Agree. The last sentence of paragraph 2, page 4-10, Section 4.3.1.1, will be replaced with the following: "In some upland valleys, alluvium of the Holocene Series overlies the glacial drift and loess, or it lies directly upon the Paleozoic bedrock."

Comment 8:

Page 4-10, Section 4.3.1.2 - This section presents several isopach and contour maps of the site presumably generated from the geologic database. A check of several data points against geologic logs, particularly on Figure 4.3-19, reveals several points in disagreement with plotted contours or isopachs. Many data points cannot be checked because geologic logs have not been presented in this document or elsewhere. Is there an explanation for these apparent conflicts?

Response to Comment 8:

The contouring package (CPS-1) used in generating Figure 4.3-19 and the other maps in Section 4.3.1.2, is an industry standard. A rectangular grid is superimposed on the control points (data) and the grid nodes are assigned values based on all of the control points within the search limit of that node. The grid nodes, rather than the control points, are contoured. Consequently, the control points which do not coincide with grid nodes may not be precisely honored in the contour map. The continuous surface is, however, best represented in this fashion.

The geologic logs that were used to develop Figure 4.3-19 and the other maps in Section 4.3.1.2 were not included in the RI because of the bulk they would add to the report. These logs are being compiled in a compendium of geologic data and will be available for review at the Weldon Spring Site.

Comment 9:

Page 4-13 - The residuum unit is described as an individual stratigraphic unit in the text but is not represented as such in the Generalized Stratigraphic Column (Figure

4.3-1). There is a problem in assigning it an age but it should be represented, perhaps as "Quaternary or pre-Quaternary" may be most appropriate.

Response to Comment 9:

Recent mapping of the area by Whitfield et al., in 1989 does not mention the residuum as being stratigraphically distinct. Figure 4.3-1 is intended to provide a more regional stratigraphic perspective rather than focusing on site-specific units. The residuum is mentioned in Figure 4.3-1 as being subjacent to various units of Pleistocene age.

Comment 10:

Page 4-14 - MDNR-DGLS does not consider a hydraulic conductivity of 5×10^{-8} cm/sec. to be representative of the residuum unit. Our experience indicates that it has a much higher permeability. We support further sampling and testing of this unit, as mentioned.

Response to Comment 10:

Agree. This sample should not be construed to be representative of the entire residuum unit. However, it does represent the lower end of the range of values possible in this heterogeneous unit.

Four additional samples were sent to the laboratory for permeability testing. Three consisted of noncohesive gravels which could not be tested. The other sample was gravelly, but cohesive. Preliminary test results for that sample indicate a hydraulic conductivity of 3.0×10^{-8} cm/sec.

Text will be changed to indicate heterogeneity of the residuum. The first two sentences of paragraph 4, page 4-14, will be replaced with the following:

"In terms of hydraulic conductivity, the residuum is extremely heterogeneous. Laboratory testing of a sample from near the top of the unit yielded a value of 5.0×10^{-8} cm/sec (1.4×10^{-4} ft/day). Four additional samples have been sent out for testing. Three of these consisted of noncohesive gravels which could not be tested. The other sample was gravelly, but cohesive. Preliminary test results for that sample indicate a hydraulic conductivity of 3.0×10^{-8} cm/sec. As indicated in the previous section, the interstitial clay within the residuum is generally quite plastic and, where sufficient clay is present, forms a tight matrix within the gravel fraction."

Comment 11:

Page 4-28 - The descriptions of gaining and losing reaches, particulary in paragraphs 2 and 3, are not clear because mentioned landmarks are incorrectly named and not represented on the reference maps. Road DD is maintained by the State and might better be referred to as State Road DD. Road C and B are Busch Wildlife Area roads and are not shown on Figure 4.4-9.

Response to Comment 11:

Agree. The figures and discussion presented in Section 4.4.4.2 will be revised as suggested in Comment 11. In addition, work performed by the MDNR to supplement that of the USGS will be acknowledged and Figure 4.4-9 will be modified to be consistent with Plate 7 of MDNR, 1989.

Text revisions will include: Section 4.4.4.2, page 4-27, paragraph 3 - after the first sentence, insert the following: "The information provided by the USGS was supplemented and slightly modified by the MDNR (MDNR, 1989)."

At the end of the same paragraph, add the following: "Figures 4.4-6 through 4.4-8 show the USGS discharge measurement locations and the estimated discharge values for subdrainages near the site. Results of the MDNR and USGS studies are presented in Figure 4.4-9."

Section 4.4.4.2, page 4-28, paragraph 2, sentence 2: change "St. Charles County Road DD" to "State Road DD."

Section 4.4.4.2, page 4-28, paragraph 3, sentence 2: change "St. Charles County Road C" to "Busch Wildlife Area Road C." In sentence 4, change "St. Charles County Road B" to "Busch Wildlife Area Road B."

Section 4.4.4.2, page 4-29, first paragraph, sentence 2: change "County Road D" to "State Road D."

Figure 4.4-9 will be modified by changing "County Road" references to "State Road" and by adding Busch Wildlife Area Roads C and B. An additional change will be made to indicate that a short segment of the Burgermeister Spring branch (drainage 6300) and the segment of Crooked Creek from State Road D to Highway 40 (drainage 6100) are losing streams.

Comment 12:

Page 4-30 - The March 1985 injection of dye was detected only at Burgermeister and its wet weather springs (SP-6301 and SP-6302). Dye was not recovered at SP-6303 (Dean, 1965; MDNR, 1989).

Response to Comment 12:

Agree. Text on page 4-30, Section 4.4.4.3, first sentence, will be revised to read "...dye were detected in those from Burgermeister Spring (SP-6301) and Overflow Spring (SP-6302) (Dean, 1985)."

Comment 13:

Page 4-35 - Second paragraph refers to Figure 4.5-5 but should probably be 4.5-4.

Response to Comment 13:

Agree. Reference was incorrect and will be changed to Figure 4.5-4 (page 4-35, Section 4.5.1, second paragraph, third sentence).

Comment 14:

Page 4-44 - Section 4.6.2.5 - Are final pump test results available? If available, the results should be presented and their significance explained.

Response to Comment 14:

The pumping tests have been performed and the resulting data prelimarily reduced. The results will be available in the Aquifer Characterization Data Report which is currently under development. It is anticipated that this report will be issued in mid-1990.

ATTACHMENT D

Comments of the Missouri Department of Natural Resources

GENERAL COMMENTS

Comment 1:

Although much of the TNT operations formerly located at the Chemical Plant were possibly taken care of at the "burn" sites, I would like to see some discussion of the leveling of the site to construct the Chemical Plant. From Plate #1 it appears TNT plants/lines 1 through 4 were located in areas extensively changed by construction of the chemical plant. It would seem logical that some TNT and DNT contaminated wastes were buried or disposed of on site or elsewhere during the construction of the chemical plant.

Response to Comment 1:

Historical records were reviewed to determine the sequence and extent of Weldon Spring Site operations and construction activities. Activities involved with TNT production and disposal, and chemical plant construction were particularly scrutinized in developing site sampling plans.

Because of the size of the site and the diversity of activities that occured, two sampling approaches - biased and unbiased - were used to provide comprehensive soil contamination characterization. The biased sampling locations were selected on the basis of historical documentation of WSOW and WSUFMP operations and the results of the more recent site investigations. Topographic modifications from cut and fill activities were also taken into account in the selection of sampling locations. Unbiased sampling was conducted across the site to provide a statistically valid database for soils characterization and to document uncontaminated areas (MKF and JEG, 1988j).

In the Phase II sampling effort, chemical soil samples were collected from 245 locations within the WSCP and WSRP areas. Soil sampling locations were surveyed to establish horizontal and vertical control prior to sampling. Soil samples were collected using continuous sampling equipment driven through conventional hollow-stem augers. This sampling method provided a relatively undisturbed sample for chemical analysis and lithologic logging (MKF and JEG, 1989a).

Areas sampled for nitroaromatic compounds included WSOW process areas, drainageways, and the burning area and rubble areas. Nitroaromatic compounds were detected at the 15 locations shown in Figure 5.2-1. The depth intervals and contaminant concentrations are presented in Table 5.2-2. The locations where nitroaromatic compounds were detected by the WSOW biased sampling program generally confirm previous results from the Phase I and IRA studies which indicated that the Ash Pond area is the area most extensively contaminated with low levels of nitroaromatic compounds. Based on review of the historical records describing site operations, a process line for TNT production near Frog Pond was identified. This

process line may have been a source of nitroaromatic contamination in the vicinity of Frog Pond. The contaminated areas are associated with primary TNT production or waste water management.

Location PH2-OWB-001 (C-1) is in the wash house area of TNT Production Line 1. Gross contamination has been identified in similar settings on the adjoining Army Reserve training area (locations PH1-27, 28, 29 and 30). The contamination probably originated as waste water spilled on the soil from the wash house. Most gross contamination in this area was apparently removed during decontamination efforts prior to construction of the WSUFMP facilities in about 1954. The depth to contamination (1.8 to 3.7 m or 6 to 12 ft) is consistent with cut and fill mapping which indicates the presence of 1.2 to 1.8 m (4 to 6 ft) of fill overlying WSOW topography. Construction and subsequent removal of building foundations would have disturbed soil, allowing contaminant migration to the depths which sampling has indicated are contaminated.

Comment 2:

Some of the Interim Response Actions listed in Table 1.2-2 would appear to require a relatively long time to accomplish. ARAR's for these actions are not discussed. EPA policy has stated ARAR's would be followed at "removal actions" to the extent practicable.

Response to Comment 2:

It is the policy of the DOE to comply with all applicable or relevant and appropriate regulations in performing the IRAs. A detailed discussion of ARARs and how compliance will be achieved for each IRA is presented in the engineering evaluation and cost analysis (EE/CA) reports. A detailed analysis of ARARs will be included in the site FS-EIS report.

Comment 3:

The fish sampling for the biological contamination portion of the report did not include any bottom feeders. Since the contaminants could be in the sediments, bottom feeders would more likely be contaminated.

Response to Comment 3:

Agree. The Biouptake Study Sampling Plan (MKF and JEG, 1987b) identified the need and plan for obtaining samples of bottom feeding and other representative fish species from water bodies receiving drainage from the WSS. Fish sampling at the Busch and Weldon Spring wildlife areas was conducted by MDOC and PMC personnel using electrofishing equipment. A few catfish, generally considered to be bottom feeders, were collected from Lakes 35 and 36 and analyzed for radionuclides. No catfish were successfully collected from the other locations at that time. Carp and largemouth buffalo, two predominantly bottom feeders, were collected from the Femme Osage Slough.

Additional sampling was conducted by MDOC in the fall of 1989 to assess lead levels in fish from Lakes 36 and 37. The PMC also collected fish at that time to be analyzed for uranium at lower detection levels. These samples also included catfish. No data are yet available for these samples. Results are anticipated in early April, 1990. These data will be finalized and included in the Biouptake Report scheduled for issue in mid-1990.

Plans for additional characterization work include fish tissue sampling in Lakes 34 and 35. Results of this work will also be available in mid-1990.

Comment 4:

Were the soil samples analyzed by depth interval (relates to comment 1 above)? It was difficult to tell from the report.

Response to Comment 4:

Yes. Sampling depths were established by evaluating cut and fill activities. For example, ordnance works sampling completely penetrated filled areas and sampled original ordnance works topography. The depth intervals and contaminant concentrations are presented in Table 5.2-2.

Text revisions will be made in Section 3.2.1.3, page 3-10, second paragraph. The third sentence in this paragraph (Topographic modifications...") will be deleted and replaced with the following: "Cut and fill activities were also evaluated in determining sampling locations and depths."

Comment 5:

Shouldn't Figure 7 of the report show the Twin Lakes development as a receptor?

Response to Comment 5:

Nitroaromatic contamination has been detected at the Twin Island Lake development. The Army is currently supplying bottled water to residents of the development. Plans are underway to connect the development to a public water system.

DOE recognizes the concern reflected by Comment 5, however, for the present, Figure 7 should remain unchanged since the Twin Island Lake development has not been established as a receptor of groundwater contaminated by substances from the WSS.

Comment 6:

Were the soils selected for background soil sampling of the same toxinomic units as those found at the WSCP site? In some instances the existing chemical plant surface soil may be a subsurface horizon due to the site grading which occurred.

Response to Comment 6:

Yes. The soil samples collected for background determinations were from the same units as those present on site. The following sentence will be added to Section 5.2.1 between sentences 3 and 4 in the third paragraph on page 5-26: "The studies focused on the same soil units at off- and on-site locations in order to compare background concentrations."

Comment 7:

Please keep in mind that those IRA's which call for off site disposal will probably require special solid waste permits.

Response to Comment 7:

The DOE is aware of this requirement for off-site disposal of waste.

Comment 8:

Has there been any effort to explain the differences in concentrations between Table 5.1-11 (BNI samples) and Table 5.1-19 (PMC samples)? The BNI results are considerably higher on average.

Response to Comment 8:

It is not known why the BNI sample results are higher (on average) than the PMC sample results. An evaluation performed to explain the difference in radionuclide concentrations reported in the BNI and PMC data sets is discussed in Section 2.4.4 of Waste Assessment Radiological Characterization of the Weldon Spring Site Raffinate Pits, Rev. 0, DOE/OR/21548-062, August 1989. This report concluded that "there exists a statistically significant difference between the mean values of the two data sets. However, there was no discernible overall pattern of bias between the data sets with regard to concentration value, concentration heterogeneity, or radionuclides".

The PMC followed documented sampling procedures during sample collection and analyses at the raffinate pits. The PMC has also performed data validation on some raffinate pit sample results. Data validation information relating to the BNI data set was not provided in the Bechtel characterization report. Attempts were made by the PMC to obtain this information from Eberline, Bechtel's technical subcontractor, but these attempts were unsuccessful. On the basis of this information, the DOE is of the opinion that the PMC's data more accurately represent the true radiological chacteristics of the raffinate.

Comment 9:

Appendix F and other portions of the report make reference to evaporating the red and yellow waters. This appears unlikely given the flow rates of 40 to 50 mgd.

Response to Comment 9:

Agree. According to Fishel and Williams, 1944, a primary purpose in the design and construction of the waste water treatment plants was evaporation of the red and yellow waste waters. However, no information is provided as to the efficiency or effectiveness of the process once the waste water treatment plants were built.

The following revision will be made to the text in Appendix F, page F-5, paragraph 5. Strike the last sentence ("The lines discharged...") and replace with the following paragraph:

"Due to the state of emergency and apparent low priority placed on wastewater treatment, details on wastewater management practices are sketchy. Early in the operation of the WSOW, wastewaters were discharged directly from production lines or pumped into lagoons. The direct discharge and leakage from the lagoons caused contamination of area streams and springs. After stream and spring contamination was noted, wastewaters were pumped directly to the Missouri River (Fishel and Williams, 1944). At some point, wastewater evaporation and incineration plants were constructed and placed in operation (Greely and Hansen, 1942), however, it is not clear that this treatment practice ever totally replaced disposal in the Missouri River."

Comment 10:

Appendix H makes at least 3 references to the disposal of red water sludges or TNT contaminated material. What efforts have been made to trace the ultimate fate of these materials? Can it definitely be stated they are not buried below the WSCP site or at the Quarry?

Response to Comment 10:

Based on a comprehensive historical review, it was discovered that during decontamination in 1944, residues from nitroaromatic-contaminated material burning areas of unknown locations were scraped into piles and attempts were made to reburn these piles. The burning process was not very successful, so the residues were dumped, presumably in the Weldon Spring Quarry (Hannon, 1944). Figure 3.1-3 indicates the location of a demolition storage area for nitroaromatic-contaminated rubble and a burning ground for nitroaromatic-contaminated material. Figure F-4 also indicates the location of the burning ground.

As described in Sections 3.2.1 and 5.2.1, four soil sampling programs have been carried out at the WSCP/WSRP areas by the PMC. Nitroaromatic contamination was detected in 15 samples ranging in concentration from 0.48 to 307 ug/g. The final phase of samplings included biases for known locations of ordnance works activities, uranium feed materials activities, and a random sampling program. No

nitroaromatic compounds were detected in the uranium feed materials-biased and random samples. With the exception of the abandoned waste pond northeast of Frog Pond, no gross contamination was discovered in the soils sampling program.

The information described above will be added to the text in Appendix F, page F-6, following paragraph 1.

Comment 11:

Has any effort been made to characterize the materials which were dumped into Pit Number 4 in December 1966?

Response to Comment 11:

The DOE is not aware of any effort to specifically characterize the materials dumped into Raffinate Pit 4 in December 1966. However, Raffinate Pit 4 characterization has been addressed in other sampling programs performed at the Weldon Spring Site, including work described in these reports: Draft: Waste Assessment Radiological Characterization of the Weldon Spring Site Raffinate Pits. Revision A. DOE/OR/21548-062. April 1989. (MKF and JEG, 1989e) and Draft Report, Waste Assessment and Chemical Characterization of the WSS Raffinate Pits. January 1989. (MKF and JEG, 1989c).

Comment 12:

VOLUME I: Page 3-23, Section 3.4.5, Domestic Well Sampling: This section references the private well information received from the St. Charles Countians Against Hazardous Waste and the U.S. Geological Survey. Figure 3.4-5 is a preliminary map of the private well locations. The report does not discuss the extensive sampling data on these and other wells obtained by the Missouri Department of Health (MDOH) from 1982 to 1989. Attached is the MDOH data on these wells.

I suggest that you summarize this data and discuss its significance in demonstrating the limits of the groundwater contamination. This information may also be relevant to the baseline risk assessment in that it shows that private wells are not being affected by the uranium processing that occurred at the site. To protect the privacy of individuals, well owner names should not be used in the RI Report.

Response to Comment 12:

Comment is noted. Text will be revised by deleting the last sentence in Section 3.4.5 (page 3-23) that reads: "Future WSSRAP efforts..." The following paragraph will be added at the end of Section 3.4.5:

"Extensive sampling of private wells in the vicinity of the Weldon Spring Site has been performed by the MDOH since 1982. Preliminary data received from the MDOH for the period 1982-1989 indicate that private wells in the vicinity are not being affected by the uranium processing that occurred at the Weldon Spring Site. Evaluation of MDOH private well data is continuing in conjunction with

interpretation of the site monitoring well data. The results of the interpretations will be used in assessing risks associated with the Weldon Spring Site."

Comment 13:

VOLUME III: APPENDIX H, Chronology of Events at the Weldon Spring Site: This chronology is very helpful. However, the information on 1986-89 is very limited. I suggest that you provide a more detailed chronology for these last three years.

Response to Comment 13:

Agree. The chronology in Appendix H will be expanded to present a more detailed discussion of activities during 1986-1989.

RCRA ARAR - COMMENTS (SEE VOL. III APPENDIX B)

General Response to ARAR Comments:

Please note that due to the current status of WSSRAP and potential ARARs, the following response pertains to RCRA ARAR comments 1-16 and State RCRA ARAR comments 1-7.

The identification and discussion of potential ARARs (Appendix B, Vol. III) is very preliminary and not intended to be all inclusive. Identification of ARARs is an integral part of the baseline risk assessment, remedial investigation, and feasibility study. Hence, ARAR determinations are expected to change as new information becomes available and as the remedial action alternatives are developed and evaluated. At this stage of the RI/FS process, it is possible to define with some assurance both the contaminant-specific and location-specific ARARs for the Chemical Plant and Raffinate Pit areas. However, the identification of potential action-specific ARARs is completely dependent upon the particular remedial alternatives being considered. This evaluation will be performed as part of the FS effort. However, it was considered prudent to identify those ARARs that may constrain or define a particular alternative as early as possible in order to highlight problems and expedite the FS process. It should be emphasized that the list of action-specific ARARs, which includes Federal and State RCRA provisions, is not intended to be complete or to presume results of the FS; rather it is an attempt to take an initial look at the ARARs associated with those alternatives which are considered likely to pass preliminary screening and/or which are perceived as being especially problematic.

A more detailed, and comprehensive assessment of action-specific ARARs will be made during the development and evaluation of the remedial action alternatives. In addition, during the detailed design phase, efforts will be made to ensure that the technical specifications will attain ARARs. The comments received on the Federal and State ARARs are both timely and helpful, as ARARs for the proposed remedial action alternatives are presently being identified. All comments pertaining to RCRA ARARs are being assessed for applicability to the various options under consideration.

Comment 1:

General - The ARAR's tables did not address the chemically contaminated portions of the buildings, process equipment, or storage tanks. In certain instances portions of the WSCP buildings and equipment may be considered hazardous waste.

Comment 2:

Table 3 - Has the EPA text; Permit Writers' Guidance Manual for the Location of Hazardous Land Storage and Disposal Facilities: Phase I. Criteria for Location Acceptability and Existing Regulations for Evaluating Locations (Feb. 1985), been evaluated for "To be considered" ARAR's?

Comment 3:

Table 4 - Airborne particulates from handling of RCRA waste must be controlled (264.251, .273, .301).

Comment 4:

Table 5A, Removal Criteria, does not address RCRA materials which are radiologically contaminated. The treatment, storage, and disposal, of these materials will need to meet RCRA requirements.

Comment 5:

Table 5B - Tank storage for some period of time in existing tanks appears to be a possibility. If so then 40 CFR 264.191 would be relevant and appropriate.

Comment 6:

Table 5B, page 3 - Some sectins of 40 CFR 264.193 and 194 may not be substantive (eg. (g), (h), (I)).

Comment 7:

Table 5B, page 4 - Inspections of storage tanks should be relevant and appropriate (40 CFR 264.195).

Comment 8:

Table 5B, page 8 - Inspection of containers would appear to be relevant and appropriate (40 CFR 264.174).

Comment 9:

Table 5B, pages 11 and 12 - Although 40 CFR 264.341, .342, and .344 are directly related to permit requirements they would appear to be substantive since the incinerator efficiency or operating limits cannot be determined by the operator without the required analysis.

Comment 10:

Table 5B, page 12 - The monitoring requirements of 40 CFR 264.347 appear to be substantive to operate an incinerator.

Comment 11:

Table 5B - Closure requirements of 40 CFR 264.351 appear to be substantive.

Comment 12:

Table 5B, page 15 - It would appear that more of 40 CFR 265 subpart P would be relevant and appropriate since it is parallel to 40 CFR 264 subpart O.

Comment 13:

Table 5C - Wouldn't 40 CFR 265.400 be a "to be considered"?

Comment 14:

Table 5G - This table should include the Land Ban (40 CFR 268) since any land filled RCRA materials will have to be in compliance with the treatability standards.

Comment 15:

Table 5G - page 5, Section 315 of 40 CFR 264 would appear to be substantive.

Comment 16:

The proposed rules of 40 CFR 269 would appear to be "to be considereds". Part of these rules were proposed on February 5, 1987 (52 FR 3748).

Comment 17:

Subpart F of 40 CFR Part 264 would appear to be relevant and appropriate to the Quarry site itself.

Response to Comment 17:

The quarry site is being managed as a separate operable unit and ARAR analysis is a part of that effort. Twenty-eight groundwater monitoring wells serve as an integral component of the routine environmental monitoring system in the quarry area.

STATE RCRA ARAS

General Response to ARAR Comments:

Please note that due to the current status of WSSRAP and potential ARARs, the response under **"RCRA ARAR - COMMENTS (SEE VOL. III APPENDIX B)"**, above, pertains to RCRA ARAR comments 1-16 and State RCRA ARARs 1-7.

Comment 1:

Table 3 - MO. hazardous waste regulations chapter 13 (PCB's) incorporate the chapter 7 (TSDF's) requirements. Locations of commercial facilities handling wastes which come under the PCB rules must comply with MO-RCRA location standards. This may be relevant and appropriate at the site.

Comment 2:

Table 4, page 1 - Missouri PCB Treatment, Storage, Disposal facilities must meet the MO. hazardous waste regulations chapter 13 and 7.

Comment 3:

Tank systems should consider the location standards of 40 CFR 264 subpart N in accordance with 10 CSR 25-7.264(2)(J)4, pages 12 and 13.

Comment 4:

Sampling methods for incineration should comply with 10 CSR 25-7.264(2)(0), page 24, where more restrictive than 40 CFR 264.343.

Comment 5:

The requirements of 10 CSR 25-7.264(P) & (Q), pages 24 through 28, would be applicable to treatment or disposal facilities.

Comment 6:

Leak detection and leachate collection systems must have a permeability of at least 0.01 cm/sec. (See 10 CSR 25-7.264(2)(N)2.a.(II), page 23).

Comment 7:

The compliance monitoring point of 40 CFR 264.95 is modified by 10 CSR 25-7.264(2)(F)2, page 5. The establishment of this point is referenced in 40 CFR 264 subpart F (See Table 5G, page 5 and 6).

ADDRESSEES

PLAN FOR MONITORING RADIONUCLIDE EMISSIONS OTHER THAN RADON AT WELDON SPRING SITE CRITICAL RECEPTORS - REV. 0, MAY 1990

Enclosed for your information is Rev. 0 of the Plan for Monitoring Radionuclide Emissions Other Than Radon at Weldon Spring Site Critical Receptors - Rev. 0, May 1990.

The Plan contains the DOE monitoring activities to be undertaken at the Weldon Spring Site for compliance with 40 CFR 61. USEPA has concurred in the plan concept, quality assurance and reporting procedures. The Plan will be fully implemented for calendar year 1990.

Sincerely,

Stephen H. McCracken
Project Manager

MONITORG.PLN/TXTJOANN

ABSTRACT

During the course of the Weldon Spring Site Remedial Action Project (WSSRAP) radionuclides may be emitted to the air. Emissions of radionuclides are regulated by the U.S. Environmental Protection Agency in 40 CFR 61. It is clear in 40 CFR 61 that, for sites being remediated according to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), no monitoring or reporting of radon emissions is required prior to completion of temporary or permanent disposal sites, other than that already required under CERCLA. For radionuclides other than radon, however, it is not clear whether 40 CFR 61 requires sites being remediated according to CERCLA to implement additional monitoring and reporting prior to completion of disposal facilities. Because the U.S. Department of Energy is committed to protection of the public and environment, a plan has been formulated which defines how the WSSRAP will implement a monitoring program for radionuclides other than radon. This plan adheres to the specifications contained in 40 CFR 61.

1 INTRODUCTION

1.1 SITE HISTORY

The Weldon Spring Site is located in St. Charles County, Missouri, about 30 miles west of St. Louis on land formerly used by the Department of Army (DA) as a trinitrotoluene (TNT) and dinitrotoluene (DNT) ordnance works. The site consists of a 9-acre former limestone quarry; a 51-acre raffinate disposal area; and a 166-acre uranium feed materials plant. The feed materials plant was built in 1955-1957 by the Atomic Energy Commission (AEC), the predecessor to the U.S. Department of Energy (DOE), and operated by Mallinckrodt Chemical Works for the AEC from 1957 through 1966. The plant processed uranium ore concentrates and recycled scrap to pure uranium trioxide, uranium tetrafluoride, and uranium metal. Thorium ore concentrates were also processed. The raffinate residues from this processing were disposed of in four large open pits. During the plant's operational period, the buildings, the equipment, the immediate terrain, the process sewer system, and the drainage easement to the Missouri River became contaminated with uranium, thorium, and their decay products.

During the period 1943-1957, the DA disposed of rubble and soils contaminated with TNT and DNT in a former limestone quarry about 4 miles from the ordnance works. Later, from 1959 through 1966, the AEC disposed of building rubble and soils contaminated with thorium and uranium and their decay products in the same quarry. The quarry now contains about 95,000 cubic yards of contaminated materials, including quarry materials contaminated by this radioactive waste.

In 1967, the feed materials plant site was selected to be converted to a herbicide production facility. Except for the materials stored in the raffinate pits, the site was transferred

back to the DA and renamed the Weldon Spring Chemical Plant (WSCP). The DA began a major effort to decontaminate three process buildings for herbicide production. The cleanup was not totally successful, and in 1969, reduced requirements for the herbicide and increased cleanup costs resulted in cancellation of the project. The 51 acres encompassing the Weldon Spring Raffinate Pits (WSRP) were transferred back to the AEC in 1971.

On November 27, 1984, the DOE was directed by the Office of Management and Budget to assume responsibility for the decontamination of the WSCP and to integrate work with other DOE remedial actions proposed for the Weldon Spring Quarry (WSQ), and the WSRP. In 1987 the WSQ was placed on the National Priorities List (NPL). The WSCP/WSRP were placed on the NPL in 1989. These NPL sites are being remediated according to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Environmental Policy Act (NEPA).

During cleanup of the Weldon Spring Site (WSS) a temporary storage area (TSA) for wastes from the WSQ is proposed. In addition, the DOE-preferred alternative for all wastes at the WSQ and WSCP/WSRP is to build a permanent disposal site at the WSCP/WSRP.

1.2 REGULATIONS PERTAINING TO RADIOACTIVE EMISSIONS

Because of the radioactive materials present at the WSCP/WSRP and WSQ, radon is emitted to the atmosphere as are other radionuclides from the U-238, U-235, and Th-232 natural decay series. Atmospheric emissions of radon and radionuclides other than radon are regulated by the U.S. Environmental Protection Agency (EPA). The regulations are contained in 40 CFR 61 which was updated and became effective on December 15, 1989. It is clear in Section G of 40 CFR 61 that, for DOE

facilities being remediated according to CERCLA, radon monitoring or reporting programs required through the CERCLA program are sufficient to protect the public health until temporary or permanent storage facilities for Ra-226-containing byproduct material are completed. Once all wastes have been placed and completely covered at the TSA, radon flux monitoring will be performed at the TSA. If a permanent disposal site is constructed at the WSCP/WSRP, radon flux monitoring will be performed after construction of the disposal site is completed. Radon flux monitoring will be performed according to 40 CFR 61, Appendix B, Method 115.

However, it is not clear in those sections of 40 CFR 61 that pertain to radionuclide emissions other than radon whether DOE sites being remediated according to CERCLA are required to monitor and report emissions prior to completion of temporary or permanent storage facilities.

1.3 MONITORING RADIONUCLIDE EMISSIONS OTHER THAN RADON

The DOE is currently determining through discussions with EPA whether the monitoring and reporting requirements for radionuclide emissions other than radon contained in 40 CFR 61, Subpart H apply to CERCLA sites prior to completion of permanent or temporary storage facilities. Regardless of whether 40 CFR 61, Subpart H applies to the WSS during remediation, the DOE is committed to protection of the public and environment. Therefore, a monitoring and quality assurance program sensitive enough to detect concentrations of radionuclides other than radon at levels specified in 40 CFR 61 will be initiated at the WSS.

Results of the monitoring will be reported in annual site environmental reports. These reports are intended to allow EPA

oversight of radionuclide emissions during remediation according to CERCLA/NEPA. The monitoring, reporting, and quality assurance program is discussed below.

2 METHODS OF EMISSION EVALUATION

The national emission standard for radionuclides other than radon is set so that no member of the general public receives an effective dose equivalent greater than 0.10 mSv (10 mrem) per year. 40 CFR 61 Subpart H requires that radionuclide emissions other than radon be measured and effective dose equivalents estimated by computer models. If the emission monitoring and modeling specified in Subpart H is impractical, alternate procedures may be acceptable. As an alternate to modeling dose equivalents, air concentrations can be monitored at critical receptors.

After evaluating the methods of assessing effective dose equivalents from radionuclides other than radon, it was determined that monitoring air concentrations at critical receptors was the most accurate means of assessing effective dose equivalents to maximally exposed individuals. This plan describes how the Weldon Spring Site Remedial Action Project will use monitoring results to estimate effective dose equivalents to members of the public resulting from emissions of radionuclides other than radon.

3 SCOPE

This plan discusses the monitoring, reporting, and quality assurance program requirements that will be used to estimate and document the effective dose equivalent from airborne emissions of radionuclides other than radon at locations of highest potential offsite exposure. The monitoring plan, including rationale for the monitoring program as well as sampler location, description, analytical methods, and frequency is discussed in Section 4. This monitoring program meets the specifications in 40 CFR 61, Subpart H. Also contained in Section 4 is a description of the annual reporting system.

Section 5 contains the quality assurance plan. This plan meets the requirements of 40 CFR 61, Appendix B.

4 PLAN

The Weldon Spring Site (WSS) is currently being remediated according to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and the National Environmental Policy Act (NEPA). It no longer operates as a uranium and thorium processing plant and has been in mothball status since about 1966. Therefore, radionuclides are no longer emitted from the types of sources (i.e. stacks, vents, or pipes) described in 40 CFR 61, Subpart H.

Airborne emissions of radionuclides at the WSS result from wind dispersal of surface soils or dust and dirt within deteriorating buildings and from fugitive dust generated during remedial actions. Monitoring these types of emission sources is not practical because of the inability to adequately characterize the emission inventory. The amount of entrainment can be estimated from fugitive dust emission factors developed by the U.S. Environmental Protection Agency (EPA) for various materials handling activities, but it is generally recognized that those estimates contain gross uncertainties. Measurement of the entrainment and emissions inventory is also extremely difficult and results are uncertain at best, because the emissions are highly variable both over time and location. Accurate measurements of area or volumetric fugitive emissions can only be made with complete knowledge of the micro-meteorology in and around the source and the use of many (usually greater than 10) concentration or measurement locations. Therefore, modeling of downwind dispersion and subsequent dose calculations using either assumed or measured emission rates leads to extremely uncertain results. The most accurate method of dose calculation at nearby receptor points is through the use of actual concentration measurements at these locations.

An assessment of the effective dose equivalents at critical receptors will be documented by environmental measurements of radionuclide air concentrations. Critical receptors are defined as those locations at which individuals abide or reside where the highest potential offsite concentrations of radionuclides other than radon are likely to occur during remediation of the Weldon Spring Site (WSS). The proposed monitoring and sample analysis plan is presented in Section 4.1. Section 4.2 describes how the monitoring meets the specifications in 40 CFR 61.

4.1 MONITORING PLAN

This section describes sampler locations, discusses rationale for selecting critical receptor locations, establishes occupancy times at critical receptor locations, describes the samplers, presents sampling frequency, and presents sample analytical techniques. Also included in Section 4.1.4 is a discussion of how the monitoring results will be reported.

4.1.1 Sampler Locations

The WSS includes the Weldon Spring Raffinate Pits (WSRP), the Weldon Spring Chemical Plant (WSCP), and the Weldon Spring Quarry (WSQ). Eleven air particulate samplers are in use at the WSS. Five samplers are located on the WSCP/WSRP perimeter. Four are located offsite, one of which measures background air. Two are at the WSQ perimeter. Sampler locations with respect to the WSCP/WSRP and WSQ are shown on Figures 4-1 through 4-3.

Sampler location AP-4007 at the Busch Wildlife Area office measures background concentrations for the WSS. This station is located 1.1 km (0.7 mile) from the WSCP perimeter. The forested and gently rolling terrain between the WSCP and this sampling

station provides a significant physical barrier to airborne particulates originating from the site.

As shown in Figure 4-1, sampler stations AP-2001, AP-4006, AP-4008, and AP-2005 are strategically located to measure radioactive air particulate concentrations around the WSCP/WSRP at the point where a maximally exposed individual resides or abides. Station AP-2001 is at the common boundary of the WSCP and Missouri Highway Maintenance Facility. Station AP-4006 is located at the Francis Howell High School. Station AP-4008 is on the Weldon Spring Army Reserve Training Area. Station AP-2005 is located between the WSCP and the Weldon Spring Site Remedial Action Project (WSSRAP) Administration Building.

Located 0.8 km (0.5 mi) west of the quarry is a residence. This residence is within 150 meters (0.1 mi) and directly in line with the quarry monitoring station (Figure 4-3).

These sites were selected as critical receptor locations because they are located within 1.0 km (0.62 mile) of the WSS where members of the public may spend at least eight hours per day for a significant fraction of a year. Other facilities (for example the St. Charles County Water Treatment Plant and the Weldon Spring Heights Subdivision) are located near the WSS; however, no other facility is closer than 2.5 km (1.6 mile) from the WSS. Because of this greater distance these facilities were not considered critical receptors.

At the one critical receptor that is a residence, occupancy will be assumed to be continuous. The number of individuals at the other receptors and typical occupancy patterns are discussed below.

There are nine workers at the highway maintenance facility. A typical worker is at the facility less than 40 hours per week, 50 weeks per year.

There are approximately 1,800 students, faculty and staff members at the high school. Faculty and staff generally spend more time at the school than do students. A typical employee spends 45 hours per week, 50 weeks per year at the school. One janitor lives on the school grounds. Occupancy for this person will be assumed to be continuous.

A remedial investigation is being conducted at the Army Reserve Training area. Subcontract workers perform site characterization tasks intermittently. One employee of the Department of the Army works at most 40 hours a week, 50 weeks per year at the office on the Army Reserve property.

Currently there are approximately 110 workers at the WSSRAP Administration Building. Workers typically spend less than 50 hours per week, for 50 weeks per year, at the facility.

4.1.2 Sampler Description and Sampling Frequency

Air particulate samplers are low volume, self adjusting carbon-vaned, oil-less air pumps at the three quarry locations, and low volume, self-adjusting, twin diaphragm, oil-less air pumps at the five WSCP/WSRP site perimeter locations and at the other three offsite locations. Each sampler is mounted in a weather-protective housing with a 110-volt outlet and a thermostat-controlled fan for cooling. Each sampler will have a timer to document the operational periods. Samplers also have a flow meter and vacuum gages to automatically maintain constant flow.

Air filters are mounted approximately 1 meter (3 feet) above ground surface. The sampling head is on the side of the protective housing opposite the cooling fan exhaust. This prevents the cooling fan exhaust from disturbing the air being drawn through the filter.

All air samplers will run continuously at a flow rate of approximately 40 liters per minute. Samples are collected on 47 millimeter diameter 0.8 micron pore size mixed ester cellulose filter paper. Filters are exchanged weekly.

4.1.3 Sample Analysis

Air samples obtained at the common perimeter of the WSCP and the highway department, the high school, the Army training area, near the WSSRAP Administration Building, by the nearest WSQ resident, and at the Busch Wildlife Area Headquarters will be used to assess effective dose equivalents to a maximally exposed individual. Other sampling locations do not represent potential locations for maximum public exposure because public occupancy times at these locations is negligible.

Each filter, representative of approximately 403,200 liters of air (40 liters per minute times 10,080 minutes per week) will be analyzed for gross alpha concentration. Following gross alpha analysis filters will be cut into three equal sections, with each section placed in an individual envelope. The filters will be cut in thirds for quality assurance. This will allow an evaluation of analytical precision. Three pieces are used because, if an error caused a difference in analytical results between two filter portions, the third portion will allow a determination of which result was erroneous.

In January of each year the three sections of 52 weekly filters will form three composite samples for each of the five

critical receptor locations and the Busch Wildlife Area background station. The 18 composite samples (filter thirds from six sampler locations) will be analyzed for isotopic thorium, isotopic uranium, Ra-228, and Ra-226. Analysis for this suite of radionuclides allows a determination of the concentration of all radionuclides at the Weldon Spring Site which could contribute more than 10 percent of the total effective dose equivalent. Radon and daughters are not included because they are not regulated by 40 CFR 61, Subpart H.

Yearly analyses of the filters is considered acceptable because it meets the intent of 40 CFR 61. The primary method given in 40 CFR 61 of determining effective dose equivalents is through computer modeling. The computer modeling exercise is to be performed and reported annually. Monitoring of airborne concentrations is also allowable. Therefore, a yearly determination of the airborne concentrations and associated effective dose equivalent at critical receptors meets the specifications of 40 CFR 61.

4.1.4 Reports

Reports of environmental monitoring for radionuclide emissions other than radon have been made for calendar years 1986 through 1988 in Annual Environmental Monitoring Reports (DOE, 1986; DOE, 1987a; DOE, 1988). These monitoring reports were transmitted to EPA Region VII. Although the monitoring at critical receptor locations was not sensitive enough to distinguish an annual effective dose equivalent of 0.10 mSv (10 mrem) above natural background, results for years 1986 through 1988 detected no significant difference at the 95 percent confidence level between gross alpha concentrations at critical receptors and the background monitoring station. This was as expected because no significant activities occurred at

the WSS during these years that generated airborne radionuclide emissions.

Beginning with air samples collected during calendar year 1990, results of the monitoring performed as specified in Section 4.1 of this plan and an assessment of the effective dose equivalent at critical receptor locations will be reported in the 1990 Annual Site Environmental Report. These annual reports meet the requirements of 40 CFR 61 because the WSS is being remediated according to CERCLA. This allows EPA oversight which is sufficient to protect the public health by providing EPA Regional Office VII with all the information it needs to assess potential impacts on public health as a result of remediating the WSS.

4.2 COMPARISON TO 40 CFR 61 SPECIFICATIONS

In order to satisfy the sensitivity requirements of 40 CFR 61 through environmental monitoring the following must be met:

1. The air at the point of measurement must be continuously sampled for collection of radionuclides.

2. Those radionuclides released from the facility that are major contributors to the effective dose equivalent must be collected and measured as part of the environmental measurement program.

3. Radionuclide concentrations which would cause an effective dose equivalent of 10% of the standard must be readily detectable and distinguishable from background.

4. Net measured radionuclide concentrations must be compared to the concentration levels in Table 2,

Appendix E of 40 CFR 61. In the case of multiple radionuclides being released from a facility, it must be demonstrated that the value for all radionuclides is less than the concentration level in Table 2, and the sum of the fractions that result when each measured concentration value is divided by the value in Table 2 for each radionuclide is less than 1.

5. A quality assurance program must be conducted that meets the performance requirements described in Appendix B, Method 114 of 40 CFR 61.

This subsection describes how the monitoring program at the WSS will satisfy items 1 through 4. Item 5 is addressed in Section 5.

Items 1 and 2 have been addressed previously. Samplers will run continuously and all major contributors to effective dose equivalent will be collected and measured.

Regarding Item 3, the sampling protocol at the critical receptor locations will be followed at the background monitoring station. Assuming typical Th-232 soil concentrations of 40 Bq/kg (1 pCi/g) and a typical rural airborne dust loading of 16 $\mu g/m^3$ (EPA, 1980), airborne Th-232 concentrations in background air would be 6×10^{-13} MBq/m^3 (2×10^{-17} Ci/m^3). (Th-232 was chosen for this example because it is the greatest contributor to effective dose equivalent.) Assuming continuous inhalation at 20 m^3/day (Cember, 1983) for 365 days/year and using a committed effective dose equivalent conversion factor of 4.43×10^{-4} Sv/Bq (EPA, 1988), a committed effective dose equivalent of 2×10^{-3} mSv (0.2 mrem) is predicted. Since the committed effective dose equivalent for Th-232 is received over a 50-year period the effective dose equivalent received in any single year would be at least a factor of ten lower. For these

TABLE 4-1 Sensitivity Analysis

Radionuclide	Required Sensitivity MBq/m³	(Ci/m³)	Ratio
U-238	3.1E-10	(8.3E-15)	0.018
U-234	2.9E-10	(7.7E-15)	0.020
Th-230	1.3E-10	(3.4E-15)	0.044
Ra-226	1.2E-10	(3.3E-15)	0.045
Th-232	2.3E-11	(6.2E-16)	0.242
Th-228	1.2E-10	(3.1E-15)	0.048
Ra-228	2.2E-10	(5.9E-15)	0.025
		SUM	0.442

reasons the annual effective dose equivalents for each radionuclide in background air is much less than 1×10^{-2} mSv (1 mrem). Monitoring results which attain the sensitivity requirements of Item 4 would, therefore, be readily detectable and distinguishable above background.

The sensitivity of the monitoring method meets the criteria in Item 4. A radiochemical detection limit for each radionuclide of 40 mBq (1 pCi) can be attained (Horton, 1990). By dividing this detection level by the 700 m³ drawn through the filter thirds in each composite sample, an airborne concentration of 5.28×10^{-12} MBq/m³ (1.5×10^{-16} Ci/m³) can be detected. Listed in Table 4-1 are the radionuclides for which monitoring will be performed, the analytical sensitivity specified in Table 2, Appendix E of 40 CFR 61, and the ratio of achievable sensitivity to the required sensitivity. Since the

ratio of the sensitivities for each radionuclide is less than 1.0 and the sum of the ratios is less than 1.0, the proposed analytical method meets the requirements of 40 CFR 61.

5 QUALITY ASSURANCE

This section discusses the quality assurance program that will be conducted to ensure that emission measurements are representative and are of known precision and accuracy. Also included are administrative controls to assure prompt response when measurements indicate unexpectedly large emissions. In addition to complying with all requirements contained in this section, this monitoring program will also comply with the Weldon Spring Site Quality Assurance Program Plan (QAPP) (DOE, 1987b).

5.1 ORGANIZATIONAL STRUCTURE

The responsibility for implementing the emission monitoring program lies within the Environmental, Safety and Health (ES&H) Department. As such, the ES&H Manager has overall responsibility. Actual sampling protocol will be carried out within the Radiation Protection Group under the guidance of the Radiation Protection Manager. Audits will be conducted by the Quality Assurance Department which reports directly to the MK-Ferguson Company Quality Assurance Director. Any corrective actions which require modifications in the way remedial actions are performed at the Weldon Spring Site (WSS) are the responsibility of the Operations Department Manager. The lines of responsibility are shown in Figure 5-1.

5.2 SAMPLE COLLECTION AND ANALYSIS PROCEDURES

Project procedures exist for all phases of sample collection and analysis except for the method of dividing individual filters in thirds and the means of compositing samples. This procedure is currently being drafted and will be forwarded upon completion.

FIGURE 5-1 Lines of Authority

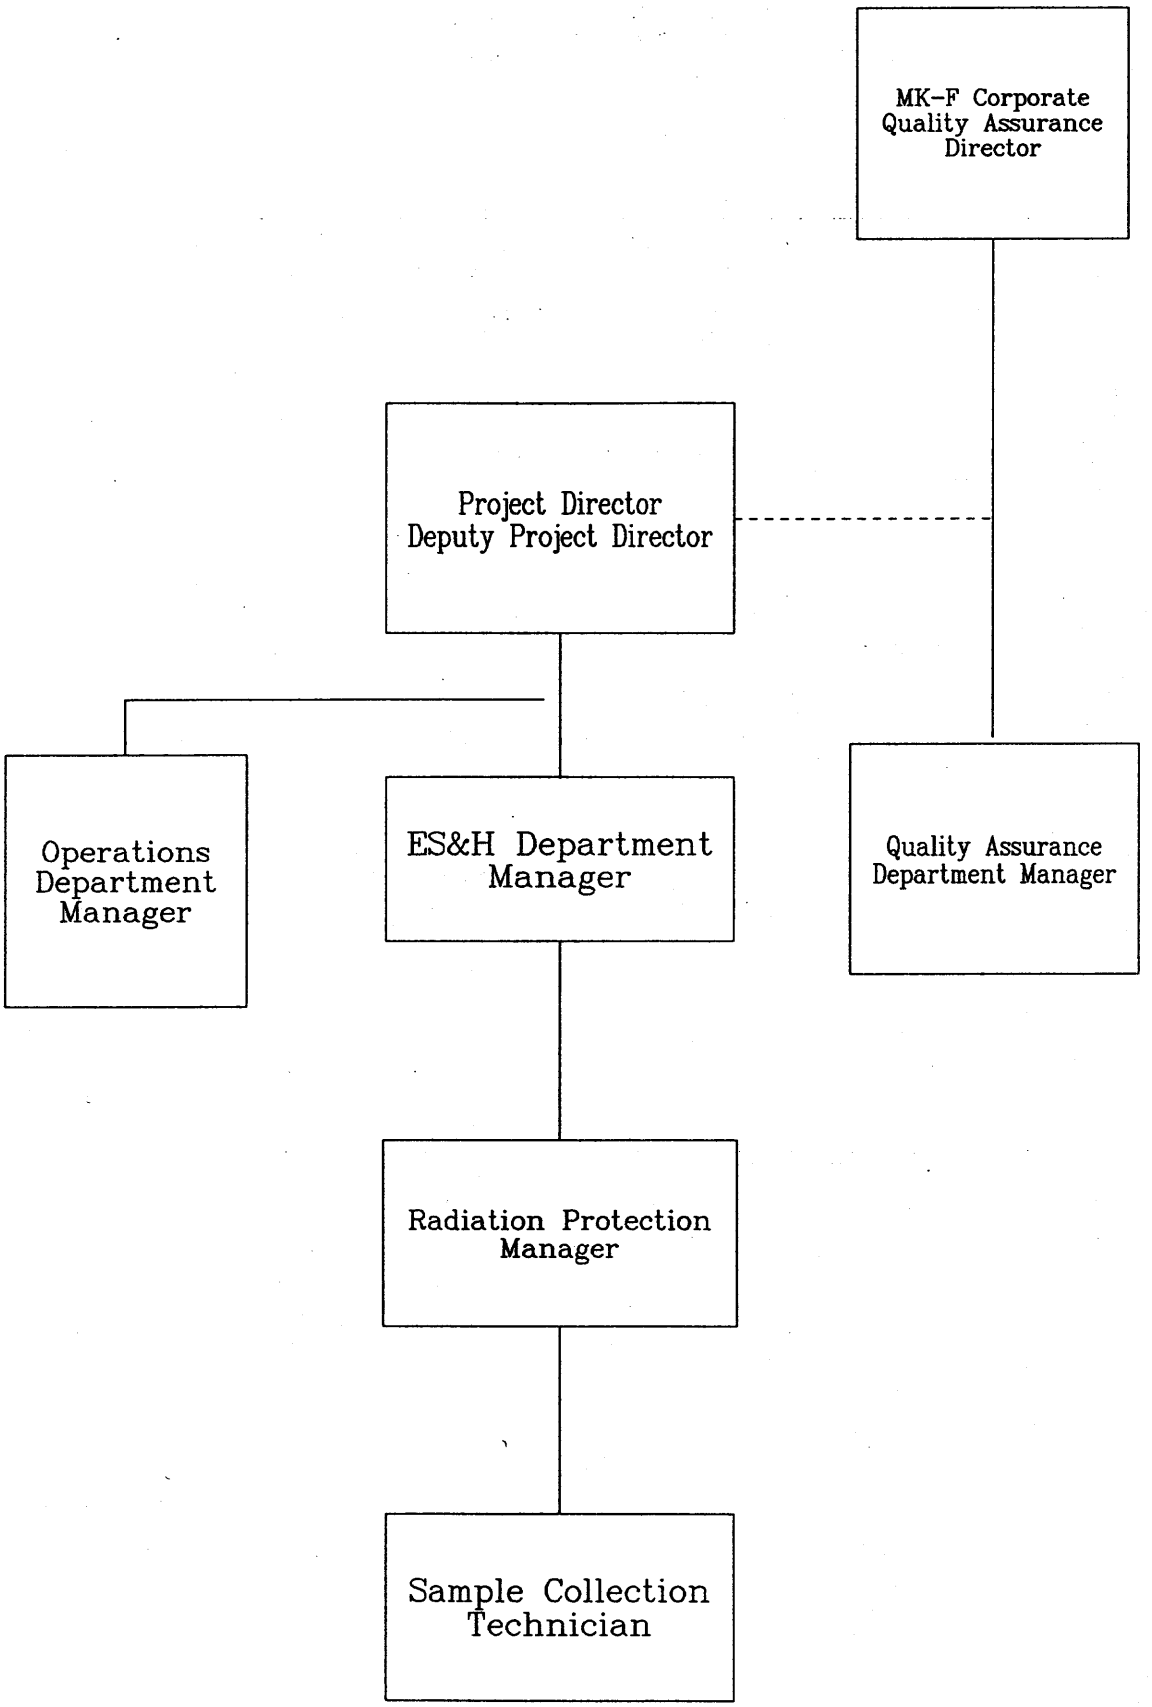

Table 5-1 presents a list of procedures and aspects of the sampling program which they govern. Each procedure is attached to this plan for reference.

