Response to Comment 14:

Agree. However, this information is too bulky to include in a figure. A new Table 4.3-1 will be added and titled "Well, Trench, and Borehole Numbering System Description", to indicate the various numbering conventions which have been employed at the Weldon Spring Site.

A sentence will be added to the last paragraph on page 4-10 (Section 4.3.1.2) following "...in a given borehole." that will read: "Table 4.3-1 lists the borehole and trench numbering conventions."

The first sentence at the top of page 4-11 (Section 4.3.1.2) that currently begins "Table 4.3-1 presents a list..." will be changed to read: "Table 4.3-2 presents a list...".

Comment 15:

In the first paragraph on page 4-21, the last sentence indicates that the four raffinate pits do not contribute to direct runoff; however, Figure 4.4-2 seems to show flow out of pit number 4. Table 4.4-2 also indicates the raffinate pits are closed basins, but Figure 4.4-3 seems to show a stream gage that measures the outflow from pit 4.

Response to Comment 15:

Agree. Figure 4.4-2 does appear to indicate outflow. This is misleading as Pit 4 does not discharge surface runoff. Figure 4.4-2 will be corrected by moving the arrow west of Pit 4.

Agree that Figure 4.4-3 is similarly misleading. As correctly indicated in Table 4.4-2, the raffinate pits are closed basins. The stream gage NP-004 shown in Figure 4.4-3 does not measure outflow from Pit 4, as there is none. Figure 4.4-3 will be corrected by moving the arrow west of Pit 4.

Comment 16:

The term "swallow holes" appears occasionally. Pages 4-26, 4-30 and 4-31 refer to "swallow holes" and Figures 4.4-4 and 4.4-11 refer to "shallow holes." Definitions should be provided since it is not clear what these holes are.

Response to Comment 16:

Agree. Text will be revised by adding a short definition on page 4-26 which will generically describe a swallow hole. On page 4-26, Section 4.4.4.1, second paragraph, after the second sentence and before "The 5000 series...", the following sentence will be added: "A swallow hole is a point in a stream bed where a sinking stream loses its discharge to the subsurface (White, 1988)."

The term "shallow hole" on Figure 4.4-4 is a typographical error and will be changed to "swallow hole". Figure 4.4-11 is correct as labeled.

Comment 17:

The method used for estimating surface runoff on page 4-24 is not a very reliable one. A better approach would have been to calibrate a model to the measured events, then use a historical sequence of precipitation events to determine average runoff conditions. An alterntive approach would be examine records from similar gaged watersheds in the area.

Response to Comment 17:

The USGS has recently completed a water budget study on a 4.6 square mile area which includes two Mississippi River subdrainages immediately northwest of the WSCP/WSRP site. Preparation of a data report is in progress and an interpretive report is expected about May, 1990 (M.J. Kleeschulte, personal communication, 1990).

Results of this study will be incorporated into estimates of average discharge volumes at Weldon Spring Site NPDES discharge points.

Comment 18:

On page 4-31, the definition of the vadose zone is misleading. The vadose zone may be temporarily saturated due to surface ponding and may have perched water tables. Perched water tables are mentioned on page 6-4. A possible definition is the zone between the soil surface and the permanently saturated zone.

Response to Comment 18:

Agree. Text will be changed by striking the first sentence of Section 4.5, page 4-31, and inserting the following in its place: "The geological profile extending from the ground surface to the phreatic surface is called the vadose zone. The term "vadose zone" is preferable to the term "unsaturated zone" because saturated conditions may be locally present in the form of perched groundwater and unsaturated flow due to infiltration, seepage, or percolation."

Comment 19:

On page 4-33, there is a discussion about lysimeters and that they were installed to determine possible contaminant migration. More explanation is needed to explain how a lysimeter would show contaminant migration. The discussion on page 5-141 about lysimeters is even more confusing on just how the lysimeters are being used. On Table 5.4-1, lysimeter LYS3506 should be LYS3606.

Response to Comment 19:

Agree. Text on page 4-33, Section 4.5.1, third paragraph, second sentence, will be changed to read: "Lysimeters, sometimes called soil-moisture samplers, are commonly used to sample soil-pore liquids in unsaturated media. The ten

lysimeters were installed by UNC Geotech in July 1987 as part of a preliminary assessment of contaminant transport by unsaturated flow in the vicinity of the raffinate pits. The lysimeters were installed in locations where seepage from the raffinate pits was expected to be encountered in the form of unsaturated flow in the vadose zone."