Actual radioanalytical procedures are not performed at the site but at a subcontractor laboratory. The radioanalytical procedures used are specified in Table 5-2.

5.3 ADMINISTRATIVE CONTROLS

Assurance that increased radionuclide emissions due to unplanned or unforeseen circumstances can be detected and controlled is achieved through weekly gross alpha analyses of each filter. Isotopes of thorium are the alpha-emitters at the WSS that have the highest potential to cause radiation dose at critical receptor locations. Isotopes of thorium are most prevalent in the quarry and in the raffinate pits. For other site areas such as Weldon Spring Chemical Plant (WSCP) buildings, uranium is the primary contaminant. At the quarry, Th-230 comprises, on average, 33 percent of the total alpha activity contributed by those radionuclides that will be measured at critical receptor locations. At the raffinate pits, Th-230 comprises, on average, 87 percent of the total alpha activity contributed by those radionuclides that will be

measured at critical receptor locations. Clearly, Th-230 has the highest potential to cause a radiation dose at critical receptor locations.

If the potential for a person to receive a yearly effective dose in excess of 0.10 mSv (10 mrem) can be detected on a weekly basis, sufficient control over radionuclide emissions can be attained. This is achieved if a dose equivalent rate of 0.002 mSv (0.2 mrem) per week can be detected. Given a typical weekly occupancy time of five 8-hour days for persons closest to the site where the highest potential airborne concentrations are expected to occur, a quantity of air inhaled during eight hours at work of 10 m^3 (Cember, 1983), and a Th-230 committed effective dose equivalent conversion factor of 8.8×10^{-5} Sv/Bq (EPA, 1989), a dose equivalent of 0.002 mSv/week (0.2 mrem/week) corresponds to an airborne concentration of 4.4×10^{-10} MBq/m^3 (1.2×10^{-14} Ci/m^3).

A natural background gross alpha concentration of $2 \times 10^{-10} \pm 1.2 \times 10^{-10}$ MBq/m^3 at two standard deviations ($5 \times 10^{-15} \pm 3.26 \times 10^{-15}$ Ci/m^3) has been documented at the site (DOE, 1988). It can be seen that a committed effective dose equivalent rate due entirely to Th-230 of 0.002 mSv/week (0.2 mrem/week) can be resolved above natural background gross alpha concentrations. In fact, an effective dose equivalent rate much lower than 0.002 mSv/week (0.2 mrem/week) can be resolved above natural background gross alpha concentrations.

The wastes at the WSS contain a mixture of alpha emitters. Although some of the detected alpha activity will be due to Th-232 and Th-228, which have a higher potential to cause internal dose, a larger percentage of alpha emitters with lower internal dose delivery potential will also be present. This is based on measured radionuclide concentrations in waste

materials. In addition, a Th-230 concentration of 4.4×10^{-10} MBq/m^3 (1.2×10^{-14} Ci/m^3) would result in a committed effective dose equivalent of 0.002 mSv/week (0.2 mrem/week). The effective dose equivalent would be much less because the dose equivalent from inhalation of Th-230 in any given year is spread out over a period of more than 10 years.

To ensure that remedial actions do not result in unplanned or unforeseen airborne radionuclide concentrations at critical receptor locations, a "sliding weekly average" gross alpha concentration will be computed for each critical receptor monitoring station. The sliding weekly average gross alpha concentration will be computed by summing all weekly gross alpha concentrations and dividing by the number of weeks of sampling during a calendar year. As successive weekly samples are analyzed, the results will be used to recompute the sliding weekly average concentration. If a sliding weekly average gross alpha concentration at critical receptor locations in excess of natural background is detected with 95 percent confidence, site operations which may have caused the elevated concentration will be evaluated to determine whether all reasonably achievable dust control measures have been implemented.

A weekly sampling frequency is adequate to control radiation exposures because the 0.10 mSv (10 mrem) level specified in 40 CFR 61 is a long-term standard (i.e. yearly). A response time of one week to control unplanned or unforeseen emissions will be adequate to maintain control over emissions.

5.4 QUALITY CONTROL

The quality control program will include spikes, duplicates, blanks, and control charts. This program is designed to meet the requirements of 40 CFR 61, Appendix B.

With each group of filters sent for radiochemical analysis, two filters will be spiked with known activities of Th-230 and two filters will be spiked with known activities of natural uranium (U-238, U-235, and U-234 in natural activity ratios).

Since each filter composite collected at critical receptor locations is cut into thirds, these filter thirds will serve as duplicates. Five percent of all gross alpha analyses are repeated to verify detector performance.

Field blanks are used each week when air filters are exchanged. These will be composited and analyzed radiochemically following analysis for gross alpha activity. In addition, each week an unused filter is analyzed for gross alpha activity. These filters will be composited and analyzed radiochemically.

Control charts are maintained to verify gross alpha detector performance. A control chart is generated to track daily detector background and daily certified standard source checks. Daily background and source counts must fall within three standard deviations of values posted when the detectors undergo semiannual calibration (MKF and JEG, 1989).

In addition to the system of spikes, duplicates, blanks, and control charts the radioanalytical analyses will be evaluated for internal consistency. At the WSS, U-238 and U-234 are in secular equilibrium. Uranium concentrations on air filters should also be in equilibrium. When radioanalytical results are provided, the degree of equilibrium will be evaluated. In most cases, Th-228 and Ra-228 are also in equilibrium. Equality between these radionuclides will also be evaluated.

5.5 DATA QUALITY OBJECTIVES

Accuracy and precision of radiochemical analyses will be measured at the 85 percent confidence level. Accuracy, as determined with the results of spiked samples, will be considered acceptable if analytical results of spiked samples are within $\pm$50 percent of known values for 85 percent of all samples. Precision will be determined by averaging the results of the three duplicate analyses. Precision will be considered acceptable if the standard deviation of duplicate analyses is within $\pm$50 percent of the average for 85 percent of the duplicate data sets. Analytical precision will also be calculated for U-238/U-234 for each composite sample. Precision will be considered acceptable if the standard deviation of the U-238/U-234 results for each composite sample are within $\pm$ 50 percent of the average for 85 percent of all samples.

Accuracy and precision of gross alpha analyses will be measured at the 95 percent confidence level. Accuracy, as determined by the daily source counts, will be considered acceptable if 95 percent of all daily values fall within three standard deviations of the certified standard source. Precision, as determined by the results of duplicate analyses, will be considered acceptable if 95 percent of the duplicate counts are within three standard deviations of the original count.

5.6 AUDITS

Internal audits will be conducted yearly by the WSSRAP Quality Assurance Department in accordance with the WSSRAP QAPP. The primary purpose of the audits will be to assure that sample collection, sample compositing, gross alpha analyses, and sample chain of custody are performed according to standard operating procedures. The internal audits will also ensure

conformance with this overall "Plan for Monitoring Radionuclide Emissions Other Than Radon at Weldon Spring Site Critical Receptors."

External audits of the radioanalytical laboratory will also be performed annually by the WSSRAP Quality Assurance Department. These audits will ensure conformance of the radioanalytical laboratory to standard operating procedures.

5.7 CORRECTIVE ACTIONS

If data quality objectives are not met, the Radiation Protection Manager will provide a report evaluating the reasons for noncompliance and providing a statement of required corrective actions. The Environmental Safety and Health Manager will ensure the appropriateness of the recommended corrective actions and ensure that corrective actions are implemented in a timely manner.

If results of gross alpha analyses indicate detectable emissions of radioactive particulates at critical receptor locations the Radiation Protection Manager shall inform the Operations Department Manager. The Operations Department Manager will be responsible for ensuring that emissions are controlled to a level which is as low as reasonably achievable.

5.8 REPORTS

Emissions measurement program results including assessment of data quality, results of internal audits and corrective actions, if any, shall be prepared annually.

1 INTRODUCTION

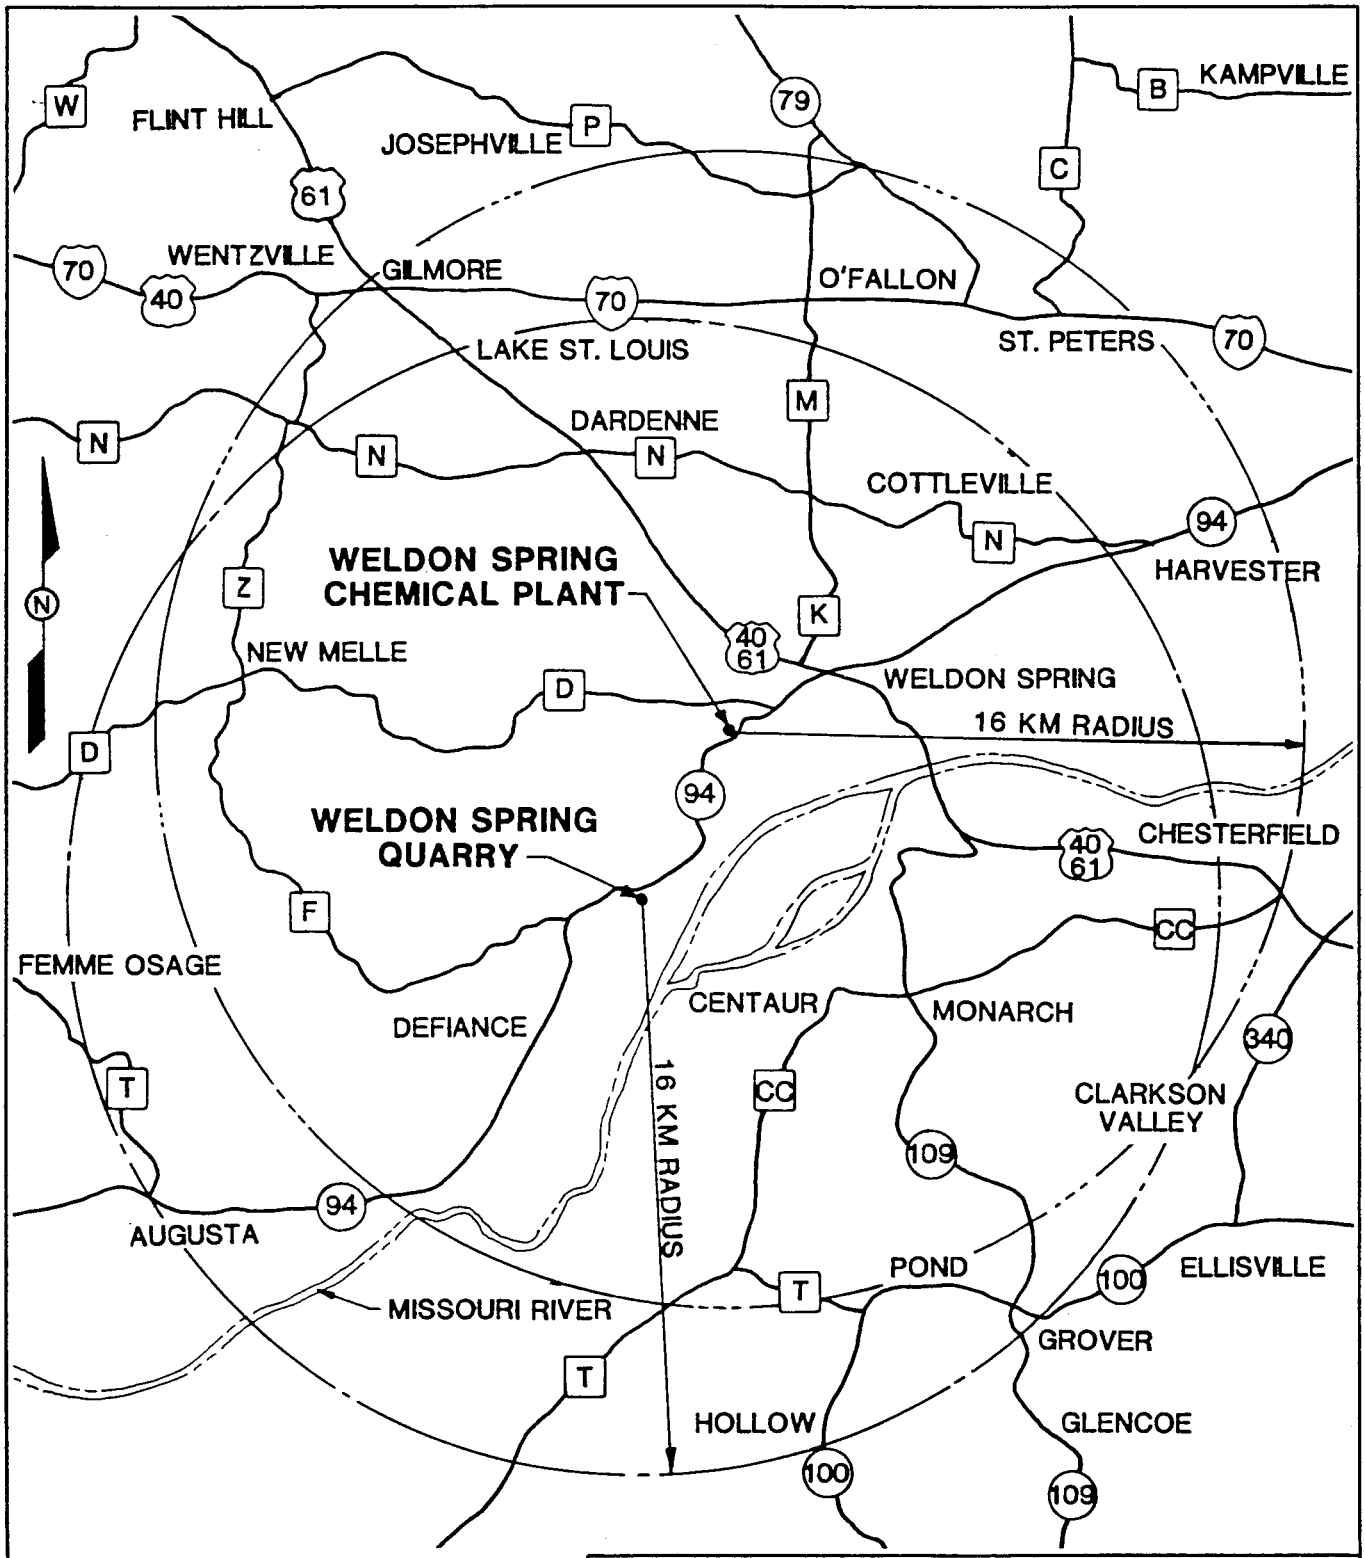
The following sampling plan is prepared in response to U.S. Department of Energy (DOE) requirements for analysis of "foodstuffs" in the *Environmental Regulatory Guide for Radiological Effluent Monitoring and Environmental Surveillance* (January 1991). In addition to these requirements, the plan responds to public concern about the potential for contamination of corn crops growing in the St. Charles County well field at the Weldon Spring Wildlife Area. The well field is located adjacent to the Femme Osage Slough near the Weldon Spring Quarry. Uranium concentrations in the slough have ranged from a low of ND to a high of 557 pCi/l, with an average around 54.8 pCi/l (MKF and JEG 1991).

The scope of this plan has been broadened to include agricultural grain products other than corn, such as soybeans, millet, and grain sorghum. Most of the land surrounding the Weldon Spring site and the Weldon Spring quarry consists of deciduous hardwood forest interspersed with old fields and croplands. Together, the Busch Wildlife Area, the Weldon Spring Wildlife Area, and Howell Island are comprised of approximately 64% forest, 17% cropland, and 15% old field (MDOC 1989). Portions of the Busch Wildlife Area and the Weldon Spring Wildlife Area are leased to sharecroppers for farming. In return, the farmers leave a portion of their crop for wildlife consumption. Along with surrounding Missouri Department of Conservation (MDOC) farmlands, there are numerous local farms in the vicinity of the Weldon Spring Chemical Plant and quarry.

1.1 Purpose

The purpose of this sampling plan is to characterize concentrations of radionuclides in agricultural products and to determine types of crops grown in the Weldon Spring area. This sampling plan describes the requirements for agricultural sampling to determine what environmental monitoring activities may be required in the future at the Weldon Spring Site Remedial Action Project (WSSRAP). By using this tiered approach, sampling can focus on food stuffs and feed products to determine the need for second tier sampling of milk, eggs, poultry, etc.

The areas to be sampled are within 16 km of either the Weldon Spring site boundary and the Weldon Spring quarry boundary (Figure 1-1) as designated by the guidance in Environmental Regulatory Guide (DOE 1991). The site and the quarry are approximately



SITE SURVEY RANGE

FIGURE 1-1

0 5 MI
0 8.05 KM
SCALE

REPORT NO.:		EXHIBIT NO.: A/VP/097/0791	
ORIGINATOR: MGT	DRAWN BY: GLN	DATE: 7/91	

6.4 km apart. Since the sample areas overlap, samples will be taken in both the overlap and non-overlap areas. Background locations will be outside the 16 km radius of both areas.

1.2 Scope of Work

This sampling plan defines field methods for obtaining agricultural samples, sample selection, analytical requirements and methods, and quality control measures.

Sampling of agricultural products will take place just before harvesting commences. This will require close communication between the Project Management Contractor (PMC), the Missouri Department of Conservation, and farmers.

Surveying local farms will require contact with Agricultural Stabilization and Conservation Service (ASCS) to determine what crops have been planted in St. Charles County including portions of Franklin and St. Louis counties and the percentage of each. Also, local farmers will be contacted, if necessary, on the basis of sample selection.

1.3 Objectives

Sampling will be conducted to achieve the following objectives:

- Characterize background radiological levels in agricultural (foodstuffs) products.
- Determine the concentration of radionuclides in agricultural products near the site.
- Determine whether crops grown within the study area (Figure 1-1) contain significantly higher levels of radionuclides in excess of background.
- Make recommendations on environmental surveillance for agricultural products.
- Summarize agricultural practices surrounding the WSS.

1.4 Sample Collection

Sample collection will be based upon farming practices in the areas of concern. Information on farming practices is provided by the County Soil Conservation Service. There will be 20 samples taken in the overlap area, 10 samples in each nonoverlap area, and 20 samples outside the radius for a total of 50 samples, plus the quality assurance samples. Samples will be taken with consideration given to the distance from the contamination source. These locations will be representative of crop areas around the Weldon Spring Chemical Plant (WSCP), crop areas around the quarry, crops in the overlap area between the WSCP and the quarry[1], and background crops.

For agricultural products, approximately 1 kg will be sent for each sample. Only grain portions of the agricultural products gathered will be sent to the laboratory for analysis. The exception to this will be corn samples which along with grain will also include samples of (1) an entire corn stalk, excluding roots, (2) leaves only, and (3) cobs. Any soil will be removed from the samples prior to shipping. Samples will be collected and documented using the Biological Sample Collection Form (Figure A-1).

Soil samples will be collected at each location in accordance with ES&H SOP 4.4.5s, *Soil/Sediment Sampling*. These samples will be subject to the same quality control sampling as the agricultural samples. All sampling equipment will be decontaminated after each sample as specified in ES&H SOP 4.1.3s, *Sampling Equipment Decontamination*. A soil sampling form will be completed for each sample, see Figure B-1.

In addition to crop sampling, informal garden surveys will be conducted within the 16 km radii. This survey will be used to gather general information and to plan future argricultural sample plans deemed necessary from the 1992 study. Information collected will include, but not be limited to, garden size, variety of species, and final destination of the product. If livestock are present, this will be noted in the logbook as specified in Environmental, Safety and Health (ES&H) Standard Operating Procedures (SOPs) 1.1.4s, *Logbook Procedure*.

---

[1] Sampling will be concentrated in locations nearest to, and downwind of, the WSCP and the quarry.

1.5 Sample Location and Identification

Exact sample locations will be chosen in the field and will be mapped and described on the field sheet. Sample locations will be at least a quarter of a mile apart.

Samples will be labelled in the format, BG-XXXX-MMDDYY, which will identify the samples by biological matrix (BG), agricultural products, and date sampled. The 3rd and 4th spaces will designate sample location. The 5th and 6th spaces will distinguish what type of agricultural product is being sampled. The last six digits will represent the date sampled. Sample identification and location will be reported on field sheets.

1.6 Background Samples

Background samples will be taken from areas outside of the 16 km radius and include crops found in the study area. Background samples will equal the total number of study samples taken. All background samples will be collected, identified, and recorded in the same manner as the study samples.

1.7 Analytical Requirements

Crop and soil samples will be analyzed for total uranium, Ra-226, Ra-228, and isotopic thorium. All samples will be field screened for radioactive contamination prior to shipment to off-site analytical laboratories. Laboratories performing radiological analyses for the WSSRAP are required to have an approved quality assurance laboratory plan and procedures. This QAPP details specific measures which the laboratory will implement to ensure data quality.

Data Quality Requirements (DQRs) are quantitative statements of selection, accuracy, and precision which specify the quality of data needed to support specified data uses. DQRs for this effort will be consistent with those established for routine environmental monitoring which are documented in the Environmental Data Administration Plan (EDAP) (MKF and JEG 1990).

Table 1-1 Requirements for Agricultural and Soil Samples

	Methods	Lower Limit of Detection	Sample Amount
Agricultural Samples:			
Total Uranium	EPA 908.1	1.0 pCi/g	500 grams
Radium-226	EPA 900.1	1.0 pCi/g	500 grams
Radium-228	EPA 904	1.0 pCi/g	500 grams
Isotopic Thorium	EPA 907	1.0 pCi/g	500 grams
Soil Samples:			
Total Uranium	EPA 908	1.0 pCi/g	500 grams
Radium-226	EPA 900.1	1.0 pCi/g	500 grams
Radium-228	EPA 904	1.0 pCi/g	500 grams
Isotopic Thorium	EPA 907	1.0 pCi/g	500 grams

1.8 Quality Assurance Samples

Quality control samples will be obtained for every 20 samples to assess laboratory performance and analytical precision. These samples will include duplicates, matrix spikes, matrix spike duplicates, and field blanks.

The labeling of QA samples will follow the same format as other samples collected with the addition of a two-character modifier at the end of the ID number.

Duplicate	XX-XXXX-XXXXXX-DU
Matrix Spike	XX-XXXX-XXXXXX-MS
Matrix Spike Duplicate	XX-XXXX-XXXXXX-MD
Field Blank	XX-XXXX-XXXXXX-FB

1.9 Sample Shipment and Chain of Custody

Samples will be shipped to off-site analytical laboratories for analysis. Sample chain of custody will comply with WSSRAP SOP ES&H 4.1.2. Shipment and packaging samples will follow Regulatory Compliance Procedures RC-11, RC-17, RC-19s, and RC-22s.

2 DATA REPORTING

Data collected during background sampling will be reported and interpretation and determinations will be made on minimum background levels of uranium, Ra-226, Ra-228, and isotopic thorium for agricultural products. These background samples will represent normal radionuclide levels in noncontaminated areas.

Data collected from study areas and from background samples will be interpreted and tested under various statistical methods. The statistical tests will determine whether concentrations found in agricultural crops within the 16 km vicinity of the Weldon Spring site (WSS) have significantly higher level of radiological concentrations than those outside the 16 km radius at a 90% confidence level.

One of two statistical tests will be used to make the determination; the Student's T-test or the Mann-Whitney U-test. The determination of which statistical test to use is based upon whether the distribution of data populations can be assumed to be normal, and whether the variances among sample populations (background and vegetative debris) are equal. Preliminary tests of variance and normality will be determined by using the W-test and F-test. For the W-test data reported as non-detects or less than the detection limit (DL) will be quantified as DL/2 per EPA guidance (EPA 1991).

Information gathered from agricultural sampling will also be compared to data results of soils taken from sample locations and the distance from source (either Weldon Spring Chemical Plant (WSCP) or Weldon Spring quarry (WSQ)). Correlation tests will be used to determine if any relationship can be drawn between soils, distance, and agricultural concentrations of radionuclides.

All data will be presented in a report prepared following the Format Guide for Formal Reports, Rev. 2 February 1991.

3 DATA ADMINISTRATION

Data will be reviewed and quality control samples compared following standard operating procedures (ES&H 4.9.1a, RC-31a) and the *Environmental Data Administration Plan* (MKF and JEG 1990).

Quality Assurance procedures will follow the guidelines established in the *Environmental Quality Assurance Program Plan* (MKF and JEG 1991).

SMALL MAMMAL SAMPLING PLAN

The subject sampling plan is enclosed for your review. The sampling plan is prepared in response to U. S. Environmental Protection Agency requirements for establishing baseline risk assessments for biota residing on or near the Weldon Spring Site Remedial Action Project (WSSRAP), as part of the Comprehensive Environmental Response, Compensation and Liability Act Remedial Investigation/Feasibility Study process.

This plan includes sampling small mammals such as rats, mice and shrew located on WSSRAP and surrounding areas to determine general population numbers, species presence, and any abnormalities which may be occurring within individuals of these species or communities of small mammals.

If you have any comments, please contact Alan D. Gibson.

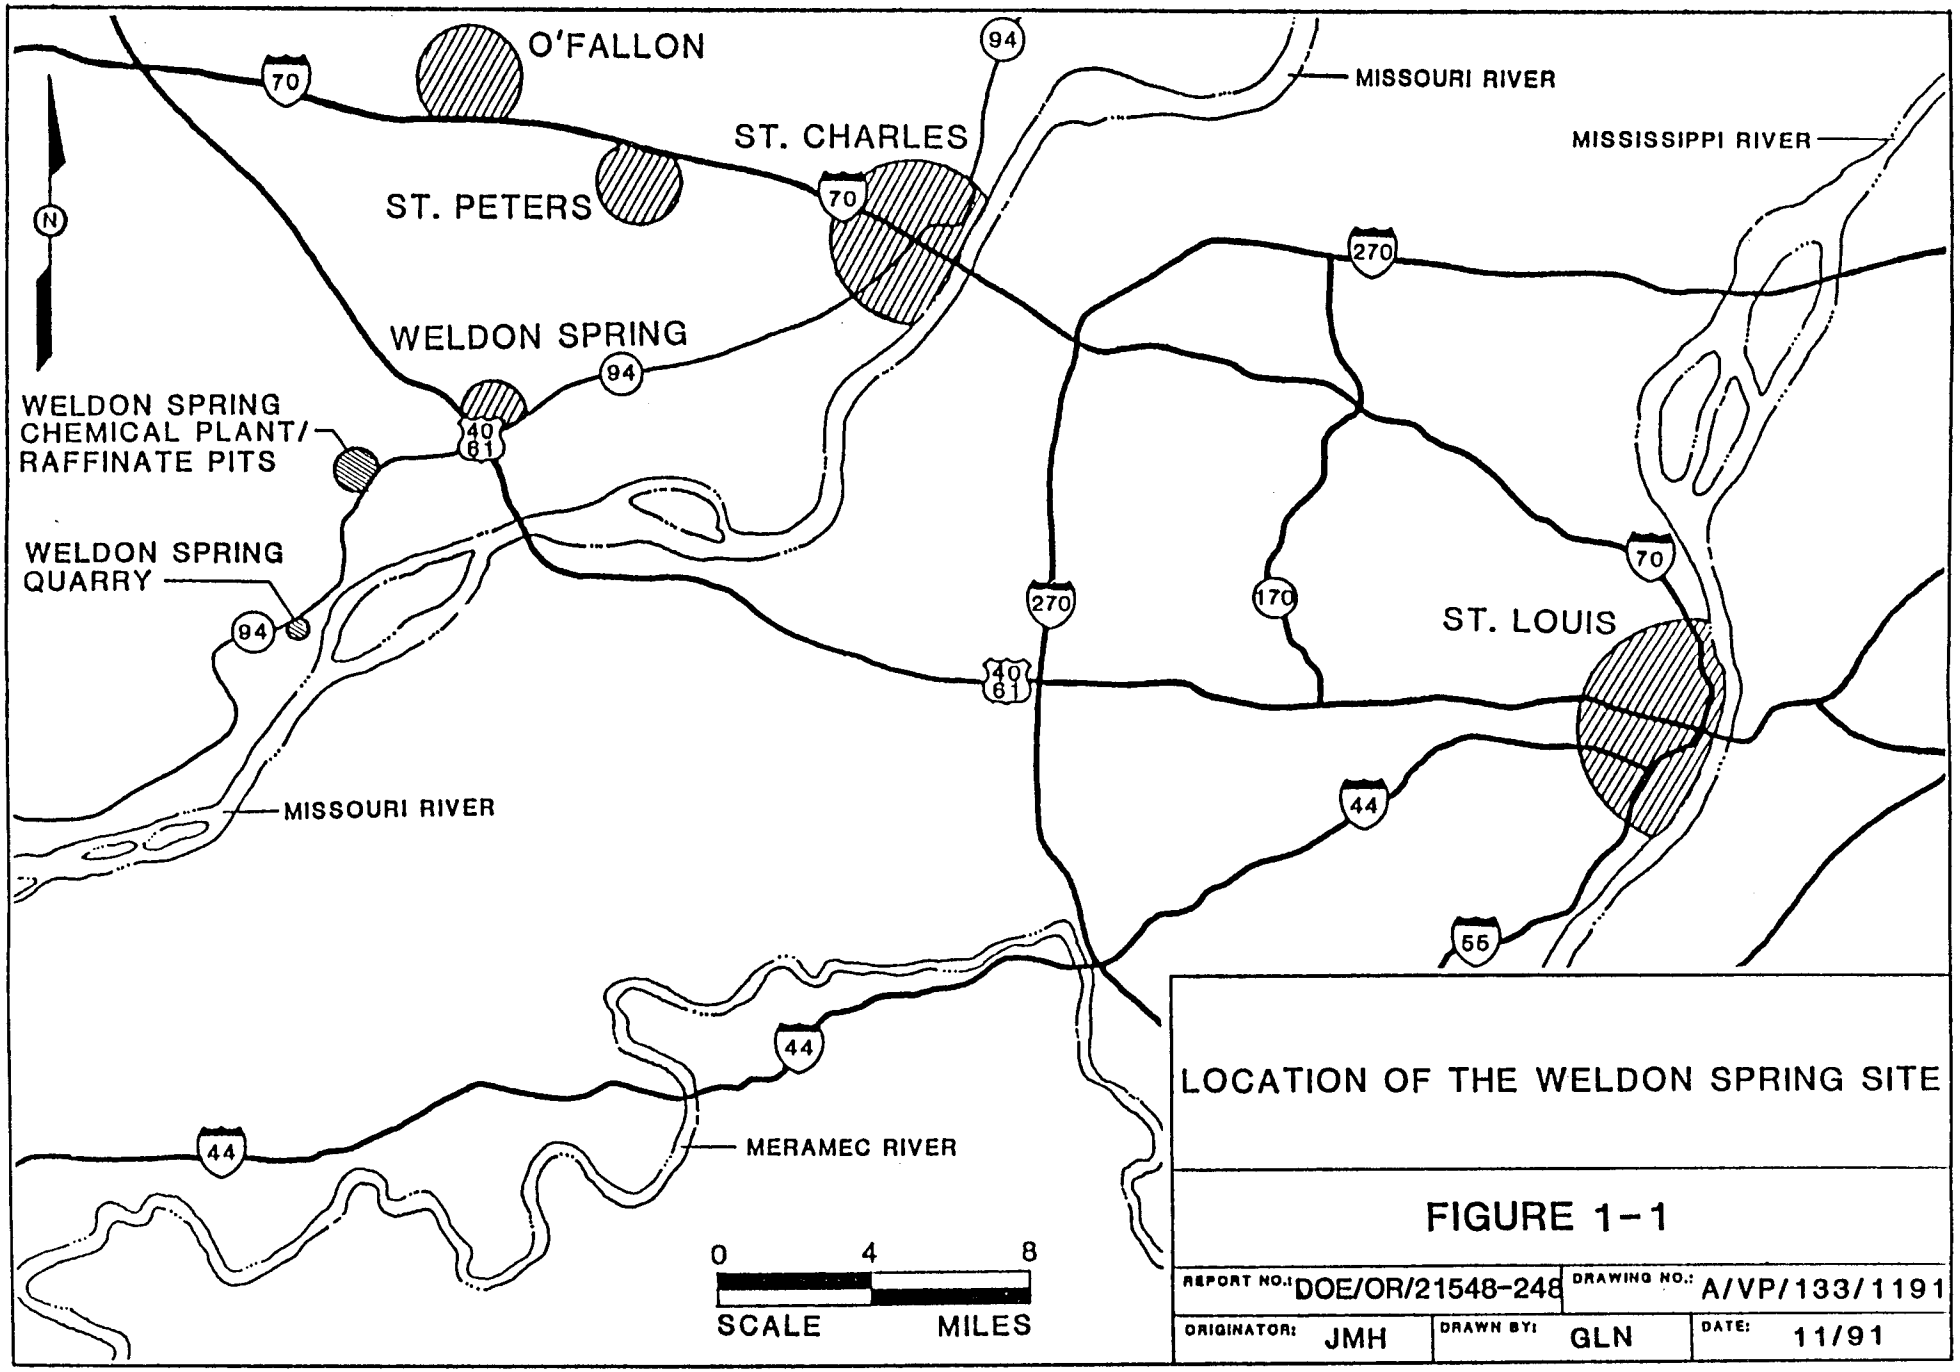
1 INTRODUCTION

The Weldon Spring Site Remedial Action Project (WSSRAP) is being conducted as a Major Systems Acquisition under the Surplus Facilities Management Program (SFMP) of the U.S. Department of Energy (DOE). The major goals of the SFMP are to eliminate potential hazards to the public and the environment that are associated with contamination at SFMP sites and to make surplus real property available for other uses to the extent possible. The WSSRAP consists of two main areas. The Weldon Spring Chemical Plant (WSCP) and the Weldon Spring Quarry (WSQ) (Figure 1-1).

The following sample plan is prepared in response to U.S. Environmental Protection Agency (EPA) requirements for establishing baseline risk assessments for biota residing on or near the Weldon Spring Site Remedial Action Project (WSSRAP), as part of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) Remedial Investigation/Feasibility Study (RI/FS) process. This study comprises a portion of the comprehensive, year-round program to monitor the impact of the contaminants from the Weldon Spring site (WSS) on the surrounding region's groundwater, surface waters, and soil properties through multiple pathways, including monitoring for potential exposure to non-receptor human populations. The chemical plant area has largely been characterized as part of the WSCP RI/FS investigation. The WSCP is one of four separate operable units (SOUs) that have been created in order to facilitate the remedial decision making. The other SOUs are quarry bulk wastes, site groundwater, and quarry residuals area. A portion of this sampling plan is directed at the quarry residual areas and is part of the ecological characterization requirements for the residual RI/FS. The quarry residual area includes the quarry proper and surrounding vicinity properties including groundwater. The regulatory requirements are detailed in the *Weldon Spring Quarry Residual Work Plan* (MKF and JEG 1991a). The other areas included in this plan are being studied as part of the on-going environmental monitoring program.

This plan includes sampling small mammal populations located on the WSS and surrounding areas, to determine general population numbers, species presence, and any abnormalities which may be occurring within individuals of these species or communities of small mammals. Small mammals such as mice, rats, and shrew serve as prey species to indigenous and transient species, some of which may be federally or state endangered. Additionally, these small mammals utilize the same resources as larger species, such as deer, which are hunted within this region and are part of the human food chain.



LOCATION OF THE WELDON SPRING SITE

FIGURE 1-1

REPORT NO.:	DOE/OR/21548-248	DRAWING NO.:	A/VP/133/1191		
ORIGINATOR:	JMH	DRAWN BY:	GLN	DATE:	11/91

As indicated by Douglas (1989), rodents are recommended for use in ecological monitoring at the population level because they are small, easy to handle, and spend their entire life cycle within a relatively small area. Additionally, the majority of avian and terrestrial carnivores, to a greater or lesser degree, utilize a rodent prey base (Douglas 1989).

Small mammals are prey for birds, snakes, and other mammals. The American kestrel, red-tailed hawk, barred owl, eastern screech owl, and the great horned owl have been sighted in the study area (MKF and JEG 1991b). Small mammals make up no less than 70% of these species' diet (Toland 1985, Wilson 1984). Other birds that prey on small mammals that potentially occur in the study area are listed on the State and/or Federal list of threatened and/or endangered species (Table 1-1).

Snakes that are known to occur within the study areas and prey on small mammals include: the black rat snake, bull snake, kingsnake, red milk snake, eastern yellowbelly racer, copperhead, and the timber rattlesnake (Johnson 1980). Larger mammals include the coyote, red fox, gray fox, skunk, and bobcat. Of the mammals that may be encountered at any of the sites, only the long-tailed weasel is listed on the State list as "rare."

Biouptake studies are conducted to determine possible exposure pathways of radiological and chemical contamination to humans by ingestion of potentially contaminated fish and game. The Project Management Contractor (PMC) began biouptake studies at the WSS in 1987. These studies have included mammals (rabbits, squirrels, and deer), reptiles (snapping turtle),and fish (large mouth bass, crappie, catfish, and sunfish). These studies are typically planned sampling events, but opportunistic sampling is also incorporated into the program. No significant biological uptake of radiological contaminants has been detected in either the fish or small mammals. Fish were also sampled for metals and showed low concentrations of chromium, arsenic, lead, and other metals which were slightly above the detection limit. These concentrations of metals are not a product of the WSS, but have been shown to be attributable to normal bioaccumulation. Radionuclide bioaccumulation factors were low, and conservatively overestimated doses would still result in negligible exposures (MKF and JEG 1989a).

A variety of wastes are present at the WSSRAP, and have been largely identified at the chemical plant during past site investigations and history of use at the WSS. The groundwater, surface water, springs and soils from various locales on the WSSRAP exhibit various amounts of nitroaromatics, inorganic ions, and radiological contaminants. Detailed information can be

Table 1-1 List of Threatened or Endangered Birds of Prey Potentially Occuring in the Study Area

Common Name	Diet on Small Mammals	Abundance[1]	State Status[2]	Federal Status[3]
Bald Eagle	Not usually small mammals	r	E	E
Cooper's Hawk	60-80%	ca	R	-
Northern Harrier	15-25%	u	E	-
Sharp-shinned Hawk	2-6%	ca	R	-
Red-shouldered Hawk	40-60%	r	WL	-
Mississippi Kite	10%	-	R	-

Notes:

[1] Abundance (MDOC 1991a)

u = uncommon, fairly frequent reports, in small numbers
r = rare, sparingly recorded but generally every year
ca = casual, has been recorded but not every year

[2] State Status (MDOC 1991b)

E = Endangered
R = Rare. Rare indicates present in small numbers. If environment worsens, status in Missouri could deteriorate to Endangered
WL = Watch list. Not currently rare or endangered, but has a restricted distribution or has experienced sufficient decline to indicate it may soon become Rare or Endangered.

[3] Federal Status (MDOC 1991b)

E = Endangered throughout range.

obtained in the *Annual Site Environmental Report* (MKF and JEG 1991c) and the *Draft Remedial Investigation Report for the Weldon Spring Site* (MKF and JEG 1991d). As part of the quarry residuals RI/FS investigation, soil, surface water, and groundwater will also be characterized for contaminates. Details of this program are outlined in the *Weldon Spring Quarry Residual Work Plan* (MKF and JEG 1991a).

1.1 Purpose

The purpose of this sampling plan is to determine if contaminants, primarily radionuclides, may be effecting small mammal populations utilizing the Weldon Spring site and vicintiy properties.

Field monitoring of resident small mammal populations can play a major role in defining the extent and scope of environmental impact, because:

- Resident organisms are continuous monitors of environmental quality.
- Accurate qualitative field assessments of natural populations directly measure adverse effects of the environmental parameters.
- Data is amenable to statistical analysis for interpretation.

1.2 Scope of Work

This sampling plan defines field methods for: measuring small mammal populations, obtaining small mammal samples, sample selection, analytical requirement and methods, and quality control measures.

Sampling of small mammal populations will occur during two distinct sampling seasons: winter (February 1992) and spring (April - May 1992). Nineteen sampling sites have been selected as representative of both control and potentially contaminated areas.

Because this will be a very limited study, it will not be possible to detect differences in population densities or fluctuations, nor to accurately assess impact. However, the utilization of background areas selected for the close similarity to the possibly-impacted areas will provide a relative comparison. As noted in an U.S. Environmental Protection Agency (EPA) Risk Assessment Forum, estimation of animal numbers at any one point in time is difficult. Ideally, population surveys should be based on several years of correlative background data and be conducted over an extended time frame, but in most instances this is cost-prohibitive (EPA 1991). The goal is to determine the presence and useage of the area by small mammals and their potential effect on threatened and/or endangered species and game species.

1.3 Objectives

Sampling will be conducted to achieve the following objectives:

- Provide a representative sampling of the taxa of small mammals present on the WSS and the surrounding area to determine approximate population numbers and genera represented.
- Determine usage of study areas by small mammals.
- Characterize background radionuclide levels in resident small mammal populations.
- Continue monitoring of the Weldon Spring Chemical Plant.
- Determine the concentration of radiological residues in selected tissues of resident small mammals located on or near study sites.
- Determine whether tissue obtained from small mammals located within the study areas contain significantly higher levels of radionuclides in excess of background.

2 SAMPLE LOCATION AND IDENTIFICATION

Sites of collection transects are outlined on Figures 2-1, 2-2, 2-3, and 2-4, and include:

- Site No. 1, perimeter of Weldon Spring Quarry (WSQ) fence.
- Site No. 2, vicinity property No. 9.
- Site No. 3, Agricultural fields.
- Site No. 4, upper southeast drainage of WSQ toward vicinity property No. 9.
- Site No. 5, Little Femme Osage Creek drainage.
- Site No. 6, Bottomland Forest of the southern arm of the Femme Osage Slough.
- Site No. 7, background locality for Sites Nos. 4 and 7.
- Site No. 8, background locality for Site No. 2.
- Site No. 9, upper southeast drainage of Weldon Spring Chemical Plant (WSCP) toward Missouri River.
- Site No. 10, lower southeast drainage of WSCP toward Missouri River.
- Site No. 11, background for Sites Nos. 12 and 13.
- Site No. 12, bottomland palustrine forest near Ash Pond.
- Site No. 13, mixed deciduous (upland) forest, near North Dump
- Site No. 14, Frog Pond and drainage

All samples will be collected, identified, and recorded in the same manner.

3 SAMPLE DESIGN AND METHODS

For this study, Sherman live traps are specified, for they are inexpensive, easily transported and set, and can be thoroughly cleaned following recovery from contaminated sites. Trap placement will be along a 100 m transect and the majority of captured small mammals will be returned alive to the field. For purposes of indicating that an animal has been captured, sequentially numbered humane ear tags will be used.

Each sampling period will consist of two trapping days, a two weeks, intervals followed by two more trapping days, for a total of 4 trapping days per period. Live trapping will occur 4 days during February 1992 (1420 trap nights) and 4 days during April - May 1992 (1420 trap nights) for a total of 2840 trap nights. On Day 1 of a given sampling period, the captured animals will have the appropriate data recorded, be ear tagged with sequentially numbered tags, and released. On Day 2, captured animals will again have the appropriate data recorded and released. The last trapping day of each sampling period, 10 snap traps per transect will be set for obtaining samples. The number of snap traps may be increased or decreased by the subcontractor depending upon the densities encountered the pervious trapping days. If possible, four animals (preferably two male, two female) per genera will be selected at random for biouptake of radionuclides. During dissection, reproductive status, litter size, and any abnormalities will be recorded (for each individual) in the logbook. Whole small mammals and organs will be stored at 4°C and sent to an analytical laboratory to be analyzed for total uranium, Thorium 228/230/232 and Radium 226/228. If visible dirt remains, whole specimens will be rinsed off with deionized water. The decision to composite samples will be made by the Contractor at the time of dissection when the amount of samples collected can be assessed. Samples will be placed in plastic bags and labeled. Labels will include the sample date, sample identification number, taxonomic identification, and sample location.

There are 19 sampling areas, each with a 100 m transect. Each transect will have 20 alternating sized traps. Two sizes of Sherman live traps will be used: approximately 8.0 cm x 8.0 cm x 25.5 cm and 10.2 cm x 10.2 cm x 22.9 cm. Traps will be placed at 5 m intervals along each transect within the indicated areas on Figures 2-2 through 2-5. No transect will be established within 100 m of any other transect. Bait will be peanut butter balls or other appropriate bait. Modification of this pattern will be dictated by such site-specific constrains as slope, presence of water/sludge or extremely wet conditions, and will be determined by the contractor at time of trap deployment. Once in the field, two transects may be placed at a site

if deemed possible by the contractor. Transects must be at least 100m apart to ensure that the same population is not being sampled. If the number of transects is increased then the number of trap nights will be increased to a maximum of 5,680 trap nights.

During the February sampling period, traps will be established in the field transects in late afternoon and collected within two hours. Traps will be partially filled with cotton to provide nesting material to prevent loss of animal due to hypothermia. If an animal is found dead in a trap, it will be returned to the laboratory for dissection and included in data. During the April sampling period, traps will be established in the field transects on the afternoon previous to the morning retrieval of animal from the traps, if weather permits. If cold weather occurs, February sampling protocol will be observed. Traps will not remain in the field between sampling periods.

3.1 Small mammal field data

The following field data will be recorded on the small mammal survey form (Appendix A), and includes:

- Taxonomic identification of species.
- Sex.
- Age (juvenile, subadult, adult).
- Reproductive condition.
- Total body weight (g).
- Length of foot (mm).
- Length of tail (mm).
- Length of right ear (mm).
- For Day Two, notation if animal is recaptured from previous day.
- Trap number and size.

3.2 Soil Sampling

Soil samples will be taken at each transect after the last sampling period. Each transect will have four distinct samples. Four soil samples will be collected along each transect from trap Numbers 1-5, 6-10, 11-15, and 16-20. The sample will be taken from a depth of 0-6 in. using a bucket auger. Environmental Safety and Health (ES&H) Standard Operating Procedure

(SOP) 4.4.5s will be followed. The equipment must be decontaminated between each sample (ES&H 4.1.3s). All information will be recorded on a Soil/Sediment Sampling Form (Appendix B).

3.3 Quality Assurance Samples

Quality control samples will be obtained for every 20 samples to assess laboratory performance and analytical precision. These samples will include duplicates, matrix spike, and matrix spike duplicates.

3.3.1 Duplicate Samples

Both soil and tissue samples will have one duplicate sample taken for every 20 samples. The following two-character modifier will be added at the end of the ID number.

Biological tissue	BG-XXXX-XXXXXX-XXXX-DU
Soil	SO-XXXX-XXXXXX-DU

3.3.2 Matrix Spike/Matrix Spile Duplicate Samples

Only soil samples will be required to have matrix spike and matrix spike duplicates taken every 20 samples. The following ID number format will be used.

Matrix spike	SO-XXXX-XXXXXX-MS
Matrix spike duplicate	SO-XXXX-XXXXXX-MD

4 ANALYTICAL REQUIREMENTS

Small mammals used for biouptake samples will be field screened for radioactive contamination prior to shipment from the Weldon Spring Site Remedial Action Project (WSSRAP) for further analysis. Laboratories performing analyses for the WSSRAP are required to have an approved quality assurance laboratory plan and procedures.

Data Quality Requirements (DQRs) are quantitative statements of selection, accuracy, and precision which specify the quality of data needed to support specified data uses. DQRs for this effort will be consistent with those established for routine environmental monitoring which are documented in the *Environmental Data Administration Plan* (EDAP) (MKF and JEG 1990). Specific DQR's for this sampling plan are listed in Appendix B. Percision will be 90% and a detection limits of 1.0 pCi/l.

Based on the WSSRAP's consistent exercise of quality assurance measures, in the form of both quality control sample collection and standard operating procedures, this survey will report all routine monitoring data and results.

4.1 ANALYTICAL PARAMETERS

Small mammals:	Total Uranium
	Thorium 228/230/232
	Radium 226/228
Soil:	Isotopic Uranium
	Thorium 228/230/232
	Radium 226/228
	Nitroaromatics
	Arsenic
	Mercury
	Lead
	Cadmium
	Barium
	Selenium
	Silver
	Zinc

4.2 Collected Specimens, Laboratory Shipment, and Chain of Custody

Samples, both soils and small mammals, will be shipped by the contractor to a contract laboratory for analysis. Sample chain of custody will comply with WSSRAP SOP ES&H 4.1.2. Shipment and packaging samples will follow Regulatory Compliance Procedures RC-11. Laboratories will conform to standard quality assurance (QA) requirements.

Sample identification will conform to ES&H procedure 4.1.1, *Numbering System for Environmental Samples and Sampling Locations*. The sample numbering structure is BG-XXXX-XXXXXX-XXXX for biological samples and SO-XXXX-XXXXXX for soil samples. See appendix C for sample identification.

5 DATA REPORTING

From the data obtained in the field, species present and approximate population numbers will be calculated. The Hill's diversity index shall be used to calculate the diversity indices.

$$NA = \sum_{I=1}^{S} (pi)^{1/(1-A)}$$

Information gathered from analysis of small mammal populations will be compared with chemical and radionuclide sampling reports from WSSRAP and from other locales nearby. Data collected from study areas and from background samples will be interpreted and tested under various statistical methods. These methods will determine whether small mammals located on or near the Weldon Spring Site Remedial Action Project (WSSRAP) are being effected by chemical and/or radiological contaminants. One of two statistical tests will be used to make the determination: the Student's t-test, or the Mann-Whitney U-test. The basis of determination of which statistical test to use is whether the distribution of small mammal populations can be assumed to be normal, and whether the variances of all sample populations are equal. Preliminary testing of normality and variance will be made by W-test and F-test. W-test data reported as not detectible (ND), or below detection limits (DL), shall be quantified as DL/2 per EPA guidance (EPA 1991).

All data will be presented in a report prepared following the *Format Guide for Formal Reports*, Rev. 2. (MKF and JEG 1991e).

6 DATA ADMINISTRATION

Data will be reviewed and quality control samples compared following standard operating procedures (ES&H 4.9.1a, RC-31a) and the *Environmental Data Administration Plan* (MKF and JEG 1990).

Quality Assurance procedures will follow the guidelines established in the *Environmental Quality Assurance Program Plan* (MKF and JEG 1991f).

APPROVED 1992 ENVIRONMENTAL MONITORING PLAN, JANUARY 1992, REVISION 1

Enclosed is the approved 1992 WSSRAP Environmental Monitoring Plan (EMP), Revision 1. The EMP is prepared to ensure that the public's health and safety are protected and that all applicable legal and regulatory requirements are met. The scope of this plan includes the effluent monitoring and environmental surveillance activities that will be performed during 1992. These activities include the monitoring of surface water, groundwater, radon, gamma radiation, air particulate, sediment, biological and meteorological conditions.

Revision 1 updates the text regarding analytical accuracy and investigation and detection levels for environmental sample analysis. Please substitute this revision for the plan that you were provided on January 7, 1992.

If you have any questions or desire a meeting to review this plan, please contact Alan D. Gibson at (314)441-8978.

Sincerely,

Stephen H. McCracken

SUBJECT: **CORRECTIONS TO WELDON SPRING ENVIRONMENTAL REPORT FOR CALENDAR YEAR 1992**

Recent evaluation of the Weldon Spring Site Environmental Report for Calendar Year 1992 has revealed an error in the units given in two tables in Section 4.0. The units of "μCi/ml" in Tables 4-5 and 4-6 on Pages 75-82 should read "$\mu Ci/m^3$". This errata sheet will be included in further reproduction of the above mentioned document and be maintained in Document Control for reference.

ABSTRACT

Environmental monitoring plans have been formulated annually since the inception of the Weldon Spring Site Remedial Action Project (WSSRAP) to ensure that the public's health and safety are protected and that all applicable legal and regulatory requirements are met. These plans have evolved over the years as characterization activities have defined the extent and magnitude of contamination.

This 1992 Environmental Monitoring Plan satisfies requirements of the U.S. Department of Energy (DOE) Order 5400.1 requiring each DOE facility with the potential for contributing to environmental pollution to prepare an environmental monitoring plan for its program.

The scope of this plan includes the effluent monitoring and environmental surveillance activities that will be performed during the 1992 environmental monitoring year (calendar year). These activities include the monitoring of surface water, groundwater, radon, gamma radiation, air particulate, sediment, biological and meteorological conditions.

1 INTRODUCTION

The Weldon Spring site (WSS) is located near Weldon Spring, Missouri, 30 mi west of St. Louis, Missouri. The WSS consists of an inactive uranium production facility including raffinate pits, a chemical plant, an abandoned limestone quarry, and associated vicinity properties. These areas contain chemically and radiologically contaminated materials originating from previous operations at the site.

Remediation of the Weldon Spring site was designated as a Major Project in May 1985. It has since been designated by the U.S. Department of Energy (DOE) as a Major System Acquisition. The program is known as the Weldon Spring Site Remedial Action Project (WSSRAP). The major goals of the WSSRAP are to eliminate potential hazards to the public and the environment, and to make surplus real property available for other uses to the extent possible. An environmental documentation approach has been developed that satisfies the requirements of both the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), as amended by the Superfund Amendments and Reauthorization Act (SARA) and the National Environmental Policy Act (NEPA). The result of this process will be a Record of Decision regarding ultimate disposal of the WSS wastes.

DOE Order 5400.1, *General Environmental Protection Program* requires the preparation of an *Environmental Protection Program Implementation Plan* (EPPIP) at all DOE sites. The Weldon Spring site EPPIP (MKF and JEG 1991a) details the methods by which the WSSRAP will comply with this order. Because the WSSRAP is a remedial action project, the overall goal is different from the standard operating and/or production facilities for which DOE Order 5400.1 was developed. Therefore, the WSSRAP EPPIP meets the intent of DOE Order 5400.1, while being tailored to the unique aspects of a remedial action project. The WSSRAP has prepared this *Environmental Monitoring Plan* (EMP) to meet the requirements for DOE environmental monitoring programs as specified in DOE Orders 5400.1 and 5400.5 and the *Environmental Regulatory Guide for Radiological Effluent Monitoring and Environmental Surveillance* (DOE 1991), hereafter referred to as the *Regulatory Guide*.

1.1 Purpose

DOE Order 5400.1 requires the preparation of an *Environmental Monitoring Plan* to define the effluent monitoring and environmental surveillance required to demonstrate

compliance with applicable Federal, State and local environmental protection laws and regulations, Executive Orders, and internal DOE policies.

The purpose of this *Environmental Monitoring Plan* is to detail the environmental monitoring requirements at the WSS. Environmental monitoring is performed at the WSS to ensure that any potential public exposure is documented and quantified, to ensure that the public's health and safety and the environment are protected, and to demonstrate compliance with applicable legal and regulatory requirements. The monitoring program also confirms adherence to DOE environmental protection policies, and supports remedial planning.

1.2 Scope

This plan describes the effluent monitoring and environmental surveillance activities that will be performed at the WSS during calendar year 1992. These activities include monitoring of surface water, groundwater, radon, gamma exposure, air particulate, sediment, and meteorological conditions. The plan also describes applicable monitoring requirements, analytical methods used, and quality assurance measures. Details and rationale regarding sampling frequencies and analytic parameters are provided. Also presented are summaries of additional programs implemented to satisfy the requirements of DOE Order 5400.1, Order 5400.5, and the *Regulatory Guide*. An evaluation of compliance or non-compliance with each regulatory guide criteria statement was not included in the 1992 EMP. Where criteria statements were applicable to the WSSRAP, recognition of satisfying the criteria was included. The 1993 EMP will include a more detailed evaluation of the criteria statements.

1.3 Site History

In April 1941 the Department of the Army (DA) acquired 17,232 acres of land where, from November 1941 through January 1944, Atlas Powder Company operated a trinitrotoluene (TNT) and dinitrotoluene (DNT) explosives production facility known as the Weldon Spring Ordnance Works (WSOW). By 1949 all but approximately 2,000 acres had been transferred to the State of Missouri (August A. Busch Memorial Wildlife Area) and the University of Missouri (agricultural land). Except for several small parcels transferred to St. Charles County, the remaining property became the Weldon Spring U.S. Army Reserve and National Guard Training Area (WSTA).

Through a Memorandum of Understanding between the Secretary of the Army and the General Manager for the Atomic Energy Commission (AEC), 205 acres of the former WSOW were transferred in May 1955 to the AEC for construction and operation of the Weldon Spring Uranium Feed Material Plant (WSUFMP) to process uranium and thorium ore concentrates. Considerable explosives decontamination was performed by Atlas Powder and the DA prior to WSUFMP construction.

The WSUFMP was an integrated facility for converting processed uranium ore concentrates to pure uranium trioxide, intermediate compounds, and uranium metal. A relatively small amount of thorium was also processed. Wastes generated during these operations were stored in four raffinate pits.

In 1958 the AEC acquired title to the Weldon Spring Quarry (WSQ) from the DA. The WSQ had been used earlier by the DA for disposal of TNT-contaminated rubble during the operation of the WSOW. The AEC used the WSQ as a disposal area for a small amount of thorium residue, but most of the material disposed of there consisted of uranium and radium-contaminated building rubble and soils from the demolition of a uranium ore processing facility in St. Louis.

The WSUFMP was shut down in 1966, and in 1967 the AEC returned the facility to the DA for use as a defoliant production plant, to be known as the Weldon Spring Chemical Plant (WSCP). The Army started removing equipment and decontaminating several buildings in 1968.

The defoliant project was canceled in 1969 before any process equipment was installed. The DA retained the responsibility for the land and the facilities at the WSCP, but the 51-acre tract encompassing the Weldon Spring raffinate pits (WSRP) was transferred back to the AEC. The WSS was placed in caretaker status until 1986, when the Weldon Spring Site Remedial Action Project was initiated.

2 OBJECTIVES AND RATIONALE

The goal of the Weldon Spring Site Remedial Action Project (WSSRAP) is to protect and enhance the environment while ensuring the protection of the public. This will be accomplished by safely disposing of hazardous and radiological wastes that resulted from operation of the Weldon Spring Uranium Feed Materials Plant and the U.S. Army's ordnance operation. Within the overall project mission, the environmental protection program focuses on the operational activities of the project.

The WSSRAP objectives for the environmental protection program are as follows:

- To assess compliance with all applicable environmental quality standards and public exposure limits.
- To determine the background levels and site contributions of contaminants.
- To determine the effectiveness of effluent treatment and controls.
- To determine the validity and effectiveness of models.
- To determine the long term buildup and prediction of environmental trends from site-released contaminants.
- To accomplish the detection and quantification of unplanned releases.

It is the purpose of this EMP to describe the rationale and design criteria for the monitoring program; determine the extent and frequency of monitoring and measurements; outline the procedures for laboratory analyses, quality assurance requirements, program implementation procedures, and preparation and disposition of related reports.

The WSSRAP environmental protection program is separated into two distinct functions: (1) effluent monitoring, and (2) environmental surveillance. Effluent monitoring assesses the quantities of substances in a migration pathway from the site at the facility boundary, or in a pathway subject to compliance with applicable regulations (e.g., National Emissions Standards for Hazardous Air Pollutants [NESHAPs]) or permit levels and requirements (e.g., National

Pollution Discharge Elimination System [NPDES]). The environmental surveillance program generally reviews environmental media within or outside the facility boundary for the presence and concentration of site contaminants to detect and/or track the migration of those contaminants. Surveillance data are used to assess the presence and magnitude of any radiation or toxicological exposures by members of the public, or to assess the effects, if any, on the local environment.

The Weldon Spring site (WSS) has maintained a relatively stable configuration of its waste products since cessation of the plant operation and decontamination of some process buildings in the early 1970s. It is believed that this stability has allowed the site to achieve a rough equilibrium regarding the migration of contaminants from the site. Since the WSS is presently under active remediation, the nature of the waste units and their physical position and chemical state are subject to disturbance. The monitoring program for 1992 has been designed to address the pathways and constituents reflective of a changing waste setting.

The U.S. Department of Energy (DOE)has defined generic performance criteria that the DOE operations offices must use in developing their programs. The environmental protection program has incorporated these criteria into the WSSRAP monitoring program. The objective of the WSSRAP environmental monitoring program is to generate all data necessary to ensure regulatory compliance, and assess the public and environmental impact of site contaminants. Therefore, a program must be developed that assesses all viable environmental pathways. The program in this EMP defines a minimum scheme of data points to be collected to evaluate whether environmental conditions are changing and whether WSS-related contaminants or activities are impacting public health or the environment. Where additional data points or density is required to verify trends or more closely evaluate environmental conditions, additional samples may be collected that are not defined in the plan. Those samples will be collected to serve the objectives of the environmental/monitoring program at the Weldon Spring site and will be consistent with the guidelines of the DOE 5400 orders. The following section describes the pathway analysis performed by the WSSRAP to arrive at the monitoring program.

2.1 Pathway Analysis

To evaluate the potential impact on human or ecological receptors of activities at the WSS it is necessary to conduct a pathway analysis. Exposure pathways are identified considering the source, release mechanisms, type and location of contaminants at the site and the probable environmental fate (persistence, partitioning, transport and intermedia transfer) of these

contaminants; and the location and activities of potentially exposed receptors. See Table 2-1 for matrix of factors considered for the exposure pathway screening process. The primary objective of the pathway analysis is to identify those pathways that are, or may be "complete" under current conditions and given reasonable assumptions about future conditions. An exposure pathway is considered complete if a linkage can be shown between one or more contaminant sources, through one or more environmental transport processes, to an exposure point where human or ecological receptors are present.

Identification of potentially complete pathways is a qualitative judgement. Procedures used are intended to be conservative. The identification of a complete pathway does not necessarily indicate that adverse effects will occur; it indicates that the effort to monitor releases is worthwhile from the standpoint of protecting human health and the environment.

Separate pathway analyses were conducted for the WSQ and the WSCP. Results of these analyses are presented in Tables 2-2 and 2-3.

2.2 Monitoring Program Rationale

The critical pathway analysis (radionuclide and media) for the WSSRAP site was conducted for the Weldon Spring Quarry (WSQ) and the Weldon Spring Chemical Plant (WSCP). These analyses were based on data developed during various characterization studies (e.g., Phase I and II soils study, groundwater study, etc.), site specific criteria, site specific assumptions and the matrix of potential exposure routes (see Table 2-1).

Site specific criteria considered in this pathway analysis included physical, chemical, and biological characteristics of the radionuclides detected; spatial distribution; concentration; depth to groundwater; geology of the area; climatic conditions; area use by public and wildlife; and the proximity of contaminated sites to potential receptors.

Site specific assumptions for this analysis were as follows:

- Off-site residents have no access to the contaminant source areas.
- Access of large game animals to contaminant source areas is limited by perimeter fencing.

Table 2-1 Potential Exposure Route Matrix

Component of Exposure Assessment	Factors to be Considered
Affected Environmental Media	Air Groundwater Surface Water Sediment Surface Soil Subsurface Soil Aquatic Biota Terrestrial Biota
Release Mechanism of Medium	Air - Volatilization, fugitive dust. Groundwater - Groundwater flow, discharge to surface water. Surface Water - Surface runoff overland flow, groundwater seepage, partitioning with sediment, volatilization. Sediment - Surface runoff overland flow, groundwater seepage leaching, partitioning with surface water, release to biota surface disturbance. Surface soil - Fugitive dust transport/depository, surface runoff, overland flow leaching, surface disturbance. Subsurface soil - Leaching. Aquatic biota - direct contact, ingestion. Terrestrial biota - direct contact, ingestion.
Contaminant Transport Pathway	Airborne transport Groundwater migration Surface water flow Sediment Transport Fluid migration through subsurface soil Surface soil erosion Transport of aquatic biota Terrestrial biota migration

Table 2-1 Potential Exposure Route Matrix (Continued)

012292

Component of Exposure Assessment	Factors to be Considered
Contaminant Fate and Transport	Physical - Volatilization Sorption, surface complexation. Chemical - Photolysis oxidation/reduction Hydrolysis Dissolution/precipitation Ion exchange, chemical portioning Aqueous complexation Chemical degradation Hydration Biological - Bioaccumulation Biomagnification Biotransformation Biodegradation
Current and future receptors	Human - On-site workers Off-site residential, recreational, commercial, industrial. Ecological - On-site aquatic, terrestrial biota Off-site aquatic, terrestrial biota
Exposure routes by medium	Air - Indoor/outdoor vapor phase inhalation, immersion Indoor/outdoor particulate inhalation Groundwater - Ingestion Dermal contact Surface water - Ingestion Dermal contact Sediment - Ingestion Dermal contact Surface Soil - Ingestion Dermal contact Immersion Subsurface soil - Indoor/outdoor vapor phase inhalation. Biota - Ingestion Inhalation Dermal contact Immersion Cross Media transfers

Table 2-2 Weldon Spring Quarry Complete Exposure Pathway Selected for Evaluation

Population Potentially Exposed	Exposure Route, Medium, Exposure Point	Pathway Selected For Evaluation	Reason for Selection
Off-site Residents	Ingestion of groundwater from local wells downgradient from the site.	Yes	Use of groundwater as a source for drinking water by residents.
	Ingestion of game and fish inhabiting wildlife area.	Yes	Ingestion of game animals and fish by residents. Magnitude of exposure is low.
	Inhalation of particulates dispersed through wind erosion and remedial action.	Yes	Inhalation of wind dispersed particulates by nearby residents.
	Dermal contact with airborne and deposited particulates.	No	Dermal contact with radionuclides is not considered to be an important exposure route because off-site concentrations are extremely low or nonexistent.
	Ingestion of surface water and/or sediments.	Yes	Use of lakes on public land which show elevated uranium levels.
Wildlife Area Visitors	Inhalation of particulates dispersed through wind erosion and remedial action.	Yes	Inhalation of airborne particulates by visitors of wildlife area.
	Dermal contact with sediment in slough, creek.	No	Dermal contact with sediment in slough, creek while wading or swimming. Exposure potential is low since wading or swimming in these areas is prohibited.
	Ingestion of surface water while swimming.	No	Potential for ingestion of surface water (slough, creek) is low since this activity is prohibited in these areas.
Terrestrial Biota (on site)	Ingestion of surface waters and sediments.	Yes	Potential use of surface water as drinking water by biota and ingestion of sediment.
	Ingestion of vegetation and soils.	Yes	Use of vegetation as food source and incidental ingestion of soils. Inhalation route for biota is not considered to significantly contribute to overall dose.

Table 2-2 Weldon Spring Quarry Complete Exposure Pathway Selected for Evaluation (Continued)

Population Potentially Exposed	Exposure Route, Medium, Exposure Point	Pathway Selected For Evaluation	Reason for Selection
Terrestrial Biota (off site)	Ingestion of surface water and sediments.	Yes	Use by biota of area surface waters as drinking water and incidental ingestion of sediments.
	Inhalation of airborne particulates due to wind erosion and soil disturbance.	No	Inhalation route for biota is not considered to significantly contribute to overall dose due to extremely low or non-existent concentrations.
	Ingestion of vegetation and soils.	Yes	Use of vegetation as food source and incidental ingestion of soils.
Aquatic Biota (on site)	Uptake of surface water and contact with sediment.	Yes	Absorption through contact with surface water and sediment in the quarry.
	Ingestion of invertebrates and vegetation.	Yes	Ingestion of invertebrates and vegetation is an important uptake mechanism.

TABLE 2-3 Weldon Spring Chemical Plant Area Complete Exposure Pathways Selected for Evaluation

Population Potentially Exposed	Exposure Route, Medium, Exposure Point	Pathway Selected for Evaluation	Reason for Selection
Off-site Residents	Ingestion of game animals and fish inhabiting wildlife area.	Yes	Ingestion of game and fish by residents. Contribution to exposure considered low.
	Inhalation of particulates dispersed through wind erosion and remedial action.	Yes	Inhalation of airborne particulates by nearby residents.
	Dermal contact with airborne and deposited particulates	No	Dermal contact with radionuclides is not considered an important uptake mechanism.
	Ingestion of surface water and contact with sediment while swimming or wading.	No	Exposure potential for ingestion of surface water/contact with sediment is low since swimming or wading in Busch lakes is prohibited.
	Ingestion of food crops adjacent to area.	Yes	Potential use by local residents of food crops grown adjacent to site.
Wildlife Area Visitors	Inhalation of particulates dispersed through wind erosion and remedial action.	Yes	Inhalation of airborne particulates by wildlife area visitors.
	Ingestion of game and fish inhabiting wildlife area.	Yes	Ingestion of game and fish inhabiting wildlife area collected during hunting/fishing season.
	Ingestion of surface water and contact with sediments while swimming or wading.	No	Exposure potential through ingestion of surface water/contact with sediments in Busch Lakes for visitors is low since these activities are prohibited.
	Dermal contact with airborne and deposited particulates.	No	Dermal contact with radionuclides is not considered a significant uptake mechanism.
Terrestrial Biota (on site)	Ingestion of surface water and ingestion of sediments.	Yes	Ingestion of raffinate pits surface water and sediment by biota.
	Ingestion of vegetation and soils.	Yes	Use of vegetation as food source and incidental ingestion of soils.

TABLE 2-3 Weldon Spring Chemical Plant Area Complete Exposure Pathways Selected for Evaluation (Continued)

Population Potentially Exposed	Exposure Route, Medium, Exposure Point	Pathway Selected for Evaluation	Reason for Selection
	Inhalation of airborne particulates dispersed through wind erosion and remedial action.	No	Inhalation route for biota is not considered to significantly contribute to overall dose.
Terrestrial Biota (off site)	Ingestion of surface water and sediments.	Yes	Use of area surface water as a source for drinking water and incidental ingestion of soils.
	Ingestion of vegetation, crops, and soils.	Yes	Use of vegetation and crops as food source and incidental ingestion of soils by biota inhabiting the wildlife area.
	Inhalation of airborne particulates due to wind erosion and soil disturbance.	No	Inhalation route for biota is not considered to significantly contribute to overall dose.
Aquatic Biota (off site)	Uptake of surface water and contact with sediments.	Yes	Uptake by biota inhabiting surface water in wildlife area.
	Ingestion of invertebrates and vegetation.	Yes	Ingestion of invertebrates and vegetation is an important uptake mechanism.

- Prolonged or year round use of on-site water bodies by waterfowl is limited.
- Frequency and duration of wildlife area visits per individual is low (MDOC 1991).
- Consumption of game animals and fish per individual averaged over a year is low.

The monitoring programs described in the following subsections were designed with specific knowledge of the active pathways and the pathway analyses performed. Each media-specific monitoring and analysis program follows a general rationale.

2.2.1 Surface Water

Surface water is influenced by three general mechanisms; the monitoring program for 1992 will address each mechanism independently. Surface water is impacted by water that flows from the site and carries with it site-source contaminants and contaminants deposited in the sediments of the stream channels. Small quantities of water migrate from the site on a regular basis due to human influenced activities, such as the permitted, treated effluent from the on-site DOE administration building. Finally, surface water is impacted by the discharge of contaminated groundwater to surface water receptors at springs around the area of the site. Each feature receiving surface water is sampled and contaminant levels measured. The migrating surface waters are subsequently sampled along their course to track their behavior until the concentrations are diluted or otherwise rendered indiscernible from background levels.

2.2.2 Groundwater

The groundwater and hydrogeology beneath the site have been studied extensively. The present conceptual model of the hydrogeologic regime incorporates the activity of diffuse flow through the fractured limestone and the influence of discrete groundwater movement through solution enlarged fractures and conduits. The rationale for groundwater monitoring is to capture the influences of the on-site contaminant sources on the groundwater through the use of conventional monitoring wells around those sources and around the site perimeter. Converging conduits transport water, which transitions from diffuse flow to discrete flow, to springs previously mentioned. Proper monitoring of the resurging water at those springs satisfies the other mechanism of groundwater movement.

2.2.3 Air and Atmospheric Migration

Air pathway and atmospheric migration of contaminants and radiation constitute a broad set of exposure pathways. Characterization studies conducted over the past four years have determined that the only significant sources for airborne contamination from the WSS-related wastes lie within the boundaries of the WSCP/WSRP and the WSQ areas. As remedial activities begin to disturb source areas, the potential for increased airborne emissions will increase. More intensive work-area monitoring will maintain knowledge of real-time airborne emission levels.

Airborne particulates, radionuclides, and atmospheric radiation released from the WSS source areas must pass the facility boundaries before migrating to uncontrolled or public access areas. Site perimeter monitoring will be utilized to detect and monitor the migration of radioactivity detectable at the facility boundaries. Finally, specific locations around the WSS where there is concentrated human activity are considered "critical receptor" locations and receive focussed attention.

2.2.4 Soil and Sediment

Soils and sediments on and around the WSS have been, and in some locations continue to be, receiving contaminants from the WSS. The soil is generally in a stable condition and, although it might act as a long term source for groundwater contamination, soil in itself does not pose a dynamic contaminant front that would require routine monitoring. Soils and associated contamination that are disturbed during remedial activities may be mobilized by surface water runoff or dispersed in the air and migrate from the site. Therefore, the surface water monitoring program will monitor levels of suspended and settleable solids to assess the quantities of materials leaving the site; the air monitoring program, combined with air modeling when appropriate, will assess potential impact to off-site receptors.

For the purposes of this plan, sediments are those solid materials that are mobilized by fluid flow and accumulate to some discernable depth in and along the stream channels. Sediments have been characterized during the remedial investigations performed at the WSS and WSQ. That characterization, along with the determinations made during subsequent, routine biological and surface water sampling will meet the environmental monitoring data needs of the project for 1992.

2.2.5 Biological Media

Biological factors such as the animal and plant vectors in a biouptake chain will be sampled to assemble and maintain knowledge of the environmental and potential human impacts of the waste sources and to assess the effectiveness of the clean-up actions as they progress.

3 SURFACE WATER SURVEILLANCE PROGRAM

Surface water samples will be collected from locations known to be or potentially impacted by the Weldon Spring Chemical Plant/Weldon Spring raffinate pits (WSCP/WSRP) area and the Weldon Spring Quarry (WSQ). Because of the differing topography and hydrologic conditions at the WSCP/WSRP and WSQ, surface water sampling programs for each of the areas of the WSS are described separately. In previous environmental monitoring plans (EMP) for the Weldon Spring Site Remedial Action Project (WSSRAP) the monitoring of springs was included as part of the surface water monitoring program. The WSSRAP has changed this approach to incorporate spring monitoring under the groundwater monitoring program, consistent with the draft U.S. Environmental Protection Agency (EPA) guidance on groundwater monitoring in karst terrains. The data on contaminants in spring water will be more directly correlated to levels in the groundwater near the site as measured using conventional monitoring well techniques. Therefore, spring monitoring is no longer discussed in the surface water monitoring program section.

3.1 Surface Water Evaluation

Surface water bodies in and around the WSS and WSQ have been radiologically and chemically characterized through sampling and analyses. A surveillance program that includes monitoring potentially impacted surface water has been established to monitor radiological and chemical conditions. The extent of the surface water environmental surveillance program is based upon applicable regulations, hazard potential of effluents, quantities and concentrations of effluents, public interest, and the nature of potential or actual impacts on surface water. The environmental surveillance program for surface water will be conducted in accordance with the requirements of DOE Orders 5400.1, 5400.5 and the *Regulatory Guide*.

3.2 Surface Water Monitoring Program at the WSCP/WSRP

The WSCP/WSRP area is located on the Missouri-Mississippi River surface-drainage divide. The topography of the WSCP/WSRP is gently undulating and generally slopes northward to the Mississippi River. Streams do not cross the properties, but incipient drainageways convey surface water runoff to off-site streams. Most surface drainage from the WSCP area discharges either via an intermittent stream in the Army Reserve Training Area to the west or into Ash Pond on the WSCP property as shown in Figure 3-1. Discharges from the

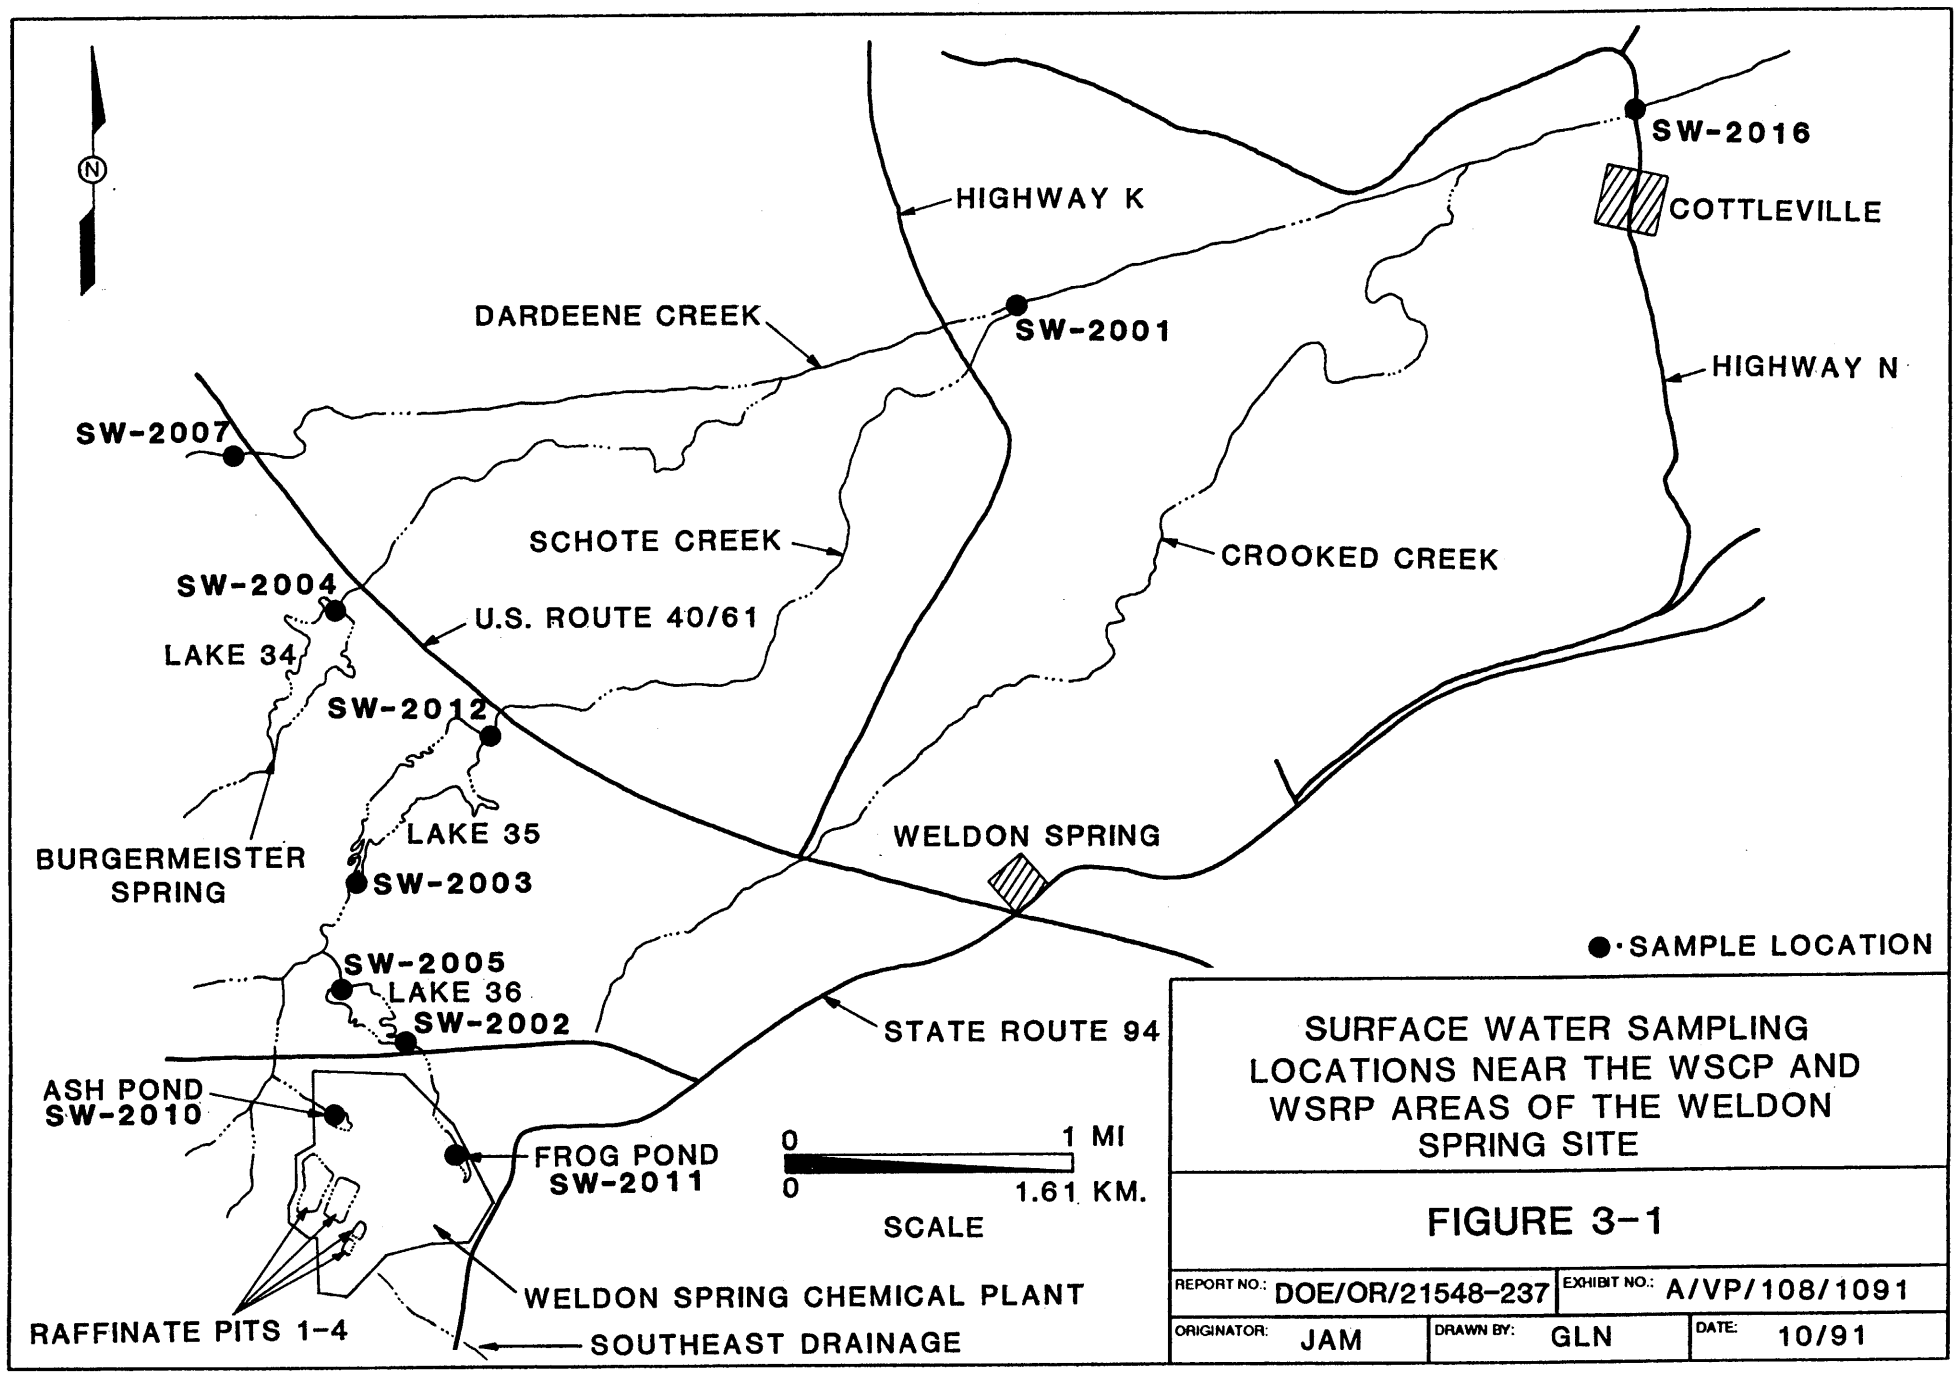
intermittent stream and Ash Pond combine near St. Charles County Road D and flow northward into Schote Creek, which in turn enters Dardenne Creek, which discharges into the Mississippi River. An additional surface drainage system ultimately reaching the Mississippi River drains the northeastern WSCP area through Frog Pond. A storm water sewer system that drains land surfaces from most of the plant area also discharges into Frog Pond. The Frog Pond drainage enters Lake 36 on the Busch Wildlife Area. Lake 36 in turn discharges into Lake 35 which ultimately discharges into Schote Creek.

Drainage from the southern portion of the WSCP property flows southeast to the Missouri River. Runoff originates from two sources. The first is the WSCP sanitary and process sewer system which merges prior to discharge from the WSCP. The sanitary sewer system was taken out of service in 1986, but receives some leakage from the storm water runoff system. The second source is surface runoff from the southern portion of the site.

Surface water which drains from the WSCP/RP area transports both dissolved and suspended element contaminants from waste materials distributed about the site. The locations chosen for monitoring of the surface water were chosen in order to provide the necessary data to track the fate and concentration of the contaminants to downgradient receiving streams and water features. The locations of the monitoring points and the rationale behind each location is described in detail in the following sections. The DOE has a firm understanding of the complex hydrogeologic system that influences the flow of surface water from the site to both the Missouri and Mississippi rivers. This understanding has come about through the cooperative efforts of the DOE with the Missouri and United States Geological Surveys.

3.2.1 Surface Water Monitoring Locations at the WSCP/WSRP

All surface water features monitored under the surface water surveillance program are situated on the north (Mississippi River) side of the drainage divide. Those waters requiring contaminant monitoring to the south of the surface divide are monitored under either the effluent monitoring or groundwater monitoring programs. The routine monitoring locations are numbered sequentially from SW-2001 through SW-2012 and SW-2016. Location numbers SW-2013, SW-2014 and SW-2015 were previously assigned to discrete temporary locations, which are not part of the 1992 routine monitoring program. Location SW-2016 is a new location added in this 1992 monitoring program and its function will be described in the following paragraphs in context with the entire sampling scheme.



SURFACE WATER SAMPLING LOCATIONS NEAR THE WSCP AND WSRP AREAS OF THE WELDON SPRING SITE

FIGURE 3-1

REPORT NO.:	DOE/OR/21548-237	EXHIBIT NO.:	A/VP/108/1091		
ORIGINATOR:	JAM	DRAWN BY:	GLN	DATE:	10/91

As shown on Figure 3-1, the sampling locations are distributed over surface water features at the down-gradient of the on-site contaminated water sources. Again, the program is designed to monitor the levels in the lakes and streams which pass through public and private lands in order to enable the DOE to assess the potential risk to down-gradient recipients. It also serves to document that the contaminant levels in the surface water diminish to background levels through dilution and other natural processes.

In previous monitoring years location SW-2001 at the confluence of Schote and Dardenne Creeks has been sampled as the furthest downstream location at which to measure the contaminant levels in Dardenne Creek after receiving the Schote Creek contribution. Location SW-2016 at the intersection of Dardenne Creek and County Highway N will now serve that function and was added because a report by the USGS noted that above background levels of uranium were measurable at that location.

Location SW-2007 is positioned on Dardenne Creek upstream of any tributaries that receive WSS contaminants in the runoff or groundwater discharge. This location serves as a background station for the determination of background contaminant levels prior to influence by the WSS discharge. Locations SW-2002 through SW-2006 and SW-2012 monitor the three lakes on the Busch Memorial Wildlife Area which lay within the receiving basin of WSS runoff. Location SW-2012 is positioned at the spillway of Lake 35. This lake leaks from its base and drains to Lake 34, among other places. Consequently, Lake 35 discharges only occasionally and monitoring of that discharge will be episodic with precipitation runoff.

The use of location SW-2006 (Busch Lake 10) has been discontinued since three years of data indicated no influence by the WSS and there is no visual or historical evidence of surface or subsurface impact. Locations SW-2008 and SW-2009 (Burgermeister Spring and Overflow Spring) continue to be monitored, but the location identifiers have been changed and monitoring is performed under the groundwater/spring monitoring program. Finally, locations SW-2010 and SW-2011 are at Ash Pond and Frog Pond within the boundary of the WSCP/RP area, and are monitored as the two major on-site surface water source features.

The raffinate pits located at the WSS are four solids-settling ponds utilized during plant operation to collect the waste products of the uranium purification and allow the decant water to discharge free of solids. The four pits vary in size; two are approximately 1 acre and contain approximately 12 ft of sludge material; Pit 3 is 9 acres in area and contains 12 ft to 14 ft of

sludge material; and Pit 4 is approximately 13 acres in area but contains only a minor amount of sludge along with some waste scrap steel and drummed wastes from the decommissioning of the plant. Although the overflow system of the pits has long been discontinued and no direct runoff from the pits is presently possible, the pits contain surface water on top of the sludge material. The WSSRAP monitors this water to maintain a database on its quality and documents notable changes. These locations are numbered SW-3001 through SW-3004 for Pits 1 through 4 respectively.

As was stated previously, other surface water locations requiring water quality monitoring, e.g., the surface water discharge points at the site boundary, are included in separate monitoring programs such as the effluent monitoring and groundwater monitoring program.

3.2.2 WSCP/WSRP Surface Water Monitoring Schedule

Surface water features at the WSCP/RP area will be monitored according to the schedule listed on Table 3-1. Samples will be collected for uranium on a quarterly basis and for metals, certain radioisotopes, and inorganic anions annually to maintain a database on these substances. Quality assurance samples will also be collected per Table 3-1 in accordance with WSSRAP QA sample policy.

3.3 Surface Water Monitoring Program for the WSQ

The 13 surface water monitoring locations within or near the WSQ have been chosen for routine monitoring to investigate and document whether surface waters near the quarry might pose a risk to human health or the environment.

The WSQ is located on the northern bluff of the Missouri River valley. Surface water within the quarry consists of the quarry pond which acts as a sump and intercepts groundwater. There is no direct surface water runoff from the quarry; however, the movement of contaminated groundwater from the quarry through the fine-grained alluvium to the Femme Osage Slough has resulted in elevated uranium levels in the slough water. The quarry pond and the slough are directly impacted by the contamination within the quarry, therefore, they are routinely monitored. Also, samples from the Missouri River, the Femme Osage Creek, and the Little Femme Osage Creek are collected routinely to provide control data for comparison with data from those locations directly impacted by contamination from the quarry.

3.3.1 Monitoring Locations

Monitoring locations SW-1001 and SW-1002 (see Figure 4-3) monitor the Little Femme Osage Creek (which lies due west of the quarry) at points upstream and down stream of the WSQ. Six sampling locations--SW-1003 through SW-1005, SW-1007, SW-1009, and SW-1010--are distributed along the Femme Osage Slough west of, adjacent to, and east of the WSQ. These locations within the slough were chosen to provide the most representative data of potentially impacted areas from the quarry contamination. Location SW-1008, which monitors the ponded water within the WSQ, gives a rough determination of the concentrations of the various contaminants in the ponded surface water that may migrate to groundwater. Locations SW-1011, SW-1012, and SW-1013 (see Figure 3-2) were added to the monitoring program in 1989 to provide baseline water quality data from the Missouri River. SW-1011 is the Missouri River location furthest upstream above any potential influences from WSS contamination, while SW-1013 is furthest downstream below the outfall point of the southeast drainage easement. Location SW-1014, shown on Figure 3-2, was added to the monitoring program in 1991 to increase the coverage of water bodies potentially affected by the WSQ.

3.3.2 Monitoring Schedule

All surface water bodies near the WSQ that are used as baseline or are potentially affected by the WSQ, including the Femme Osage Slough, Femme Osage Creek, Little Femme Osage Creek, the Missouri River, and the quarry pond, will be sampled as shown in Table 3-2 at the locations shown in Figure 3-2.

All locations will be monitored bimonthly, (once every two months), for uranium. This frequency will allow any trends to be identified in addition to maintaining a surveillance of uranium in surface water bodies near the WSQ. Additionally, all locations will be monitored at least annually for arsenic, barium, nitrate, sulfate, nitroaromatic compounds, and other radiological parameters, including Th-230, Th-232, Ra-226, Ra-228, gross alpha, and gross beta to provide baseline data and early detection of these parameters within surface water bodies near the WSQ. The quarry pond is monitored bimonthly for all parameters listed above, with the exception of arsenic and barium, to maintain surveillance of the contaminants within the quarry.

4 GROUNDWATER SURVEILLANCE PROGRAM

4.1 Groundwater Evaluation

Groundwater within and around the Weldon Spring Chemical Plant/raffinate pits (WSCP/RP) and Weldon Spring Quarry (WSQ) has been radiologically and chemically characterized through sampling and analyses. A surveillance program that includes monitoring potentially impacted groundwater has been established to monitor radiological and chemical conditions. The extent of the groundwater environmental surveillance program has been determined based upon applicable regulations, hazard potential of effluents, quantities and concentrations of effluents, public interest, and the potential or actual impacts on groundwater. The environmental surveillance program for ground water will be conducted in accordance with the requirements of the U.S. Department of Energy (DOE) Orders 5400.1, 5400.5 and the *Regulatory Guide*.

4.1.1 Groundwater Characterization

Groundwater within or near the WSCP/RP and the WSQ was sampled to determine potential exposure pathways. Chemical and radiological characterization of the groundwater within or near the WSCP/RP and WSQ was provided through the implementation of work plans, sampling plans, and other characterization plans. These plans, which were approved by the DOE and the EPA, include environmental monitoring, sampling locations, procedures, equipment, frequency and analysis required, minimum detection levels and quality assurance and quality control components. The evaluation of the characterization data and potential exposure pathways has provided the basis for the environmental surveillance program for groundwater as described in the Groundwater Monitoring Program Section of this *Environmental Monitoring Plan*.

4.1.2 Groundwater Estimated Release Quantities and Public Doses

It is the objective of the groundwater monitoring program at both the WSCP/RP and WSQ to collect sufficient data to estimate the approximate quantity of radionuclides released along that migration route. The radionuclide release information will be used to calculate the public dose to hypothetical groundwater users. At present, no wells are actively pumped as water supplies within a 1 mi radius of the WSCP/RP site. Wells outside that area have been

sampled in the past and have shown no evidence of radionuclide contamination from the Weldon Spring Site Remedial Action Project (WSSRAP). Those private wells will continued to be routinely sampled and analyzed by the Missouri Department of Health as part of an independent program by that agency. The results are also made available for review by WSSRAP staff.

The data collected from the WSQ and county wellfield region will allow a determination to be made on whether the WSQ presents an increased incremental risk to users of that water. No measurable increases in uranium levels above background at the wellfield have been seen to date.