Sentence 3 of paragraph 1, Page 5-141, Section 5.4.1, will be changed to read: "Wells MW-3013 and MW-3018 also monitor the quality of perched and mounded water within the overburden."

On Table 5.4-1, the heading "LYS3506" will be changed to "LYS3606."

Comment 20:

The second paragraph on page 4-35 refers to Figure 4.5-5 when it should really be 4.5-6.

Response to Comment 20:

Agree. The reference on page 4-35 (Section 4.5.1, second paragraph, fourth line) will be changed from Figure 4.5-5 to Figure 4.5-4; this is the correct reference.

Comment 21:

On page 4-40 in the third paragraph, briefly explain why the Bouwer and Rice method is believed to be the more reliable method.

Response to Comment 21:

Agree. Text changes will be made to include an explanation. The fifth sentence of the third paragraph on page 4-40, Section 4.6.2.1, will be deleted and replaced with the following:

"The Bouwer and Rice method is believed to be more reliable for calculating in situ hydraulic conductivities than the Hvorslev method due to the difference in methodologies used to determine the effective radius of influence for a test occurrence (i.e. the radius over which head loss or gain is dissipated). Bouwer and Rice (1976) pointed out that the Hvorslev method, in most cases, assumes that the effective radius of influence is equal to the distance from the bottom of the well to the potentiometric surface. However, in reality, the effective radius of influence is considerably less than the distance from the bottom of the well to the potentiometric surface. Bower and Rice used an electrical resistance network analog to determine the effective radius of influence for different slug test geometries. An empirical equation was then developed to relate the effective radius of influence to the geometry of the well and the aquifer. This technique is applicable to determining the effective radius of influence for partially penetrating and fully penetrating wells in unconfined aquifers. It can also be used to estimate the hydraulic conductivity of confined aquifers that receive water from the upper confining layer through recharge or compression.

"With this in mind, the Bouwer and Rice method was used to analyze all data because it is considered to more closely simulate Weldon Spring Site conditions. The Hvorslev technique was used because its widespread industry use allows comparison of WSS data with other data analyzed by that method."

Comment 22:

The loss by seepage from the raffinate pits should be reported as a volume per unit of time. The second paragraph on page 4-47 only specifies an apparent velocity.

Response to Comment 22:

Agree. Text on page 4-47, Section 4.6.3.1, second paragraph, fourth sentence, will be changed to read: "The water balance study at the raffinate pits indicated average losses of 6.16m^3/d for Pit 2 to 50.13 m^3/d for Pit 3 due to seepage (BNI, 1987)."

Comment 23:

In Chapter 5, many concentrations are discussed in various samples. Generally, these concentrations are not referenced with any standard to indicate if the concentration is significant in terms of human health or the environment. Page 5-16 has numerous examples of this. Page 5-22, last paragraph, provides the kind of comparison to an established standard that would be helpful throughout the document.

Response to Comment 23:

Tables and figures are presented in Vol. II that compare background concentrations in soils and water quality standards to the analytical results for soils, sediments, surface water, and groundwater (see Figures. 5.2-1 through 5.2-30 and Tables 5.2-2 through 5.2-31, 5.3-1, and 5.4-2). Because of the extensive amount of information presented, it was determined that the most effective means of presenting these comparisons is in tabular form.

The presence of contamination in any medium does not by itself necessarily indicate risk to human health or the environment. The determination of risk is also dependent upon exposure to the contaminants. Exposure pathway analyses and dose calculations were made as part of the baseline risk assessment. Details of these calculations are provided in the Site Baseline Risk Assessment Report. A summary is also provided in chapter 7 of the Site Remedial Investigation Report. In addition, the Site FS-EIS will include a risk analysis.

Comment 24:

An inconsistency was noted in Section 5.1.2.3, page 5-14, second paragraph. The report indicates that the evaporation of all water from raffinate pits 1 and 2 has not happened since 1980; however, Table 5.1-16 indicates a dry surface in 1987. A clarification is needed.