4.2 Groundwater Monitoring Program for the WSQ

Forty-eight groundwater wells including 36 DOE monitoring wells, four St. Charles County monitoring wells, and eight municipal wells owned by St. Charles County have been chosen for routine monitoring to investigate and document the possibility that groundwater near the WSQ may pose a risk to human health or the environment.

4.2.1 Rationale

Chemical and radiological wastes at the quarry are of particular concern because of their proximity to the St. Charles County well field approximately 0.5 mi to the south. The issue of protection of the well field is one of great sensitivity to the public, the DOE, and other regulatory agencies. The DOE has issued a number of orders providing direction on the assessment of exposure to the public, including directions for protection from radiation and other chemical species where applicable. The monitoring strategy for and around the quarry has been developed to ensure the protection of public health and the environment.

Previous groundwater quality studies performed at the WSQ indicated several contaminants are present in or near the WSQ. Elevated uranium concentrations have been detected in the immediate WSQ area and in the alluvium north of the Femme Osage Slough. Elevated nitroaromatics, arsenic, barium, and inorganic anion concentrations have also been observed.

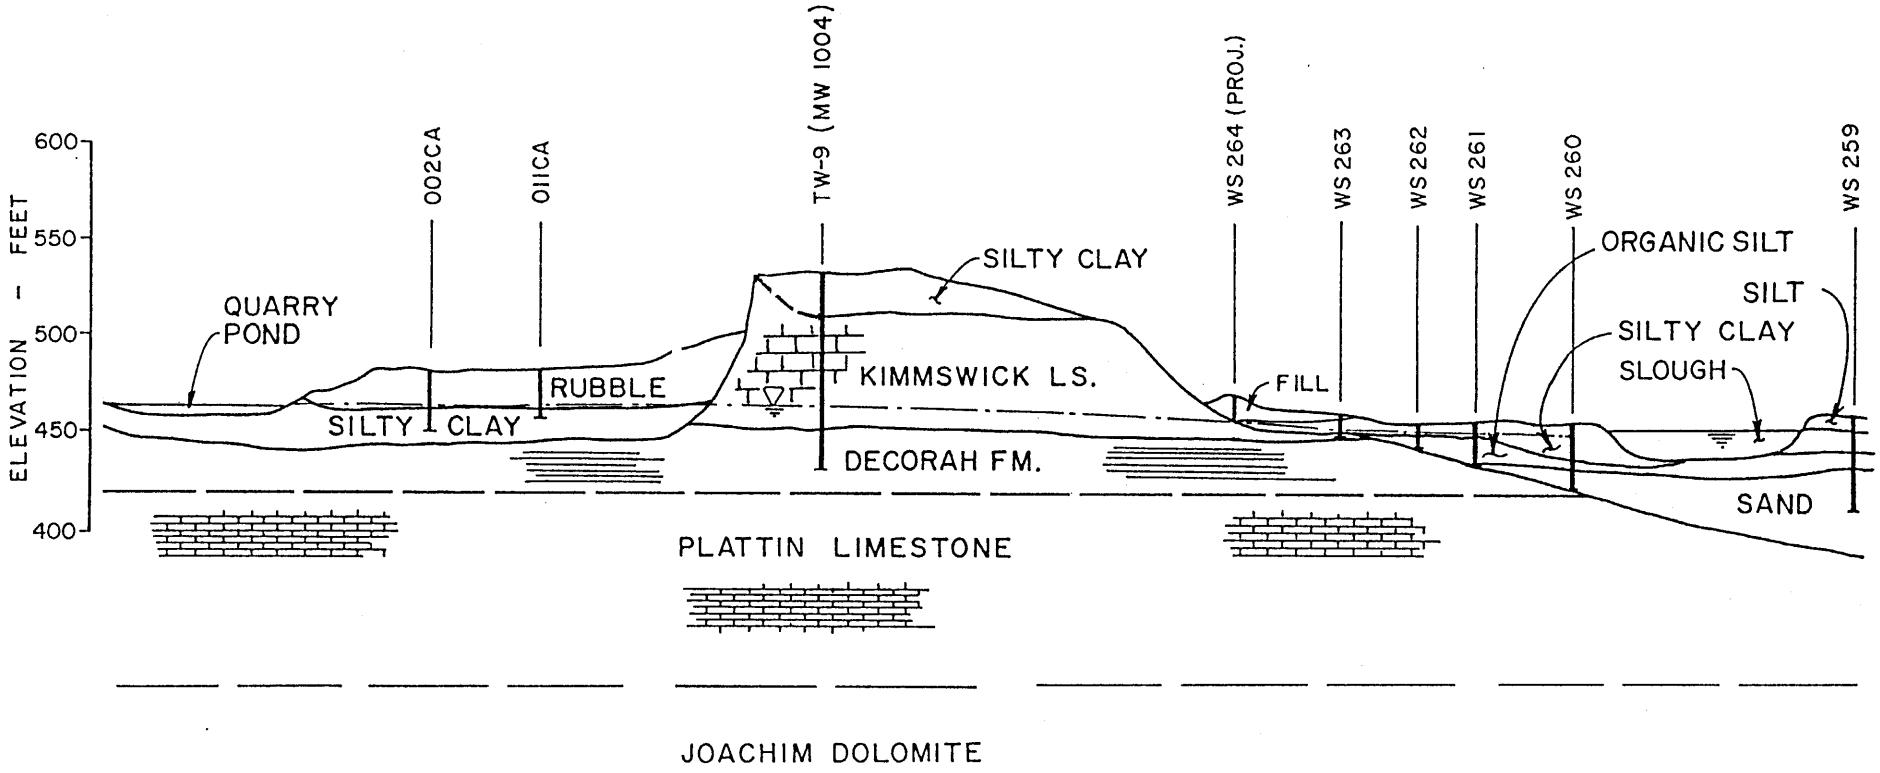
4.2.2 Monitoring Locations

The geology of the WSQ area is generally separated into upland overburden, Missouri River alluvium, and bedrock. The Missouri River alluvium and bedrock units produce groundwater and it is within these units that the groundwater is monitored. A general description of each unit follows and Figure 4-1 displays a generalized cross section of the quarry geology.

The unconsolidated upland material overlying bedrock consists of up to 30 ft of silty clay soil and loess deposits. A residual soil is present in some areas between the silty clay and the bedrock, however, the upland soils near the WSQ are generally not saturated and are not monitored.

The sediments comprising the alluvium along the Missouri River vary from clays, silts, and sands, to gravels, cobbles, and boulders. The maximum alluvium thickness near the WSQ is approximately 100 ft. The alluvium is truncated at the erosional contact with Paleozoic bedrock bluffs along the now-abandoned Missouri, Kansas, and Texas (MK&T) railroad bed. The alluvium thickness increases dramatically with distance from the bluff. Silts and clays with minor amounts of sand are the primary sediments between the bluff and the Femme Osage Slough. The thick, water-producing sands and gravels of the alluvial aquifer give way to fine-grained organically rich overbank deposits beneath the Femme Osage Slough. The potentiometric surface of the alluvial aquifer fluctuates in response to pumping of the St. Charles County production wells and the stage of the Missouri River. This indicates that the Missouri River is the primary recharge source for the alluvial aquifer.

Currently there are 33 wells including eight municipal production wells, four county-owned monitoring wells, and 21 DOE-owned monitoring wells which are screened within the alluvial material located between the quarry and the Missouri River. Five of the wells, MW-1035 through MW-1039 (see Figure 4-2), are located west of the quarry to monitor the immediate area surrounding the quarry water treatment plant equalization basin and effluent ponds. Six wells, MW-1006 through MW-1009, MW-1014, and M-1016 are located between the quarry and the slough to monitor contaminant migration south of the quarry within the alluvium. The monitoring wells MW-1010, MW-1011, and MW-1017 through MW-1024 are located south of the slough within the alluvium and are monitored to enable detection of contaminants south of the slough. County monitoring wells RMW-1 through RMW-4 are



NOTE:

SCALE FEET

GEOLOGIC CROSS-SECTION ACROSS QUARRY AND WELL FIELD AREA

FIGURE 4-1

REPORT NO: DOE/OR/21548-237	DRAWING NO.: A/PI/190/1091	
ORIGINATOR: JAM	DRAWN BY: GLN	DATE: 10/91

monitored to (1) ensure that the quarry contaminants are not migrating toward the municipal wellfield, and (2) enable an early warning of contaminant migration toward the county production wellfield if this should occur. The eight county municipal wells, PW-2 through PW-9, are also monitored to ensure that the quarry contaminants are not affecting the quality of the municipal wellfield water supply. See Figures 4-2 and 4-3 for monitoring and production wells near the WSQ.

Bedrock at the WSQ consists of three distinct Ordovician formations. In descending order, they are the Kimmswick Limestone, limestone and shale of the Decorah Group, and the Plattin Limestone. The Kimmswick Limestone is a coarsely crystalline limestone with numerous solution-enlarged joints. The Decorah Group consists of interbedded limestone and green shale; it is approximately 30 ft thick, and is horizontally fractured. The Plattin Limestone is a thinly bedded limestone about 100 ft to 125 ft thick. Currently, there are 15 DOE owned monitoring wells which are screened within either the Kimmswick-Decorah or Plattin Formations to monitor contaminants near the quarry within the bedrock. Monitoring wells MW-1002, MW-1004, MW-1005, MW-1012, MW-1013, MW-1015, MW-1026, MW-1027, MW-1029, MW-1030, MW-1032, and MW-1034 were installed to monitor contaminants within the Kimmswick-Decorah Formation surrounding the quarry. It should be noted that MW-1012 and MW-1034 are north and upgradient of the quarry and have been designated as background wells. Monitoring wells MW-1028, MW-1031, and MW-1033 are located south of the quarry within the Plattin Limestone to determine whether vertical contaminant migration has occurred.

4.2.3 Monitoring Schedule

Two separate groundwater monitoring programs have been developed for the WSQ. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough and also includes two wells, MW-1010 and MW-1011, south of the slough. These two wells were added to the bimonthly sampling because uranium levels above historical limits were detected for a short period during 1991 but returned to background levels by mid-year. This program is summarized in Table 4-1, and was developed to monitor contaminant migration and the effects of impoundment at the quarry water treatment plant scheduled to begin operation in the fall of 1991.

The second program monitors the area south of the Femme Osage Slough including the St. Charles County well field. Active production wells and select monitoring wells are sampled quarterly and annually. The raw and treated waters are also sampled. Table 4-2 presents the analytical parameters and sampling frequency of these wells. This portion of the WSQ groundwater monitoring program has been developed by representatives of the DOE, the Missouri Department of Natural Resources (MDNR), the Environmental Protection Agency (EPA), and St. Charles County.

The well field monitoring program includes sampling both untreated and treated water. Gross alpha analysis will be performed on the quarterly treated-water samples. This portion of the monitoring program satisfies the portion of the *Regulatory Guide* and DOE Order 5400.5 requiring the monitoring of affected or potentially affected public drinking water supplies as defined in 40 CFR Part 141.26. The quarterly gross alpha values will be averaged and presented in the *Annual Site Environmental Report.* All monitoring well locations are shown in Figures 4-2 and 4-3.

4.3 Groundwater Monitoring Programs for the Weldon Spring Chemical Plant/Raffinate Pit Area

The groundwater flow and contaminant transport mechanisms that make up the groundwater pathway are very different between the WSCP and the WSQ due to different geologic conditions. Groundwater monitoring at the chemical plant is conducted under two distinct monitoring programs. The first is the conventional application of monitoring wells at the site close to the contaminant source areas. The second is the monitoring of water from springs that represent the resurgence point for discrete flow paths receiving recharge in part from the site. The following sections describe the plans for both monitoring programs.

4.3.1 Geology and Hydrogeology

Geology at the WSCP and WSRP may be divided into two major units based on gross lithologic characterization: the unconsolidated glacial and residual soils, and the underlying bedrock.

The unconsolidated material consists of topsoil loess, glacially derived sediments, and residuum. Unconsolidated material to a depth of 20 ft to 50 ft is present at the WSCP/ WSRP.

These glacial soils are generally silty clays with minor amounts of gravel. The unconsolidated materials are generally not saturated and therefore are not monitored.

Groundwater occurs in the bedrock underlying the WSCP/WSRP. The first bedrock unit encountered is the Burlington-Keokuk Limestone. The Burlington-Keokuk Limestone consists of two zones containing different lithologic characteristics: competent (unweathered), and weathered.

The shallow weathered Burlington-Keokuk Limestone is typically a grayish-orange to yellowish-gray, argillaceous limestone commonly containing as much as 60% chert nodules and interbeds. The weathered limestone is a low-yield, semi-confined, heterogeneous, anisotropic aquifer that is fractured and susceptible to natural solution processes. At the site, the aquifer generally exhibits diffuse flow properties overlain by discrete flow zones such as saturated highly weathered bedrock and saturated residuum in paleochannels.

The fracture flow, solution-effected discrete flow, and conduit flow are most effectively monitored by sampling springs at the resurgence points for that flow (Quinlan 1989).

The competent (unweathered) portion of the Burlington-Keokuk Limestone is thinly to massively bedded, gray to light gray, finely to coarsely crystalline, stylolitic, and fossiliferous. The fracture densities are significantly lower in the competent limestone than in the weathered limestone.

4.3.2 Groundwater Monitoring Program for the WSCP/WSRP

Groundwater monitoring is required by DOE 5400.1 to determine and document the effects of DOE operations on groundwater quality and quantity, and to demonstrate compliance with applicable Federal and State laws and regulations. Groundwater monitoring has been conducted at the WSCP/WSRP since the first quarter of 1987. The program has been adjusted yearly according to changes in laws and regulations, specific project needs, and Comprehensive Environmental Response, Compensation and Liability Act-National Environmental Policy Act (CERCLA-NEPA) requirements.

4.3.3 Rationale

Groundwater monitoring in the immature karst present at the WSCP/WSRP requires a two-pronged approach of monitoring wells and spring sampling. This stems from the fact that immature karst terrains have not developed a system of convergent conduit-dominated flow, but reflect components of both discrete and diffuse Darcian flow.

The groundwater monitoring program at the WSRP/WSCP has been modified from the 1991 Environmental Monitoring Plan (EMP) in order to provide the data necessary to:

- Ensure protection of public health and the environment.
- Develop a baseline for studying long term and short term effects of source removal to be conducted as part of CERCLA-NEPA activities slated for 1993-1994. At least one year of baseline data taken quarterly will be necessary in 1992 to provide adequate information for future comparisons.
- Develop a baseline for studying the effects of the settling ponds associated with the wastewater treatment plant.
- Perform spatial and temporal trend analyses.
- Provide information to support the groundwater separate operable unit (GWSOU) activity planning slated to begin in fiscal 1993.

The 4000 series wells will be monitored more frequently in 1992 than in 1991 to monitor contamination migrating off site. The density of the yearly data needs to be increased to determine trends and effectively monitor the surrounding environment.

Specific on-site wells will also be monitored more frequently than in 1991. Historical data has indicated increasing concentrations in these wells over time. More frequent sampling will provide information to analyze temporal and seasonal trends associated with these wells.

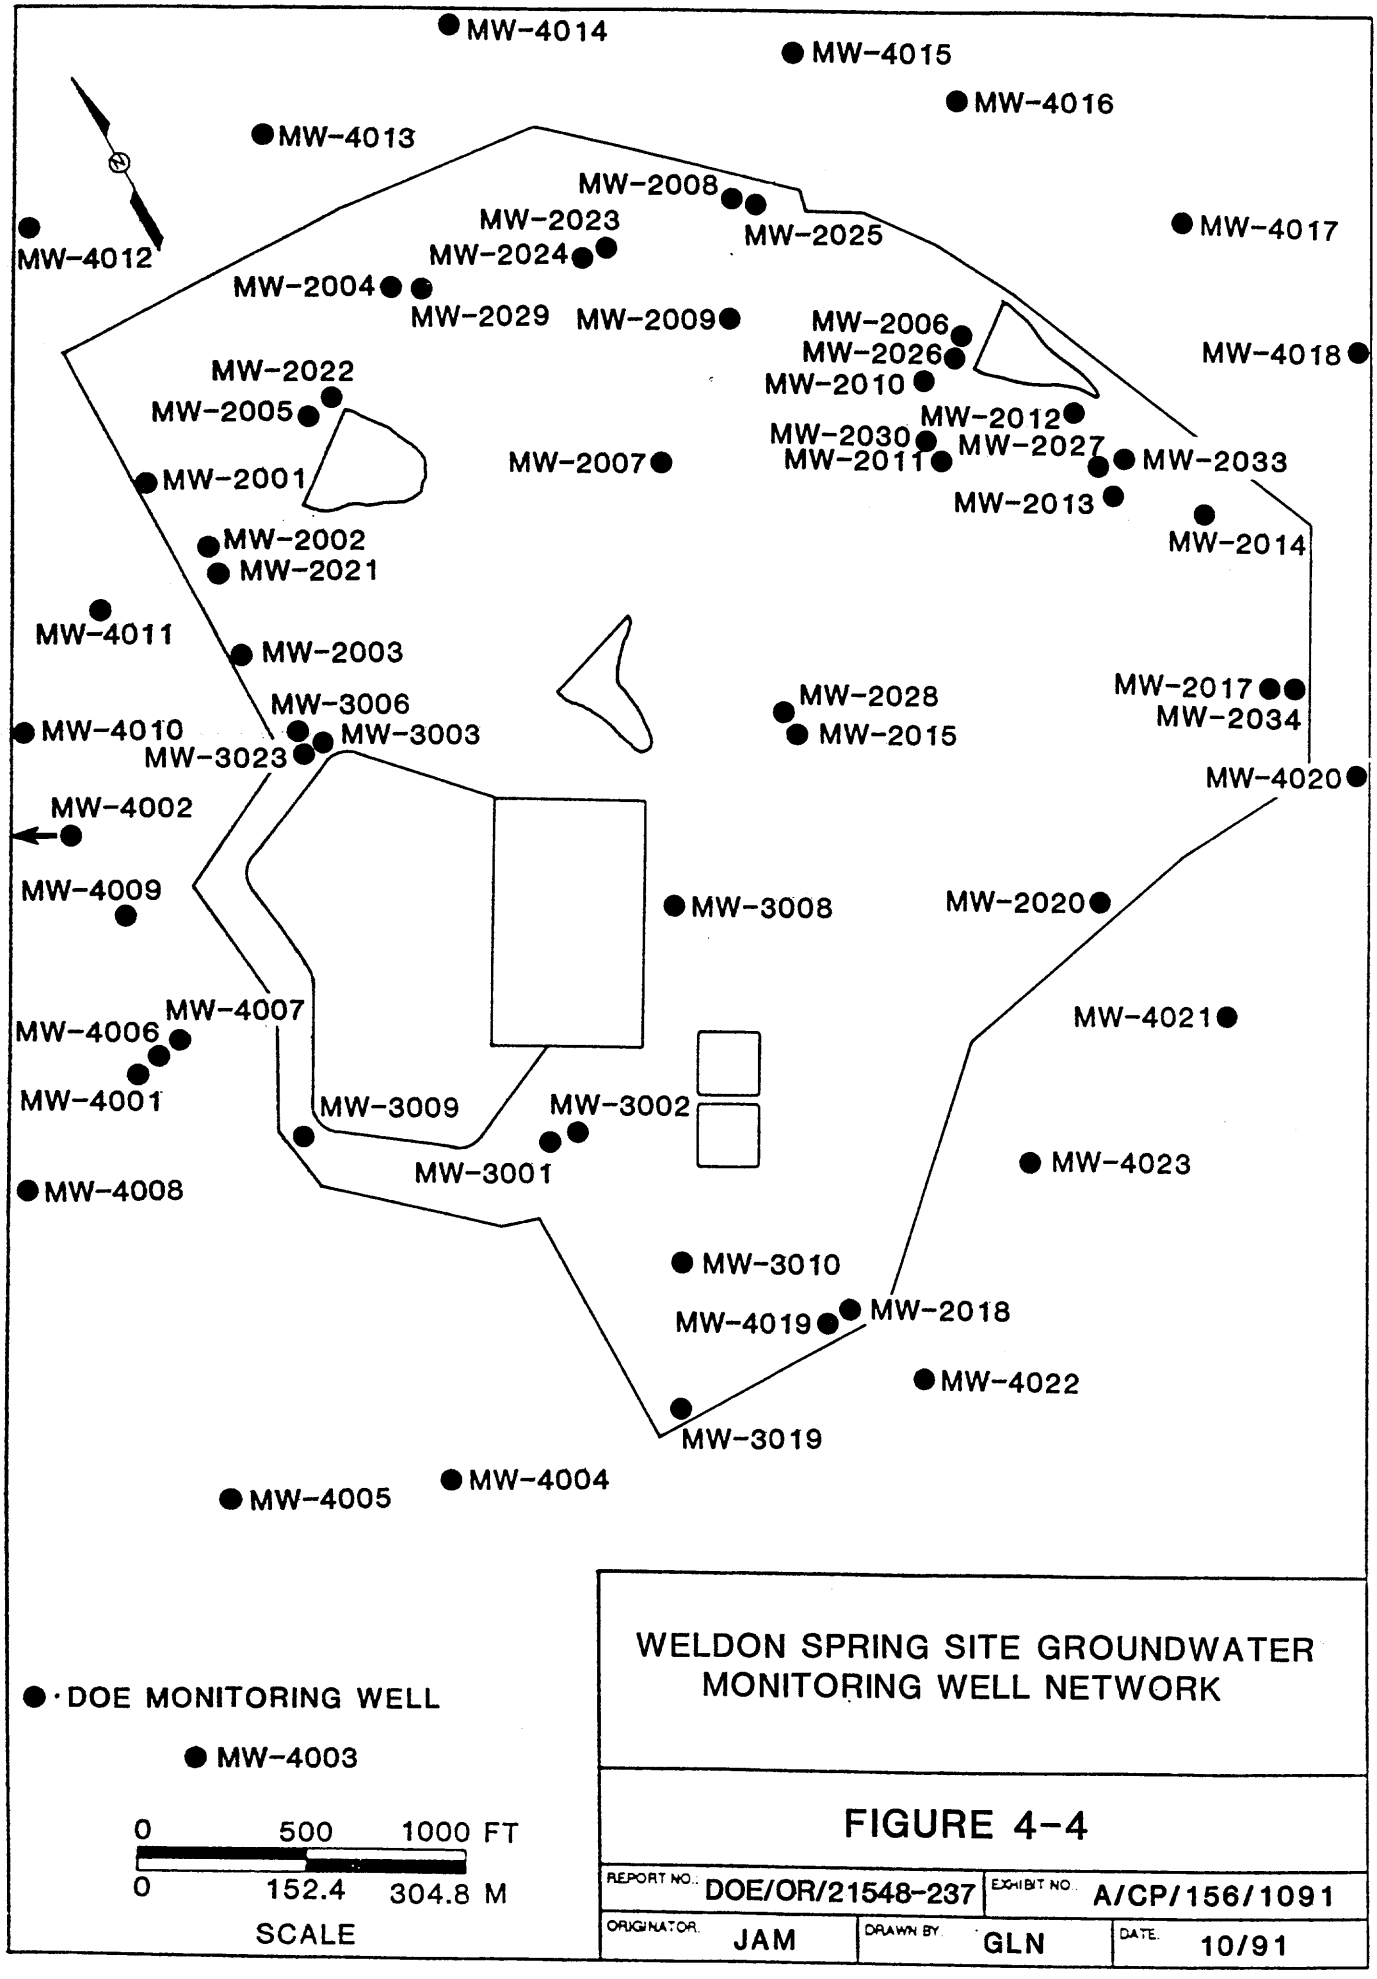
Frequent monitoring of a larger constituent list is necessary at specific wells to perform accurate spatial and temporal statistical comparisons. Greater frequency of data points is necessary to perform meaningful statistical analyses.

4.3.4 WSCP/RP Groundwater Monitoring Location

The number of monitoring wells in the 1992 sampling program will increase at the WSCP/WSRP. Additional monitoring wells will be installed in 1992 to obtain additional baseline information before contaminant source removal begins. Water quality of new and existing wells surrounding the source location will be monitored closely to analyze the short and long term effects of source removal. New wells will also be installed in 1992 according to Resource Conservation Recovery Act (RCRA) regulations to monitor the new water treatment plant. Monitoring well locations are shown in Figure 4-4. All monitoring wells are completed in the Burlington-Keokuk Limestone and are constructed of stainless steel or polyvinyl chloride (PVC). Monitoring wells are installed and developed in accordance with accepted procedure as discussed in the U.S. Environmental Protection Agency Resource Conservation and Recovery Act (RCRA), *Technical Enforcement Guidance Document* (EPA 1986) and Missouri State regulations, *Handbook of Suggested Practices for the Design and Installation of Groundwater Monitoring Wells* (EPA 1989) and the *Groundwater Protection Program Management Plan* (GWPPMP) (MKF and JEG 1991b). Fifty-eight of these wells monitor the upper portion of the formation. Eight wells monitor deeper portions of the bedrock aquifer, especially near potential source areas and in areas of known groundwater contamination. By monitoring these locations and depths, changes in the horizontal and vertical components of contaminant migration can be detected.

4.3.5 Monitoring Schedule

Quarterly sampling will be conducted at the perimeter 4000 series wells and key interior wells. The remaining interior wells will be sampled on a semiannual basis. The quarterly and semiannual samples will be analyzed for the same constituents that have historically been detected in the groundwater. In addition, for precautionary reasons, each well on site will be sampled and analyzed once per year for a suite of radionuclides that are present in the raffinate pit sludge. Analyses for volatile and semivolatile organic compounds, PCBs, and pesticides



WELDON SPRING SITE GROUNDWATER MONITORING WELL NETWORK

FIGURE 4-4

ORIGINATOR	JAM	DRAWN BY	GLN	DATE	10/91

were performed once and not detected in the groundwater (MKF and JEG 1988c). These data, along with historical records, indicates there is no need to continue monitoring those parameters.

The specific wells, analytical constituents, and schedule for the quarterly and semi-annual sampling events are listed in Tables 4-3 and 4-4 respectively. Each well is identified and is followed by the coded summaries of the analyses to be completed during 1992. The coded summaries also identify the quality assurance duplicate samples that will be taken. The code letters for each sample are explained at the bottom of the table.

Using monitoring well 2013 (MW-2013) in Table 4-3 as an example, the letters U, I, N, and R in the First Half column indicate that the full set of analyses will be performed during that sampling event. The letter U indicates that the sample will be analyzed for uranium; the letter I indicates that the samples will be analyzed for nitrate, and sulfate (inorganic anions); and the letter N indicates that the sample will be analyzed for nitroaromatic compounds; and the letter R indicate that the sample will be analyzed for radium, thorium, and uranium isotopes. The remaining letters indicate the laboratories where duplicate samples will be sent. The letter D indicates that a set of duplicate samples will be collected and sent to the primary analytical laboratory.

Additional quality control samples will be collected to assess sample quality. These samples will include field blanks, distilled water blanks, and equipment blanks. The frequency of these samples will vary, depending upon the type of sampling equipment used. These samples will be collected to ensure that no contamination is introduced as a result of cross-contamination, field procedures, or shipping. Collection methods and utility are discussed in Section 10 - Quality Assurance.

4.3.6 Groundwater Monitoring at Springs

Due to the complex nature of the groundwater flow system beneath the WSS, involving both diffuse flow and discrete flow components, an adequate and complete groundwater monitoring program must involve both the use of conventional groundwater monitoring wells near the contaminant sources, and monitoring at springs to detect the transition of diffuse flow migration to the discrete (conduit) pathway. Springs in the vicinity of the site have been monitored since 1987 beginning with the DOE/Project Management Contractor (PMC) broad-based Phase I Spring and Seep characterization wherein some 30 springs and seep features were

located within a 2-mi radius of the site. The springs were inventoried and sampled at varying flow rates. The set of springs impacted by the site was determined and a program of regular monitoring established around those springs. Through that program, and the additional studies conducted by the DOE, PMC, and State and U.S. Geological Surveys, the flow characteristics of the springs and their recharge basins were determined.

Phase I determined that a total of 11 springs, (nine perennial and two wet weather) were impacted or potentially impacted by site related contaminants. Each of these springs has been observed over time and their flow characteristics studied and recorded. Each spring has a unique recharge influence and response to varying recharge conditions. For this reason, the spring monitoring program described below will be of lesser or greater intensity than others in the program.

Following are the characteristics of the discrete flow mechanisms in action around the WSCP area. The rationale for monitoring and the particular structure of the individual monitoring programs are derived from these characteristics.

Regionally, the WSS resides on both groundwater and surface water divides. Waters that migrate from the site move toward the Mississippi River to the north of the divides and toward the Missouri River on the south side of the divides. This characteristic has allowed the WSSRAP to segregate the springs according to their respective geographic position within these basins. Although many springs were inventoried by both the DOE/PMC and the MDNR/DGLS, it was determined that springs located in only two major surface drainages were receiving contributions from contaminated water sources. Figure 4-5, shows the springs that have been routinely monitored for site-related contaminants.

Those drainages include Valley 5300 (southeast drainage), and Valley 6300 (Burgermeister Spring branch). The two source scenarios are quite different. The southeast drainage was used during operation of the Weldon Spring Uranium Feed Materials Plant as a discharge route for contaminated decant water from the sludge settling ponds. As a result of the imposition of contaminated water to the drainageway, the sediments have become contaminated by various substances including radionuclides. The natural springs along that drainage now discharge water containing uranium. Whether contamination at the Valley 5300 springs represents discharge of contaminated groundwater along conduit flow from an upstream source or the contamination comes from the sediments in the drainage itself, is not yet known.

ORIGINATOR: JAM	DRAWN BY: GLN	DATE: 10/91			

In the Burgermeister Spring branch, four springs receive site contaminants. The most prominent of the four, Spring 6301 (called Burgermeister Spring), is a perennial spring which receives both contaminated surface water runoff from the site and discharges contaminated groundwater at base flow conditions. Spring 6302 is an estuella or overflow point which discharges when the conduit capacity of the Burgermeister Spring is exceeded. Previous data indicate that the Burgermeister Spring and the overflow spring are effectively the same water discharging at two different points. Spring 6303 is a small perennial spring up-valley of the 6301/6302 set. Although too low and sporadic to draw final conclusions, the concentrations indicate at least occasional communication with uranium contaminated groundwater. The evidence thus far suggests that continued monitoring is warranted to (1) provide the data necessary to ensure environmental protection, and (2) provide additional information regarding the behavior of the conduit flow system.

Finally, Spring 6306, located below Busch Lake 34, is downstream of the previously described springs and evidence suggests it is derived in part from waters leaking from Lake 34. The presence of uranium in the waters at that spring may be due in part or entirely from the contaminated source waters of the lake. Other evidence suggests that a connection of leakage from Busch Lake 35 to that spring provides a second mechanism and source for the contaminated water at the spring.

4.3.6.1 Monitoring Program. Based upon what is known about the flow characteristics of the springs, the following program will be implemented to monitor the variations in contaminant levels in the site-effected springs. The monitoring program for 1992 will emphasize the flow rate from the springs at the time of sampling as a critical sampling component. Low flow is defined and intended hereafter to mean seasonal baseflow, or the stage of spring discharge when not influenced by active surface water runoff from the local land surfaces. Conversely, high flow is induced by precipitation events. The spring monitoring program will be implemented so as to sample spring waters at periods when they best represent the undiluted groundwater component of flow. To meet this criteria, springs will be sampled no sooner than a minimum of one week following the end of a precipitation event of sufficient intensity to cause surface runoff to occur. Planning and an extra level of scheduling flexibility will be required to implement this selective water sampling program.

Springs SP-5303 and SP-5304 will be monitored at low flow only, since the contributions from surface discharge to spring flow during high flow periods yield unrepresentative samples.

Spring 6301 (Burgermeister Spring) may accurately be described as the most critical point of contaminated groundwater resurgence associated with the WSS. Its discharge reflects the quality of both groundwater and surface water as they migrate from the areas impacted by WSS wastes. It follows that its quality, if characterized and monitored correctly throughout the site cleanup, should also reflect the improvements in environmental conditions. This "correct" monitoring will entail a close correlation of measured contaminant levels with the rate of discharge at the spring as well as the type of discharge event (baseflow, high groundwater level, or precipitation runoff) in progress at the time of sampling (Quinlan 1989).

Sampling of Spring 6302 (overflow spring) will be discontinued during 1992, since the historical data collected to date suggests that the waters which emanate at that spring when it flows are effectively the same as at Spring 6301. The continued collection of data from that location will no longer benefit the project.

The monitoring of Spring 6303 has shown that the spring is minimally impacted by WSS related contaminants. Continued monitoring of that spring provides data of limited usefulness since the cumulative impacts of contamination from that spring, and others in that drainage, are measured in the samples collected at Lake 34. Therefore, monitoring of Spring 6303 will also be discontinued for the 1992 monitoring year.

Spring 6306 has the potential to receive water from multiple sources including Busch Lakes 34 and 35. Although it is not believed that contaminant data from that spring will provide the DOE with any long term insight into the status of groundwater contamination or remedial effectiveness, the location of this spring, and the levels historically measured, warrant continued monitoring on a regular basis. This data will allow the DOE to make current, knowledgeable statements regarding its contamination status.

The data collected at wet-weather Spring 5503 suggest no impact by the WSS and it is appropriate at this time to discontinue monitoring that location.

Table 4-5 details the 1992 spring sampling program and schedule. In summary, springs that have historically been shown to receive contamination from the WSS, and whose measured contaminant levels continue to provide the DOE valuable environmental health and safety data,

will be monitored more intensely. Those springs which have been shown to be minimally impacted or whose contaminant levels can be measured at other routine sampling locations will be discontinued for 1992.

5 BIOLOGICAL MONITORING PROGRAM

U.S. Department of Energy (DOE) Orders 5400.1 and 5400.5 and the *Regulatory Guide* require the development of surveillance programs for ecological systems to protect the health of the public and the environment. Specifically, these orders designate that samples of air, water, soil, foodstuffs, biota, and other media be collected for assessment. Ecological risk assessments are also an integral part of the *Comprehensive Environmental Response, Compensation and Liability Act* (CERCLA) process for the remediation of hazardous waste sites. U.S. Environmental Protection Agency (EPA) and DOE guidance require ecological surveillance to summarize site impacts and to the assess the effectiveness of proposed remedial actions. Other Federal and State laws covered by DOE orders include the *Threatened and Endangered Species Act*, the *Clean Water Act* and the *Wetlands Protection Act*. Primarily, the goal of the biological monitoring program is to support CERCLA ecological risk assessments conducted as part of the Remedial Investigation/Feasibility Study (RI/FS) process and to comply with the National Environmental Policy Act (NEPA) requirements. Identifying the ecosystem around the Weldon Spring site (WSS), the fauna and/or flora potentially at risk, and the levels and extent of contaminates with the ecosystem is the basis of the ecological Environmental Monitoring Plan (EMP) program.

A comprehensive biological surveillance program (Table 5-1) consisting of aquatic and terrestrial studies will be conducted at the Weldon Spring site (WSS) in order to meet these requirements. The focus of studies will include both qualitative and quantitative assessments of the ecosystems. The studies will collect data to determine evidence of biotic contamination, and identify receptor populations and the effects on biotic migration pathways as presented in Section 2.0. Various sites will be surveyed to examine community structure and population dynamics and to provide information on flora and fauna of the area.

Previous characterization studies at the WSS have defined the source areas of contamination and the potential pathways of contaminant migration. A lake and stream investigation was conducted in 1988 and sediment and water samples were analyzed for metals, nitroaromatics, polychlorinated biphenyls (PCBs), volatiles, semi-volatiles and radiological compounds. Elevated levels of radionuclides were detected (MKF and JEG 1989); however, no other compounds were detected. Biotic investigation conducted from 1987 to 1990 have included sampling of fish and small mammals (MKF and JEG 1988; 1989). No PCBs were

detected in fish samples. Arsenic, iron, lead, and chromium were detected in these samples, but were not attributed to site contaminants due to their equal presence in fish samples in control lakes (MKF and JEG 1988). No radionuclides were detected in small mammal samples. The Aquatic Biological Screening Investigation (ABSI) conducted in 1991 sampled benthic invertebrate, zooplankton, sediment and surface water. Elevated levels of uranium in surface water and sediment were found. Zooplankton diversities were higher in the contaminated lakes which may be the result of fish stocking practices. A report summarizing this study is in draft. Waterfowl were sampled from Raffinate Pit 4 during 1990. Results showed detectable levels of radionuclides in organ and bone samples. No control samples or documentation of use of the pits by waterfowl were taken. These needs are addressed in the 1992 EMP.

The biological surveillance program for 1992 will investigate the uptake and effects of radionuclides in select populations of biota. Other chemical contaminants will be studied as detailed below, based upon results as documented by previous soil, sediment, and surface water studies. Community structure and diversity will also be examined to determine any ecological effects of site contaminants. The 1992 EMP program is comprehensive in that an overall evaluation of ecological systems at the WSSRAP has not been previously performed. Based upon results in 1992, the ecological EMP will be re-evaluated to include only those areas considered at risk, requiring additional study, or of specific concern. Data gathered under the EMP will be used to monitor and assess the migration of contaminants from the site, the risks and effects to biota, and will also be used to guide future remedial action alternatives.

5.1 Aquatic Monitoring

Twelve locations will be included in the aquatic habitat studies of the biological surveillance program. Six locations will be monitored at the Weldon Spring Chemical Plant (WSCP), including the four raffinate pits, Ash Pond and its drainage to the northwest, and Frog Pond and its drainage to the north. At the Weldon Spring Quarry (WSQ), the Femme Osage Slough located south of the quarry will be routinely monitored.

Other aquatic sampling locations in the surrounding area include: the southern fork of the Little Femme Osage Creek, the Missouri River near the WSQ water treatment plant outfall, Lakes 34, 35, 36, and Burgermeister Spring at the Busch Wildlife Area; Schote Creek and the southeast drainage upper and lower springs; and SP-5301 and SP-5304 as designated in

Section 4. In addition, various lakes and creeks will be monitored as part of the background sampling program.

Past characterization studies conducted for the site have shown that the primary concerns to aquatic resources are the sediments and surface waters of ponds, lakes, and drainages. Chemical and radiological contaminants of concern include uranium, thorium, radium, nitrate, sulfate, fluoride, metals, and nitroaromatics. The aquatic monitoring program is designed with consideration to presence, concentration, chemical and radiological behavior, and the potential of human and ecological risk associated with the contaminants.

5.1.1 Fish Sampling

In conjunction with the Missouri Department of Conservation (MDOC) fisheries programs, fish samples will be taken annually from Lake 34, 35, 36, and the Femme Osage Slough. Background samples will be taken from Busch Lakes 33 and 37 because these lakes demonstrated no surface or subsurface connection to the WSS along water flow paths, and they resemble the study lakes in size and dynamics. Adult and juvenile fish will be collected using the electrofishing technique in which fish are stunned with a low electrical current, dip-netted from the water, and placed in holding tanks prior to data collection. All fish collected during the study will be identified, measured (total length), and counted. In addition, a gross examination of each fish will be made to determine the incidence of external disease, parasites, or physical abnormalities.

Specific game species, i.e., bass, sunfish, crappie, and catfish will be collected for radiological analysis. Edible portion, whole fish, and organ samples will be analyzed for isotopic uranium. Previous investigations of lake water and sediments and analysis of metals, nitroaromatics, PCBs, semivolatiles and volatile organics, and radiological compounds have shown uranium to be the only radiological contaminant of concern. The slightly elevated levels of arsenic, lead, mercury, and chromium found in fish samples were not attributed to WSS contaminants.

Results from radiological analyses will be used to calculate the effective dose equivalent to humans based upon consumption of fish. Bioaccumulation factors will also be calculated to determine whether fish from contaminated lakes result in factors above normal background levels of radiation (NCRP 1985, Gilbert 1985).

5.1.2 Invertebrates

Benthic invertebrates and zooplankton are routinely used as indicators of water quality. In 1991 a characterization program called the Aquatic Biological Surveillance Investigation (ABSI) was initiated. Fourteen locations were sampled and included lakes, streams, and springs. All but one designated location in the ABSI will be sampled in 1992. Schote Creek will be sampled instead of the original location at the confluence of Dardenne and Schote creeks.

Lakes and ponds will be sampled for benthic invertebrates and zooplankton; creeks and drainages will be sampled for benthic invertebrates. Benthic samples have been taken twice annually during April and July. For each lake, four locations have been selected based upon depth and sediment type. A composite sample will be collected for each location from three separate grabs using a dredge type sampler. Zooplankton samples will be collected weekly from April to June using a plankton net. Vertical tows will be taken, starting at the deepest end of the lake, and an estimate of water flow made using a flow meter connected to the plankton net.

Streams and drainages will be sampled at three sites: the riffle zone, the immediate upstream pool, and the immediate downstream pool. Riffle samples will be taken and will be composited from three Surber samples. Each pool sample will consist of three dredge grabs. A qualitative sample will be taken at each stream and drainage location in order to collect a representative community of benthic invertebrates. All invertebrates collected will be identified by species and enumerated to determine population densities and species diversities.

Biomass samples of benthic invertebrates will also be collected and retained for analysis of total uranium. Three grab samples taken from each lake and stream area will be separated into sub-samples by family or genus or composited based on total mass of sample collected.

A variety of hydrological data will be collected to assist in the interpretation of the biological data. Temperature, dissolved oxygen, conductivity, pH, water clarity (Secchi disc), total suspended solids, total phosphorus and alkalinity will be measured. A measure of the productivity of the lakes and streams will be taken by analyzing water samples for chlorophyll. Sediment and water samples will be analyzed for total uranium and toxicity metals (As, Hg, Pb, Cd, Cr, Ba, Se, Ag, Zn).

Total density and diversity will be calculated for benthic invertebrates and zooplankton. Comparisons will be made to uncontaminated lakes to determine if contaminants are effecting the invertebrate community in the lakes, springs, and streams. Water and sediment data will also be correlated to population densities and diversities to determine what factors or contaminants directly influence populations.

5.1.3 Aquatic Vegetation

The aquatic habitats found in the WSCP area and the Femme Osage Slough are all man-made impoundments, but have been classified as wetlands on the National Wetlands Inventory Map (U.S. Fish and Wildlife Service 1984). Even though these ponds are chemically and radiologically contaminated, they are utilized by fauna for foraging, breeding, and resting. A primary mechanism of contaminant entry is root uptake of radionuclides by aquatic vegetation.

A vegetation survey will be conducted of wetland areas to document the species, density, and seasonal occurrence of plants growing in the ponds. A reconaissance survey was conducted in August of 1991, and a wetland survey will be conducted in May and August of 1992, to make the necessary quantative field measurements during dry and wet conditions. This information will be used to assess wetland status of the aquatic habitats under Federal wetland guidance (FICWD 1989).

Four areas will be sampled for bioaccumulation of radionuclides in aquatic vegetation. The basin of Frog Pond and Raffinate Pit 4 is densely populated with various rooted aquatic vegetation. The Femme Osage Slough contains various species such as cattails and arrowheads. Whole samples (stems, roots, and leaves) will be taken in the late summer from these locations and analyzed for total uranium. In addition, aquatic and terrestrial vegetation along the Missouri River will be analyzed for total uranium concentrations under the preoperational monitoring of the National Pollution Discharge Elimination System (NPDES) program (Section 8).

Concentrations of radionuclides in vegetation will be measured and compared to background locations. These results, along with water and sediment data, will be used to determine if toxic effects could be occurring. Primarily, vegetation in aquatic habitats will be analyzed to determine whether fauna feeding on this vegetation are potentially exposed to radionuclides above background levels.

5.1.4 Waterfowl

Aquatic habitats at the WSS attract waterfowl and shorebirds throughout the year including mallard, spotted sandpiper, Canada goose, and herons. Many species utilize the waters for foraging, shelter, rest, and nesting.

In 1991, a summer resident census was conducted to determine waterfowl use of the aquatic resources at the WSCP and Femme Osage Slough. The results of this survey are not currently available, but based upon documentation of extended residency, samples of waterfowl game species will be collected. Samples will be analyzed for uranium, thorium, and radium concentrations in bones, flesh, and internal organs.

This characterization program may require that additional samples be taken in 1992. If so, a summer census will be conducted and additional games species will be sampled to determine bio-uptake of radionuclides. In addition, samples will be solicited from local hunters to be used as study and background data.

A winter migratory census will be taken, starting in September of 1991, and will continue one week per month through April 1992, and again from September to December of 1992.

5.1.5 Other Aquatic Studies

The Blanding's turtle is a semi-aquatic species considered endangered in Missouri. Two recent sightings were recorded for the turtle in the Busch Wildlife Area immediately north of the WSS. In order to determine if this endangered species occupies the aquatic habitats within the chemical plant or quarry area, a herpetofauna survey will be conducted. In addition to the Blanding's turtle, other species of frogs and toads will be surveyed. NEPA also requires a threatened and endangered species prior to any construction of, or modification to, facilities due to remedial actions.

Herptofauna occurring in the area will be determined by habitat searches and roadside and wetland observations. Surveys will include overturning logs, debris, and rocks during vegetation surveys. Incidental sightings during other ecological programs will be documented as well. Individuals will be identified either visually at a distance, or captured using a dip net, then identified and released. Specific sampling locations will include the Femme Osage Slough,

Raffinate pits 1 through 4, Ash Pond and Frog Pond and their drainages, and Burgermeister Spring and the southeast drainage. Sampling will be conducted in March for breeding frogs and toads, and in the early summer for the Blanding's turtle.

5.2 Terrestrial Habitats

The terrestrial community of the WSS area is diverse. The WSCP and WSQ are primarily old field or maintained grass habitats with remnant upland and slope forests. Much of the land immediately surrounding and adjacent to the WSS is state-owned wildlife area (ANL 1990). Habitats within these areas include old field, cultivated farmlands, upland slope, and bottomland forests.

The terrestrial community supports a wide variety of fauna including avian and mammal species. White-tailed deer, gray squirrels, and cottontail rabbits have been sighted within the chemical plant boundaries. Opossum, fox, and coyote roam within the Weldon Spring and Busch Wildlife areas. Many birds are summer residents in the area and many spring and fall migratory species utilize the field and forest habitats. Eastern screech and barred owls have been sighted along deciduous forests south of the chemical plant.

Specific terrestrial habitats will be surveyed and routinely monitored as part of the biological surveillance program. At the WSCP, these areas include the north dump area, the upland and riparian forests surrounding Ash Pond and Frog Pond and their drainages, and the old field habitat surrounding the raffinate pits. At the WSQ, these areas include the quarry floor, Femme Osage Slough, and the upland and bottomland forests, north and south of the Katy Trail. The riparian and upland areas along the southeast drainage, and forest along Burgermeister Spring will be also be included in the terrestrial survey programs.

Past characterization studies conducted for the site have shown that the primary concerns to terrestrial resources are the soils and vegetation in contaminated zones. Radiological contaminants of concern include uranium, thorium, and radium.

5.2.1 Vegetation

Terrestrial ecosystems are generally categorized according to the vegetation that dominates the plant community (EPA 1989). As a basis for terrestrial studies, a vegetation and

habitat map will be developed that delineates terrestrial ecosystems. Aerial photographs will be used to construct maps that will detail drainages, plant associations, historic and current land use, and ecosystem patterns.

Vegetation surveys will be conducted in each study location to document the community structure. Descriptions and inventories of plant species occurring at each location will be conducted during spring and summer. Vegetation communities will be quantified using the stratified random sampling methods. Species presence, percent vegetative cover, and percent canopy cover will be obtained. Qualitative notes on species abundance, growth factor, and terrain slope will be documented. Above-ground plant conditions will be visually examined for discolorations, parasitic galls, and leaf necroses. Specific efforts will be made in searching suitable habitats for species listed as threatened or endangered by the Missouri Department of Conservation.

Data collected from vegetation studies will primary be used to document vegetative habitats, identify effected areas and/or potentially effected environments. In addition, habitats that support or have the potential to support species of special concern (threatened or endangered) will be noted.

5.2.2 Birds

Avifauna surveys will be conducted using observational census methods. Binoculars, spotting scopes, and vocalizations will be used to document species occurrence. Surveys will be conducted bimonthly at each primary location. At each location, a 15-min observation period will be made and species will be recorded according to visual or audio identification. Data recorded will include habitat type, weather, sex, behavior, and species. Data collected will be used to estimate species diversity, density, and habitat use. In addition, all active nests found during surveys will be documented.

Particular attention will be paid to the surveying of threatened and endangered species including the bald eagle and Cooper's hawk based upon terrestrial habitat preferences. In addition, areas particularly favored by large bird populations and/or migrating birds will be noted in support of ecological assessments for the site and quarry.

5.2.3 Mammals

Large and small mammal surveys will be completed in order to determine the species, communities, and use of land within the boundaries of the WSS and within surrounding wildlife areas. Particular attention will be given to game species such as the white-tailed deer and eastern cottontail which are known to frequent the chemical plant area.

For large mammals, observational surveys will be conducted weekly within the chemical plant area. Site-specific locations, activities, and species will be documented. Observations will include visual sightings, detection of tracks, scats, and nests.

Opportunities will be taken to sample large mammals due to road-kill, accidental death, or donated samples; these samples will be analyzed for total uranium concentrations. Only mammals utilizing the chemical plant and quarry locations and those taken as background samples will be considered.

Small mammals will be biannually sampled during winter and spring. Live traps will be baited and placed along transects at the north dump area, south dump area, Frog Pond drainage, southeast drainage, and area surrounding the Femme Osage Slough. Small mammal densities and communities will be determine by the trap and recapture sampling method. Traps will be set for four nights and all captured mammals will be tagged and released. Species, age, sex, tail length, right hind-foot length, and previous capture data will be determined for each capture.

Small mammals will also be collected for radiological analysis. Primarily, rodents will be taken including deer mice, voles, and shrews. Each specimen will be identified by species and sex. The length and live weight will be determined and each species will be examined externally for the presence of lesions, tumors, or other abnormalities and reproductive condition. Whole-body specimens will be analyzed for uranium, thorium, and radium concentrations.

Small mammals are being surveyed to determine what populations are potentially at risk, what levels of contaminants are being accumulated, and the potential for larger mammals and birds that prey upon these mammals to biomagnify these contaminants.

5.2.4 Agricultural Products

Agricultural lands surrounding the WSS comprise approximately 20% of the terrestrial habitat. The Busch Wildlife and the Weldon Spring Wildlife areas contain approximately 2,200 acres and are leased to sharecroppers for farming (MKF and JEG 1991f). Besides state-owned property, many private farms are located within the immediate area. Agricultural products grown in the area include corn, soybeans, sunflowers, and sorghum. These products are grown primarily for cattle and wildlife feed and forage.

The wellfield located adjacent to the Femme Osage Slough south of the WSQ is also activity farmed. Uranium concentration in the slough has ranged from a low of $<$ 1pCi/l to a high of 557 pCi/l, with an average around 54.8 pCi/l. In addition to the U.S. Department of Energy (DOE) requirement for monitoring of "foodstuffs", the public has expressed concern over the potential for elevated levels of radionuclides in the agricultural products.

According to the requirements of the *Regulatory Guide*, an 8-mi radius of agricultural lands surrounding the site will be surveyed for farm and gardening practices. Samples will be selected and analyzed for uranium, thorium, and radium. Samples will be taken based upon farming practices within the study area as provided by the county Soil Conservation Service and the Missouri Department of Conservation.

The number of samples (for each crop type) will be equal to 1% of the total number of acres planted within the study area (example: 2,000 acres of corn planted = 20 samples for corn). A minimum of four samples will be collected. Samples will also be taken with consideration for the distance from a contamination source, such as the quarry pond. Soil samples will be collected from each location in addition to foodstuff samples. Samples will be analyzed for uranium, thorium, and radium concentrations. Determinations will be made on the significance of radiological concentrations found in agricultural samples taken within an 8-mi radius of the WSS and those collected from background locations.

5.3 Background Sampling

Sampling of similar ecological habitats and fauna as those found within the Weldon Spring site will be conducted. These background samples are necessary in order to establish baseline environmental conditions that occur within the surrounding area. Areas that have no

exposure pathway from the site, are in close proximity to the site, and that mirror ecological habitats in terms of water, chemistry, and topography. will be selected to serve as background sampling locations. Locations for aquatic studies include Busch Lakes 33, 37, and 26; the upstream branch of the Little Femme Osage Creek; Geoke Spring (SP-6501); and the upstream branch of Dardenne Creek. Locations for terrestrial studies include Marais Temps Clair Wildlife Area, Prairie Lake, Augusta Farm, Weldon Spring Wildlife Area (WSWA), Yellow Trail, and WSWA Agricultural Field 1 and 5.

Background sampling will be conducted for the 1992 *Environmental Monitoring Plan* (EMP) for all biouptake studies. These specifically include sampling for fish, benthic, invertebrates, zooplankton, agricultural products, aquatic vegetation, small mammals, and waterfowl.

5.4 Data Reporting

All information gathered from ecological survey and monitoring activities will be used to characterize the flora and fauna of the Weldon Spring site. Survey data will be summarized to indicate population densities, species presence, and species diversities. Estimates will be made on vegetative cover, faunal ranges, and usage patterns. A general overview of the ecological populations will be documented and used in determining significant receptor populations.

Data collected for biouptake studies will be used to determine exposures for human populations and for other animal populations. Dose calculations for humans based upon ingestion of contaminant biota will be performed as discussed in Section 9. Exposure indicators (bioaccumulation factors) and contaminate concentrations will be determined for biota. Behavioral indicators and habitat degradation or modification will be examined as part of the assessment. Contaminant concentrations will be compared to background concentration to determine evidence of biouptake. The statistical tests that will be used will determine whether selected biota utilizing contaminated resources have significantly higher levels of contaminant concentrations than background biota at a 90% confidence level. The student's T-test or the Mann-Whitney U-test will be used based upon whether the distribution of data populations can be assumed to be normal. Preliminary tests of variance and normality will be determined by using the W-test and F-test. For the W-test, data reported as non-detects or less than the detection limit (DL) will be quantified as DL/2 according to EPA guidance (1989).

5.5 Collection Permits

The taking of specific fauna for scientific study is authorized by permits from the Missouri Department of Conservation and the U.S. Fish and Wildlife Service. Applications for permits, as required by sampling plans and State and Federal regulations, will be submitted prior to sample collection. Compliance with all applicable State and local laws will also be followed in all ecological sampling programs designated here.

5.6 Natural Resource Trusteeship

The Project Management Contractor (PMC), under the authority of the DOE and Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), acts as Natural Resource Trustees at the Weldon Spring Site Remedial Action Project (WSSRAP). Other agencies at the WSSRAP also act as Natural Resource Trustees. These include the U.S. Fish and Wildlife Service, the Missouri Department of Conservation and the Missouri Department of Natural Resources. The PMC coordinates with these agencies at the State and local level to notify them of releases of CERCLA hazardous substances. The biological monitoring program outlined here gathers the information necessary to provide an assessment of existing ecological conditions as required under the Natural Resource Trustee Act. In addition, the monitoring program provides a means to monitor unplanned releases and to assess the threat posed by a release. The results of annual monitoring as presented in the *Annual Site Environmental Report* are provided to these Federal agencies.

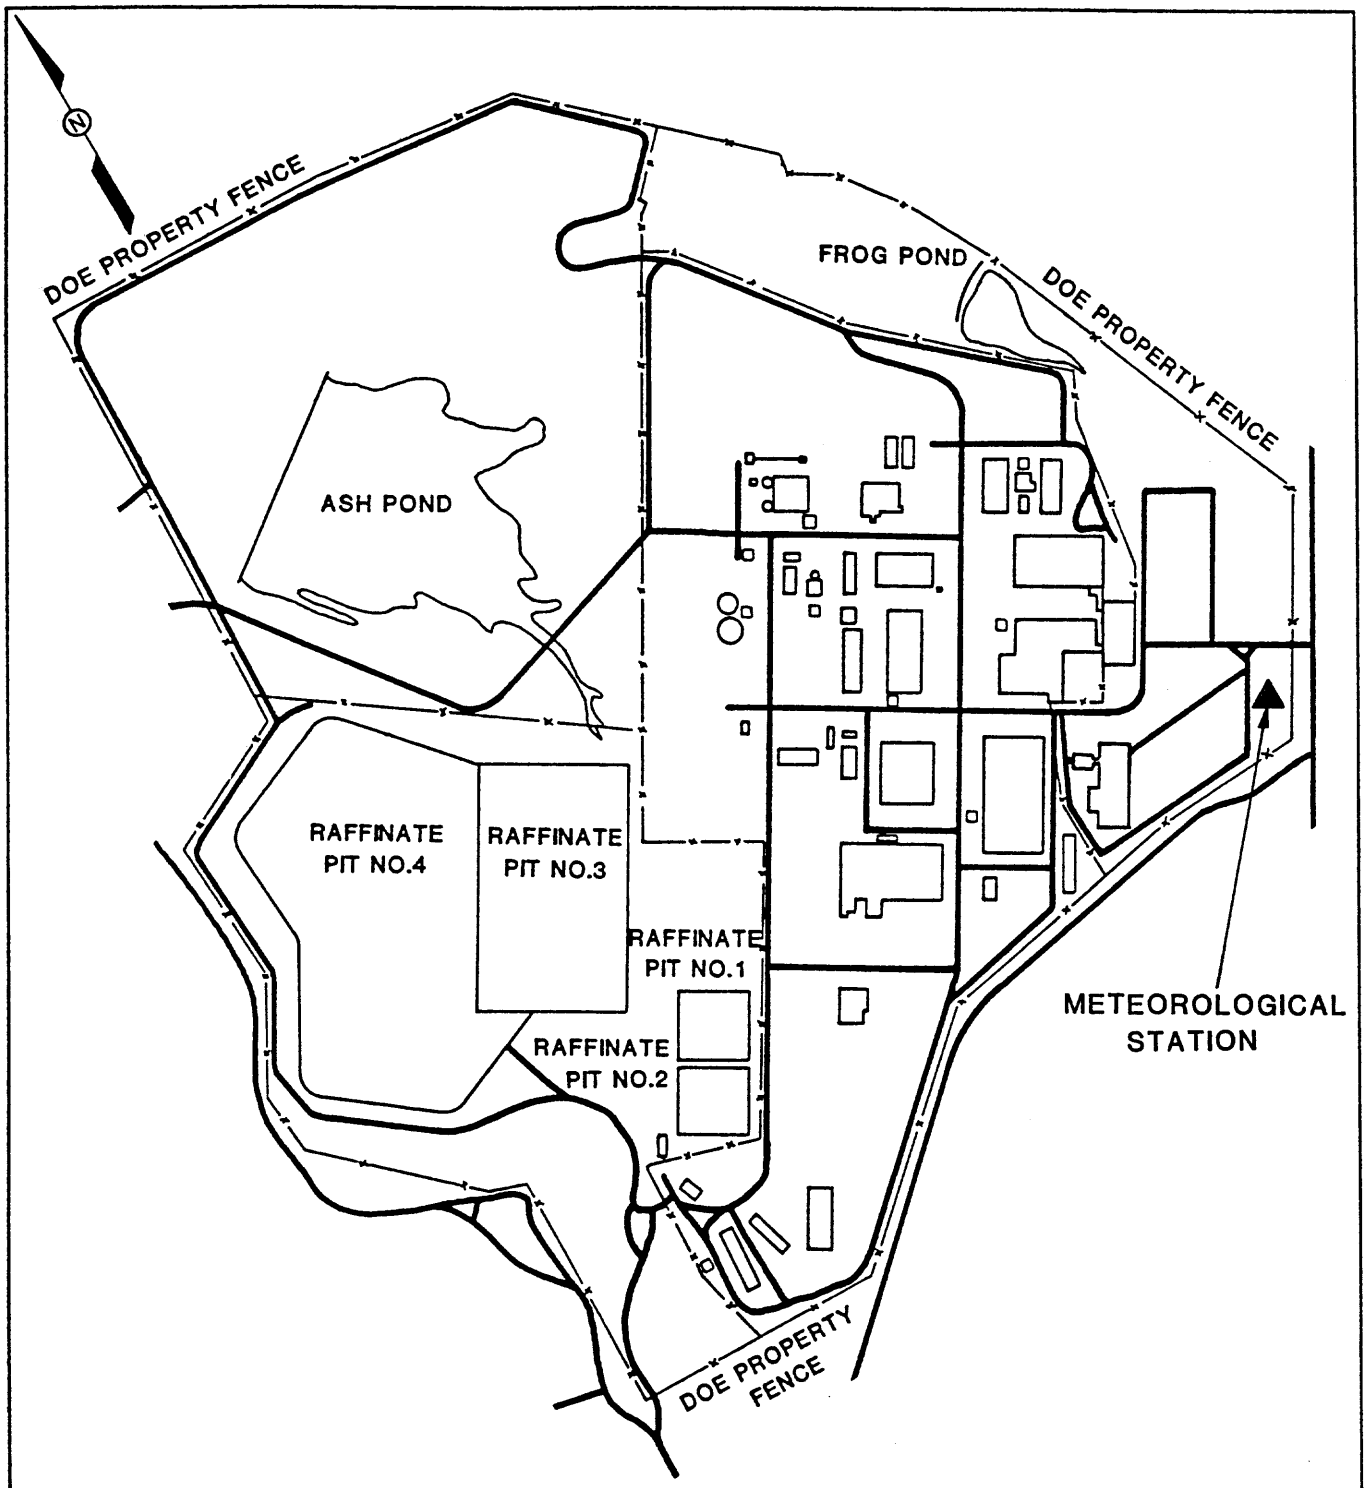
6 METEOROLOGICAL MONITORING PROGRAM

This section provides a description of the meteorological parameters measured, meteorological instrumentation, and computer programs and models that are utilized to support the environmental surveillance and emergency response activities at the Weldon Spring Site Remedial Action Project (WSSRAP). Radiological dose calculation to the general public is based upon measurements from critical receptor locations (Section 8.2.3). The use of actual concentration measurements at these locations yields more accurate dose calculations than those based upon modeling of downwind dispersion. The sources for off-site airborne releases that exist at the site are diffuse sources from waste areas and site remedial activities. No point source (stack-type) releases are in operation at the site.

The WSSRAP has two diffuse sources of airborne radiological emissions: the Weldon Spring Chemical Plant and Weldon Spring raffinate pits (WSCP/WSRP), and the Weldon Spring quarry (WSQ). An assessment of the two diffuse sources was conducted as required by the *Regulatory Guide*. The assessment included documenting the different radionuclides that could potentially be released from the sources and their concentrations.

The WSQ diffuse source is a 9-acre limestone quarry located approximately 2.4 mi south-southwest of the 217 acre WSCP/WSRP area. The WSQ is located 650 ft above sea level while the WSCP/WSRP is 500 ft above sea level. As determined by a certified meteorologist, the WSQ and the WSCP/WSRP meteorological conditions do not differ significantly and thus do not require separate meteorological monitoring stations. The location of the meteorological station is on the eastern edge of the WSCP/WSRP area more than 400 ft from the nearest building (Figure 6-1). Source term assessments are further discussed in Section 8.1.1 for the WSQ and in Section 8.1.2 for the WSCP/WSRP.

The meteorological station for the WSSRAP is designed to sample and record meteorological variables: wind speed, wind direction, horizontal wind fluctuation, ambient air temperature, barometric pressure, and precipitation intensity and accumulation. The station performs computations on the sampled signals and the data are stored electronically. Provision is also made to record the signals on a back up chart recorder located at the tower site. Data collected by the monitoring station will enable dispersion and diffusion modeling to supplement critical receptor monitoring in the event of an airborne release.



SCALE 0 500 1000 FT
0 152.4 304.8 M

LOCATION OF THE WELDON SPRING SITE METEOROLOGICAL STATION

FIGURE 6-1

REPORT NO.:	DOE/OR/21548-193	EXHIBIT NO.:	A/CP/162/1191		
ORIGINATOR:	JAM	DRAWN BY:	GLN	DATE:	11/91

The meteorological station consists of a 10 m retractable, tilt-down tower with wind speed and direction sensors located at the 10 m level. Sensors at greater heights are not necessary since potential releases of airborne emissions are at or near ground level. The wind-aspirated temperature sensor is located on a post at the 2 m level and the precipitation gauge is located at ground level. The barometric pressure sensor is located inside an electronic enclosure situated adjacent to the tower. The horizontal wind fluctuation is computed by the station electronic circuitry. The aforementioned meteorological parameters are collected and stored as digital signals every 60 sec. Every hour, the one min recordings are averaged and stored as hourly data. This hourly data is then downloaded once per day to a remotely-located computer. The hourly data are then reviewed on a daily basis and archived onto floppy and hard drives.

These data are used to support the WSSRAP environmental surveillance program. Precipitation measurements will be correlated to aquifer water level fluctuations in the Femme Osage Slough and the WSQ. Water level fluctuations will be studied to aid in the determination of the cause of fluctuating uranium concentrations at the aforementioned locations. Wind direction results will be analyzed to determine if studies on foliar absorption by vegetation are needed. Radon and radon-daughter real time data will be coordinated with meteorological data at some future date.

Furthermore, the real-time data read out of meteorological variables aids site personnel in observing and analyzing the dispersion of potentially released airborne materials during and after an incident.

The computer program METDSPL is a qualitative atmospheric dispersion program designed to provide a schematic view of dispersion at the WSSRAP. This will aid the emergency response team in the event of a release. The plume depicted by METDSPL is based on an eulerian formulation. It simulates the path of a series of hypothetical gas particles released from a point source. The tracks of these particles are then plotted to scale on the computerized map of the site. METDSPL continuously polls the remote station for wind speed and wind direction values that are then updated on the screen, and a sector plot drawn. At the end of a segment time step, the vector averages over that interval are used to plot the distance and direction each segment moved during the period. The new paths and the background map are then redrawn.

Inspection and maintenance of the meteorological station, daily review of meteorological data, and semiannual calibration of the meteorological station are documented in Environmental Safety and Health procedures.

7 EXTERNAL RADIATION EXPOSURE ENVIRONMENTAL SURVEILLANCE MONITORING

The external radiation exposure environmental surveillance program at the Weldon Spring site (WSS) was designed to monitor potential external exposure points at the Weldon Spring Chemical Plant/Weldon Spring raffinate pits (WSCP/WSRP) and Weldon Spring Quarry (WSQ) perimeters, vicinity properties, and at off-site locations where the highest potential for an exposure to a member of the general public to gamma radiation exists. Gamma radiation is emitted by nearly all the radionuclides of the U-238 and Th-232 decay series. These radionuclides are found in above-background concentrations on the WSS, and as a result gamma radiation is monitored.

In addition, the environment contains naturally occurring radioactive substances which emit gamma radiation. Terrestrial radiation sources are natural radioactive elements in the environment (soil, water). Cosmic radiation is high-energy radiation that originates in outer space and filters through the atmosphere reaching the Earth's surface. Together, these two sources account for natural background gamma radiation. Terrestrial and cosmic radiation fluctuates depending on the soil composition and elevation above sea level.

The spherical environmental thermoluminescent dosimeters (TLD), which will be employed to monitor gamma radiation, are composed of five lithium fluoride chips in a durable spherical polyethylene holder. The TLDs will be collected and analyzed on a quarterly basis.

The locations chosen as external monitoring stations were based on the characteristics of the WSS. The potential for external gamma exposures to a member of the public as a result of fugitive dust emissions from the WSS is an unrealistic exposure pathway. Any airborne emission from the WSS will be intermittent, have low concentrations of radionuclides, and would have a low probability of drifting toward a location where a member of the public would frequent. Thus, this pathway would not result in a measurable external exposure to a member of the general public. In addition, there are no high energy accelerators, industrial x-ray, or large isotopic radiation sources present at the WSS. The only potential for external exposure to a member of the general public results from contaminated soils located at the WSCP/WSRP, WSQ, and vicinity properties.

Exposure from gamma radiation at the WSS will be monitored at 30 monitoring stations using environmental TLDs. Ten monitoring stations are located around the perimeter fence of the WSCP/WSRP (Figure 7-1). Five will be located around the perimeter of the temporary storage area (TSA) (Figure 7-2) located within the WSCP/WSRP. The TSA is one of the waste control facilities to be utilized in 1992 for the storage of bulk radioactive and chemical wastes from the WSQ. Eight monitoring stations will be located along the WSQ perimeter fence (Figure 7-3) spaced at intervals of 80 ft to 350 ft.

The 10 monitoring stations at the WSCP/WSRP are spaced at intervals ranging from 700 ft to 2,000 ft around the site perimeter. The five TSA monitoring stations will be located around the perimeter at intervals of 420 ft to 780 ft. The six monitoring stations at the WSQ will be spaced at intervals of 300 ft to 840 ft. The monitors at the perimeters of the WSCP/WSRP, TSA, and WSQ will be used to measure gamma exposure rates at the boundaries of those areas.

Spacing of the monitoring stations around the perimeters of the WSCP/WSRP, TSA, and WSQ is based on the relative potential for external exposures. The perimeter of the WSQ, which has the shortest distances between monitoring stations, is the most accessible to a member of the general public. In addition, the contaminated materials within the WSQ at some points are less than 150 ft from the perimeter. The intervals between monitoring stations at the TSA are similar to those at the WSQ. Material presently at the WSQ will begin to be moved to the TSA during 1992. In some places the TSA perimeter is less than 100 ft from the WSCP/WSRP perimeter. The intervals between monitoring stations at the WSCP/WSRP perimeter are larger because the potential for external exposure to a member of the general public at the WSCP/WSRP perimeter is less significant.

Five off-site monitoring stations (Figure 7-1), as well as two of the perimeter monitoring stations, will be used to assess gamma radiation exposure rates at locations near the WSCP/WSRP where members of the general public abide or reside. The monitoring stations at the Francis Howell High School and the Busch Wildlife headquarters were chosen because they have the largest populations near the WSCP/WSRP. The State of Missouri Highway Department, TD-2004; the Army Reserve guard house, TD-4002; and the WSSRAP administration building, TD-2005; are the closest locations to the WSCP/WSRP where a member of the general public abides or resides.

BACKGROUND AIR MONITORING STATION

FIGURE 7-5

REPORT NO.: DOE/OR/21548-237			EXHIBIT NO.: A/VP/112/1091		
ORIGINATOR: JAM		DRAWN BY: GLN		DATE: 10/91	

The monitoring station near the residence, TD-4007 (Figure 7-3), was chosen because the individuals who reside there have an assumed continuous exposure time, the longest of any of the WSS nearby receptors. The location at the Femme Osage Slough vicinity property, TD-4008, was chosen because it has the greatest potential of the WSS vicinity properties to cause an external dose to a member of the general public. The Femme Osage Slough vicinity property is located near the Katy Trail, which has the largest population group that visits the WSS vicinity, and is used by individuals who fish from the Femme Osage Slough.

Five monitoring stations are used to measure background gamma radiation exposure rates (Figures 7-1, 7-4 and 7-5). The monitoring locations are TD-4001, TD-4004, TD-4005, TD-4006, and TD-4009. In 1989, background gamma radiation exposure rates were measured in each of the three distinct geological regions in the vicinity of the WSS. The three distinct regions are the dissected glacial till deposits, the alluvial deposition of the Missouri River, and the Salem Plateau. Statistical analysis of the data from the background measurements indicated that at the 95% confidence level there was no reason to suspect a difference in the gamma exposure rates between the three geological regions. Since there was no reason to suspect a difference between the gamma exposure rates in the three geological regions, an average of the results of the five background locations will give a better approximation of the background gamma radiation exposure rate.

Four of the background monitoring stations are within 4 mi of the WSCP/WSRP or WSQ. The fifth background station, TD-4009, is approximately 8 mi from the WSCP/WSRP and 7 mi from the WSQ. The *Environmental Regulatory Guide for Radiological Effluent Monitoring and Environmental Surveillance* (DOE 1991) suggests that background stations should be located at a minimum of 6 mi to 9 mi from a site. Although three of the background stations are not located at the distances suggested in the *Regulatory Guide*, they are at appropriate distances with respect to the WSS. As mentioned, the WSS will not render external radiation exposures as a result of any airborne emissions. There are no high energy accelerators, industrial X-ray, or large isotopic radiation sources at the WSS, thus the distances that the four background stations are from the WSCP/WSRP or vicinity properties are more than sufficient to attenuate the gamma radiation from on-site contaminated soils.

Measurements with a pressurized ion chamber (PIC) as suggested in the *Environmental Regulatory Guide for Radiological Effluent Monitoring and Environmental Surveillance* (DOE 1991) will not be made at monitoring stations used in previous years. Because the TLDs

integrate gamma exposure for 13 wk, the TLDs actually provide a better assessment to determine if any natural occurring anomalies are present at the location than would a short term PIC measurement. Results of previous TLD measurements are consistent with yearly background gamma exposures made by the Project Management Contractor (PMC) and other DOE contractors around the WSS. Results have ranged from 60 mR/year to 104 mR/year (BNI 1984; BNI 1985a; BNI 1985b, and MKF and JEG 1989a), with the exception of some of the monitoring stations at the WSQ. The monitoring stations at the WSQ, located in the controlled area, are positioned near contaminated soils and material. The above background results are due to the proximity of the monitoring stations to the contaminated soils. Because previous TLD measurements are consistent with background exposure rates performed by the PMC and others and are within the expected range for this altitude, it is concluded that there are no naturally occurring anomalies present. Thus, pressurized ionization chamber (PIC) measurements are not necessary.

New monitoring locations in 1992 include: background monitoring station TD-4009, monitoring station TD-4008 at the Femme Osage Slough, monitoring station TD-4007 near the residence west of the WSQ, WSQ perimeter stations TD-1005, TD-1007, and TD-1008, and WSCP/WSRP perimeter stations TD-2004 and TD-2005. The WSQ perimeter station TD-1005 and the WSCP/WSRP perimeter station TD-2004 and TD-2005 are previously existing stations which have been moved to new locations in order to obtain more useful monitoring data. Prior to installation of the new monitoring stations, a survey of the locations will be conducted as suggested in the *Regulatory Guide* to determine the absence of possible naturally occurring anomalies that could affect later measurements. The survey will be conducted with a PIC.

The five monitoring stations at the TSA, TD-5001, TD-5002, TD-5003, TD-5004, and TD-5005 will also be new stations in 1992. Because these stations are located in the controlled area where contaminated soils will be stored, PIC measurements are not necessary prior to installation of the stations. Measurements would be expected to be greater than background due to the contaminated soils in the area. However, baseline measurements will be taken with TLDs prior to arrival of bulk waste material from the WSQ to the TSA. The TLDs will be placed at the TSA for 13 weeks (calendar quarter) and from that data any increase in the external gamma radiation exposure rate as a result of TSA activities can be assessed.

The quality control measures that will be implemented for environmental TLDs include duplicates, chain-of-custody forms, field sheets, and review of vendor data. At least two

duplicate TLDs will be deployed, one at the WSQ and one at the WSCP/WSRP. When the TLDs are exchanged and retrieved, field sheets will be used to document placement and any unusual occurrences. Chain-of-custody forms will also be filled out as specified in the appropriate WSSRAP standard operating procedures (SOP). The data that is received from the vendor will be reviewed and any anomalies identified and investigated. In addition, performance testing and deployment and storage of TLDs will be done according to ANSI-N545-1975 and Nuclear Regulatory Commission (NRC) Regulatory Guide 4.13.

8 EFFLUENT MONITORING

The Weldon Spring Site Remedial Action Project (WSSRAP)has established two distinct monitoring programs which it characterizes as "effluent monitoring." These include airborne and waterborne effluents which might exceed the site perimeters. These programs are described in detail in the following sections.

8.1 National Pollution Discharge Elimination System (NPDES) Program

As a Federal facility, the WSSRAP is subject to, and complies with, Executive Order 12088, which requires all Federal facilities to comply with applicable pollution control standards. Further, U.S. Department of Energy (DOE) Order 5400.1 states that the DOE is to "conduct operations in compliance with the letter and spirit of applicable environmental ... regulations and standards." In this light, and since the WSSRAP contains point sources for waterborne pollutants, the project operates in compliance with Clean Water Act requirements.

8.1.1 Goal

To minimize the discharge of waterborne contaminants from the site, WSSRAP policy dictates that all surface water be closely monitored and controlled with treatment as necessary. Table 8-1 presents the known sources of water on the site. Erosion is to be minimized and sediment removed to a level commensurate with "best available technology." Contaminated water on the site is to be treated where appropriate, to ensure that water discharges meet Federal and State requirements.

The objective of the effluent monitoring program is to establish a base of information regarding water treatment requirements, and to verify compliance with State and Federal regulations. The remedial action goal is to clean up the site with no increase in contaminant discharge or degradation of the off-site streams. The elements of the program consist of source identification, periodic sampling and analysis to determine treatment requirements, transport, and treatment as required.

The program consists of studies and reports to identify, analyze, and evaluate appropriate measures to accomplish effective control of runoff, erosion, sediment, and contamination

sources. Also, procedures are required to ensure that appropriate measures are designed and built into projects, and to ensure appropriate maintenance measures are practiced.

8.1.2 Effluent Evaluation

Effluent monitoring at the Weldon Spring site (WSS) includes five surface water outfalls, one treated sanitary sewer discharge from the administration building, and one treated water discharge from the site treatment facility designed to treat the various contaminated waters that exist on the property. The wastewater treatment facility at the Weldon Spring Quarry (WSQ) will operate one permitted outfall. The treatment plant will treat contaminated water from several sources: (1) WSQ pond, (2) stormwater, and (3) waste water resulting from the equipment decontamination facility. Also, at the quarry water treatment plant, there will be a discharge or discharges of uncontaminated water used to test the treatment plant, ponds, and associated equipment. A similar discharge is proposed for the site water treatment plant.

Preoperational monitoring of receiving waters associated with both water treatment plants will be continued into 1992 to develop baseline values prior to operation. All of these discharges are monitored in accordance with National Pollutant Discharge Elimination System (NPDES) permits issued to the WSS by the Missouri Department of Natural Resources (MDNR).

Existing or potential site water sources are listed in Table 8-1. An estimate of the quantity of the sources are described in rates or total volume depending on the source. The current treatment category is also provided for the source. Certain of the waters, however, are not clearly defined and the treatment category for these waters will also require monitoring on a case-by-case basis for final determination.

8.1.2.1 Permitted Outfalls. Three permits have been issued by the Missouri MDNR for discharges from the WSSRAP. Permit MO-0107701 for the chemical plant contains seven outfalls and MO-0108987 for the quarry contains one outfall. *Quarterly Discharge Monitoring Reports* (DMR's) are required as compliance deliverables for these outfalls. Permit MO-G340001 for the quarry water treatment plant contains one outfall that requires a discharge monitoring report (DMR) as a compliance deliverable within 30 days of each discharge event. A similar outfall is proposed for the site water treatment plant. The *Annual Site Environmental Report* (ASER) (MKF and JEG 1991) and the *Quarterly Environmental Data Summaries* (QEDSs) also summarize the data from these outfalls. Discharge data is also reported to EG&G Idaho Nuclear Engineering Laboratories (INEL) and to DOE's Oak Ridge - Environmental Protection Division (OR-EPD) as detailed in the *Effluent Information System* (EIS) and *Onsite Discharge Information System (ODIS) Users Manual* (EG&G 1977).

NPDES permit MO-0107701 was issued to the DOE on July 29, 1988, for the discharge of surface water runoff through five outfalls from the Weldon Spring Chemical Plant (WSCP). A sixth outfall was added on November 4, 1988, for discharge from the sewage treatment plant at the administration building. A seventh outfall was added on October 1, 1990, for the discharge of treated effluent from the WSCP water treatment plant which will be used to treat contaminated water during remedial activities at the WSCP. Operation of the treatment facility associated with outfall NP-0007 will include storage of treated effluent (for additional treatment if necessary) until testing confirms all effluent standards have been met. Figure 8-1 shows the location of the permitted outfalls from the site.

NPDES permit MO-0108987 was issued to the DOE on May 5, 1989, for the discharge of treated effluent from the WSQ water treatment plant which will be used to treat contaminated water during remedial activities at the WSQ. Operation of this treatment plant will include storage of treated effluent (for additional treatment if necessary) until testing confirms all effluent standards have been met. Figure 8-2 shows the permitted outfall for the quarry.

NPDES permit MO-G340001 was issued to the DOE on December 19, 1991, for the discharge of contaminated water used to conduct tests on the quarry water treatment plant, basins, and associated equipment. The water will be pumped from the basins to Little Femme Osage Creek.

8.1.2.2 Permitted Parameters. Monitoring parameters for the stormwater outfalls NP-0001 through NP-0005 include: flow, settleable solids, total suspended solids (TSS), nitrate-N, uranium, lithium, gross alpha, and pH. The parameters for the discharge for the administration building sanitary treatment system (NP-0006) include: flow, total suspended solids (TSS), pH, biological oxygen demand (BOD), and fecal coliform (Table 8-2). Monitoring parameters for outfall NP–0007 at the chemical plant and NP-1001 at the WSQ water treatment plant are similar and are shown on Table 8-3. These parameters are to be monitored before a batch of treated effluent is discharged to the Missouri River. The parameters for the chemical plant will be monitored at two locations; in the effluent basins prior to discharge to the Southeast Drainageway (NP-0007), and in the drainageway prior to discharge to the river to assess reintroduction of contaminants from the drainageway.

In addition to the batch parameters, other parameters are periodically monitored. Monitoring for 110 priority pollutants (Table 8-4) is required for these discharges once per year. These priority pollutants are organic compounds that are included in the following major categories: volatile organic compounds, semi-volatile organic compounds, pesticides, and polychlorinated biphenyls (PCBs). During the public comment period, xylene and trinitrotoluene (TNT) were added to the list of 110 priority pollutants. Priority pollutants for the chemical plant will be monitored at the same two locations as the other parameters.

Additional monitoring associated with these discharges includes in-stream monitoring to be conducted during discharge of each batch of treated effluent into the Missouri River. Four in-stream monitoring locations in the Missouri River are to be monitored for the following radiological parameters (expressed as activity): gross alpha, gross beta, uranium, Ra-226, Ra-228, Th-230, and Th-232. These radiochemical species constitute the primary radiological concern to potential downstream receptors. If measured levels appear to show an influence by site discharge, gross gamma emitters will be analyzed to evaluate incremental contribution toward proposed gamma and photon maximum contaminant level (MCL).

Table 8-5 NPDES Permit MO-G340001, Monitoring Requirement - Quarry Water Treatment Plant Equipment Testing

Parameter	Permit Limit	Frequency	Sample Type
Flow	Monitor-Total Gal.	Once/event	24-hr total
Oil and grease	15 mg/l	once/event	grab
Total suspended solids	50 mg/l	once/event	grab

Additional periodic monitoring is required for other parameters such as whole effluent toxicity (WET) screens, supplemental monitoring of additional radionuclides, analysis of river sediment for uranium, and uranium analysis of terrestrial and aquatic flora. In order to encourage good erosion control practices, both NPDES permits place limitations on total suspended solids and pH for runoff from material storage or construction areas.

The parameters required for the water treatment plant equipment and basin testing, permit MO-G340001, include flow, oil, and grease and total suspended soilds (Table 8-5).

8.1.3 Preoperational Needs

DOE Order 5400.1 requires preoperational monitoring of processes which have the potential for environmental impact. Preoperational monitoring will be performed in or near the Missouri River since this is the receiving stream for discharge from both of the water treatment plants.

8.1.3.1 Sampling and Analysis. This monitoring includes surface water, sediment, and vegetation (aquatic and terrestrial) and will include all of the parameters that are regulated by the permits. Preoperational monitoring for uranium in surface water began in 1989 at locations SW-1011, SW-1012, and SW-1013 shown on Figure 8-2. In 1991, the parameters listed in Table 8-2 were added at these locations in addition to SW-1015 and SW-5311 also shown on Figure 8-2. These sample locations are positioned such that analytical data for these four locations may be used as preoperational data for discharges associated with both the WSQ and WSCP treatment plants. Monitoring will continue into 1992 for the above, as well as for total uranium on sediments and flora (terrestrial and aquatic).

8.1.3.2 Additional River Data. In addition to the sampling and analysis of the Missouri River for preoperational parameters, existing data reported by others will be obtained to expand the available data base. A major source of information is the river monitoring by Union Electric relative to the Callaway Power Generation facility. Raw water data from the Howard Bend Water Treatment Plant and its neighbor, the Hog Hollow Water Treatment Plant will also be retrieved. These represent the nearest downstream public water supply intakes from the Missouri River.

8.1.4 Additional Monitoring

8.1.4.1 Outfall Upsystem Sources. The source of runoff through the stormwater outfalls is from a variety of storm control systems including storm sewers, drainage channels, and retention basins. Monitoring these upsystem facilities is not part of the permit requirements, but they are sources for contamination of the outfalls. Monitoring is often needed to fully understand the waste characteristics at the permitted outfall. With this in mind, additional samples will be taken in these upstream facilities and may be taken in other areas on a case-by-case basis. Since explanations of exceedance are required by the MDNR when the sampling results vary significantly from the norm, upsystem data are often needed for these explanations.

8.1.4.2 New Stormwater Regulations. On November 16, 1990, the U.S. Environmental Protection Agency (EPA) issued the long awaited rule defining the entities which must apply for NPDES permits to discharge stormwater. These regulations implement Section 405 of the Water Quality Act of 1987, and require selected industries and municipalities to obtain NPDES stormwater permits from all storm drains exiting to public waterways. Initial attempts to regulate stormwater began in 1973. The deadline for individual industrial permits has been established as October 1, 1992.

The WSSRAP is subject to these rules because: (1) it currently processes five permitted outfalls which are considered stormwater; (2) it is classed in our permits as SIC 1629-heavy construction, dredging and surface cleanup; (3) it was historically involved in the mineral industry, coal handling, and hazardous materials; and (4) it is a future construction site of landfill, treatment works, decontamination, and recycle facilities.

Although additional monitoring requirements may not be needed in 1992, the rule will require that monitoring data be developed prior to reissuing of the permits. This data will be associated with two types of permit requirements.

- One application deals with the runoff from sites potentially contaminated from operating facilities and stored materials. This requirement applies to the WSSRAP, although facilities such as the WSSRAP operating under previously issued permits will not have to meet new quantification application requirements for existing permitted outfalls until they apply for renewal. Application requirements may apply for unpermitted outfalls.

- The other application deals with erosion and sediment control for construction activities of over 5 acres. The construction application requirements are much less stringent and stress best management practice.

8.1.5 Description of Effluent Monitoring Program

The monitoring system is best shown in tabular form. Tables 8-2 through 8-5 summarize the permit requirements for both permits and all nine outfalls.

8.1.5.1 Routine Monitoring Requirements. As the tables indicate, the outfalls are sampled at various frequencies. The continuous discharge outfalls are sampled on a monthly or quarterly basis as they discharge. The batch discharge outfalls from the site and quarry water treatment plants are to be sampled and the effluent held until compliance with the permit standards is determined.

Several parameters in the tables show monitoring only, and no effluent standard is applied. The site has established goals for these parameters, especially those associated with the radiological parameters. These goals are based on current NPDES permits and grouped into three general classes.

The administration building sewage treatment plant outfall, NP-0006, involves treatment of a sanitary waste with little or no radioactive contamination. The permit requirements are typical of a domestic treatment facility with discharge to an intermittent stream. The requirements are considered a high level of treatment: BOD 10 mg/l, and TSS 15 mg/l. Other nonradioactive sanitary wastewater generated on the site would be expected to meet these requirements. Non-radioactive is defined in the table as water containing less than the proposed drinking water standard for uranium of 30 pCi/l.

The stormwater outfall permit requirements have been established to monitor the rain-induced discharges and ensure the MDNR that the waters are rain-induced, and not seepage from one of the more contaminated sources. The site areas are being evaluated for future stormwater permit application requirements. The contamination levels in stormwater are highly variable, but considered as below the correction level because the annual average is historically less than the DOEs derived concentration guideline (DCG) for natural uranium of 600 pCi/l. The waters have contacted contaminated soil or material, but have not become contaminated enough to

warrant in-plant treatment. The primary contaminant encountered in the surface water is sediment derived from erosion occurring during overland or channel flow. This process has been occurring for years but has been minimized by natural vegetation. The only imposed standard deals with controlling erosion and sediment during remedial activities: settleable solids 1 ml/l/hr after the Record of Decision, total suspended solids (if no erosion control) 50 mg/l, and monitoring for other parameters including uranium. Stormwater discharge levels for uranium have been monitored over a significant time and vary considerably. The established goal for rain-induced discharges is that they discharge no water that exceeds historic levels. New or additional contaminant controls must also meet the DCG of 600 pCi/l natural uranium established by DOE Order 5400.5.

The contaminated water in the quarry sump, raffinate pits, and potentially in other miscellaneous waters requires treatment to the high levels shown in Table 8-3. The high levels of treatment imposed by the permit are due to the desire by the State to meet standards associated with potential contamination of groundwater. Although the DOE goal for uranium is to discharge less than the DCG, the treatment required to remove the non-radioactive contamination allows for a significantly lower goal for these discharges. The lower level is based on the as-low-as-reasonably-achievable (ALARA) concept that showed by calculation that since a high level of treatment is required for levels above 600 pCi/l, treatment to a goal of 30 pCi/l and not to exceed 100 pCi/l is cost effective. This 30 pCi/l level has recently been proposed by the EPA as the drinking water standard for uranium.

8.1.5.2 Intermittent Monitoring Requirements. The DOE has agreed to additional monitoring associated with the site and quarry water treatment plants in response to regulatory and public concerns. Concern over a negative effect on the Missouri River led to additional water monitoring that will be conducted in the river during discharge of each batch of treated effluent. In-stream monitoring locations are shown on Figure 8-2 and include a location upstream of the quarry outfall (SW-1011); between the quarry outfall and the southeast drainage (SW-1012); downstream of both outfalls (SW-1013); and at the water intake for the Howard Bend WTP-St. Louis City-River Mile 37 (SW-1015). Radiological parameters (expressed as activity per liter) are required for in-stream monitoring and include: gross alpha, gross beta, uranium, Ra-226, Ra-228, Th-230, and Th-232.

The southeast drainageway, which receives the site effluent at its upper end, is a vicinity property and contains some areas of contaminated sediment. To gain knowledge of the

contamination that is resuspended by the effluent flow down the drainageway, the outfall parameters for the site water treatment plant will also be analyzed just prior to entry to the river (SW-5311).

River sediment will be collected semiannually from the two locations shown on Figure 8-2, and analyzed for total uranium. Terrestrial and aquatic flora will be sampled from the river and levee areas upstream and downstream of the discharge point and analyzed for total uranium.

WET screens are required for the treatment plant effluent on a quarterly basis. Representative samples will be obtained from effluent ponds and used to perform the toxicity analysis on fish (pimephales), as described in the special conditions of the NPDES permit.

Po-210, Ac-227, and radon will be monitored semiannually for the quarry water treatment plant effluent. Preoperational monitoring for these parameters will be performed on the quarry sump water.

8.1.5.3 Upsystem Source Identification Needs. Sources of contamination occur upsystem of the three main stormwater discharges. These main discharges are the Frog Pond weir, NP-0002, Ash Pond weir, NP-0003 and the southeast drainage weir, NP-0005. Drainage facilities above each of these outfalls have an influence on the character of the discharges that is not fully understood. The variability of these discharges can best be determined by a concerted effort to monitor the upsystem facilities. This understanding will be more important as the new regulations are implemented and as more construction takes place on the site.

Additional sites that require investigation are not fully developed at this time. A full development will be presented in the *WSSRAPs Surface Water Protection Program Management Plan* that will be completed in early 1992. Certain locations are being considered for monthly monitoring; these include: Frog Pond, Ash Pond, Ash Pond diversion pond and outfall, the material staging area (MSA) pond, and the siltation basin (SB) pond. Other candidate locations may include periodic monitoring of the nonpermitted outfalls and some of the water entering the site.

The parameters needed to understand the contaminant sources do not include the full list of parameters needed for permit requirements. Flow estimates, uranium, and nitrate

concentrations will provide the necessary information for preliminary evaluations. Periodic scans using an expanded list of parameters may be of value for baseline information as remediation progresses.

8.1.6 Stormwater Requirements and Needs

8.1.6.1 Current Erosion and Sediment Control Requirements. Permits for both the site and quarry place limitations on total suspended solids and pH levels for runoff from material storage or construction areas. If this runoff is not treated in a facility designed, constructed, and operated to treat the volume of water associated with a 10-yr, 24-hr rainfall event, the total suspended solids must not exceed 50 mg/l and the pH must remain in the range of 6.0 to 9.0 standard units at the outfalls.

In order to evaluate the effectiveness of erosion control measures, the DOE/Project Management Contractor (PMC) will periodically collect surface water samples adjacent to construction or material storage areas for analysis of pH and total suspended solids. Total suspended solids and pH measurements from the permitted outfalls are reported to MDNR in the regular discharge monitoring report.

8.1.6.2 Future Characterization Data. The new regulations require stormwater characterization data be obtained in a prescribed manner. Specific methods are:

- Grab samples are required for pH, temperature, cyanide, total phenols, residual chlorine, oil and grease, fecal coliform, and fecal streptococcus.

- All samples from stormwater discharges shall be taken from the discharge resulting from a precipitation event of 0.1 in. and at least 72 hr from the previously measurable event.

- A flow weighted composite shall be taken for either the total discharge or the first 3 hr of discharge. The weighted sample should be taken with a continuous sampler or based on three grabbed aliquots per hour separated by a minimum of 15 min.

- Only one analysis is required for the composite. The grabbed aliquot taken in the first 30 min of the discharge shall be analyzed separately.

- A minimum of one grab sample may be taken in impoundments with retention greater than 24 hr.

- All samples shall be analyzed by methods approved under 40 CFR part 136 where applicable.

8.1.6.3 Reapplication Data

The collection of characterization data is needed for the reapplication and approval of current permits using the new sampling and quantification procedures. These activities will begin immediately to ensure adequate data for reapplication. The program needed to accomplish the activity includes three documents.

Surface Water Protection Program Management Plan -- The plan will describe the regulations, orders, and procedures governing the management of the site surface water. Transport, storage, treatment, and discharge of surface water will all be covered by the plan.

Site Hydrology Report -- The report will delineate the site watershed units, present the precipitation and flow data, and coordinate these data to develop runoff coefficients and predict surface water movement.

Stormwater Characterization Report -- The first part of this report will provide chemical data for the stormwater discharge using discrete samplers combined with flow information. The data will be used to develop sampling procedures to best describe the character of the discharges. These procedures will then be used to chemically characterize the discharges using the parameters required for the application.

Additional sampling of tributaries upstream of the regulated outfalls will also be needed to fully understand the discharge character. The characterization of the discharge may require a minimum of three storm events at each of the regulated points. The chemical characterization of the stormwater may also require sampling of a minimum of three events at each point. Additional details will be provided in a sampling plan.

8.1.6.4 Construction Application Data. Documentation to satisfy the application requirements for permits must be obtained because of the construction on the site. Most of the required data is currently being developed as part of other activities of the site and no sampling is needed to satisfy these requirements. Current studies will develop and detail the design requirements for controlling surface water for the site during and after the construction. A *Surface Water and Erosion Control Report* will propose the best combination of facilities that will constitute the best management practice (BMP) for the site. The presentation of this material to the MDNR will satisfy the relevant and appropriate requirements for the application. A formal application is not anticipated because of Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) regulations, however the spirit of the regulations is evident through the use of best management practices.

8.2 Airborne Effluent and Environmental Surveillance Program

This section documents the rationale and requirements of the programs that will be implemented to monitor airborne emissions from the WSSRAP and to evaluate the impacts of those emissions on the public and the environment. The WSSRAP has two diffuse sources of airborne radiological emissions; the WSCP/WSRP, and the WSQ. Emissions from these sources and the estimated exposures are predicted to be low. The emissions monitoring program is tailored to be commensurate with the low potential for exposure.

8.2.1 Source Assessment

As required by DOE guidance, an assessment of the two diffuse sources was conducted. The assessment included documenting the different radionuclides that could potentially be released from the sources and their concentrations. In addition, the assessment addressed the factors that could potentially contribute to the suspension of contaminants. The assessment provided a basis for the airborne emissions monitoring program and ensured that the design would provide timely, representative, and adequately sensitive monitoring results.

8.2.1.1 Weldon Spring Quarry Source Assessment. The WSQ diffuse source is a 9-acre limestone quarry located approximately 4 mi south-southwest of the WSCP/WSRP area. The WSQ is essentially in a closed basin; surface water within the rim flows to the quarry floor and into a pond which covers approximately 0.5 acre. The WSQ was used as a disposal area for dinitrotoluene (DNT), trinitrotoluene (TNT) process waste, uranium, radium and

thorium residues and the associated daughter products from on-site and off-site processing of uranium, and building rubble and soils from the demolition of a uranium processing facility in St. Louis. Airborne emissions from the quarry result from the wind blown resuspension of radioactive particulates from quarry soils and resuspension of radioactive particulates from activities at the WSQ such as the operation of heavy equipment and the excavation of soils. In addition, there are also airborne releases from the WSQ due to the decay of Ra-224 and Ra-226, daughters of Th-232 and U-238, into Rn-220 (thoron gas) and Rn-222 (radon gas).