Response to Comment 24:

Agree. The "Surface Water Volume" entries in Table 5.1-16 will be changed from "dry surface" to "<5,000 m^3".

Comment 25:

Tables 5.1-6 and 5.1-7 have the same title. One of them should be changed to reflect the differences in the data presented.

Response to Comment 25:

Agree. The title of Table 5.1-6 will be changed to "Compilation of Asbestos Data, Samples with Suspected Radiological Contamination". The title of Table 5.1-7 will be changed to "Compilation of Asbestos Data, Samples Not Suspected to be Radiologically Contaminated". Title notations in the table of contents for Volume I and Volume II will also be changed.

Comment 26:

Section 3 of the report describes the investigations conducted at the site. To keep the report consistent, we suggest that the radiological investigations be described in that section as well, rather than in Section 5.

Response to Comment 26:

Agree. Descriptions of radiological investigations will be moved from Section 5 to Section 3.

Comment 27:

On Tables 5.2-2 through 5.2-31, there does not appear to be any difference between the constituents labeled "Other contaminants at levels about two times their upper background limit" and those labeled "...above their upper background limit."

Response to Comment 27:

Agree. Tables 5.2-2 through 5.2-31 will be corrected.

Comment 28:

The last paragraph on page 6-7 uses a comparison of Figures 4.6-3 and 4.6-4 to indicate a deep ground water "trough" extending from the Weldon Spring site to the Burgermeister Spring. It is suggested that conduit flow velocities in this "trough" are on the order of two feet per minute. This velocity is several orders of magnitude greater than any other reported velocities in the area. Because of this and the

potential for very rapid offsite migration of contaminants, there should be more discussion about this "trough." How were these velocities calculated? How does the comparison of the two figures lead to the conclusion of a deep "trough"? The discussion which continues onto page 6-B appears to contradict this conclusion. This paragraph is confusing and needs clarification.

Response to Comment 28:

Agree. The groundwater flow velocities in the conduit system discussed in this paragraph are based on MDNR dye studies. Results of these studies are presented in Section 4.4.4.3, page 4-30. The dye was carried approximately 1,980 m (6,500 ft) in 40 to 72 hours. The velocity figures presented in Section 6.1.3.2, page 6-7, will be presented on page 4-30. The text in on page 4-30, Section 4.4.4.3, second paragraph, third sentence, will be revised to read: "The time of travel is estimated to be 48 to 72 hours, indicating flow velocities of 0.76 to 1.1 cm/sec (1.5 to 2.2 ft/min), depending on rainfall conditions (Dean, 1984a)."

The text in Section 6.1.3.2 will be revised as follows: The paragraph beginning at the bottom of page 6-7 and continuing onto page 6-8 will be deleted and replaced with this paragraph:

Figure 4.6-3 illustrates the potentiometric surface of the water table aquifer in the vicinity of the WSCP. The prominent feature of the potentiometric surface is a linear depression which extends from the area west of the WSCP northward toward Burgermeister Spring and Lake 34. Figure 4.6-5 is a potentiometric map of the water table aquifer in the WSCP/WSRP areas. The steep potentiometric gradient near MW-4002 and the linear depression in Figure 4.6-3 are inferred to be a function of both surface relief and conduit flow. The axis of the linear depression closely follows the surface drainage pattern. The MDNR conducted ground water dye tracing tests which confirmed the presence of conduit flow within the area of the linear depression. Figure 6.1-1 illustrates the locations where the dye traces were conducted and the places to which the conduits flowed. The potentiometric linear depression is present because water normally in storage within the pore spaces of the water table aquifer is being drained by conduit flow. Conduit flow by its nature is orders of magnitude greater than the predominant Darcian laminar flow in the nonhomogeneous, antisotropic porous medium limestone aquifer.

Comment 29:

The discussion on the factors affecting the persistence and attenuation of organic compounds should be expanded. Sometimes degradation products are more toxic than the parents. Were the degradation products adequately sampled and analyzed?