Characterization of the WSQ soils has been completed in support of the WSQ Remedial Investigation/Feasibility Study (RI/FS). The radiological contaminants in the WSQ are uranium and thorium and their respective daughters. Concentrations range from 3.0 pCi/g to 1600 pCi/g U-238, <1.0 pCi/g to 2780 pCi/g Ra-226, 0.7 pCi/g to 36 pCi/g Th-232, <1.0 pCi/g to 2200 pCi/g Ra-228, and <1.0 pCi/g to 6800 pCi/g Th-230. A study is being conducted to determine the lung solubility class of WSQ bulk waste. Until the lung solubility classes have been determined, the most restrictive solubility classes will be assumed for uranium and thorium in the bulk waste.

Statistical evaluation of the results from effluent monitoring at the WSQ during 1990 indicated the results from one of the air particulate monitors and four of the radon track etch detectors were greater than background. The calculated effective dose equivalent to a hypothetical maximally exposed individual from the airborne emissions from the WSQ was 3.3 mrem (MKF and JEG 1991d). The 3.3 mrem dose calculated for the hypothetical individual from the airborne inhalation pathway was almost exclusively due to radon emissions. The assumptions that were used to calculate the dose were conservative. It was assumed that the daughter equilibrium ratio at Highway 94, where the individual walked twice daily, was 50% and that the concentration of radon at Highway 94 was the same as the concentration measured within the WSQ controlled area. These conservative assumptions resulted in a higher calculated dose to the hypothetical individual than would have otherwise been calculated using a less conservative daughter equilibrium ratio and a computer model to estimate the concentration at Highway 94.

Excavation of soils and placement of contaminated materials from remediation of the WSQ water treatment plant area are believed to be responsible for the above background air particulate monitoring results. These activities are similar to the activities that will occur during 1992. However, beginning in August of 1992, soils and bulk waste will be excavated within

the WSQ that have significantly higher concentrations of radiological contaminants. Engineering controls will be used during bulk waste removal to restrict the release of airborne particulates from the WSQ during excavation of soils and bulk waste removal. In the *Feasibility Study for Management of the Bulk Waste at the Weldon Spring Quarry* (ANL 1990a) the dose estimate from airborne radioactive particulates for a hypothetical individual who walked along Highway 94 twice a day, during the 1.25 years that will be required to remove the bulk waste, was 1.3 mrem. The dose estimate calculated for a nearby resident with a assumed 100% occupancy time during the 1.25 years was 0.18 mrem.

In order to remove the bulk waste from the WSQ, the sump will have to be dewatered. The water that will be removed from the sump will be treated and released from a water treatment plant that is adjacent to the WSQ. Although the potential for airborne emission from the water treatment plant is small, there is some potential for the release of radioactive airborne emissions at one stage during operation of a filter press. The filter press will be housed in a small building. The filter press will also have a metal shroud to minimize emission within the building. Finally, the building will be ventilated with a high efficiency particulate air (HEPA) filter system to minimize releases to the environment. No above background radioactive emissions are expected from the operation of the WSQ water treatment plant.

Radon concentrations measured at the WSQ have historically been above background because the radium concentrations in WSQ wastes are typically higher than other areas and because the WSQ is a large depression in the terrain with side walls ranging from 10 ft to 50 ft high. In conjunction with stable meteorological conditions, this tends to trap emanating radon within the quarry and raises the concentrations at the WSQ. During 1992 the bulk waste will begin to be removed from the WSQ. Evaluation of the potential emissions of radon during the excavation of the bulk waste was also done in the feasibility study. The results of the study indicate that a dose of 1.0 mrem would be received by the hypothetical individual who walked along Highway 94 twice a day for 1.25 years. Although the dose estimate in the feasibility study is lower than the calculated dose to the hypothetical maximally exposed individual from airborne emissions during 1990, it is based on more realistic assumptions. A daughter equilibrium ratio of 10% was assumed based on measured radon and radon daughter concentrations taken during 1989 (Haroun et al 1990), and the concentration at Highway 94 was calculated using the computer model MILDOSE (Strenge and Bander 1981) which was modified to more accurately assess airborne concentrations resulting from releases from large areas (Yuan et al. 1989). The dose calculated for a nearby resident in the feasibility study was 2.3 mrem.

8.2.1.2 WSCP/WSRP Source Assessment. The WSCP/WSRP diffuse source encompasses 217 acres on which 33 buildings and four raffinate pits are located. Airborne emissions from the WSCP/WSRP result from the windblown resuspension of radioactive particulates from site soils and chemical plant buildings, and resuspension of radioactive particulates from site operations such as building demolition, and soil excavation. In addition, there are airborne emissions from the WSCP/WSRP due to the transformation of Ra-224, Ra-226 daughters of Th-232 and U-238, into Rn-220 (thoron gas) and Rn-222 (radon gas). Because the site is not an operating facility there are no point sources.

Characterization of the WSCP/WSRP buildings and soils have been completed in support of the site RI/FS. Radiological contaminants in the WSCP buildings are uranium, thorium, and the respective daughters. Concentrations in bulk samples collected from the WSCP buildings range from background levels to 1000 pCi/g U-238, 17 pCi/g Ra-226, 2682 pCi/g Ra-228, and 250 pCi/g Th-230. As at the WSQ, a lung solubility study is being conducted using materials from the WSCP/WSRP. Bulk samples from process buildings and the raffinate pits have been collected. Until the lung solubility classes have been determined, the most restrictive solubility classes will be assumed for thorium and uranium.

The site soils characterization also indicates that the contaminants in the soils are uranium and thorium and their associated daughters. Most of the 217 acres of the WSCP/WSRP have above background concentrations of uranium (>1 pCi/g). Concentrations range from 0.3 pCi/g to 2,259 pCi/g U-238, 0.6 pCi/g to 452 pCi/g Ra-228, and 0.3 pCi/g to 123 pCi/g Th-230.

In the past several years statistical evaluation of the results from effluent monitoring and environmental surveillance monitoring at the WSCP/WSRP has indicated that there is no reason to suspect at the 95% confidence level that the results were greater than background (i.e., no above background exposure to the public from WSCP/WSRP operations has occurred). Activities that will be performed during 1992 are similar to those that were performed in previous years, such as excavation of low level radiologically contaminated soils and building demolition. Although building demolition during 1992 includes buildings that have significantly higher concentrations of contaminants than those that have been demolished previously, additional engineering controls will be used to control emissions. These engineering controls include cleaning or removing loose contamination (i.e., dust or dirt) from the internal and external surfaces of the building and equipment prior to the start of demolition. In addition, water will be used during demolition to control dust emissions.

As mentioned in the WSQ source assessment, the bulk waste from the WSQ is expected to begin being placed at the temporary storage area (TSA) during August of 1992. Engineering controls such as the use of water to control airborne particulate emissions will also be used at the TSA. Radon gas emissions due to the higher radium concentrations in the bulk waste will be minimized through the use of an attenuating cover material. In the *Feasibility Study for Management of the Bulk Waste at the Weldon Spring Quarry* (ANL 1990a) a dose estimate for airborne emissions from the bulk waste at the TSA was calculated. In the study a dose estimate was calculated for a worker in an on-site office building and a student at Francis Howell High School. The calculated dose to the office worker was 0.08 mrem from radon, and 0.84 mrem from radioactive particulates for a total of 0.92 mrem. The calculated dose for the student was 0.05 mrem from radon, and 0.05 mrem from radioactive airborne particulates for a total of 0.1 mrem.

8.2.2 Airborne Monitoring Programs

To effectively monitor the two WSSRAP diffuse sources that have been described, three air monitoring programs will be utilized; site specific monitoring, perimeter monitoring, and critical receptor monitoring. These three programs are designed to meet the requirements for airborne effluent monitoring and environmental surveillance as specified in the *Environmental Regulatory Guide for Radioactive Effluent Monitoring and Environmental Surveillance* (DOE 1990) and DOE Orders 5400.1 and 5400.5.

The location, equipment, sampling time, minimum detection levels, accuracy, and investigation levels will be discussed in the site specific, site perimeter, and critical receptor monitoring program sections. In addition, sample heights, proximity to obstructions, and linear flow rate will also be discussed in the individual monitoring program sections.

8.2.2.1 Site Specific Monitoring Program. As mentioned in the WSCP/WSRP source assessment, the large WSCP/WSRP diffuse source is made up of a number of smaller diffuse sources that include wind blown resuspension of radioactive particulates from contaminated soils and buildings, and resuspension of radioactive particulates due to site remediation activities such as building demolition and excavation of soils. Although there is some potential for resuspension of radioactive particulates due to natural meteorological occurrences, it is small compared to the potential for site remediation activities to resuspend radioactive air particulates. In order to assess the contribution of site remediation activities to

the total airborne emissions from the WSCP/WSRP, site specific monitoring will be utilized. Site specific monitoring will also be used at the WSQ to supplement data from the WSQ perimeter monitors. Site specific monitoring will use mobile air particulate samplers placed upwind and downwind from smaller diffuse sources.

Site specific monitoring, in addition to providing data concerning the contribution of specific activities to the total airborne inventory, will provide faster feed back concerning the effectiveness of engineering controls and data concerning dispersion patterns. Filters from site-specific monitors will be collected on a daily basis as compared to weekly for the perimeter samplers, which means data can be obtained as much as six days sooner. In addition, by varying the distances and configurations of the samplers, valuable information concerning dispersion patterns can be obtained for the WSSRAP.

During demolition of a building within the WSCP/WSRP area, for example, mobile air particulate samplers would be used to monitor airborne emissions from the specific activity. At least four monitors would be used, one upwind and three downwind from the activities. Placement of the samplers would be based on current meteorological conditions provided by the site meteorological station and experience gained from previous placement of samplers. During 1991, site specific monitoring was initiated during the demolition of four non-process buildings. The samplers were placed at various distances and configurations with respect to the source. The experience and data gained in 1991, and as 1992 progresses, will be used to assess the best placement for the samplers.

The air samplers will be placed in areas, when possible, that are free from obstructions or conditions that could effect the air sampling results. When possible, the air samplers are two times the distance from one obstruction or structure as the obstruction or structure is high (i.e., an air sampler would be placed 10 ft from a 5 ft tall tree). In addition, the samplers will be placed if possible, in areas that do not have turbulent air conditions, such as near busy roads, or active equipment.

Site specific monitoring will be utilized during remediation activities at the WSQ. Monitors will be placed just outside the work areas based on the current meteorological conditions. Site specific monitoring will be used to assess airborne emissions from specific activities and areas within the WSQ.

Equipment that will be used for site specific monitoring includes a portable air particulate sampler with a filter holder and a vacuum pump, a mass flow meter, filter, portable power supply, and air sampler stand.

There are two types of portable air samplers that will be used for site specific air monitoring; high volume self-adjusting brush motor air blower, and low volume carbon vaned oil-less vacuum pumps. The high volume samplers are generally operated at approximately 400 l/min, and the low volume pumps at approximately 40 l/min. The linear flow rates for the high and low volume air samplers, volume sampled per unit time, divided by the filter area, is 48 m/min and 23 m/min, respectively.

A mass flow meter which is calibrated in a NIST traceable wind tunnel will be used to set the flow rates of the portable air monitors at the beginning of each sampling period. The mass flow meter electronically compensates for temperature and pressure to read in standard liters per minute (sl/min, a liter of air at 0°C and barometric pressure of 76 cm Hg). The mass flow meter will also be used to check flow rates at the end of the sampling period.

The filters that will be used for low-volume samplers are a mixed cellulose esters membrane. These filters have a pore size of 0.8 μm and are 47 mm in diameter. The manufacturer states that the filter media retains 99.98% of dioclylphalate particles with an aerodynamic mean diameter of 0.3 μm at 32 l/min across a 100 cm^2 surface area. Filters for the high volume samplers are 102 mm in diameter glass fiber filters which retain 99.98% of dioclglphate particles with an aerodynamic mean diameter of 0.3 μm. The samplers will be placed on portable stands at a height of approximately 1 m off the ground. The air samplers will be placed at 1 m rather than 2 m as specified by the EPA due to the weight of the pumps and the safety problems that would be brought about by placing the pumps at 2 m off the ground. The 2 m height would require personnel to lift the pumps, which are relatively heavy and will be moved frequently, above their heads. In addition, the stands would have a high center of gravity, making the stands susceptible to tipping in strong winds.

Because there is presently no electrical service in the controlled area of the WSCP/WSRP where the portable air samplers will generally be used, portable generators will be used to power the air samplers.

The minimum detectable concentration (MDC) that will typically be achieved during site specific monitoring is approximately 5.0E-14 μCi/ml. Because work activities may not always have a duration long enough to collect a large sample volume, a sample MDC may be higher than the typical MDC of 5.0E-14 μCi/ml. In addition, the high-volume, site-specific samplers, due to the higher flow rates, can collect a large enough sample volume so that a sample MDC could be significantly lower than the typical MDC. Whenever possible a large sample volume will be collected in order to reduce the MDC.

The total typical accuracy or uncertainity associated with a site perimeter air particulate sample, at a concentration of 1E-15 μCi/ml, is 1.0×10^{-16} μCi/ml. The total sample accuracy or uncertainty is dependent on the uncertainty associated with a number of sources which include the volume sampled, detector calibration, uncertainties with efficiency and background count rate, and sample count rate.

After samples are collected, the filters will be stored for a minimum of 72 hr before they are counted to allow for decay of the short lived radon and thoron decay products. The activity of the samples will then be counted on an alpha-scintillation detector or a gas-flow proportional counter. Counting times for the alpha scintillation detector and the gas flow proportional counter will generally be 60 min. Counting times may be longer in order to achieve a lower MDC.

The investigation level which will be implemented for the site specific monitoring will be a downwind measured concentration of two times the up-wind concentration. The investigation will attempt to determine the source of the airborne contamination.

The Quality Control (QC) procedures that will be implemented as part of the site- specific monitoring program include the calibration of instruments, source and background counts, recounts of samples, and review of documentation. The QC procedures are intended to ensure the accuracy and validity of the data.

Calibration will be required for the alpha-scintillation and gas-flow proportional detectors, and the mass flow meter. The alpha-scintillation detector will be calibrated a minimum of every six months using NIST traceable radioactive sources. The gas-flow proportional counter will be calibrated when repairs are made to the detector. The mass flow meter will be calibrated on an annual basis by the manufacturer in a NIST traceable wind tunnel. In addition, the portable

airborne particulate samplers will be leak tested on an annual basis to ensure that the measured volume of air is passing through the sample collection filter.

Daily source and background counts will be made on the alpha-scintillation and gas- flow proportional detectors. The daily source and background count results are compared to the calibration results. If daily checks are within three standard deviations when compared to results obtained during calibration, instruments will be put into service. Instruments failing the daily background check will be taken out of service as described in the applicable WSSRAP standard operating procedure (SOP).

At least one in 20 samples will be recounted and the results compared to the initial count results. The precision between the two sample counts will be determined and the results kept on file.

A review of the sample documentation and calculations by an individual other than the sampler will be required as part of the QC procedure. The reviewer will be responsible for ensuring that the documentation is complete and the calculations correct.

8.2.2.2 Site Perimeter Monitoring. In order to monitor the airborne emissions from the two large diffuse sources, the WSCP/WSRP and the WSQ, which encompass large areas of soils having above background radionuclide concentrations, a perimeter monitoring program will be utilized. The program will require the use of eight air particulate monitors and radon track etch detectors at permanent locations. The monitors will be used in conjunction with site specific monitoring to estimate the total airborne emissions that leave the two diffuse sources. The use of air monitors at the WSCP/WSRP and WSQ perimeter, in conjunction with site specific monitoring, is the most effective way to monitor airborne emissions from the WSS. The sources described in the WSCP/WSRP and WSQ source assessment are essentially ground sources. Sources such as stacks or vents that release radioactive material at a significant distance from the ground have the highest measured concentrations at ground level some distance from the source. This occurs because it takes time for the material to reach the ground, and as the material falls, it is driven from the source by the wind. Ground sources however, have the highest concentration measured at the ground level at points closest to the source. As a result, the highest concentrations that leave the WSCP/WSRP and WSQ are at the perimeters.

There will be five perimeter radioactive air particulate monitoring stations at the WSCP/WSRP (Figure 7-1). The WSCP/WSRP perimeter monitors are generally equally spaced along the perimeter fence with distances ranging from approximately 2,079 ft to 2,970 ft. Because the potential for airborne emissions from the WSCP/WSRP is low, any airborne emissions that do occur will be intermittent and have low concentrations. The use of five perimeter monitors is commensurate with the potential for an exposure to a member of the general public.

There will be three perimeter radioactive particulate monitoring stations at the WSQ (Figure 7-3). The WSQ perimeter radioactive air particulate monitoring stations are located on the southeastern end of the WSQ and at the southern edge of water treatment plant area adjacent to the WSQ. The two sampling locations at the southeast end of the WSQ and the sampling location at the southern end of the water treatment plant facility represent areas that have the highest potential for airborne emissions. The prevailing winds in the vicinity of the WSQ are from the south and southwest during summer and fall, and from the north, northwest, and west during spring and winter. The WSQ is surrounded by steep cliffs on the north, east, and south and is accessible by relatively flat land only from the west. The third monitor will be used to monitor any potential emissions from the flat entrance area at the west end of the WSQ during remediation activities.

There will be 10 radon monitoring stations at the WSCP/WSRP perimeter (Figure 7-1) placed approximately 2,310 ft to 6,600 ft from one another. Due to the characteristics of the WSCP/WSRP diffuse radon source, the density of radon monitoring stations around the perimeter will be commensurate with the potential for causing an exposure from radon to a member of the general public. Remediation of the WSCP/WSRP is not expected to increase radon emissions, but some increase may occur during the transfer of bulk waste from the WSQ to the TSA which is located within this area. The TSA will be monitored for radon at the TSA perimeter. Five monitoring stations will be used at the TSA perimeter (Figure 7-2). The stations will be placed at intervals of 420 ft to 780 ft from one another. Because the waste that will be transferred from the WSQ to the TSA has higher concentrations than the WSCP/WSRP soils, there is higher potential for radon emissions from the TSA than from WSCP/WSRP. As a result, the distances between radon monitoring stations at the TSA will be less than WSCP/WSRP station separation.

An effective dose equivalent of 0.08 mrem was calculated at the nearest WSCP/WSRP critical receptor with the highest potential for an exposure to a member of the general public as a result of radon emission. Therefore the 10 radon monitoring stations at the WSCP/WSRP perimeter will be sufficient to monitor potential radon emissions.

There will be eight radon monitoring stations on the WSQ perimeter (Figure 7-3). The radon monitoring stations at the WSQ are approximately 264 ft to 825 ft apart. The distance between monitoring stations at the WSQ is less than at the WSCP/WSRP because of the higher radium concentration at the WSQ and because the WSQ is a large depression in the terrain with side walls ranging from 10 ft to 50 ft high. This, in conjunction with stable meteorological conditions, tends to trap emanating radon within the WSQ and raises the concentrations along the WSQ perimeter. As a result there is higher potential for radon emissions from the WSQ than from the WSCP/WSRP, and thus the distance between stations at the WSQ is smaller.

The number of radioactive air particulate and radon monitoring stations at the WSCP/WSRP and WSQ is in proportion to the potential for emissions from the sources. In addition, the use of site specific monitoring will allow monitors to be placed such that the density of monitors will be increased in the direction dictated by the current meteorological conditions.

Equipment for the site perimeter monitoring program includes low volume air particulate samplers, continuous radon-gas and radon-daughter monitors, a mass flow meter, scintillation detectors, a gas-flow proportional detector, filters, and radon track etch detectors.

The low volume air particulate samplers at the five WSCP/WSRP site perimeter locations are self-adjusting, twin-diaphragm, oil-less air pumps. At the two WSQ perimeter monitoring locations self adjusting, carbon vaned, oil-less air pumps are utilized. Each sampler will be mounted in a weather-protective housing with a 110-volt outlet and a thermostat-controlled fan for cooling. Each sampler will have an hour meter to document the operational periods. Samplers will also have a flow meter, vacuum gauges, and be equipped with a regulator to maintain a constant flow rate.

The continuous radon gas and radon daughter monitors (Figures 7-1 and 7-3) are portable, fully automated instruments capable of continuously monitoring for radon, and radon and thoron daughters. The radon detectors contain a 5 in. diameter tube that is optically coupled

to a 3 liter Lucas Cell coated with silver activated zinc sulphide to detect radon gas. The working level monitor uses a ruggedized silicon barrier diode detector which is used to detect radon and thoron daughters deposited on a membrane filter with a 0.45 μm pore size. The continuous radon and working level monitors have internal data storage capabilities. The data will be retrieved from the sampler locations by downloading the data from the samplers to a portable computer. The sensitivities of the continuous radon and radon daughter monitors are 1.0 pCi/l and 1.0 mWL. The manufacture stated accuracy for the continuous radon and radon daughter monitors is within $\pm$10% of the measured concentration.

A mass flow meter is used to set and measure the flow rate of the low volume air particulate samplers. The low volume air particulate samplers will be run continuously at a flow rate of approximately 40 l/min (1.4 cu ft/min) with weekly filter replacement. Prior to changing the filter each week, the flow rate is measured with the mass flow meter which electronically corrects for pressure and temperature to read in standard liters per minute. After the filter is changed the flow rate will be adjusted on an as-needed basis to 40 l/min. The starting flow rate of 40 l/min is then averaged with the ending flow rate, and the average flow rate used to calculate the total volume of air sampled. If the flow rate changes by more than 20% during the sampling period, the monitor will be evaluated to determine if service is required. The data will be flagged and used for qualitative purposes only. The linear flow rate for the perimeter low volume air particulate samplers is 23 m/min at 40 l/min. The site perimeter airborne particulate and continuous radon and radon daughter monitors will be leak tested on an annual basis. Leak testing will be done to ensure that the measured volume of air passed through the filters or detection system.

The filters used to monitor the site perimeter are the same mixed cellulose ester filters used for site-specific monitoring. The filters are 47 mm in diameter, have a pore size of 0.8 μm and retain 99.98% of dioclyphalate particles with an aerodynamic mean diameter of 0.3 μm.

The perimeter air particulate samplers will be placed at approximately 2 m above the ground. The radon track etch detectors and the continuous radon and radon daughter monitors will be placed approximately 1 m above the ground, respectively. The locations where samplers, detectors, and monitors will be placed are free from unusual localized effects or other conditions (e.g., in proximity to a large building, vehicular traffic, or trees) that could result in artificially high or low concentrations with the exceptions of the WSQ perimeter monitors. Several of the WSQ perimeter monitoring stations are in proximity to trees. Because the trees

serve as a natural barrier to airborne emissions, the trees will not be removed from the areas near the monitoring locations. In addition, due to the limited space available along the ridge at the southeastern perimeter of the WSQ, the stations cannot be moved to monitor the area and not be in proximity to the trees.

The radon detectors that will be deployed are track etch detectors that have a minimum sensitivity of 0.2 pCi/l. The vendor stated accuracy for the radon tract etch detectors is $\pm 25\%$ of the measured concentration. Data from 1990 indicated the average accuracy was $\pm 17\%$ with an average concentration of approximately 4.5 pCi/l which includes background. The detectors will be placed in pairs at each of the locations, and will be exchanged on a quarterly basis.

The air particulate filters will be counted to determine the gross alpha concentrations using an alpha scintillation detector or a gas flow proportional detector. The counting times for samples will in general be 60 min for the alpha scintillation detector and 5 min for the gas-flow proportional detector. The difference in count times between the alpha scintillation detectors and the gas-flow proportional detectors is due to differences in the background count rates and efficiencies of the instruments.

Each sample will be collected for a period long enough to ensure that a minimum detectable gross alpha concentration (MDC) of 1E-15 μCi/ml can be obtained. Because naturally occurring Po-210 and Pb-210 exist in the atmosphere at concentrations on the order of 2.5E-15 μCi/ml, obtaining a MDC less than 1E-15 μCi/ml is of little value due to the interference from Po-210 and Pb-210. An MDC of 1E-15 μCi/ml is sufficient to detect concentrations less than the derived concentration guides (DCGs) for radionuclides that are present at the WSS. The MDC is dependent on sample valume (sample time multiplied by the flow rate), the efficiency and background count rate of the instrument used to measure the activity on the filter, and the sample an dbackground count times.

The total typical accuracy or uncertainty associated with a site perimeter air particulate sample at a gross alpha concentration of 1E-15 μCi/ml is 1E-16 μCi/ml. The total sample accuracy or uncertainty is dependent on the uncertainty associated with the volume sampled, detector calibration uncertainties with the determination of detector efficiency, and detector background count rate, as well as the uncertainty associated with the sample count rate. Because difference detectors are used and because of variations in the other sources of uncertainty, the

accuracy may vary, but 1E-16 μCi/ml represents a typical accuracy which would be achieved of a sample with a gross alpha concentration of 1E-15 μCi/ml.

The investigation levels that will be established for the perimeter air monitoring program are measured concentrations greater than the concentrations measured at the background station. The low volume air particulate sampler and the continuous radon and radon daughter monitor results will be compared to the background station results on a weekly basis. The radon track etch detectors will be compared to the background stations results on an annual basis.

The low volume air particulate samplers and continuous radon and radon daughter cumulative measured concentrations will be compared to the background station cumulative measured concentrations. The perimeter stations will be compared to the background station using a statistical test to identify locations that have weekly measured concentrations greater than background. If it is determined that the measured concentrations at a location are greater than the background station's measured concentrations, an investigation will be conducted in order to attempt to identify the source of above background concentrations.

Because the radon track etch detectors are collected on a quarterly basis, and as a result there are only four data points per year per location, the radon track etch detectors are compared to the background stations results only on an annual basis. Each location's monitoring results are compared to results from the background stations. If the results from a location are found to be statistically greater than the results from the background stations, an investigation will be conducted to determine the source of the above background concentrations, with the exception of the quarry monitoring stations which are historically greater than background because of the radiologically contaminated material that was placed in the quarry.

The QA/QC procedures for the low volume air particulate samplers are the same as those described for site specific monitoring.

The QA/QC procedures that will be implemented for the continuous radon gas and radon daughter monitors include calibration and source checks. The continuous radon gas and radon daughter monitor will be calibrated annually at the Technical Measurement Center at Grand Junction, Colorado.

The QA/QC procedures that will be employed for the perimeter radon track etch detectors include duplicates, spikes, chain-of-custody and laboratory authorization forms, field sheets, and review of vendor data. The pair of radon track etch detectors placed at each location will serve as duplicates. Three spikes, track etch detectors exposed to a known source, will be returned to the vendor for analysis on an annual basis. In addition, field sheets will be used during deployment and recovery of the radon track etch detectors to document detector locations and any unusual occurrences. Chain-of-custody and laboratory authorization forms will be filled out in accordance with the applicable SOP in order to track the radon track etch detectors. Finally, the data received from the vendor will be reviewed for any anomalies.

8.2.2.3 Critical Receptor Monitoring. The most accurate method of dose calculation at nearby receptor points is through the use of actual concentration measurements at these locations. Measurements from nearby receptor points or critical receptors will be an important element in determining the emissions from the WSCP/WSRP and the WSQ when used in connection with site-specific monitoring data and the perimeter air monitoring data. Critical receptors are defined as those locations at which individuals abide or reside where the highest potential off-site concentrations of radionuclides other than radon are likely to occur during remediation of the Weldon Spring site (WSS). The sites that were selected as critical receptors are located within 0.62 mi of the WSS where members of the public may spend at least 8 hr/d for a significant fraction of the year.

Critical receptor locations AP-2001, AP-4006, AP-4008, and AP-2005 (Figure 7-1) are strategically located to measure radioactive airborne emissions for the WSCP/WSRP at points where maximally exposed individuals reside or abide. Station AP-2001 is at the common boundary of the WSCP and Missouri Highway Maintenance Facility. Station AP-4008 is located at the Weldon Spring Army Reserve Training Area. Station AP-2005 is located between the WSCP and the WSSRAP administration building. Station AP-4011 (Figure 7-3) is located 165 ft from the nearest residence 0.12 mi west of the WSQ.

Other facilities (i.e., the St. Charles County Water Treatment Plant and the Weldon Spring Height subdivision) are located near the WSS; however, because of the greater distance and previous monitoring data from closer critical receptor locations indicating that there has been no reason to suspect above-background radioactive airborne concentrations with 95% confidence, these facilities are not considered critical receptors.

The critical receptor monitoring program will utilize high volume air samplers, low volume air samplers, and radon track etch detectors at all locations; and continuous radon and radon-daughter monitors at critical receptor locations AP-2005 and AP-4006, and the background station AP-4012. The high volume samplers have heavy duty, turbine-type blowers and feature an electronic controller that automatically adjusts the speed of the sampler to correct for variations in line voltage, temperature, pressure and filter loading. The low volume air samplers are the same samplers described in site perimeter air sampling. They have dual diaphragm air pumps at all locations with the exception of the critical receptor nearest the WSQ (Figure 7-3) that utilizes the carbon vaned air pump. The continuous radon and radon daughter monitors are the radon track etch detectors as described in the site perimeter air monitoring program.

Mass flow meters will be used as described in the perimeter monitoring program for the low volume air samplers. A mass flow meter will also be used to measure and set the flow rates of the high-volume air samplers. The low volume and high volume air particulate samplers will be run continuously at 40 l/min and 950 l/min respectively. The linear flow rates for the low volume and high volume air particulate samplers are 48 m/min and 23 m/min respectively. The low volume air samplers, and the high volume air samplers flow rate will be checked at the end of each week and then readjusted to the desired flow rate after the new filter is installed. The start and finish flow rates will be averaged, and the average flow rate used to calculate the total volume sampled. If the flow rate changes by more than 20% during the sampling period, the monitor will be evaluated to determine if service is required. The data will be flagged and used for qualitative purposes only.

The critical receptor high volume and low volume air particulate samplers will be leak tested on a annual basis. The leak testing will be used to ensure that the measured volume of air is passing through the sample collection filter.

The filters used for the low volume air samplers are the same filters used for site specific monitoring, and are 99.98% efficient in retaining 0.3 μm DOP particulates at a flow rate of 32 l/min across 100 cm^2. The high volume air samplers use 203 mm x 254 mm glass fiber filters that have a mean DOP efficiency of 99.99% for particulate diameters of 0.3 to 0.4 μm.

The low volume air particulate samplers and continuous radon and radon daughter monitors will be placed at the same height specified in the perimeter monitoring section. The high volume air particulate samplers have a sample height of approximately 2 m. In addition,

the monitoring receptor stations will be located in proximity to unusual localized effects or other conditions (e.g., in proximity to a large building, vehicular traffic or trees) that could result in artificially high or low concentrations.

On a quarterly basis, each of the 13 weekly filters from high volume air particulate samplers at critical receptors and at the background station will be composited by location. The composite sample will then be dissolved and divided into three aliquots. The 18 composite samples (three aliquot from six sampler locations) will be analyzed for isotopic thorium, isotopic uranium, Ra-228, and Ra-226.

The filters from the low-volume air samplers will be collected on a weekly basis and analyzed for gross alpha concentrations using the same procedure described in the perimeter air monitoring program. The data stored in the continuous radon-gas and radon-daughter monitors will be collected weekly as described in the perimeter air monitoring program.

The investigation level for the critical receptor monitoring locations will be concentrations greater than background concentrations. The monitoring results from each location will be compared to the background stations location using a statistical test. If a station is found to be statistically different than background, an investigation to attempt to determine the source of the above background airborne radioactive material will be conducted.

The quality control procedures for the low volume air samplers and the continuous radon-gas and radon-daughter monitors will be the same as those described in the perimeter air monitoring program. The quality control program for the high volume air samplers will include spikes, duplicates, and blanks.

With each group of high volume sampler filters sent for radiochemical analysis, two filters will be spiked with known activities of Th-230, and two filters will be spiked with known activities of natural uranium (U-238, U-235 and U-234 in natural activity ratios). Since each filter composite collected at critical receptor locations is split into thirds, these thirds will serve as duplicates.

Field blanks will be collected each week when filters are exchanged. A field blank is an unused filter that is taken with the technician in the field. In addition, an unused filter will be collected directly from the filter package. The two sets of blanks will also be composited and

analyzed radiochemically. Results from the blank composite will be used to identify field or laboratory contamination of filters.

In addition to the system of spikes, duplicates, and blanks, the radioanalytical analyses will be evaluated for internal consistency. At the WSS, U-238 and U-234 are in secular equilibrium. Uranium concentrations on air filters should also be in equilibrium. When radioanalytical results are provided, the degree of equilibrium will be evaluated. In most cases, Th-228 and Ra-228 are also in equilibrium. Equality between these radionuclides will also be evaluated.

8.3 Asbestos Monitoring

During 1992, site perimeter air monitoring for asbestos will be routinely performed only when asbestos removal is taking place. Perimeter asbestos monitoring locations at the WSCP/WSRP and at the WSQ are the same as those used for radioactive air particulate monitoring (Figures 7-1 and 7-3). At least two perimeter asbestos monitoring stations at the WSQ and WSCP/WSRP will be used: one upwind and the other downwind from the asbestos removal activities. A determination of which monitoring stations to use will be based on current meteorological condition when asbestos removal begins. During asbestos removal activities at the WSCP/WSRP, an asbestos monitor will be placed at the Francis Howell High School in the same location as the radioactive air particulate monitoring station. Finally, asbestos monitoring will be performed inside and adjacent to asbestos removal work areas.

When asbestos removal activities are being performed at the WSS, daily asbestos monitoring will be performed in the immediate work area. Samples from the perimeter asbestos monitoring stations will be collected on a weekly basis. Samples from the Francis Howell High School monitoring station and from monitoring stations inside and adjacent to asbestos removal work areas will be collected on a daily basis.

9 ENVIRONMENTAL MONITORING PROGRAM ADMINISTRATION

This section describes the activities that will constitute much of the structure and substance of the environmental monitoring program at the site. Aspects of data management and presentation are discussed along with regulatory compliance and the performance of dose assessments. In addition, the performance of special studies that are outside the scope of this document, emergency preparedness, and changes in the scope of investigations are also addressed.

9.1 Data Analysis and Statistical Treatment

Proper data analysis and statistical treatment practices are essential to produce quality results from the effluent monitoring and environmental surveillance programs required by DOE 5400.1 and DOE 5400.5 and the *Regulatory Guide*. Therefore, it is necessary to develop a plan for implementing the following action items:

- Determining contaminant concentrations at each sampling location for each sampling period, and evaluating the accuracy and precision of those concentrations.

- Comparing the contaminant concentrations at each sampling location to previous concentration estimates at that point and to identify changes or inconsistencies in contaminant levels.

- Comparing the contaminant concentrations at each sampling location to the established limits for those contaminants.

- Comparing contaminant concentrations at single sampling locations or groups of locations to those at control (i.e., background) or other points and evaluating the reliability of those comparisons.

In order to ensure that environmental data are reviewed in a consistent manner and that appropriate and timely action is initiated when and if criteria are exceeded, the Weldon Spring Site Remedial Action Project (WSSRAP) has taken steps to establish investigation levels. The criteria applied by WSSRAP for defining the investigation levels for all environmental monitoring data (except asbestos) are described in several ES&H procedures. The procedures

have been written to direct the WSSRAP staff in the evaluation of the monitoring data. These evaluations will determine whether data collected over the course of routine environmental monitoring programs exceed specific action levels and refer to an administrative procedure (still in draft form) which will define the general actions to be taken for eceedence of any criteria. These procedures include:

ES&H 4.6.4 - *Constant Flow Low Volume Air Sampler Operation and Air Sample Filter Handling*

ES&H 4.6.6 - *Constant Flow High Volume Air Sampler Operation and Air Sample Filter Handling*

ES&H 4.6.7 - *RGA-40 Radon Gas Monitor: Operation and Data Handling*

ES&H 4.9.3 - *Surface Water and Groundwater Data Review Procedure*

These procedures are intended to effectively address the U.S. Department of Energy (DOE) guidance criteria for determining investigation levels for environmental monitoring programs.

The statistical techniques used to evaluate and analyze the data will be designed with consideration for the characteristics of effluent and environmental data. These characteristics may include skewed distributions of time series data, high variability analytical results, large amounts of missing data, and data that are below analytical detection limits.

9.1.1 Summary of Data Analysis and Statistical Treatment Requirements

The following sections summarize the methods of data analysis and statistical treatment of the effluent and environmental data. Immediately upon receipt from the laboratory, all new data will be evaluated against the corresponding historical statistics and entered into the WSSRAP environmental database. Apparent outliers will only be excluded from use after investigation confirms that an error has been made in the sample collection, preparation, measurement, or data analysis process.

Data will be summarized using a range, variance, standard deviation, standard error, median, mean, and confidence interval about the mean. The confidence level of the data will be estimated by using blank and spike samples, and comparing the results of these analyses to the known concentrations. The precision of the data will be estimated by comparison to replicate samples.

9.1.2 Variability of Effluent and Environmental Data

The variability of the effluent data will determine the degree of precision and accuracy that can be achieved with the results. Careful design and execution of the monitoring program can substantially improve the quality of the effluent monitoring and environmental surveillance results.

9.1.2.1 Sources of Variability. Variability of data may arise from six sources; sampling errors, analytical errors, statistical counting variations, data recording errors, and temporal, and spatial variability between environmental samples. Variability due to sampling and recording errors can be controlled. However, variability due to the environment cannot be controlled and must be checked through statistical summaries.

9.1.2.2 Estimating Accuracy and Precision. The validation process will assess the accuracy and precision of each data set according to WSSRAP data validation procedure (RC-31a) using replicate samples. The *Annual Site Environmental Report* (ASER) will present the results of specific validated data points (10 percent of all environmental data collected) and will report the average and standard deviationof the accuracy and precision by data set, including parameter and media specific data points.

9.1.3 Summarization of Data and Testing For Outliers

In order to adequately analyze the environmental data, it must be summarized. Testing for outliers in new data sets also requires that historical data be statistically summarized. The following subsections describe statistical methods used to summarize the historical data.

9.1.3.1 Distribution Analysis. Most common statistical tests rely on the assumption that the data being tested follows a normal distribution. However, this is not the case for most environmental data which generally follows a log-normal distribution. Therefore,

all data sets containing 10 or more samples will be tested for distribution type and, if necessary, the appropriate transformation will be made prior to calculation of summary statistics. Alternatively, nonparametric hypothesis testing will be used.

9.1.3.2 Measures of Central Tendency. For normally distributed data with only a small number of extreme or less-than-detectable values, the arithmetic mean is the appropriate estimator of central tendency. When the data set contains large numbers of extreme values or concentrations below the analytical detection limits, the median, which is less sensitive to extreme values than the mean, will be used to summarize the data. Trimmed means or minimum variance unbiased estimators may also be used in these cases.

9.1.3.3 Measures of Dispersion. Dispersion in normally distributed data, without large numbers of outliers and less-than-detectable values, will be represented as a variance, standard deviation, standard error, or confidence interval. If a large number of extreme values are contained within a data set, the interquartile range and the median absolute deviation will be reported.

9.1.3.4 Less-Than-Detectable Values. An effort will be made to obtain uncensored radionuclide data. If nondetects (NDs) are reported, different techniques may be used depending on the percentage of NDs in the data set. For analyzing data sets with a small percentage of NDs, the special techniques described by Gilbert and Kinnison (1981) will be used. For data sets with a larger percentage of NDs, rank dependent or proportion type hypothesis testing will be used.

9.1.3.5 Testing for Outliers. Rosner's (1975) test for detecting outliers will be used when the data is normally distributed. If the data is log normally distributed, the test will be conducted on the log transformed data.

9.1.3.6 Elements of Good Practice. Procedures will be used to aid in the interpretation of the effluent monitoring data and improve the quality of the results from the program by helping to detect erroneous measurements. Comments on the quality of the samples taken will be entered into the data base with the sample contaminant concentration measurements. In addition to the data collected during the regular sampling program, field logs describing events that might affect contaminant concentrations will be reviewed and incorporated as appropriate.

9.1.4 Treatment of Significant Figures

Any calculations performed using the analytical data will follow the accepted rules for significant figures. Results of any calculations will not contain more significant figures than that of the least precise value used in the calculation.

9.1.5 Parent-Decay Product Relationships

The delays associated with sample collection to sample analysis are insignificant compared to the half-lives of the radionuclide present and routinely monitored at the WSS. Therefore, it is not necessary to take into account decay times when calculating parent-decay product relationships.

9.1.6 Comparisons to Regulatory or Administrative Control Standards and Control Data

One reason for obtaining reliable estimates of contaminant concentrations at the monitoring stations is to compare the values to regulatory or administrative control standards or values at control stations to determine whether action must be taken to reduce the contaminant levels in the effluents.

9.1.6.1 Single Concentration Measurements. Statistical tests are not appropriate for comparisons of single values, such as when a single radionuclide concentration measurement is compared to its regulatory limit. Single values can have a large associated uncertainty, and they are not necessarily an accurate representation of how well the facility is complying with the limit. Statistical summaries of groups of related samples will be used when possible. If single concentration measurements cannot be grouped, statistical tolerance limits will be used.

9.1.6.2 Groups of Measurements. Concentration estimates from groups of sampling locations will be compared using standard analysis of variance techniques when the data meet the underlying assumptions of those tests. Standard nonparametric statistical comparison techniques will be used when the assumptions of the parametric tests are not met by the data. Caution will be used when comparing groups of readings from single points over time, because of the likely strong autocorrelation in the time series of data.

9.2 Dose Calculations

This section is intended to provide a description of models, computer programs, input data, and data sources that will be used to assess accurate and realistic radiation doses to the population and to a hypothetical maximally exposed individual that could result from remediation activities at the WSSRAP. Environmental monitoring data will be used either as direct input data in dose calculations or, where appropriate, will serve as data input in exposure and dose models.

The results of the dose calculations will be reported in the *Annual Site Environmental Report* (ASER). The methodology used to calculate the exposure point concentration and estimate dose will also be documented in the ASER.

9.2.1 Surface Water and Groundwater Dose Calculations

The radiological dose assessment from groundwater and surface water will be accomplished by using data gathered from groundwater and surface water effluents monitoring and environmental surveillance monitoring programs. Site-specific monitoring data representing surface water and groundwater radionuclide concentrations will be used as input in the dose assessment calculation. This data will allow a more accurate assessment of doses to a maximally exposed individual and the population surrounding the WSS.

The exposure and dose assessment estimate will be conducted for both the general off-site population and a maximally exposed receptor. Intake variables for a given pathway will be selected to reflect a reasonable, realistic exposure mode.

The results from the surface water and groundwater effluent monitoring and environmental surveillance programs will be evaluated in the ASER for the potential to contribute a radiological dose to a member of the general public. If measured concentrations in surface water and groundwater effluent from the WSS exceed natural background concentrations with 95% confidence, an exposure scenario will be developed to assess the dose. Realistic ingestion rates and times will be assigned for a maximally exposed individual. A standard dose conversion factor will be assumed and referenced for the calculations.

9.2.2 Airborne Radiological Dose Calculations

The radiological dose assessment from airborne emissions will be conducted using environmental data as well as computer models. Exposures for critical receptors and hypothetical maximally exposed individuals will be determined through monitoring data. For sources where perimeter monitors indicate exceedance of background with 95% confidence, population dose estimates will be made by computer modeling. This would constitute a change over previous monitoring years when computer modeling was not utilized. The new site specific monitoring program, in conjunction with existing perimeter monitoring data will be used to obtain a more reliable source term. This will allow computer modeling to be used if necessary.

The computer models that will be considered for use in this dose assessment include AIRDOS PC, LTSAMP, and COMPLY. COMPLY and LTSAMP are computer models that have the capability to assess radiological dose from airborne emissions at distances less than 300 m. COMPLY is a U.S. Environmental Protection Agency (EPA) computer model designed mainly to model emissions from stacks or vents rather than large diffuse sources. LTSAMP is a computer model developed at the Uranium Mill Tailings Remedial Action (UMTRA) project to calculate doses from large diffuse sources.

Because of the diverse nature of the sources at the WSSRAP, any one of these programs or all three may be used to assess doses due to airborne emissions from the two WSSRAP sources. The use of LTSAMP would also be dependent on gaining approval from the U.S. Department of Energy (DOE) headquarters.

Those pathways that are complete and could realistically contribute to the dose to a member of the general public will be assessed and documented in the ASER. Justification for elimination of any pathways will also be provided in the ASER. Scenarios that reflect realistic but conservative assumptions will be developed for those pathways that could contribute to the dose to a member of the general public. Realistic occupancy times will be assumed for potentially exposed individuals. Standard breathing rates and dose conversion factors from the Federal Guidance Report No. 11 (Eckerman et al. 1988) will be used in the calculations.

9.3 Records and Reports

The WSSRAP recognizes numerous DOE orders, notices, and directives in addition to Federal, State, and local regulations. Since the WSS is a remedial action project, rather than an operating facility, the distinction between applicable and nonapplicable guidelines must be determined when interpreting these regulations. The project must comply with appropriate regulations, and ensure that reports are written and distributed in a timely manner and records are properly maintained.

9.3.1 Reports and Reporting

The following DOE Orders: Order 5000.3A, Order 5400.1, Order 5400.5, Order 5284.1B and Order 5484.1 govern activities at the WSS. These orders are described below in the following paragraphs.

DOE Order 5000.3A, *Occurrence Reporting and Processing of Operations Information*, is a system of reporting those occurrences listed in 5400.1, 5400.5, and 5484.1. Occurrences are categorized into nine groups such as environmental, personnel radiation protection, and divided into three categories in order of decreasing severity: emergencies, unusual occurrences, and off-normal occurrences.

DOE Order 5400.1, *General Environmental Protection Program*, requires that all DOE facilities comply with those Federal, State, and local environmental protection laws that are applicable. Both environmental occurrences and routine monitoring reporting are covered. WSSRAP has prepared an *Environmental Protection Program Implementation Plan* (EPPIP) (MKF and JEG 1991a) to meet the specific requirements of DOE Order 5400.1. Environmental occurrences will be reported as stated in DOE 5484.1 and DOE 5000.3 in accordance with WSSRAP procedures. Reports prepared by the WSSRAP include the *Environmental Monitoring Plan, Annual Site Environmental Report, Groundwater Protection Program Management Plan, Groundwater Monitoring Plan, Radioactive Effluent Information System and On-site Discharge Data Reports*, the *Quarterly Environmental Data Summary* and the *Environmental Protection Program Implementation Plan* (EPPIP).

The *Environmental Monitoring Plan* (EMP) details environmental and effluent sampling. The EMP is reviewed annually, as needed, and reissued at least every three years. The *Annual*

Site Environmental Report (ASER) presents data results and interprets these results, highlighting any unusual data. The ASER is produced annually (see Section 9.3.1.1). The *Groundwater Protection Program Management Plan* structures the groundwater program into a consistent program which facilitates periodic review. This plan is reviewed and updated annually. The *Groundwater Monitoring Plan* is taken directly from the EMP, with the focus on the groundwater monitoring program. The *Radiation Effluent Information System and On-site Discharge Data Report* is an annual report which consist of a letter and DOE form F 5821.1 which covers any releases from the site. The *Environmental Protection Program Implementation Plan* (EPPIP) as mentioned above outlines DOE Order 5400.1 as it applies to WSSRAP. This plan is updated annually and should be referred to for a complete and thorough listing of applicable regulations.

DOE Order 5400.5, *Radiation Protection of the Public and the Environment*, states that Department of Energy facilities will adopt specific standards and requirements that will not allow undue risk from radiation to effect the public or the environment. The WSSRAP has formulated its environmental protection program to meet the requirements of this order and the regulatory guide.

DOE Order 5482.1B, *Environment, Safety, and Health Appraisal Program*, establishes a review and appraisal program for the Environmental, Safety and Health (ES&H) programs at WSSRAP. There are six levels of appraisals and audits: management appraisals, technical safety appraisals, functional appraisals, internal appraisals, environmental surveys, and environmental audits. Each appraisal and audit requires a quarterly status report or a report as otherwise directed, to report on corrective actions.

DOE Order 5484.1, *Environmental Protection, Safety, and Health Protection Information Reporting Requirements*, outlines requirements and procedures for investigating occurrences which may impact environmental protection, safety, and health. Occurrences are categorized into three levels - A, B, and C. In addition, the Annual Radiation Exposure Information Reporting System (REIRS) requires an annual report of any exposures obtained by DOE or Project Management Contractor (PMC) employees, nonemployee radiation workers, and visitors.

9.3.1.1 Annual Site Environmental Report Description. The WSSRAP *Annual Site Environmental Report* (ASER) presents the findings of the environmental monitoring program conducted at the Weldon Spring site (WSS) in each monitoring year. The report

presents summary environmental data, discusses compliance with environmental standards, and highlights significant programs and efforts undertaken at the WSS. Annual environmental monitoring reports have been prepared for this site (or portions thereof) since 1981.