Response to Comment 29:

The section describing contaminant persistence and attenuation for nitroaromatic compounds (Section 6.2.7) in the RI Report will be rewritten to include more detailed information on factors affecting the environmental fate of TNT, DNT, NB, TNB and DNB. The environmental fate for some of these compounds is also discussed in Appendix A of Vol. III. In a chemical characterization survey of the

quarry conducted by BNI from October to December 1984 and May 1985, soil and sediment samples were analyzed for 2,6- diamino - 4 - nitrotoluene and 2,4-diamino - 6 - nitrotoluene, known biotransformation products from TNT. Results of this survey indicated the presence of these potential biotransformation products in several samples. No other efforts have been made to test for the presence of biotransformation products.

The rewritten section 6.2.7 is as follows:

6.2.7.1 2,4,6-TNT

2,4,6 TNT is almost insoluble in water, sparingly soluble in alcohol, and readily soluble in benzene, toluene and acetone. Upon exposure to sunlight or ultraviolet light, decomposition of TNT in water occurs by a process known as photolysis. The rate of photolysis is accelerated by the products formed during the photolytic process as well as the presence of other natural substances. Humic substances in natural water are also subject to photolysis, yielding hydrogen ions and hydroxyl radicals that can reduce organic compounds. Nitrate ions in water can also promote photochemical oxidation of trace organic compounds through production of hydroxyl radicals. The half-life of TNT in natural surface waters due to photolysis is estimated to be between 3 and 22 hours (Spanggord et al., 1980).

The primary photodegradation product of 2,4,6 TNT is 1,3,5-trinitrobenzene; other by-products include 2,4,6-trinitrobenzonitrite and 1,3,5-trinitrobenzaldehyde (U.S. Army, 1986a). These photoproducts will readily volatilize from sediments and water (Cullahan, 1979). However, based on the relatively low Henry's Law constant for 2,4,6-TNT, (0.18 torr M^{-1}), volatilization is not an expected pathway for attenuation of 2,4,6-TNT (Spanggord et al., 1980).

The tendency for 2,4,6-TNT to adsorb to soils is primarily dependent upon the organic content of the soil (U.S. Army, 1986b). Due to the extremely low organic content of the Ferrelview and clay till formations, adsorption is not expected to be an important retardation factor in WSS soils. Minimal adsorption is expected on carbonate minerals and chert in the limestones, so dispersion and dilution are the most likely mechanisms by which TNT concentrations will decrease in the bedrock aquifer.

The biotransformation of 2,4,6-TNT in natural waters is very slow, even in the presence of organic nutrients (Spanggord et al., 1980). The half-life for biotransformation of 2,4,6-TNT in surface waters is estimated to be 8-25 days, which is far longer than for photolysis (Burlison, 1980). Hence the fate of TNT in surface water will primarily be controlled through photolysis.

The biotransformation process for 2,4,6-TNT involves reduction of the nitrogroups through the nitroso and hydroxyl amino to either amines or azoxy dimers. Transformation of TNT in soil is known to occur under both aerobic and anaerobic conditions by bacteria and fungi. Biotransformation products can include the following:

4-amino - 2,6-dinitrotoluene
2-amino - 4,6-dintrotoluene
2,6-diamino - 4-nitrotoluene
2,4-diamino - 6-nitrotoluene
4-hydroxylamino - 2,4-dinitrotoluene
2,2', 6,6'-tetranitro - 4,4' azoxytoluene
4,4', 6,6'-tetranitro - 2,2' azoxytoluene
2,4,6-trinitrotoluene (McCormick, 1976; Won, 1974)

Many of these compounds are more hazardous and soluble than the parent compound 2,4,6-TNT. Accumulation of the biotransformation products can be inhibitory to soil microorganisms, hence reducing the rate of transformation.

The environmental factors shown to affect the rate of TNT transformation include initial TNT concentration, soil moisture, the presence of microorganisms, temperature, and oxygen levels. Of these factors, the initial concentration of TNT has the greatest overall effect on the rates of biotransformation; the greatest biotransformation rates occur at very low concentrations of TNT (0.1%), with progressively slower transformation rates occuring at 1% and 10% concentration of TNT (Kaplan et al., 1985).

After TNT concentration, the presence or absence of microorganisms and temperature has the greatest effect. Moisture level is less important, and organic matter and oxygen levels are insignificant in affecting the rate of biotransformation. However, the presence or absence of oxygen does alter the biotransformation products. Under anaerobic conditions, increased production of triamines occurs over aerobic conditions. Aerobic conditions lead to the formation of diamines and monoamines.