This DOE Order also requires a listing of environmental permits. Existing permits and compliance with those permits is discussed in the report.

The ASER is the DOE's vehicle for documenting the results of its extensive monitoring program at the WSSRAP. The report provides the public and concerned regulatory agencies with summary level discussions regarding the routine environmental monitoring program. It explains how the WSSRAP effluent monitoring program meets the requirements of the National Pollution Discharge Elimination System (NPDES) program and compares the measured contaminant levels to applicable standards. Further, the report indicates whether changes are occurring in contaminant distribution or contaminant source conditions on and around the site--changes which might equate to variations in potential exposure scenarios to the public or environmental receptors.

Environmental monitoring is the WSSRAP's most effective means by which to assess the impacts from the site. The data and evaluations contained in the report provide the summary of that monitoring for each monitoring year. The ASER reports results of the contaminant level measurements and compares the environmental levels of radioactivity and chemical contaminants released from the site with applicable standards.

In addition to the routine environmental monitoring conducted in each monitoring year, a number of related activities and special studies are performed. These activities and studies are directly applicable to the assessment of the overall impact of site operations on the environment. Therefore, these activities are described and the results are discussed in the ASER. These include Oak Ridge National Laboratories (ORNL) research on site, Federal Facility Agreement driven activities, and activities not scoped in this EMP.

The report contains trend analyses and figures for groundwater wells, definitions of selected terms used in the report, a discussion of the environmental guidelines that apply to the monitoring program, and presents dose assessment calculations.

Though not required by a DOE Order, the *Quarterly Environmental Data Summaries* (QEDS), are produced to aid in communicating site environmental data to the public and participating regulatory agencies. The QEDS summarizes environmental data, highlights any significant findings, and offers tentative interpretations. The QEDS allow preliminary data to be reviewed by interested individuals and organizations on a more frequent basis.

Permits issued under the National Pollutant Discharge Elimination System (NPDES), provisions of the *Clean Water Act*, also require recordkeeping and reporting. Recordkeeping requirements are stated in the NPDES permits issued by Missouri Department of Natural Resources (MDNR). Discharge Monitoring Reports (DMRs) are issued on a quarterly basis to MDNR and include information on sample collection, flow, and laboratory results. If there is a noncompliance event, MDNR must receive an oral response within 24 hours followed by a written response within five days. Written reports may also need to be filed with the DMRs.

The DOE Performance Indicator Program (PI) is a requirement of SEN-29-91, that calls for the production of a quarterly report. This program allows trending and analyzing operational data which will improve the DOE and contractor line management control of operations. The report contains a management summary, a PI summary, trends and analysis, and quantitative data.

Under the Federal Facilities Agreement, DOE must submit status reports of activities and technical documents to EPA for their review and approval. These include, but are not limited to, the ASER, EMP, QEDS, sampling plans, and unplanned sampling activity notifications. Each of these reports have their own reporting requirements and time constraints which are detailed in the *Federal Facility Agreement Implementation Plan* (MKF and JEG 1991g).

Other reports covering environmental issues are produced by the Environmental Compliance Department. The *Quarterly Compliance Report* is required by SEN-7-89. This report covers issues of non-compliance for the quarter with corrective actions. Also, the *Annual Report on Environmental Permits* is issued annually to the DOE. this report is required by DOE Order 5400.2 and covers all environmental permits issued to the site.

9.3.2 Records

DOE Order 5400.1 requires that all environmental surveillance and effluent monitoring records, computer programs, raw data, and procedures be maintained. These records must be protected against damage or loss. The WSSRAP maintains an *Environmental Data Administration Plan* (EDAP) (MKF and JEG 1991h) which governs sampling plan preparation, data verification and validation, database administration, and data archiving.

The EDAP provides a tracking system for sampling activities. Field log books and field data forms are filled out at sample collection. A chain-of-custody (COC) form is completed and accompanies the sample until it is properly disposed of or returned to WSSRAP. A laboratory authorization form is sent along with the sample, COC, and the shipping order form to authorize testing by an off-site laboratory. The sample information, such as identification number, date, and parameters is then entered into the Environmental Sample Tracking (EST) System. EST tracks the samples, calculates costs, invoice payments, and budget reports. Upon receipt of data from a laboratory, it is reviewed through verification and validation processes. The verification process reviews data delivery, sample preservation and identification, chain of custody, holding times, and data review to ensure compliance with DQO and standard operating procedures, validation reviews and evaluates laboratory data.

Data is accessed by the DOE and the PMC using a computerized data management program developed on site, the Generic Universal Report Utility (GURU). The database allows data to be selected and sorted based on identification number and parameter. Records are protected from alteration by the user.

Other computer programs used are: the Safety, Health, And Radiation Protection (SHARP) program, the Site Wide Audit Tracking System (SWATS), and the Waste Inventory Tracking System (WITS).

All environmental data and documentation from sampling, analysis, and quality review programs are maintained in hard copy records; i.e., documents and data in written, typed, or printed forms; and electronic records, i.e., computerized records of environmental data. Original documents are transferred to Quality Assurance and stored in the WSSRAP quality control area in a fireproof safe. Copies are kept in the ES&H files. Work data files and

electronic data records are maintained by the Data Administration sections and archived annually.

For a more detailed description, refer to the *Environmental Data Administration Plan* (MKF and JEG 1991h).

9.4 Environmental Activities Varying from EMP Scope

When additional characterization and monitoring activities are conducted that are not defined within the scope of the EMP, a judgement will be made by the Environmental Protection Group Manager as to the relevance of each of those activities to the overall environmental reporting requirements. An example of an activity which might be reported in the ASER is a soil or water characterization effort that exceeds the scope of those previously performed in the area. Conversely, an example of activities that may not warrant ASER reporting are what are termed "engineering characterization" efforts performed in support of various construction activities at the site. Those data would not contribute significantly to the overall understanding of the environmental conditions at the site.

During the 1992 monitoring year, it may be determined necessary to alter the scope of the monitoring program. In such case, the changes in monitoring schedule, frequency, and/or location will be authorized by the Environmental Protection Group Manager with notification given to the ES&H Department Manager. All variances from the program scope will be documented with a memorandum to project management and reported in the ASER.

9.5 Emergency Preparedness

The WSSRAP maintains on site the management and staffing structure necessary to respond to environmental and medical emergencies. Plans and procedures are in place that detail the response and reporting program, implementation criteria, and routine environmental response and safety drills. The specific plans which address these measures include: the *Emergency Response Manual* (MKF and JEG 1991j) and the *Emergency Preparedness Plan* (MKF and JEG 1991k). These plans encompass environmental emergencies, spills, fire, medical and natural disasters.

9.6 Laboratory Programs

Laboratories that are performing analysis for the *Environmental Monitoring Plan* are mainly using Contract Laboratory Program (CLP) methodologies. For certain analyses (such as radiochemical) the laboratories are using EPA 600 (drinking water), EPA 900 (radiochemical analysis of drinking water) or a method that is reviewed and approved by the PMC prior to analysis of a sample. Contracted laboratories have all submitted a site-specific *Quality Assurance Project Plan* (QAPjP) to the WSSRAP and have sent controlled copies of their standard operating procedures (SOP). The QAPjP and SOPs are reviewed and approved by the PMC prior to sample shipment to a laboratory. All of the current laboratories being used by WSSRAP have had a preliminary assessment of their facilities to make sure that they have the capability and facilities to perform work according to the specifications in their contract.

Site-specific QAPjP from laboratories consist of standard practices that ensure that the laboratory is performing high quality work. Each QAPjP prepared for WSSRAP is in accordance with the current *Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans* (EPA 1980). The laboratories also demonstrate compliance with additional QA/QC as specified in their contracts which includes: sample preparation and analytical methods; calibration of instrumentation; periodic inspection, maintenance and servicing; statistical procedures to control precision and accuracy; corrective action programs; participation in external EPA Performance Audit Program; maintenance and storage of WSSRAP records; hardcopy and electronic formatting; notification of nonconforming issues; and WSSRAP internal QC samples.

Accuracy of all chemical and radiological analyses of water media samples is monitored by the routine use of control samples. This is a requirement of many published protocols (i.e., EPA) and is good laboratory practice. At the WSSRAP, 10% of all data are routinely validated (according to the WSSRAP Data Validation procedure) including all associated control samples. Also, approximately 8% of the existing database has been validated and its overall accuracy has been determined. These accuracy values have been extrapolated to represent the accuracy of the database as a whole.

Further, for radiological analyses which use counting methods, the counting accuracy is also assessed and reported with each such data point from the laboratory. These values are presented in the database under the "percent error" field.

Specific analytical methods used by the laboratories are specified in their contracts and documented by the PMC receiving controlled copies of the SOP used by the laboratory. Any changes to the standard analytical methods are documented in the controlled SOP copies.

The details of the WSSRAP data collection and management program are included in several documents including the *WSSRAP Environmental Data Administration Plan* (EDAP) (MKF and JEG 1991h) and various ES&H department procedures. The EDAP presents the minimum detection levels for environmental sample analysis by media and parameter. The levels represent the contract required detection limits (CRDLs) under the EPA Contract Laboratory Program (CLP) and represent the levels to which the laboratories are required to perform. Often times the laboratory instruments can achieve lower levels based upon the calibration, operational efficiency, and sample media and concentrations. In such cases, this instrument detection limit (IDL) is requested to be reported. Analyses for nitroaromatic compounds are performed according to USATHAMA-approved methods, which generally achieve lower detection levels than EPA Method 609. For water analyses, all samples are analyzed first by gas chromatography, with all positive detection confirmed with high performance liquid chromatography (HPLC). Radiological analyses are conducted by either EPA Method 520/5-84-006 or EPA Method 600/4-80-032. Again, these minimum detection levels are reported in the Appendix of the WSSRAP *Environmental Data Administration Plan.*

10 QUALITY ASSURANCE

Quality assurance (QA) for environmental monitoring activities at the Weldon Spring site (WSS) is divided into two separate categories. The first, programmatic or overall project QA, relates to the incorporation and documentation of the quality of all site activities. This approach is discussed in section 10.1. The second category is specific to the environmental monitoring activities presented in this plan and is discussed in Section 10.2.

10.1 Programmatic Quality Assurance

The Weldon Spring Site Remedial Action Project (WSSRAP) is obligated to comply with the requirements of American National Standards Institute (ANSI) and American Society of Mechanical Engineers (ASME) Nuclear Quality Assurance Program-1 (NQA-1-1986) as outlined in DOE Order 5700.6B. These requirements were developed to assure that work performed at facilities handling, processing, or utilizing radioactive materials is of documented quality. To satisfy this obligation, Morrison Knudsen Corporation has prepared a corporate *Quality Assurance Manual* (MKC 1991) which addresses's the requirements of NQA-1. This corporate plan is consistent with the 18-element format of NQA-1. In addition to this corporate plan, the Project Management Contractor (PMC) has prepared a project specific quality assurance program plan (QAPP) which details how the various aspects of NQA-1 and MK-Ferguson's quality assurance program, as described in the corporate QA manual will be implemented at the Weldon Spring site. This QAPP has been reviewed and approved by project management, the project's Quality Assurance Manager, and the U.S. Department of Energy (DOE) Project Manager.

The QAPP details numerous ANSI/ASME NQA-1 requirements which support, control, or guide the environmental monitoring program. These requirements include: documented project organization, a documented quality assurance program, a document control system, the identification and control of items, inspections, the control of measuring and test equipment, handling, storage, and shipping of quality-affecting items, a program for implementing and verifying corrective action, a program for maintaining quality assurance records, and a routine audit program. QA procedures detail implementation of these requirements. Specific procedures include: QAPP-8, *Nonconformance and Corrective Action*, QAPP-9, *Quality Assurance Records*, QAPP-10, *Audits*, SQP-1, *Site Wide Audit Tracking System* and SQP-2, *Quality Assurance Surveillance*.

The WSSRAP also has prepared an environmental QAPP (EQAPP) to meet the intent of EPA QAMS 005/80. This document supports the project QAPP and is specific to environmental monitoring and characterization. Effective February 1992, the QAPP and EQAPP will be revised to meet the requirements of DOE Order 5700.6C. Root cause analysis and lessions learned will be addressed by a WSSRAP specific document which is presently being drafted and will be completed in 1992.

10.2 Environmental Monitoring Program Quality Assurance

The quality of the environmental monitoring program is maintained and documented through a number of measures described in the following subsections. The measures include: the use of standard operating procedures, the collection, analysis, and evaluation of quality control samples, performance audit samples, the use of standardized analytical methods, data management activities (data verification), data quality evaluation (data validation), maintaining quality assurance records, performing self assessments, supporting project quality assurance personnel in auditing and evaluating analytical laboratories, and audits by quality assurance personnel. Each of these items will be discussed in the following subsections.

10.2.1 Standard Operating Procedures

Standard operating procedures (SOPs) have been developed for routine activities associated with environmental monitoring at the Weldon Spring site. These procedures have been developed from U.S. Environmental Protection Agency (EPA) and DOE guidance and from standard industry practices and are specific to the WSS. Procedures at the WSS are prepared, reviewed, and approved by cognizant department managers, the Quality Assurance Manager, and project management. Controlled copies of procedures are maintained in accordance with the document control requirements of ANSI/ASME NQA-1. Procedures are reviewed at least annually and revised as appropriate.

Personnel undergo training specific to their responsibilities varying from procedure review through classroom training and "hands on" training under the supervision of a qualified individual. This training is tracked through the use of a training matrix. Each manager prepares for each individual a unique subset of procedures from all site procedures. Training records are maintained by the Productivity Improvement Coordinator. As procedures are revised, the matrices are updated and personnel are retrained.

TABLE 10-1 Procedures Applicable to Environmental Monitoring Activities

Procedure Number	Procedure Title
ES&H 4.1.1	Environmental Numbering System
ES&H 4.1.2	Chain of Custody
ES&H 4.1.3	Sampling Equipment Decontamination
ES&H 4.1.4	Packaging and Shipping Requirements for Non-regulated Samples
ES&H 4.3.1	Surface Water Sampling
ES&H 4.4.1	Groundwater Sampling
ES&H 4.4.2	Groundwater Level Monitoring and Well Integrity Inspections
ES&H 4.4.5	Soil/Sediment Sampling
ES&H 4.5.1	Ph and Temperature Measurements in Water
ES&H 4.5.2	Specific Conductance Measurement in Water
ES&H 4.5.7	Measurement of Settleable Solids
ES&H 4.5.8	Water Sampling Filtering
ES&H 4.6.1	Area TLD Deployment for Environmental Sampling
ES&H 4.6.2	Radon Concentrations Measurement in Ambient Air
ES&H 4.6.4	Constant Flow Air Sampler Operation and Sample Filter Handling
ES&H 4.6.6	Constant Flow High Volume Air Sampler Operation and Sample Filter Handling
ES&H 4.9.1	Environmental Monitoring Data Verification
CM&O-15	Task-specific Safety Assessments
RC-30	Monitoring Well Waste Management
RC-31	Environmental Monitoring Data Validation

Procedures applicable to environmental monitoring activities are listed in Table 10-1. These procedures cover all activities from groundwater sampling through chain-of-custody samples and provide detailed instructions to monitoring personnel.

10.2.2 Quality Control Samples

Numerous QC samples are collected in support of environmental monitoring activities. These include: duplicate samples, replicate samples, blank samples, and rinsate samples. Samples are also provided to the laboratory to perform internal laboratory quality control evaluations specific to sample media (matrix spikes and matrix spike duplicate samples). Table 10-2 presents a summary of the various quality control samples that will be collected to support environmental monitoring activities. Duplicate samples will be collected on a frequency of one per 20 samples collected or one per every 14 day period during which samples are collected if the sampling, by matrix, yields fewer than 20 samples during that period (EPA 1989). The WSSRAP will also participate in the DOEs laboratory cross-check program for radiological and chemical sample analyses. Performance audit samples prepared by an off-site laboratory will be submitted to WSSRAP-contracted laboratories for an evaluation of analytical performance.

10.2.3 Analytical Methods

Standardized analytical methods will be used to perform analyses related to environmental monitoring. This, combined with duplicate and replicate samples, will ensure that environmental monitoring results are comparable. The analyses to be performed and the analytical methods that will be used are discussed in Section 6 of this plan.

Each laboratory is required to prepared a project-specific *Quality Assurance Project Plan* (QAPjP). These QAPjPs are reviewed and approved by the WSS Project Quality Manager prior to performing analyses for the WSS.

10.2.4 Data Management Activities

Overall environmental data management activities for the Weldon Spring site are detailed in the *Environmental Data Administration Plan* (EDAP) (MKF and JEG 1991h). The EDAP provides guidance for the development of sampling plans, describes data management activities, and details general data quality requirements. These general data quality goals have been

Table 10-2 Field Quality Control Sample Summary

QC Sample Type	Frequency	Purpose
Duplicate	*1 per 20 or 1 per 14 days	Assess intralaboratory variability
Replicate	*1 per 20 or 1 per 14 days	Assess interlaboratory variability
Equipment Blank	1 per 20	Assess effectiveness of decontamination
Distilled Water Blank	1 per quarter	Assess quality of distilled water
Trip Blank	1 per day when analyzing for VOAs	Assess potential cross-contamination during shipping
Field Blank	1 per 20	Assess impact of ambient conditions on samples

* Whichever is of higher frequency

adopted for this monitoring program. The primary activities associated with this environmental monitoring program include data verification, database management, and data validation. These programs document the quality of data generated by on-site and off-site analyses of samples.

Data verification is the WSSRAP's process of reviewing the sampling documentation and analytical data to ensure that adequate documentation is maintained and that all results are reported in compliance with established reporting requirements. All data generated by analytical laboratories are verified.

The verification process consists of: reviewing accounting aspects, reviewing sampling documentation and chain-of-custody documentation, comparing actual holding times to method specified holding times, and a review of the data for comparability with historical results. All of these activities are documented according to Environmental, Safety and Health (ES&H) Procedure 4.9.1.

Following completion of data verification, data are merged into the site database and are available for general use. All databases are backed up regularly. Access to edit the data base is restricted to maintain the integrity the computer files.

Data validation is an independent (of the analytical laboratory) formal review of laboratory records performed to assess the quality of the reported data. Actual laboratory records are reviewed by data validation personnel to determine whether the analytical instruments were within calibration and to ensure that adequate documentation is available to support the validity of the data. Data validation is performed on approximately 10% of the all data generated. Approximately 5% of these data are randomly selected by the laboratory coordinator. An additional 5% is selected for validation based on the data review. Validation activities provide the WSSRAP with qualified data. All validated data receive a qualifier that provides information for data users to evaluate the useability of the data. These activities are performed and documented in accordance with procedure RC-31a/1.

10.2.5 Quality Assurance Records

Records generated as a result of environmental monitoring are maintained as quality assurance records. Field sampling forms, analytical data, equipment calibration records, and verification and validation documentation records are all considered quality assurance records and are maintained by the Quality Assurance Department in accordance with the requirements of QAPP-9. This provides both security and protection to critical records.

10.2.6 Self Assessments

Consistent with Department of Energy Order 5482.16, the WSSRAP has developed a formal self assessment program. This program is detailed in WSSRAP procedure MGT-1. Implementation of this procedure requires that all departments perform a self assessment at least annually. Self assessments are scheduled and tracked by the Quality Assurance Department and are performed by a team led by the manager of the department being assessed. A report which summarizes the areas evaluated and the assessment results is prepared following each self assessment. Findings and proposed corrective actions are tracked according to the Site Wide Audit Tracking System (SWATS).

10.2.7 Audits

Three aspects of the WSSRAP are audited to evaluate the quality-related activities of the environmental monitoring program. These include analytical laboratories, sample collection activities and programmatic procedures.

Analytical laboratories performing analyses for the WSS are audited annually. These audits are directed by a lead auditor from the Quality Assurance Department, with support provided by a select team of site personnel who have with knowledge of analytical methods and procedures. These audits focus on compliance with the project-specific *Quality Assurance Project Plan* (QAPjP) prepared by the laboratories prior to performing sample analysis and with laboratory-specific procedures and policies. An audit report is generated and corrective actions tracked by the QA Department.

The WSS QA Department routinely audits site operations, including environmental monitoring activities. These audits evaluate compliance with project-specific procedures. As with all other audits, an audit report is generated and corrective actions are tracked by the QA Department.

The Weldon Spring site is also routinely audited by numerous external entities including DOE - Headquarters and DOE - Oak Ridge. These audits assess compliance with applicable regulations, DOE orders guidance, site plans, and procedures. Formal reports and corrective actions are tracked using the SWATS.

Dear Mr. Wall:

SAMPLING PLAN FOR DETERMINATION OF HYDRAULIC PROPERTIES OF UNDISTURBED SOILS IN THE WELDON SPRING DISPOSAL FACILITY STUDY AREA

Enclosed are 2 copies of the above sampling plan. Principal elements of this plan include two-stage borehole field permeability tests and triaxial permeability tests using synthesized leachate. These tests are being undertaken in response to MDNR comments on site suitability issues. Additional testing activities are proposed to obtain information to be used to resolve remedial design and performance assessment issues. Portions of this plan have been made available, in draft form, to MDNR-DGLS staff in order to facilitate the timely acquisition of this data.

If you have any questions, please feel free to contact me.

Sincerely,

Jerry S. Van Fossen

ABSTRACT

Sampling and testing is proposed to obtain information on the hydrologic properties of site soils within the disposal facility study area (DFSA). Sampling and testing will focus on assessing the effects of naturally occurring fractures and synthesized leachate on soil permeability. Proposed activities will also help satisfy location standards defined by the Missouri Code of State Regulations for proposed landfills. Proposed activities include testing, exploratory trenches and laboratory chemical and physical analyses.

Six geotechnical boreholes are proposed to obtain soil samples for determination of saturated and unsaturated hydraulic conductivity and associated properties.

Sixteen two-stage borehole tests at six locations and five largey diameter sealed-double ring infiltrometer tests at four locations are planned to obtain information on in situ permeability of unsaturated site soils.

Three exploratory trenches are planned to obtain information on perched water conditions within the DFSA.

1 INTRODUCTION

This sampling plan has been developed to provide the U.S. Department of Energy (DOE) and the Missouri Department of Natural Resources (MDNR) with reliable and reproducible data on the hydraulic properties of unsaturated soils at the Weldon Spring site (WSS) in the area of the proposed disposal facility (DF). Sampling and testing will focus on assessing the effects of naturally occurring fractures and synthesized leachate on soil permeability. This plan supercedes proposed actions outlined in the *Disposal Facility Siting Demonstration Proposal* (MKF and JEG 1991a).

The WSS is a DOE surplus facility located in St. Charles County, Missouri (Figure 1-1). The site has been contaminated by trinitrotoluene (TNT) and dinitrotoluene (DNT) from past ordnance production activities and more recently by radionuclides and metals from the processing of uranium ore (MKF and JEG 1992a).

1.1 Purpose

The primary purpose of this investigation is to obtain representative soil samples of principal soil units beneath the proposed DF (Figure 1-2) and through laboratory analysis, determine their saturated and unsaturated hydraulic conductivity, the effect of leachate on soil permeability, and other hydraulic parameters. Fractures observed in the exposed glacial and post-glacial soils beneath the WSS are a concern to the State of Missouri and the DOE because of the effect these features might have on the hydraulic conductivity of the soils and the subsequent transport of leachate born contaminants.

This sampling program will also help satisfy design criteria for the cell foundation that are consistent with the Missouri Code of State Regulations 10 CSR 25-7.264(2)(N)1.A,B.

Zones within the overburden soils at the Weldon Spring Chemical Plant (WSCP) are considered to potentially contain perched groundwater. The remedial investigation report for the WSCP/Weldon Spring raffinate pits (WSCP/RP) areas summarizes the occurrence of perched water conditions known to exist at the site (MKF and JEG 1992a). Known areas of perched water are generally associated with seepage emanating from the raffinate pits. However, the site has been extensively reconfigured and differs from the topography that existed prior to development for the Weldon Spring Ordnance Works (WSOW). Therefore, it is reasonable to

expect that pre-WSOW and pre-WSCP drainages actively transmit unsaturated flow at the fill and undisturbed soil interface. Organic soils may also be associated with perched water conditions. In order to facilitate the development a disposal cell foundation excavation plan, trenches will be excavated in locations specified as part of this plan to determine whether perched water or unsuitable soils are present. Figure 1-3 shows three trenches within the proposed DF footprint at locations of suspected seepages or perched water.

1.2 Scope

To determine the effects of fractures and other structures on soil permeabilities, field sealed double ring infiltrometer (SDRI) and two stage borehole (TSB) permeability tests (Boutwell 1992) of representative soil structures will be conducted in the proposed DF footprint. The permeability values obtained will be compared to those determined from laboratory techniques. Samples will be collected and tested as follows:

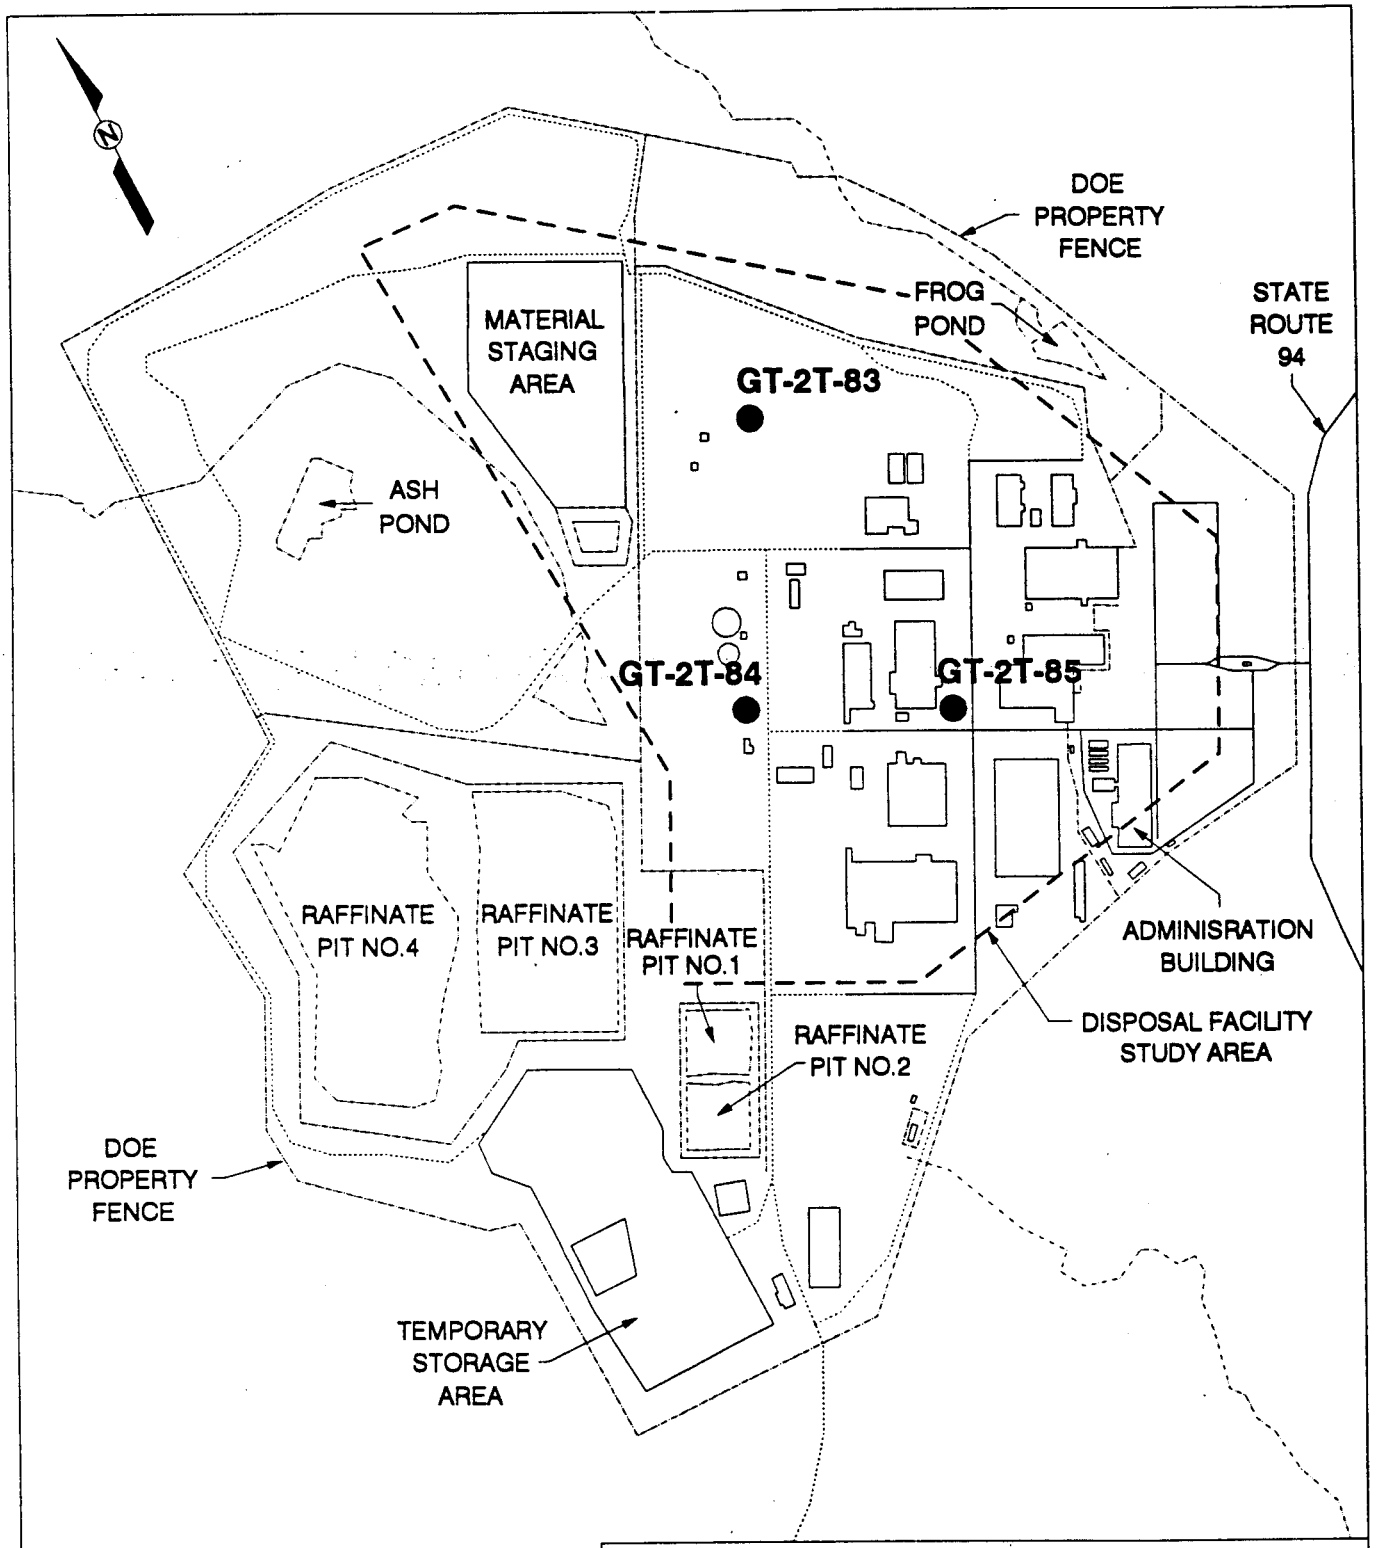
- Standard undisturbed samples (3-in. Shelby Tube type) will be collected for permeability test runs with both water and with a formulated leachate. Undisturbed and remolded samples from each unit of interest will be tested.

- Submersible pressure outflow cell (SPOC) tests will be run on standard-sized undisturbed samples to develop soil moisture retention curves. These curves will document the capillary retention properties of different units at varying temperatures. The saturated hydraulic conductivity will be determined directly from the tests; the unsaturated hydraulic conductivity will be calculated.

- General mechanical soil properties such as grain size distributions, Atterberg limits and specific gravities will also be determined from the standard size samples.

- Two stage borehole permeability (TSB) tests will be performed in the same locations and depths as the Ferrelview and clay till standard size samples.

- SDRI field tests will also be performed at the same locations and depths as noted above for laboratory testing and TSB tests.



LOCATION OF TRENCHES FOR PERCHED WATER INVESTIGATION

FIGURE 1-3

REPORT NO.:				EXHIBIT NO.:	A/CP/090/0892

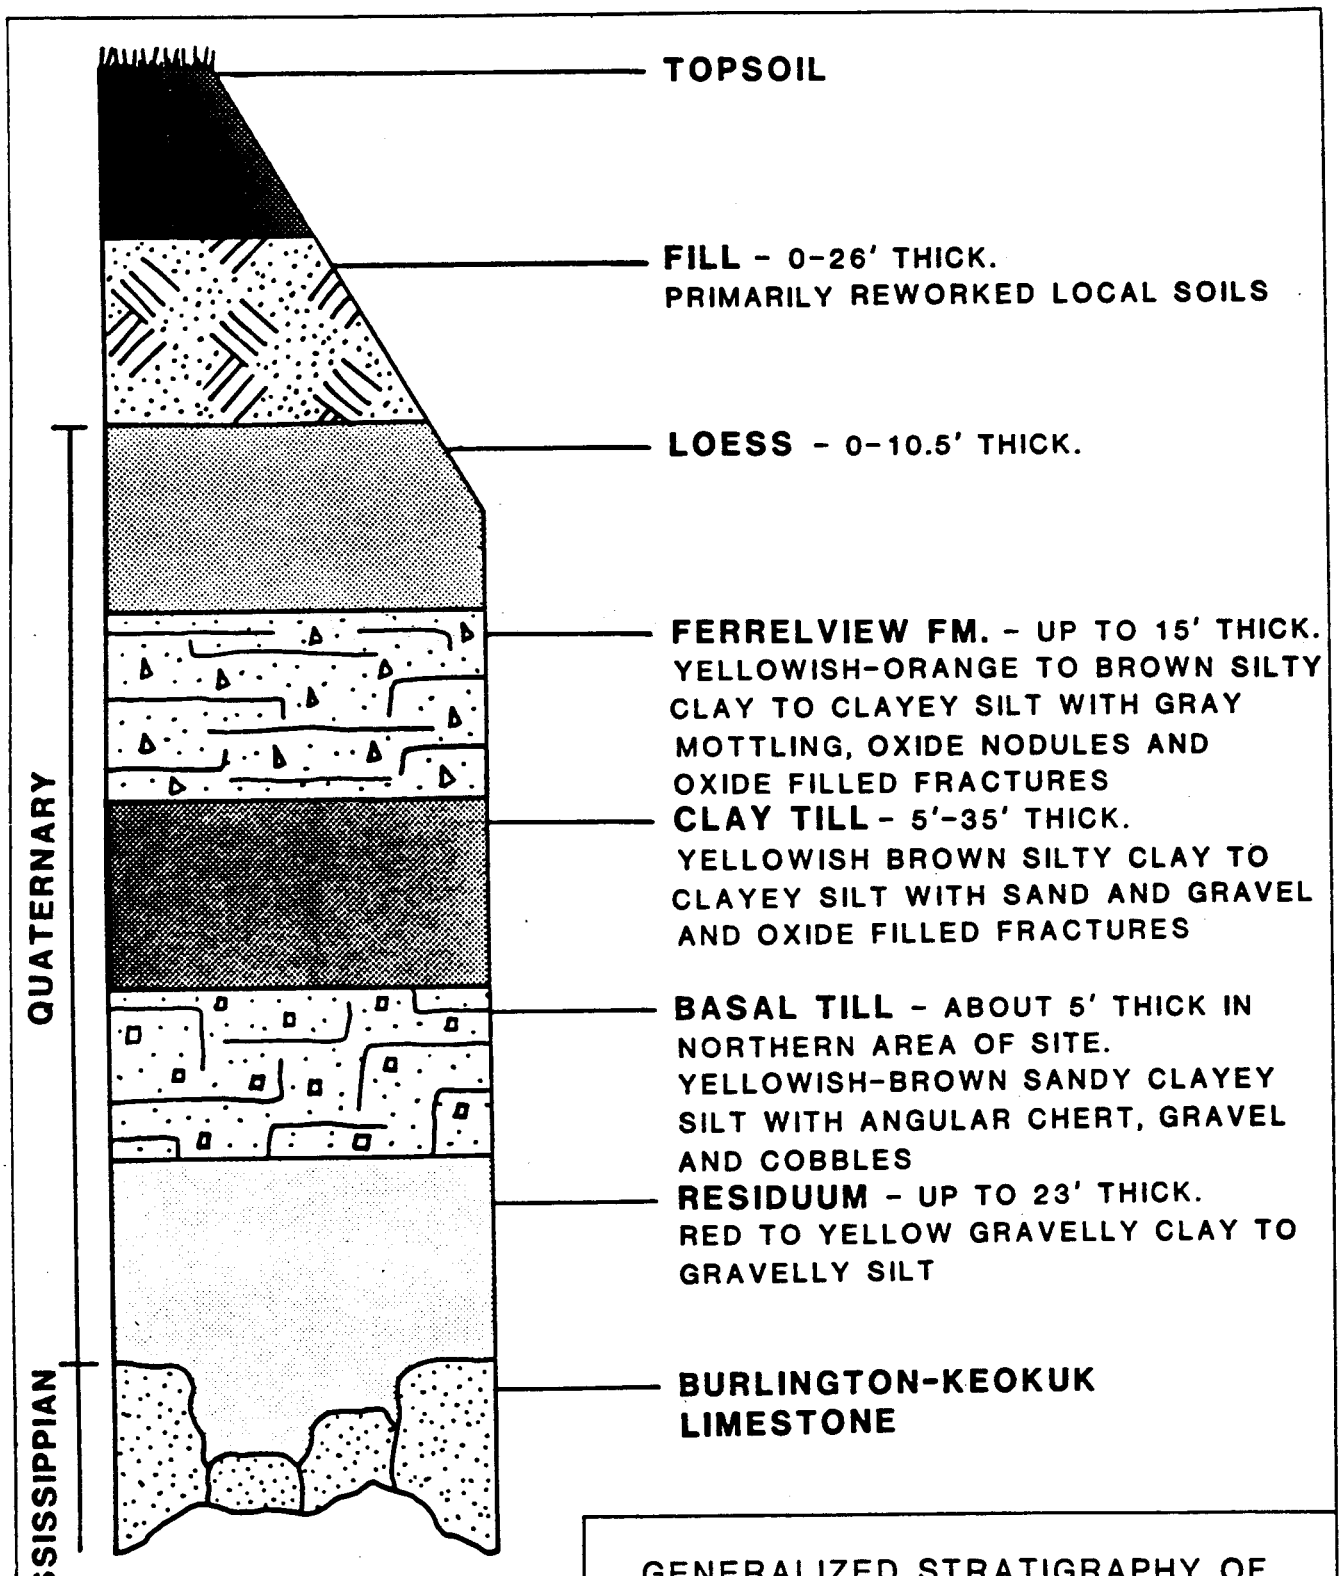
- Trenching will be performed to delineate and geotechnically characterize suspected seepages along backfilled former drainages at the WSS in the areas shown on Figure 1-3. Seepages occur at the contact of the old drainage surfaces and overlying fill.

1.3 Background

Past drilling and trenching programs at the WSS have delineated six principal soil units above the first bedrock unit. The Burlington-Keokuk Limestone is the first bedrock unit underlying the unconsolidated overburden (MKF and JEG 1992a). Figure 1-4 shows the generalized stratigraphy of the unconsolidated materials beneath the WSS (MKF and JEG 1990). The thickness of the unconsolidated material ranges from 15 ft to 40 ft beneath the WSS and is controlled by site development construction, surface erosional features, and bedrock topography. The unconsolidated material is generally thickest in the north-central portion of the site and becomes thinner toward the east.

In descending order, the six principal soil units are; the topsoil/fill unit, the loess unit, the Ferrelview Formation, the clay till unit, the basal till unit, and the residuum unit. The soil units of interest for the purposes of this investigation are the loess, Ferrelview Formation, and clay till units. The topsoil fill unit will be removed as part of the disposal facility foundation preparation. The basal till unit is thin and sporadically distributed under the site, and consequently this unit is not considered a good barrier to contaminant migration and will not be sampled. The residuum overlying the Burlington-Keokuk Limestone bedrock is highly heterogenous with significant percentages of coarse grained materials. It is not expected to retard contaminant migration to any significant extent. This unit will not be sampled or tested.

The upper Pleistocene loess unit underlies the topsoil/fill unit but is found mostly on hilltops (unless disturbed or removed by site construction activities). This unit is a windblown silt. It was affected by the topography at the time of its deposition and eroded from lower drainages by post-depositional stream action (MKF and JEG 1992a). The thickness of the loess varies from 0 ft to 10.5 ft across the site. The unit consists primarily of a silt to clayey silt with small amounts of sand. It has a low plasticity. The unit is the uppermost unit of interest with regard to permeability and other hydraulic properties.



NOT TO SCALE

GENERALIZED STRATIGRAPHY OF UNCONSOLIDATED MATERIALS AT THE WELDON SPRING SITE

FIGURE 1-4

REPORT NO.: DOE/OR/21548-164	DRAWING NO.: A/PI/178/1091	
ORIGINATOR: JDC	DRAWN BY: SRS	DATE: 10/91

The Ferrelview Formation, another unit of interest for this investigation, is an interglacial deposit of mid-Pleistocene age, believed to have been deposited as a till plain sediment (Howe and Heim 1968). The transmissivity of these fractures and joints will be tested with samples obtained by this plan. Iron oxide nodules and conchoidal fracturing with slickensides are characteristic of this unit. Earlier particle size distribution laboratory testing of this unit has determined that it is primarily a silt to clay with small amounts of sand and fine gravel. Most particle sizes are less than 0.063 mm (0.002 in). The unit ranges from 0 ft to 22 ft in thickness across the site. A dark yellowish-orange to brown silty clay to clayey silt with gray mottling, this unit has joints or fractures, some of which contain secondary minerals such as pyrolusite.

The clay till unit underlies the Ferrelview Formation and is the most areally extensive overburden unit on the site. The clay till ranges in thickness from 0 ft to 30 ft and is found in almost all boreholes and trenches on site. This unit is a lower Pleistocene glacial till composed of yellowish brown silty clay and clayey silt. Pyrolusite as fracture coatings and nodules of iron oxide (limonite) are common. The unit is very stiff and moderately to highly plastic (MKF and JEG 1992a). The unit is characterized by pebbles of igneous and metamorphic origin. This soil unit is considered to have good potential as a barrier to leachate transport and will be sampled and tested in this investigation.

The basal till unit is the lowest member of the Pleistocene glacial sediments found on site. It underlies the clay till, reaching a maximum thickness of 5 ft in the area of Ash Pond and the western portion of the WSS. It is absent beneath the main portion of the WSS. It consists typically of yellowish-brown sandy, clayey silt with angular chert gravel and cobbles. The basal till will not be sampled in this investigation as it is too heterogenous, sporadic in distribution across the site, and too thin to rely on as a principal barrier unit with respect to leachate transport.

Modification of site topography for the Weldon Spring Ordnance Works, and later, the Weldon Spring Uranium Feed Materials Plant site development resulted in the placement of fill in natural surface drainages on the site. Infiltration and seepage from impoundments and leaky utilities on site has resulted in localized areas of saturated fill and topsoil within filled drainages. In some areas these conditions have resulted in a zone of perched water, while at other locations conditions may simply be characterized by porous fill or organic soil of a high moisture content. Section 2.4.2 of this sampling plan details plans to excavate trenches in locations suspected of containing perched water, or conducting seepage, within the Disposal Facility Study Area (Figure 1-3).

2 SAMPLE COLLECTION AND TESTING

2.1 Objective

The objective of this sampling plan is to provide representative undisturbed samples and field permeability test data necessary to determine the overburden permeabilities and hydraulic properties. Results of field and laboratory tests and field observations obtained from the implementation of this plan will be used in conjunction with the properties of engineered backfill to be placed as part of the cell foundation to achieve design criteria based on the state landfill location standards as defined under 10 CSR 25-7.264(2)(N)1.A,B.

2.2 Geotechnical Testing Requirements

The proposed laboratory testing program will follow American Society of Testing and Materials (ASTM), U.S. Army Corps of Engineers (COE), and U.S. Environmental Protection Agency (EPA SW-846) standards. Representative samples will be tested for general physical soil characteristics and engineering and hydrologic properties in order to characterize the ability of each overburden unit. General mechanical soil properties of interest include specific gravity, size gradation, soil classification, natural moisture, and dry density. Engineering properties include unconsolidated undrained triaxial compression and consolidated undrained triaxial compression tests.

Table 2-1 lists the test methods, hydraulic properties of interest, and the sample type to be submitted for each test (ASTM standards were used unless a COE or EPA standard was preferred). Tests for which a standard has not been developed will be described in detail in the specifications for that phase of the study. Undisturbed and recompacted samples will be obtained by hollow stem augering and pushing Shelby (thin-walled) sample tubes. Leachate developed on site from cement stabilized/solidified material and soil will be used to test leachate constituent effects on the permeability of these samples.

Figure 2-1 shows the locations of, and numbering system for, the hydraulic properties samples (locations correspond to the areas of Figure 1-2). These samples will be taken prior to carrying out the sealed double ring infiltrometer (SDRI) and the two stage borehole (TSB) test programs. The boreholes will be used to further define the units prior to locating the in situ tests.

The current disposal facility construction plan does not use the loess soils for any structural load bearing fill. However, it is possible that some of this unit may unavoidably be incorporated into the facility's subgrade. Therefore, the hydraulic properties of the loess in both disturbed (recompacted-remolded) and undisturbed samples should be tested (MKF and JEG 1991a). On the other hand, the small volumes of loess soils relative to the Ferrelview Formation and clay till require only the minimum number of triaxial shear strength tests on this unit (Table 2-1). Field testing of the loess unit by either the TSB or the SDRI methods will not be necessary as these tests are for undisturbed, in situ conditions. During disposal facility (DF) construction, any suitable loess material present in the cell footprint will be excavated, mixed with other low permeability soil types, and recompacted.

The Ferrelview Formation and the underlying clay till all have a significant impact on the DF as leachate transport barrier units. These units will be tested for the effect of leachate on their permeabilities and shear strengths as undisturbed soil units (Table 2-1). The current construction plan for the DF will not disturb significant volumes of the underlying clay till unit, so this unit will not be tested for either remolded (disturbed) triaxial shear strength or remolded hydraulic conductivity parameters.

Table 2-2 lists the laboratory tests in support of the SDRI program. Individual SDRIs will be installed at four of the six areas. Areas I and II will not have any SDRIs installed. They will, however, have two each of the two stage borehole (TSB) permeameters installed. At each site, one TSB will be installed in the Ferrelview and one in the clay till. One Shelby Tube sample will be obtained for general engineering soil classification parameters from each TSB site.

The SDRIs will be constructed and maintained according to test plans and specifications specifically developed for the WSSRAP by D.B. Stephens & Associates (DBS&A) (1991). Figures 2-2 and 2-3 list locations and designations of the SDRI and TSB installations, respectively. Site Areas III and IV will be the locations for SDRI installations FP-01 and FP-02 (Figure 2-2), both installed in the clay till unit (Table 2-2).

Area V will have a duplicate set of SDRIs installed, one in the upper Ferrelview Formation (FP-03) and one in the lower Ferrelview (FP-04). A TSB will be installed near each SDRI to the same approximate depth. The purpose of these duplicate field permeameter installations is to determine to what degree the Ferrelview varies in permeability with depth.

TABLE 2-2 List of Field Tests and Supporting Samples

Test Area	SDRI No.	Soil Unit	TSB No.	Pre-Test[a] SDRI Samples for Soil Hydr. Prop.	SDRI Post-Test Soil Samples for Moisture and Bt

TWO-STAGE BOREHOLE (TSB) PERMEABILITY TESTS LOCATION MAP

FIGURE 2-3

REPORT NO.:		EXHIBIT NO.: A/CP/089/0892	
ORIGINATOR: SDG	DRAWN BY: GLN	DATE: 8/92	

Area VI will have one SDRI, FP-05 and two TSBs (Figures 2-2 and 2-3). One of the TSBs and the SDRI will be installed to test Ferrelview Formation. The remaining TSB will be installed to test the clay till at this location.

Each SDRI installation requires that initial, pre-test soil samples be taken (Table 2-2) for laboratory measurement of hydraulic soil properties. Table 2-3, as modified from DBS&A (1991), lists the specific test methods that should be followed in testing these pre-SDRI test samples. The number of tests required are included in the totals of Table 2-1. One sample for each soil type and location should be obtained. As shown on Table 2-2, two sets of duplicate soil samples will be obtained and tested for the complete set of hydraulic parameters as listed on Table 2-3. One set of duplicate soil samples will be for the Ferrelview Formation (potentially obtained from SDRI installation site FP-04, refer to Figure 2-2 for locations). The other set of duplicate soil samples will be for the clay till (potentially obtained from SDRI installation FP-01).