6.2.7.2 1,3,5 TNB and 1,3 DNB

TNB detected at the WSS is probably the product of oxidation of the methyl group of TNT by photolysis. It is essentially insoluble in water, sparingly soluble in hot alcohol, and readily soluble in acetone, ether, and benzene. It is a very stable compound; it is resistant to hydrolysis and is not photolytically or biochemically degraded or transformed as readily as TNT.

TNB is more volatile than TNT (See Table 6.2-1) by nearly one order of magnitude (half-life is approximately 130 days) hence, volatilization from surface waters is expected to be a major fate process. The estimated value of K_{OC}, the sorption partition coefficient based on organic carbon content, is 520, suggesting that adsorption on sediments and soils with a sufficient organic fraction may be a significant environmental fate. However, due to the very limited organic content of the WSS soils, adsorption is probably not a major factor in retarding migration of TNB. Volatilization from soils is also not considered a significant factor affecting the persistence of TNB in soil.

1,3 DNB is sparingly soluble in water and slightly less volatile than TNB (Table 6.2-1). Volatilization from surface waters is considered an important fate process. Although studies have shown that DNB is subject to photolysis, the rate of volatilization is much higher; hence photolysis is not considered to be a significant environmental fate.

The sorption partition coefficient, K_{OC}, is estimated to be 64, which indicates soil sorption is not expected to be an important fate for 1,3-DNB.

It has been reported that 1,3-DNB is resistant to attack by soil microorganisms (Alexander and Lustigman, 1966), but is nearly completely degraded in a two-stage model waste water treatment system (Bringman and Kuehn, 1971). Laboratory studies performed by McCormick (1978) using an enzyme preparation of V. alalescenes demonstrated that 1,3-DNB and 1,3,5 TNB were reduced by hydrogen.

6.2.7.3 2,4 and 2,6 DNT

2,4-DNT and 2,6-DNT are formed as impurities and intermediates during the production of TNT. They are sparingly soluble in water, alcohol, and ether, but readily soluble in acetone and benzene. Based on calculated soil adsorption coefficients (Spanggord et al., 1980) these compounds are expected to have only a slight tendancy to sorb to soils, sediments and suspended solids. Some biotransformation in soil may occur in both the aerobic and anaerobic zones. In natural water systems, large amounts of supplemental carbon are needed for biotransformation to occur. Photolysis in water systems is rapid and is probably the most important removal process for DNT in surface waters. Volatilization may be a significant factor for 2,6-DNT in surface water but not for 2,4-DNT; neither compound is expected to volatilize from soils.

The biotransformation products of DNT are the aromatic amines and aminonitrotoluenes, and include the following:

2-nitroso - 4-nitrotoluene
2-amino - 4-nitrotoluene
4-amino - 2-nitrotoluene
4-nitroso - 2-nitrotoluene
2,2'-dinitro - 4,4' azoxytoluene
4,4'-dinitro - 2,2'-azoxytoluene
4-acetamino - 2-nitrotoluene
4-methyl - 3-nitroaniline
2-methyl - 5-nitroamine (McCormick et al., 1978)

Many of the biotransformation products are toxic and inhibit the biotransformation process. With sufficient supplemental carbon, the anaerobic biotransformation process proceeds much faster than the aerobic process, and tends to favor production of the amine 2-methyl - 5-nitroamine.

Both isomers of DNT rapidly photolyze in ultraviolet light or sunlight. Photolysis of 2,4-DNT results in production of the following compounds (Burlinson and Glover, 1977):

2,4-dinitrobenzaldehyde
2-amino - 4-nitrobenzaldehyde
2,2'-carboxaldehyde - 5,5'-dinitroazoxybenzene
2,4-dinitrobenzoic acid
2-amino - 4-nitrobenzoic acid
2,2'-carboxy - 5,5' dinitroazoxybenzene

The nitrobenzoic acids may be further broken down into other products such as 1,3-dinitrobenzene. The final products of reaction are carbon dioxide, water, and nitric acid.

The photolysis half-life in sunlight for 2,4-DNT is estimated to be between 2 to 10 hours, depending upon the amount of humic substances present and concentration of activated transformation products. These factors can accelerate the rate of photolysis by 1.3 - 2.5 times (Simmons and Zepp, 1986).

The photolysis half-life for 2,6-DNT is 12 minutes by indirect photoreaction. The rate is affected by the presence of humic materials in natural waters, which can accelerate photodecomposition 11-17 times (Mill and Mabey, 1985; Simmons and Zepp, 1986)

The half-life of 2,4-DNT in water by volatilization is estimated to be 410 days (Spanggord et al., 1980); hence, volatilization is not considered a significant environmental fate for 2,4-DNT. On the other hand, the volatilization half-life of 2,6-DNT is 140 days (Spanggord et al., 1980) which indicates this process is an important fate process for 2,6 DNT.

6.2.7.4 Nitrobenzene

Nitrobenzene is moderately soluble in water, and has a moderate tendency to sorb on soils and sediments. Greater adsorption is associated with soils and sediments which have high organic fractions. Nitrobenzene can be expected to leach into the ground from a release on land and degrade within a few months as biodegradation in both aerobic and anaerobic environments can be significant. Reduction of the NO_2 group of the NB ring may be an important degradation process in groundwater under the reducing conditions occurring in the groundwater beneath the site. NB in surface waters is also subject to photolysis; the main photoproducts are azobenzene and anailine (Barltrop and Bunce 1968). The photolysis half-life of NB is estimated to be 133 days. The half-life can be accelerated by 1-3 times due to the presence of humic substances and nitrate ions (Simmons and Zepp, 1986).

Comment 30:

On page 6-16 in the first sentence of Section 6.2.7.2, change "deleted" to detected".

Response to Comment 30:

Agree. Text in Section 6.2.7.2, page 6-16, first paragraph, line 1, will be changed to read: "TNB detected at the WSS is probably the product of oxidation of the methyl group of TNT by photolysis."

Comment 31:

From January 1967 to February 1969, the Department of the Army prepared plans to design and construct a plant at the site to produce the herbicide "agent orange". This fact is mentioned in the appendix, but the appendix does not indicate that there was no actual production of the herbicide at the Weldon Spring site during that two-year period.

Response to Comment 31:

Agree. Text on page H-5 of Appendix H will be revised by inserting the following sentence between the second and third sentences in entry Feb. 1969: "No herbicide production occurred."

Comment 32:

Important information appears missing from the appendices. Descriptions of the monitoring well construction and sampling techniques should have been included.

Response to Comment 32:

Agree. Monitoring well completion diagrams should be published along with the borehole logs for the wells. However, these diagrams and logs have not been included in the RI Report because of the excessive bulk they would add. At this time, no plans exist to publish these logs. However, the logs are to be compiled in a compendium of geologic data which will be available for review at the Weldon Spring Site.

Sampling techniques are described in the Hydrogeologic Investigations Sampling Plan. This document is indirectly referenced on page 2-4, Section 2.2.1 of the RI Report. The reference to this and other sampling plans will be more clearly defined by revising the text in Section 2.2.1 as indicated in the response to General Comment 2 of this attachment.

ATTACHMENT B

Comments of the Missouri Department of Conservation

GENERAL COMMENTS

Comment 1:

Page 5-112 through 5-122. It appears that the Department of Conservation sites 1, 3, 4, 5, 7 and 9 require remediation while sites 2, 6, 8 and 10 apparently do not require remediation. Sites 1, 2 and 10 apparently have been cleaned up. Site 6 is recommended to be remediated during quarry cleanup. Why not include site 8 in the remediation of quarry cleanup?

Response to Comment 1:

Site 8 will be remediated during bulk waste removal to a level that assures proper worker protection in the quarry support area. The final verification of remediation will be performed as a part of the follow-on quarry cleanup after bulk waste removal to a level consistant with unrestricted use in that area.

Comment 2:

Page 5-123. We concur in the need for cleanup of Southeast Drainage.

Response to Comment 2:

Comment is noted. As stated in the report text, the Southeast Drainage will be characterized after major site remedial actions are completed and may be remediated as part of the final soil and pit cleanup. However, before a decision to remediate the Southeast Drainage is made, the potential environmental damage to the area will be weighed against the risks posed if the area is not remediated.