Post-test wetting front determination for the SDRI test is obtained by taking continuous thin wall tube samples from trenches excavated through the dismantled SDRI sites. The procedure for excavating the trenches, pushing the thin-walled samples, and ultimate wetting-front depth determination is detailed in DBS&A (1991) Sections 3.7, 3.8, and 3.9.

2.3 Sampling/Testing Locations and Identification

Sampling/testing locations are shown on Figure 1-2 as Areas I through VI. These locations were selected based on the following criteria.

- Minimum potential for future disturbance due to excavation of building foundations, underground utilities, or fill.
- Availability of the Ferrelview Formation and clay till unit.
- Easy access for sampling and testing equipment such as drilling rigs, backhoes, and infiltrometers.

The use of these criteria resulted in multiple sampling/testing locations in the northern portion of the disposal facility study area (DFSA) and a lack of locations in the southern portion

TABLE 2-3 Summary of Recommended Methods for Laboratory Hydraulic Parameter Testing of Soils at SDRI Sites

Hydraulic Parameter To Be Measured		Recommended Method	
1.	Soil-Moisture Retention Characteristics[a]	1.	SPOC Test
2.	Saturated Hydraulic Conductivity Using Flexible Membrane or Triaxial Cells	2.	ASTM D 5084-91
3.	Saturated Hydraulic Conductivity in Thin-Walled Sample Tubes	3.	Engineer Manual, 1980, Laboratory Testing of Soils, U.S. Dept. of Army, Office of Chief Engineer, Washington, D.C., Publication No. 1110-2-1906, Appendix VII, pp. 16-17.
4.	Unsaturated Hydraulic Conductivity (Calculated)	4.	van Genuchten, M., 1980, A Closed Form Equation for Predicting the Hydraulic Conductivity of Unsaturated Soils, Soil Sci. Soc. Am. J., v. 44, pp. 892-898.

Table is modified from D.B. Stephens & Associates, Inc. 1991.

[a] The Submerged pressure outflow cell (SPOC) method of Constantz and Herkelrath (1984) yields saturated and unsaturated hydraulic conductivity of soil specimens in the same apparatus. It is used here in lieu of ASTM moisture retention characteristics test methods D2325-68 and D3152-72.

[b] As recommended by D.B. Stephens & Associates 1991.

of the DFSA. This is because the units of interest are not easily accessible in the south and site remediation activities involving building demolition, foundation removal, fill removal, and contaminated soil removal will result in intense modification of surficial soils in the southern portion of the DFSA.

2.3.1 Area I

Sample Area I is in an open, grassy area, between chemical plant (CP) Building 202 and the main east-west site access road (Figure 1-2). The area is located on the south side of the road, across from CP Building 406, on a corner formed by the east-west access road and a deadend driveway that leads south to Buildings 201 and 301. The area is easily accessed by both these roadways. This location is near the center of the proposed DF's southern portion.

As shown on the logs of the three closest geotechnical boreholes (Appendix B, Figures B-2, B-3, and B-4), sporadic loess deposits of 0 ft to 3 ft in thickness may be encountered upon drilling in this area. The loess overlies between 7.5 ft to 17 ft of Ferrelview Formation (between 3 ft and 17.5 ft in depth). The Ferrelview overlies 10 ft to 20 ft of clay till, encountered at depths of between 15 ft to 20 ft. Appendix B, Figure B-1, summarizes symbols and designations used in geotechnical boring logs.

Area I will be the location for two TSB permeability tests. Table 2-2 lists the TSB and SDRI test sites, and the number and type of related soil samples. One TSB test will be conducted in the Ferrelview Formation and a second TSB test will be conducted in the clay till unit.

2.3.2 Area II

Area II is approximately 570 ft west and north of the first sample area, located just west of a large storage tank and the CP water tower. It also lies in an open area accessible from the east-west site access road. A source of subsurface control for this site includes test pit excavation GT-2T78 and geotechnical borehole log GT-53 (Appendix B, Figures B-5 and B-6). On the basis of this information, it is expected that 1 ft to 4 ft of topsoil, 1 ft to 2 ft of loess, 6 ft to 7 ft of Ferrelview Formation, 12 ft of clay till, and 1 ft to 2 ft of basal till will be encountered in this area. Two TSB permeability tests will be carried out at this site, one each in the Ferrelview and clay till soil units (Table 2-2).

2.3.3 Area III and IV

Areas III and IV are located 1,000 ft and 900 ft, respectively, to the north and west of Areas I and II (Figure 1-2). Area III is a at a lower elevation than the other areas, located just east of, and adjacent to, a drainage channel that flows north-northeast through the site. Area IV is just east of the material staging area (MSA) and adjacent to a roadway that runs north around the CP perimeter.

In Area III, the logs for G-7, T-6, GMW-9 (MW-2009), GT-42, and GT-69 (Appendix B, Figures B-7, B-8, B-9, B-10, and B-11) all indicate the presence of 0 ft to 2 ft of topsoil/fill overlying anywhere from 0 ft to 11 ft of Ferrelview Formation and loess soil (from 0.5 ft to 11.5 ft depth) in turn overlying 9 ft to 11 ft of clay till (from 1.5 ft to 20.5 ft in depth). The clay till increases in thickness to the west, in the direction of Area IV. One SDRI test and one TSB test will be conducted at the 8 ft depth in the clay till at this location. If a thickness of 5 ft or more the Ferrelview Formation is present, it will also be tested with the TSB method.

Area IV thicknesses are based on the logs of borings GMW-9 (Appendix B, Figure B-9), G-3 (Appendix B, Figure B-12) and GT-42 (also designated GT-2B42) (Appendix B, Figure B-10). The logs indicate a sequence of 0.5 ft to 4 ft of gravel fill overlying 6 ft to 11 ft of Ferrelview and 24 ft or more of clay till (beginning at 6 ft in depth and extending down to between 20.5 ft and 31 ft). Possible loess soil deposits could exist in this area within the upper 10 ft (see log GMW-9). This location will have a single SDRI installed in the clay till at approximately the 8 ft depth. Two TSB tests will be run at this location, one in the Ferrelview Formation, at an estimated depth of 5 ft, and one in the clay till unit at a depth of 8 ft (Table 2-2).

2.3.4 Area V

Area V is located just south of the MSA and east of the Ash Pond, near the intersection of two site roads, the Patrol Road that runs north-south and the Ash Pond Road (Figure 1-2). Geologic logs G-5, G-6, and GT-61 (Appendix B, Figures B-13, B-14, and B-15) indicate up to 14 ft of Ferrelview Formation, either exposed at the surface or overlain by 1 ft of fill; and 10 ft of clay till from approximately 14 ft to 24 ft in depth. Loess soil may on may not be present at this site as it appears from 2 ft to 5 ft in depth at GT-61, but is not reported on logs G-5 and G-6.

This area will be the site for two SDRI installations, one in the upper Ferrelview Formation approximately 2 ft in depth, and one in the lower Ferrelview at 10 ft in depth (Table 2-2). Three TSB tests will be run at this site. One TSB corresponding to each of the two SDRIs will be installed in the upper and lower Ferrelview. A single TSB test will be conducted within the clay till at this location (Table 2-2).

2.3.5 Area VI

Area VI is located at the northwest corner of the No. 407 Building Block, across the street from Building 105, to the west, and Building 403, to the north (Figure 1-2). Based on geologic logs G-8 and GT-55 (GT-2B55) (Appendix B, Figures B-16 and B-17), up to 6 ft of fill overlies 3 ft to 4 ft of loess (from 6 ft to 10 ft in depth). In turn, the loess overlies 6 ft to 10 ft of Ferrelview Formation (9 ft to 20 ft in depth) and 7 ft to 11 ft of clay till (from 15 ft to 27 ft in depth).

Area VI will be the location of a single SDRI test, constructed in the upper Ferrelview Formation at an estimated depth of 10 ft. Two TSBs will be run at this location; one at the same depth of Ferrelview as the SDRI, and a second one in the clay till unit at an estimated depth of 16 ft (Table 2-2).

2.3.6 Trench Locations

Figure 1-3 shows the locations of trenches proposed as part of this sampling plan. These trenches will be excavated to determine if filled drainages are presently acting to contain perched seepage or contain volumes of debris, organic material, or otherwise unsuitable soil which must be accounted for as part of the formulation of the disposal cell foundation excavation plan.

GT-2T-83

This trench location is in the coal pile area. The 1954 topographic map indicates the existence of a drainage and a surface drainage pipe in this location. The cut and fill map indicates the presence of 2 ft to 4 ft of fill. Adjacent areas contain up to 14 ft of fill based on information presented on the cut and fill map.

GT-2T-84

This trench location is about 85 ft northeast of Building 412. The map of 1954 topography indicates the presence of a drainage and surface drainage pipe in this area.

GT-2T-85

This trench location is about 80 ft north of the northernmost corner of Building 408. the 1954 topographic map indicates the presence of a drainage and closed depression in this area. Since this location is next to a site road, excavation will take place at the northwest corner of the road. Site development drawings indicate that this area is free of subsurface piping and utilities.

2.4 Sample Collection Methods

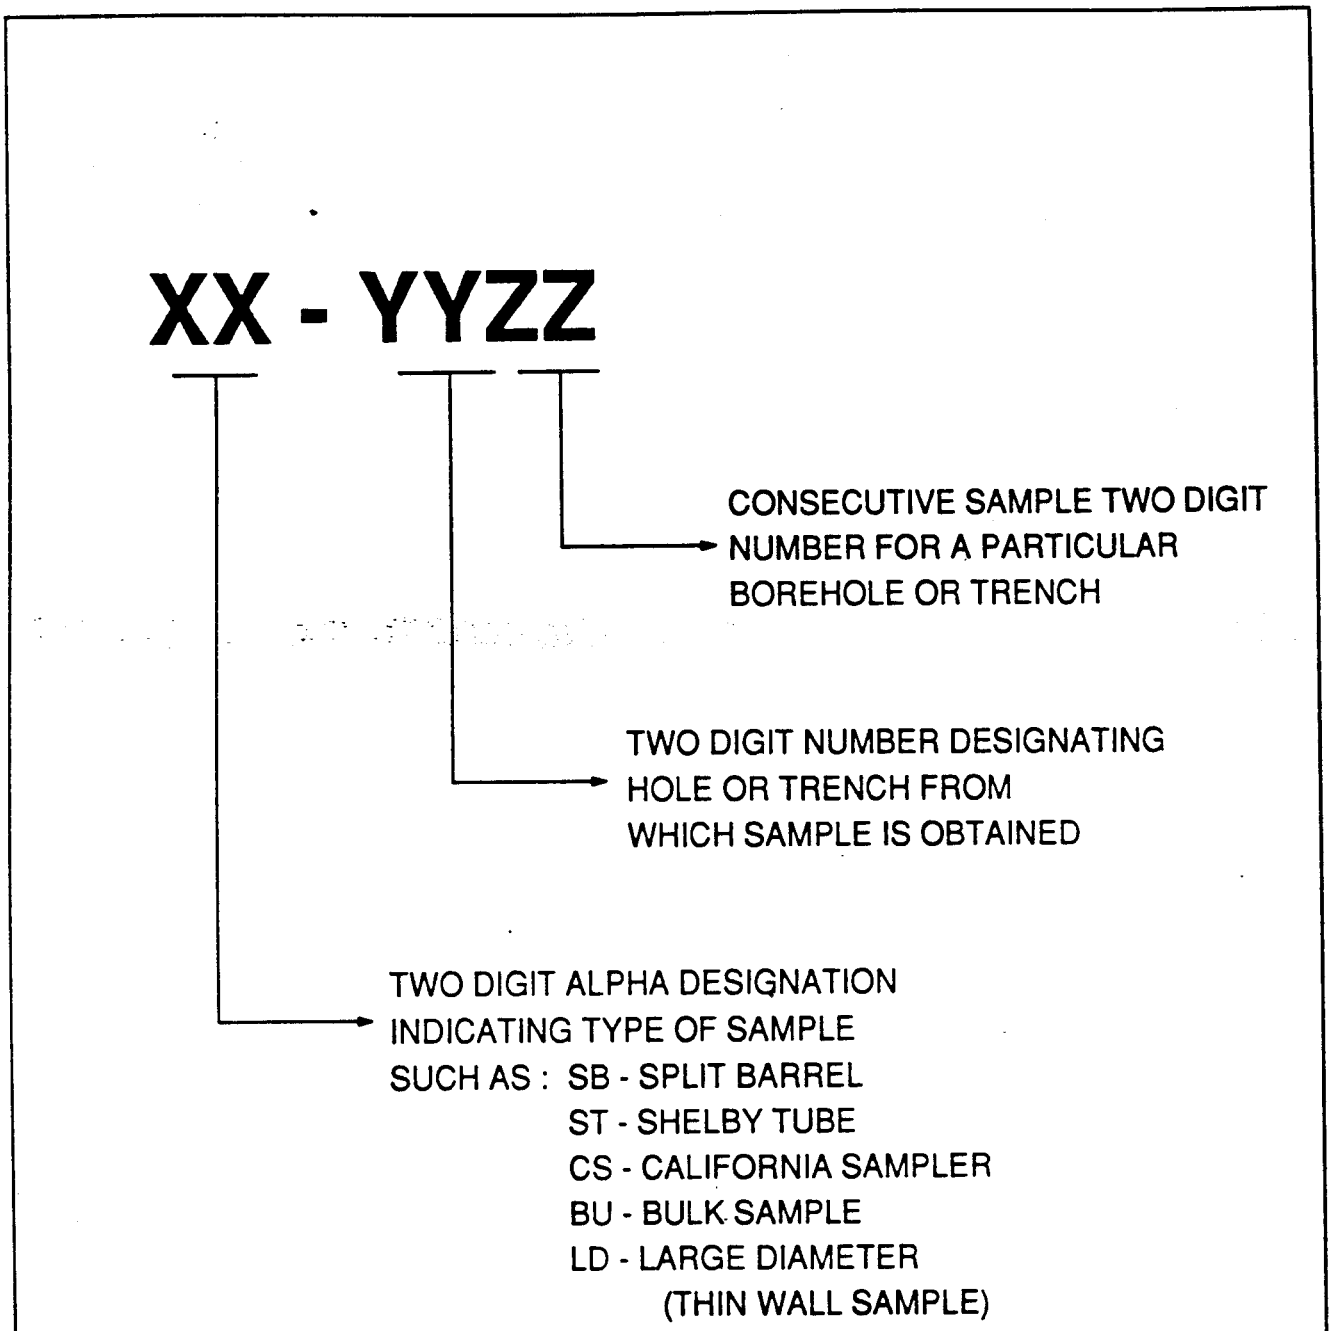
Figure 2-4 presents the alphanumeric designation that will be used for all sample identification.

2.4.1 Soil Hydraulics Sample Collection Methods

Sample collection methods will vary depending on the particular test method (see Table 2-1). Disturbed and undisturbed samples will be collected in a continuous manner at each sample area using a hollow-stem auger drilling rig. A minimum of one sample per unit from each of the test areas will be obtained. Sampling methods, sample preservation and shipping, and field descriptions of each unit sampled will be in accordance with ASTM, EPA and COE standards as they apply to each of the test methods being sampled for (ASTM D620, COE EM 1906, EPA SW-846). Undisturbed samples will be sealed with bees wax and packaged to retain moisture and avoid shifting during shipment in their original sample tubes.

2.4.2 Perched Water Investigation and Sampling

Trenches will be excavated to undisturbed soil or a maximum depth of 12 ft. Trench walls should be vertical or as close to vertical as practicable due to sloughing. Personnel shall not enter the trenches for any reason and shall not approach within 2 ft of the edge of the trench



EXPLANATION OF SAMPLE DESIGNATION SYSTEM

FIGURE 2-4

REPORT NO.: DOE/OR/21548-164		EXHIBIT NO.: A/PI/194/1091	
ORIGINATOR: JDC	DRAWN BY: GLN	DATE: 10/91	

excavation. Excavated materials will be placed adjacent to the excavation for examination by the Project Management Contractor (PMC) field geologist or geotechnical engineer.

Excavated soils must be replaced in the same order as removed. Site restoration will be in accordance with Section 2.6 of this sampling plan.

Soil and seepage water encountered during trenching may be sampled for waste characteristics as deemed necessary by environmental safety and health (ES&H) personnel. Water samples will follow collection protocols for groundwater samples. Samples will be obtained from the backhoe bucket or by dipping from the ground surface using a ladle with an extension handle. Soil samples will be obtained from the backhoe bucket. All samples obtained from the backhoe bucket will be removed with minimal contact of the bucket walls. A total of four water samples and 10 soil samples, including duplicates, is planned. Soil and water samples will be analyzed for the constituents listed in Table 2-4.

2.5 Sample Shipment and Chain of Custody

Chain of custody and sample shipping will follow Weldon Spring Site Remedial Action Project (WSSRAP) standard operating procedures ES&H 4.1.2s, RC-17s, and RC-19s as applicable. All samples taken within the boundary of the WSS will be considered potentially contaminated and treated accordingly. Samples will be checked for radioactive contamination before being released to the laboratory. After the completion of the testing program, all contaminated samples will be returned to the Weldon Spring site (WSS).

2.6 Borehole, Excavation and Trench Abandonment

In order to avoid compromising soil integrity due to investigation disturbance, the following abandonment requirements will be followed for all boreholes, trenches, and excavations.

After sampling has been completed, all boreholes will be abandoned by tremie placing of a high solids bentonite based grout. Grout will be mixed and placed through a mud pump and tremied under positive pressure to the bottom of the hole. The ratio of clay grout to fresh potable water must achieve a weight of at least 9.4 lbs/gal as measured with an approved mud weight measuring device in the field (MKF and JEG 1991b).

TABLE 2-4 Water and Soil Sample Analytes

Media	Analytes
Water	HSL Metals PCBs PAHs Nitroaromatics[a] Uranium (total)
Soil	HSL Metals PCBs PAHs Nitroaromatics U-238 Ra-226 Th-230 Th-232

[a] 1,3,5-trinitrotoluene, 1,3-dinitrotoluene, nitrobenzene, 2,4-dinitrotoluene, 2,6-dinitrotoluene, 2,3,6-trinitrotoluene.

Any borehole or trench not backfilled immediately after sampling will be either covered by the drill rig tools or barricaded with tape and traffic barricades.

Excavations will be backfilled with suitable low permeability excavated material and finally capped with the original topsoil material. Excavation backfill will be placed in 8 in. lifts and compacted to a minimum of 95% of maximum dry density as determined by ASTM D698 and a moisture content within 2% below to 4% above optimum moisture content. Narrow exploratory trenches in fill will be thoroughly compacted using a backhoe bucket. Shallow trenches excavated in upper portions of undisturbed soils will be backfilled and compacted to the same requirements as stated above for excavations.

2.7 Decontamination

Decontamination of sampling equipment will follow procedure ES&H 4.1.3s. Personal protective equipment (PPE) will be covered in the health and safety plan for each subcontract. All sampling equipment, augers, and other equipment that come into contact with contaminated soils will be decontaminated by high pressure water before each borehole is drilled. The entire drilling rig, or backhoe, will be decontaminated upon arrival on site and upon completion of drilling activities. Interior portions of equipment, such as pumps and hoses that are not accessible for cleaning with a pressure cleaner, will be thoroughly cleaned and flushed with potable water. Decontamination will be performed at the site decontamination pad. Split-spoon, Shelby Tube, or California samplers will be washed with a dispersant and water, rinsed with potable water, and reassembled after each sample is taken.

3 QUALITY ASSURANCE

The quality assurance (QA) plan for drilling, test pits, trenches, sampling, and testing includes all applicable Weldon Spring Site Remedial Action Project (WSSRAP) procedures established in the Weldon Spring *Environmental Quality Assurance Project Plan* (MKF and JEG 1992b) and in accordance with U.S. Environmental Protection Agency (EPA) guidelines. Work will be carried out in accordance with WSSRAP engineering procedures and standard operating procedures (SOPs). Forms required for geotechnical sampling include:

- Chain-of-Custody Form
- Sample seals and tapes
- Field data sheets
- Borehole logs
- Test pit logs
- Geotechnical laboratory testing reports

In addition, geotechnical laboratory testing of soil samples and analytical testing of soil and water samples will be performed in accordance with the subcontractors' quality assurance (QA) program, subject to Project Management Contractor (PMC) review and approval. Testing laboratories providing services under this plan must be approved by the PMC Project Quality Department.

QA during drilling, sampling, test pit excavation, and sampling operations will consist of surveillance and inspection of the drilling and excavating subcontractor. Drilling, excavating, and sample procedures will be established. All soil samples will be labeled immediately after removal from the sampler.

The correlation of sample identification to assigned laboratory tests will be verified at the laboratory upon receipt of each sample. Thorough sample tracking and documentation will be initiated and maintained throughout the testing program. Laboratory test results will be reviewed and approved by an individual other than the person who is performing the test before being submitted to the PMC.

4 HEALTH AND SAFETY

In accordance with CM&O-15a, safety concerns and mitigative measures related to sampling activities carried out under this plan will be identified and documented with task specific safety assessments (TaSSAs) which will be prepared, reviewed, approved, and filed with the Construction, Maintenance and Operations Department on a daily basis before work begins in the controlled area. Safety, industrial hygiene, and health physics personnel will also monitor health and safety conditions during sampling. Health physics personnel will monitor personnel and equipment working in areas of radiological contamination.

Personal protective equipment (PPE) will be worn as required at each sampling location. The requirements are outlined in the WSSRAP *Personnel Protective Equipment Requirements Manual* (MKF and JEG 1992c).

Subcontractors will submit a health and safety plan (HASP) prior to coming on site and their plan will be reviewed and approved by the site safety officer prior to commencing sampling work.

5 DATA DOCUMENTATION

Data documentation will follow Weldon Spring Site Remedial Action Project (WSSRAP) standard operating procedures and the *Project Management Contractor Quality Assurance Program*, Section 4 (MKF and JEG 1992d) relating to Documents and Records. During the course of the geohydrologic sampling, a qualified geological or geotechnical engineer will record the daily activities, following field logbook procedures (procedure ES&H 1.1.4) including:

- Date
- Weather conditions
- All personnel involved
- Chronological record of activities

Borehole and test pit logs will be kept on site and updated as the sampling progresses. These logs will be prepared by a qualified geologist, geological engineer or soils engineer (MKF and JEG 1991b). The following data will be included in each borehole or test pit log:

- Test pit or borehole identification.
- Test pit or borehole location.
- Drilling/sampling method and equipment.
- Drilling or excavating contractor.
- Date of commencement and completion.
- Total depth.
- Depth to water table and bedrock (if applicable).
- Hole diameter or test pit dimensions.
- Standard Penetration Test (SPT) number of blows per 6 in. of advancement.

- Lithologic description of materials and soil classification in accordance with ASTM D2488 (ASTM 1991).

- Munsell color chart number code.

- Sample numbers, depth of sample, and sample interval.

- Length of sample recovered (drilling only).

- Description of sampling method (i.e., number of blows for the standard penetration test - SPT.

- Description of completion operations (i.e., borehole or test pit abandonment operations).

- Borehole or test pit logs will be transmitted to the WSSRAP Project Quality Department in accordance with SQP-9a *Inventory, Valdiation, and Transfer of QA Records* for retention.

Daily logs maintained by the subcontractors will include the activities performed, personnel involved, locations, time, weather conditions, equipment used, and any problems encountered. A field report will be prepared after each geohydrologic investigation is completed. Geotechnical and hydraulic laboratory testing data will be evaluated by the Project Management Contractor (PMC) and transmitted to the Project Quality Deparmtent in accordance with SQP-9a for review and retention as a QA record.

LOG OF TEST PIT GT-2T78

- Location: 50 feet plan west of northwest corner of fence around facility 428
- Type of excavator: Cat 416 extendable backhoe (new)
- Start excavation: 4:30 p.m. 07/13/88
- Finish excavation: 5:05 p.m.
- Finish backfilling: 8:05 a.m. 07/14/88
- Finish decontamination: 9:05 a.m.

Depth, Feet		Description
0-1.0	CL	Fill: Silty clay; dark yellowish-brown (10YR4/6); some gravel (1/2" to 2"); dry; medium plasticity; medium stiff.
1.0-4.0	CL	Silty Clay: Yellowish-brown (10YR6/8) and light brownish- gray (10YR6/2); dry; medium plasticity; very stiff.
4.0-6.5	CL	Silty Clay: As above but moist to wet and stiff (possible reworked loess).
6.5-12.0	CH	Silty Clay: Yellowish-brown (10YR5/8) mottled with light brownish-gray (10YR6/2) and brownish-yellow (10YR6/8); wet; high plasticity; very stiff.

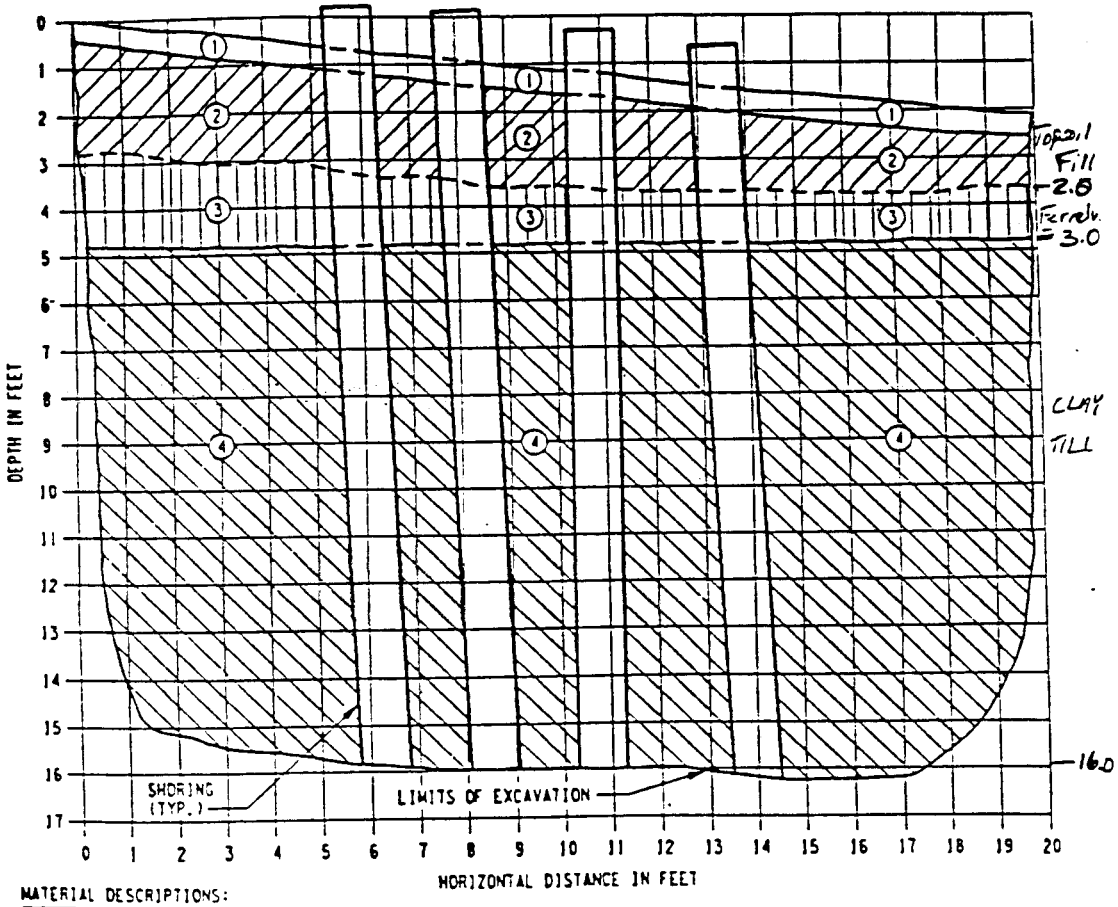
DATE EXCAVATED 5-1-86 METHOD OF EXCAVATION BACKHOE DATE BACKFILLED 5-2-86



MATERIAL DESCRIPTIONS:

(1) TOPSOIL - BROWN, CLAYEY SILT, SLIGHTLY SANDY, SOME FINE TO MEDIUM GRAVEL. DRY.

(2) FILL - MOTTLED GRAY AND YELLOW-BROWN, SLIGHTLY SILTY TO SILTY CLAY, WITH SCATTERED FINE TO MEDIUM GRAVEL AND A FEW COBBLES. SLIGHTLY DAMP.

(3) CLAY (FERRELVIEW FORMATION) - MOTTLED GRAY AND YELLOW-BROWN, SILTY CLAY, FEW IRON NODULES AND RARE SAND GRAINS (QUARTZ AND CHERT). DAMP. MODERATELY PLASTIC.

(4) CLAY TILL - MOTTLED YELLOW-BROWN AND GRAY, VERY SILTY CLAY, SAND CONTENT UP TO 5%, SAND SUBROUND, MEDIUM GRAINED CHERT AND QUARTZ. DAMP TO SLIGHTLY DAMP, VERY LOW PLASTICITY. BLOCKY FRACTURE WITH FRACTURE SURFACES COATED WITH MANGANESE. GRAVEL, COBBLES, AND BOULDERS MAKE UP 10 - 15%. GRAVEL IS SUBANGULAR TO SUBROUNDED, FINE TO COARSE GRAINED. COBBLES AND BOULDERS ARE SUBROUNDED AND UP TO 1 1/2'Ø. GRAVEL IS CHERT AND LIMESTONE. COBBLES AND BOULDERS ARE VERY WEATHERED WHITE LIMESTONE AND GRAY CHERT WITH WHITE WEATHERED RIMS.

PHASE I CHEMICAL SOIL INVESTIGATION DATA REPORT FOR THE WELDON SPRING CHEMICAL PLANT/RAFFINATE PITS

Enclosed is a final copy(s) of the Phase I Chemical Soil Investigation Data Report for the Weldon Spring Chemical Plant/Raffinate Pits for your use. This investigation was designed to supply baseline soil information for the site.

Results from the sampling indicate the presence of elevated levels of nitrate, sulfate, and certain metals in the soils at the Chemical Plant and Raffinate Pit area. The data presented in the report will be used to develop the Chemical Soil Investigation Sampling Plan which will contain the overall soil characterization strategy for the site.

Sincerely,

R. R. Nelson

1.0 INTRODUCTION

This report presents the Phase I Chemical Soil Investigation data for the Weldon Spring Chemical Plant/Raffinate Pits (WSCP/WSRP). Sample collection methods, sampling equipment decontamination techniques, analytical procedures, and analytical results are also presented in this report, as well as limited interpretations of those results. This investigation was not intended to fully characterize chemical soil contamination at the WSCP/WSRP. The objective of this investigation was to supply baseline soil information for development of a detailed Chemical Soil Investigation Sampling Plan that will more fully define the extent and magnitude of chemical soil contamination at the WSCP/WSRP.

The WSCP/WSRP portions of the Weldon Spring Site (WSS) consist of 217 acres located approximately 2 miles southwest of Weldon Spring, Missouri. Uranium ore concentrate was processed at the WSCP from 1957 until 1966 when it was known as the Weldon Spring Uranium Feed Materials Plant (WSUFMP). Process wastes from uranium ore concentrate processing are contained in four raffinate pits located on the site. Prior to 1955, the WSCP/WSRP area was part of the Weldon Spring Ordnance Works (WSOW). The WSOW produced trinitrotoluene (TNT) and dinitrotoluene (DNT) during World War II. Three complete TNT batch plants and portions of a fourth plant existed within the confines of the present WSCP/WSRP 217-acre area.

Prior to this investigation, only limited amounts of chemical data were available for the soils at the WSCP/WSRP. In 1975-76 the Department of Army (DA) documented low levels (ug/Kg) of nitroaromatics in WSCP soils (DACDIR, 1975). This report provided the only documentation of chemical soil contaminants at the WSCP/WSRP. In the spring of 1987, United Nuclear Corporation (UNC) was contracted through the Department of Energy (DOE) to perform a radiological characterization of the WSCP/WSRP soils.

Soil samples were split from selected radiological sampling locations by on-site personnel for chemical analysis. Field work began in May and was completed by mid-July 1987. Analytical results were received in August 1987.

1.1 Purpose

This investigation was designed to provide baseline data regarding chemical soil contamination and to develop on-site background metals concentrations at the WSCP/WSRP. Sampling locations were selected to investigate potential chemical soil contamination source areas from TNT production and/or uranium processing and to provide areal coverage of the site. Samples were collected concurrently with the radiological soils characterization performed by UNC. The results of this investigation and previously collected data have been used to

develop a comprehensive chemical soil characterization sampling plan.

1.2 Scope

This sampling effort consisted of collecting 149 samples from 37 locations. Sampling locations were selected by evaluating WSOW and WSUFMP processes. Potential source areas were identified and targeted for sampling. Additional locations were added to provide areal coverage.

Analytical parameters were selected based on results of the Phase I Water Quality Assessment which detected elevated levels of nitroaromatics, nitrate, sulfate, fluoride and metals in the groundwater beneath the WSCP/WSRP. No organics (except nitroaromatics) were detected, so soil samples were not analyzed for organic compounds.

2.0 SAMPLING

2.1 Sample Collection

Soil samples were collected from 37 locations at or near the WSCP/WSRP. Figure 2-1 shows the sampling locations. Thirty-two locations were within the fenced WSCP/WSRP boundary. Four of the remaining five boreholes were drilled in WSOW Waste Lagoon

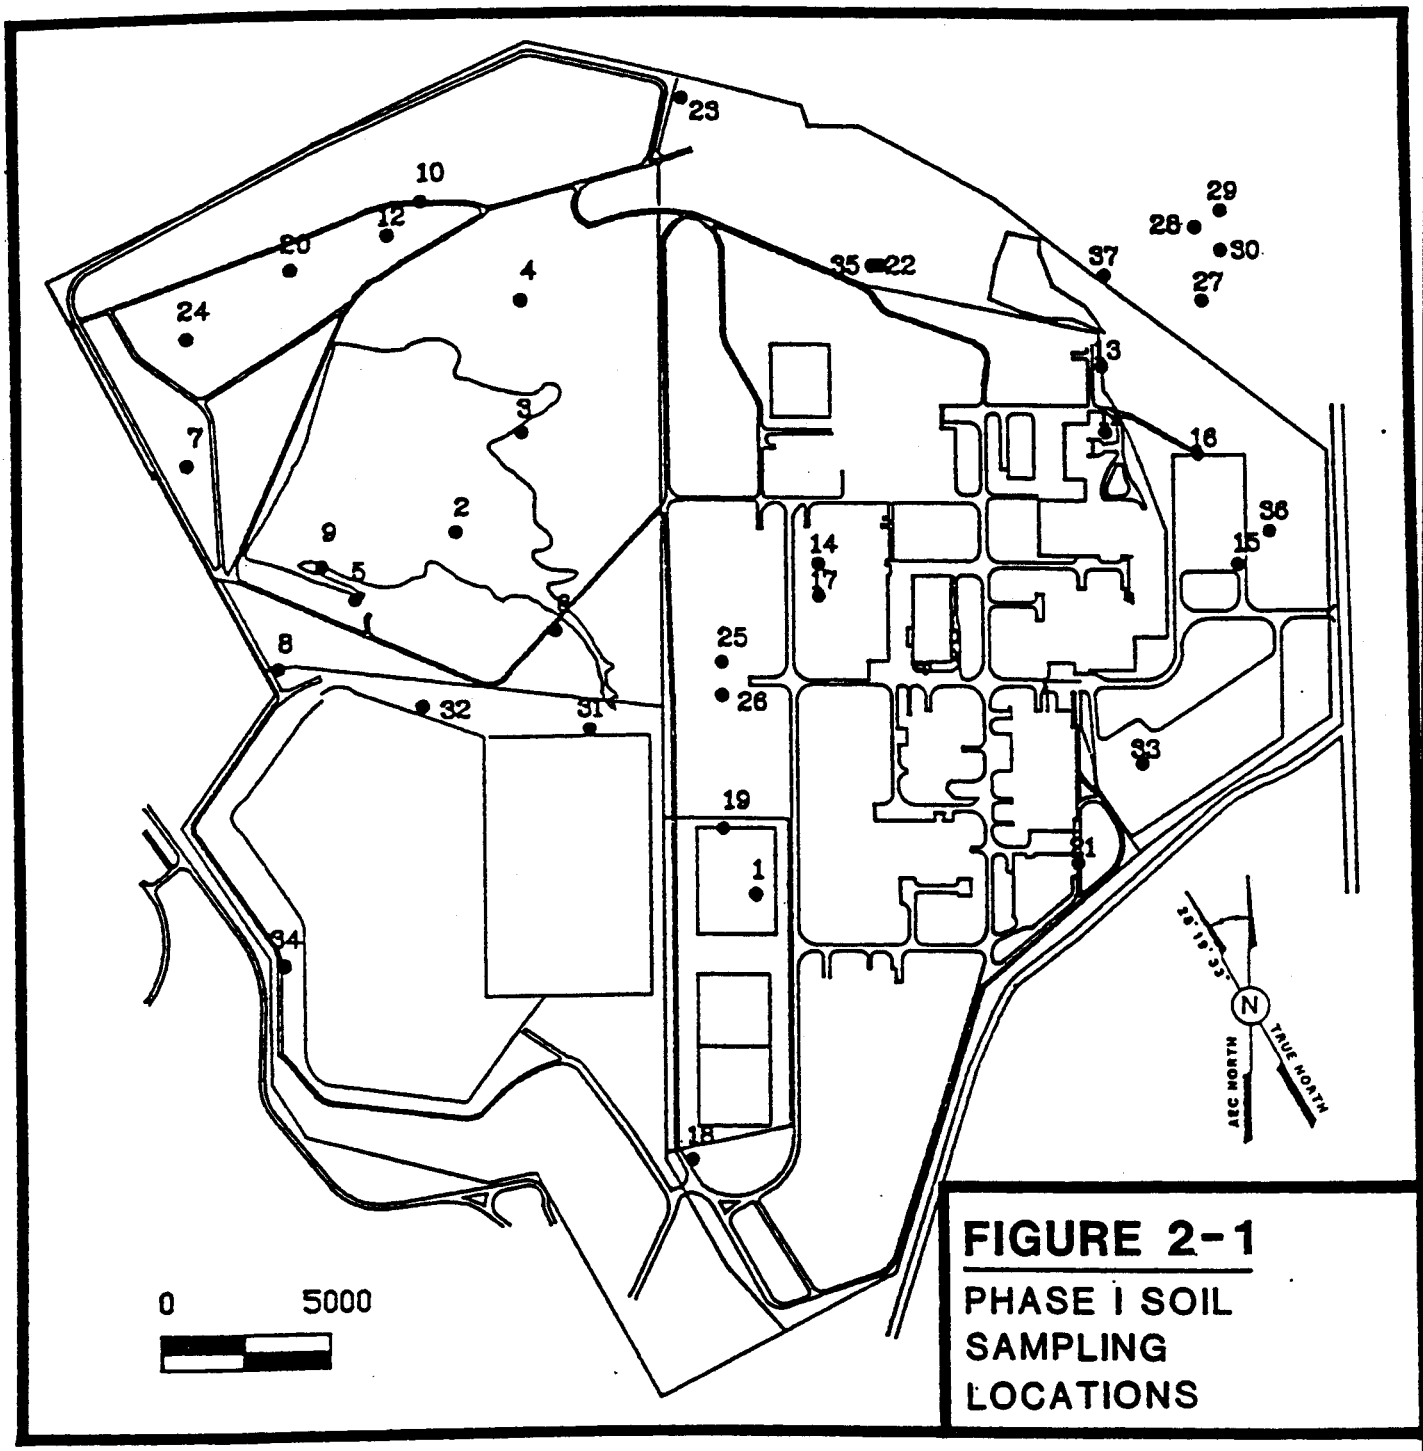

FIGURE 2-1
PHASE I SOIL SAMPLING LOCATIONS

No. 1, located just northeast of Frog Pond to, investigate this potential source area.

The final borehole was located between the WSCP and the WSOW waste lagoon. Table 2-1 details borehole coordinates, numbers, depths and date drilled.

Samples were collected using a truck-mounted CME-55 drill rig employing 6 5/8" outside diameter (O.D.) hollow stem augers for drilling and a 3" O.D. by 24 inch long split tube sampler. Samples were collected continuously by driving the split tube sampler with a 140 lb. drop weight.

After driving the sampler two feet, it was removed from the borehole and taken to a shaded area prior to opening, in order to prevent the photolysis of nitroaromatic residues in the soil. Samples were obtained using a stainless steel spatula to fill the sample containers. Samples were collected in the following increments at most locations:

0 to 6 inches
6 to 24 inches
24 to 48 inches
48 to 72 inches

If the borehole advanced beyond 6 feet, samples were composited over 4- to 10-foot intervals. The 0- to 6-inch interval was

collected using a post hole digger since the split tube sample did not provide enough soil for both chemical and radiological analyses.

Sample collection information was recorded on field data forms. Sample chain-of-custody was maintained throughout the sample collection and shipping process according to approved WSSRAP procedures.

2.2 Equipment Decontamination

Soil sampling equipment was cleaned using a hybridized decontamination procedure designed to protect against cross-contamination by nitroaromatics and other chemical species. All augers, drill rods, and split tube samplers were washed using a hot water high-pressure washer. Augers and drill rods were cleaned between boreholes while split tube samplers were decontaminated between samples.

After washing with hot, high-pressure water, the split tube samplers were allowed to air dry. They were then rinsed with toluene, followed by acetone and hexane. The toluene rinse was used to dissolve any nitroaromatic residues. Acetone and hexane rinses were employed to remove toluene and other contaminants not removed by the hot water high-pressure wash. The split tube samplers were again allowed to air dry prior to being reassembled. All rinsing solvents were collected.

Stainless steel spatulas and pans and the post hole digger were washed with distilled water, followed by the same solvent rinse sequence as used on the split tube samplers. This procedure was performed before every sample.

Field personnel wore new disposable vinyl gloves when collecting soil samples. Gloves were changed after decontaminating sampling equipment.

2.3 Sample Preservation

After soil samples were collected, the filled sample containers were placed in a cooler with Blue Ice or similar reusable ice product. All samples were chilled to 4 degrees centigrade. This temperature was maintained throughout sample collection and shipment. No other preservation techniques were used.

2.4 Sample Analyses

Soil samples were analyzed by metaTRACE, Inc. of St. Louis, Missouri. Analytical parameters included nitroaromatics, metals, nitrate, sulfate, chloride, fluoride, and percent moisture. Selected surface samples were analyzed for asbestos. Precleaned sample containers were supplied by metaTRACE, Inc.

Analytical parameters were selected based on known or suspected contaminants from the WSOW and WSUFMP.

Nitroaromatic analyses were performed according to the U.S. Army Toxic and Hazardous Materials Agency (USATHAMA) High Pressure Liquid Chromatography (HPLC) methodology. Metals analyses were performed to U.S. EPA Contract Laboratory Program (CLP) standards. Nitrate, sulfate, chloride and fluoride analyses were performed according to EPA method 300.0.

3.0 RESULTS

Analytical results are presented in Appendix A of this report. Each group of analytical parameters is discussed in detail in the following sections. All interpretations made in this report are based on analytical results, field observations, past waste management practices, aerial photography, and the draft UNC report "Radiological Characterization of the Weldon Spring, Missouri Remedial Action Site", October 1987.

3.1 Nitroaromatics

All soil samples were analyzed for nitroaromatics using HPLC according to USATHAMA methodology. No detectable levels of nitroaromatics were present in any samples collected on-site. Detectable levels were measured in soil samples taken from the waste lagoon used in WSOW production located off-site, just north of the WSCP (Figure 2-1). Table 3-1 presents nitroaromatics results from soil samples collected in WSOW Waste Lagoon No. 1.

TABLE 3-1

Source: WSSRAP, 1987

Soil sampling locations were not chosen to confirm previous positive results for nitroaromatics as reported in the 1976 Department of Army Report "Assessment of Weldon Spring Chemical Plant in St. Charles Missouri--Final". The validity of this previously collected data and the need for additional sampling will be discussed in the Chemical Soil Investigation Sampling Plan.

3.2 Metals

All soil samples were analyzed for CLP metals and lithium. Lithium was used in pilot studies at the WSCP and is present in the WSRP and groundwater. Acid usage in both explosives production and uranium processing make metal contamination of the soil a distinct possibility. Metal contamination of the soil has been documented at other ordnance works such as the West Virginia Ordnance Works and Alabama Army Ammunition Plant (ESE, 1986).

3.2.1 Elevated Concentrations Detected

Several metals were detected in elevated concentrations in several soil samples. Lead, barium and zinc were present in concentrations above background and appear to be related to WSOW sources. Based on the sampling effort, there appears to be a relationship between elevated levels of lead and zinc.

Sample-specific analytical results are presented in Appendix A of this report.

The use of lead in explosive production equipment has been documented at other ordnance works (ESE, 1986) and is the primary non-nitroaromatic soil contaminant.

Lead was used in WSOW process buildings and as flooring to minimize static electricity. Acidic spills could have dissolved lead and other metals. Spill control probably consisted of neutralization with lime or soda ash and/or dilution followed by washing.

Lead concentrations in the soil at the WSCP ranged from <0.6 ug/Kg to 43,000 ug/Kg. The highest value was observed at Location No. 3 (Figure 2-1) north of Ash Pond in the 2- to 4-foot interval downslope from the final production area of TNT Line No. 2.

Elevated zinc levels were present with elevated lead levels in numerous samples. Zinc concentrations were much lower, however, only ranging up to 820 ug/Kg. The source of the zinc contamination is not known at this time.

Barium was also present in elevated concentrations in select samples. Up to 4,000 ug/Kg of barium were detected in soils

from the Ash Pond area. The source and/or reason for barium contamination is not known at this time.

3.2.2 Background Metals Determinations

Another purpose of this investigation was to establish background metals concentrations in on-site soils. On-site background concentrations were determined statistically. Concentrations for each metal were analyzed statistically to determine average background concentrations and ranges. Frequency histograms were plotted for each metal. These histograms were evaluated to detect concentrations outside of the normal distribution of the population. These elevated values were removed from the background data set prior to calculating the arithmetic mean, arithmetic standard deviation and the geometric mean. This data is presented on Table 3-2 with the background ranges.

Several metals appear to be present as low-level contamination throughout soils at the WSCP/WSRP. These metals include: aluminum, antimony, barium, iron, lead, magnesium, manganese, nickel, vanadium and zinc. Background samples will be collected from off-site locations during the overall soil characterization as described in the Chemical Soil Investigation Sampling Plan. These "on-site" background values will be compared to background

TABLE 3-2

samples collected as described in the Chemical Soil Investigation Sampling Plan.

3.3 Inorganic Anions

Soil samples collected during this investigation were also analyzed for nitrate, sulfate, fluoride and chloride. Elevated levels of nitrate and sulfate were observed at numerous locations, most commonly in surficial soil samples. This is to be expected since the nitrates probably originated from neutralized nitric acid. Nitric acid was used both at the WSOW and the WSUFMP. The highest concentration of nitrate (868 mg/Kg) was detected in a ditch carrying waste from a WSOW process building at Location 36. Elevated nitrates and sulfates were also observed in WSOW Waste Lagoon No. 1 north of the WSCP.

Elevated sulfate levels were occasionally associated with elevated nitrate levels, especially in the WSOW Waste Lagoon. This would be expected due to the use of mixed nitric and sulfuric acid in TNT production. Other areas of sulfate contamination are also probably related to WSOW production due to the use of sulfuric acid as a catalyst. Additional investigations are required to determine the source and extent of this contamination.

Some slightly elevated chloride and fluoride levels are present

Some slightly elevated chloride and fluoride levels are present in WSCP/WSRP soils. The source of these species is not known at this time.

Selected surface soil samples were analyzed for asbestos based on the usage of asbestos in WSOW process buildings. All submitted samples contained less than 1 percent asbestos and no elevated levels were observed.

4.0 CONCLUSIONS

This investigation was designed to supply baseline soil information and establish on-site background metal concentrations. This investigation indicates the presence of elevated levels of nitrate, sulfate and certain metals in the soils at the WSCP/WSRP. Limited conclusions regarding the extent and magnitude of contamination can be made based on the data collected. The data presented in this report will be used in developing the Chemical Soil Investigation Sampling Plan, which details the overall soil characterization strategy for the Weldon Spring Site.

Several preliminary conclusions can be made from the data presented in this report. These conclusions are:

1. Nitroaromatic compounds were not detected in the on-site soil samples collected in this investigation. Additional

sampling