Comment 3:

Page 5-132. Sediment samples from site SD-4001, Lake 36, SD-4007 and Lake 35 have mean uranium levels of 31 pCi/g, 30 pCi/g, 26 pCi/g and 23.6 pCi/g. The reference level for uranium indicated on page 5 of the Executive Summary is 15 pCi/g. Would it follow that remediation on these sites is warranted since they exceed the reference level?

Response to Comment 3:

The decision on remediation of the sites in question will be made after final cleanup criteria are established. Page 5 of the Executive Summary does not adequately

explain the purpose of reference levels as used in the RI. The following explanation will be included as a new paragraph in the Executive Summary, page 5, and will become the fourth paragraph in Contaminant Sources:

"It is important to understand that the radionuclide reference levels presented here are not intended to guide site remediation. The reference levels were used because site-specific cleanup guidelines have not yet been developed for the WSS. The RI presents reference levels only for the purpose of estimating area and volumes of soil containing radionuclide concentrations. Once final cleanup guidelines have been established, the estimated areas and volumes will be revised. Pages 5-45 and 5-46 of the RI provide further detail as to the purpose and justification of reference levels."

Comment 4:

Page 5-155 and 5-157. Data are puzzling to us. We have collected a set of fish flesh samples for lead analyses. We would hope that as more data become available a decision can be made on appropriate action to respond to elevated lead levels. With very high lead levels in Ash Pond and upstream of Lake 36, how will the Department of Energy interact with the Department of Army on cleanup activities?

Response to Comment 4:

DOE is very interested in the results of the MDOC fish analyses for lead. DOE will continue to coordinate its work in the Busch Wildlife Area with the MDOC in order to establish the nature and extent of lead contamination or other constitutents that may originate at the Weldon Spring Site. As part of the ongoing effort to determine the extent of WSS contamination, DOE is continuing its plans to perform media and biological characterization in conjunction with MDOC sampling in the Busch Wildlife Area. Routine monitoring activities at the Weldon Spring Site are also ongoing in order to provide a better definition of contaminant discharges. Although isolated soil locations with high lead concentrations exist at the WSS, samples collected from surface water monitoring locations during 1987 and 1988 indicate that no lead is being discharged from the site. Samples collected during lake and stream sediment characterization (MKF and JEG, 1989h) showed little difference in lead concentrations between Lakes 34, 35, 36 and 37 (background lake). It should be noted that Lake 37 is in a drainage basin that does not carry runoff from the Weldon Spring Site.

ATTACHMENT C

Comments of the Missouri Department of Natural Resources

GENERAL COMMENTS

Comment 1:

Please reference MDNR's First Annual Report on the Shallow Groundwater Investigations at Weldon Spring, Missouri as MDNR, 1989 rather than Hoffman, 1989. Citations occur on pages 4-24, 26, 46, 50 and 51, on Table 4.6-9, and perhaps elsewhere.

Response to Comment 1:

Agree. References to this report will be changed throughout Section 4.0 from "Hoffman, 1989" to "MDNR, 1989" on pages:

4-24, paragraph 3, last line.
4-26, paragraph 4, line 3.
4-46, paragraph 1, last line.
4-50, paragraph 3, last line.
4-51, paragraph 2, last line.
Table 4.6-9 footnote "d".

A search will also be conducted for this reference in the other report sections.

Entry 3 on page 4 of the Reference Section in Volume I will be changed from "Hoffman, 1989" to "MDNR, 1989. First Annual Report on Shallow Groundwater Investigations at Weldon Spring, Missouri."

Comment 2:

Figure 4.1-2 presents a topographic map of the Weldon Spring area but is not detailed with respect to the site. Nowhere else is there a topographic map of the site. We would suggest adding a topographic map of the site at the same general scale as many of the other site maps in the report. Drainage patterns and surface features would be much more obvious with such a map in combination with the text descriptions.

Response to Comment 2:

Agree. A new Figure 4.1-3 will be drafted which will consist of a site topographic map at approximately the same scale as the other site maps. The present Figure 4.1-3 will be renumbered to become Figure 4.1-4.

DETAILED COMMENTS

Comment 1:

Table 4.6-1 - footnote (f) is not explained.

Response to Comment 1:

Agree. This is a typographical error, "(f)" will be replaced with "(d)" in last footnote.

Comment 2:

Page 3-22 - MDNR Dye Tracing Studies - this section does not report MDNR-DGLS dye tracing experiments correctly. Only two borehole dye traces were attempted in 1983 (MW-2020, March 9; MW-3007, April 7) by Dean. The report only mentions one losing stream dye trace (from West Raffinate Pit Drainage, Feb. 1984) of three conducted. The other two were from the head of the Southeast Drainage (June 1984) and from Ash Pond Drainage (March 1985). The 1985 attempted borehole traces are adequately described. Fig. 3.4-4, Water Tracing Sample Locations, appears to be a modified version of a map produced by MDNR-DGLS (MDNR, 1989).

Response to Comment 2:

Agree. Section 3.4.4, paragraph 1, sentence 2, will be revised to read: "...dyes were injected into two boreholes (MW-2020 and MW-3007)..."

Agree. Section 3.4.4, paragraph 2, will be revised to read: "Dye was placed in a surface drainage west of Raffinate Pit 4 in February 1984 and west of Ash Pond in March 1985. These drainages are unnamed tributaries to the Schote Creek drainage to Lake 35. In November 1984, MDNR-DGLS also released dye at the sewer outfall at the head of the Southeast Drainage. The summary of the dye trace results can be found in the MDNR-DGLS, 1989, Shallow Groundwater Investigation Phase I Report. (MDNR, 1989)."

Figure 3.4-4 will be modified to indicate "MDNR, 1989" rather than "MKF & JEG, 1988" as the source.

Comment 3:

Page 3-29, Section 3.7.1.6 - This section mentions recent (1988-1989) exploration programs, to help describe site geology, conducted by the PMC. Some information from these programs is presented in tabular form (Table 4.3-1) but drilling logs are not presented in the RI Report. Are drilling logs from these recent programs presented in another document?

Response to Comment 3:

These logs were not included as an RI Report appendix because of the bulk they would add. Although there are currently no plans to publish these logs in document form, the logs are to be compiled in a compendium of geologic data which will be available for public review at the Weldon Spring Site.

Comment 4:

Page 4-9, Section 4.3.1.1 - The Bushberg Sandstone has been reported in the literature as a Devonian age formation (Kleeschulte and Emmett, 1987; Miller, et al, 1974; Koenig, 1961). However, more recently the Bushberg has been assigned to the Mississippian System (Thompson, 1986). The text and Figure 4.3-1 should reflect current understanding.

Response to Comment 4:

Agree. Text on page 4-9, Section 4.3.1.1, second paragraph, first sentence, will be changed to read: "The sequence from the Bushberg Sandstone unit of the Lower Mississippian system to the Burlington and Keokuk Limestones form the shallow bedrock aquifer."

The fifth sentence will also be changed to read: "The Chouteau Limestone unconformably overlies the Bushberg Sandstone."

Figure 4.3-1 will be altered to indicate that the Bushberg Sandstone is Mississippian rather than Devonian in age.

Comment 5:

The term "unit" is not customarily capitalized since it is not part of the formal name of a formation. Unit is capitalized several places on this page.

Response to Comment 5:

Agree. The term "unit" will be changed from upper to lower case in the following text of Section 4.3.1.1, on page 4-9: paragraph 2, line 1 to line 7; paragraph 3, line 1; and paragraph 4, line 2. Other report sections will also be searched and this terminology change made as required.

Comment 6:

The thickness figures given for the Warsaw and Salem formations do not agree with those given in Figure 4.3-1. The thickness figures in the text refer to the site area for most formations. The descriptions of the Warsaw and Salem do not, and may mislead the reader.

Response to Comment 6:

Agree. The last sentence of paragraph 5, page 4-9, Section 4.3.1.1, will be changed to read: "In the vicinity of the Weldon Spring Site, the Warsaw Formation ranges in thickness from 18.3 - 24.4m (60-80 ft) (Whitfield et al., 1989)."

Paragraph 6 of page 4-9, Section 4.3.1.1, will be revised to read: "In the vicinity of the Weldon Spring Site, the Salem Formation ranges in thickness to 4.5m (15 ft) (Whitfield et al., 1989). The Salem Formation is a light gray...".

Comment 7:

Page 4-10, paragraph 2 - Alluvium overlies units other than glacial drift and loess in the vicinity of the site. The last sentence of this paragraph is incorrect.

Response to Comment 7:
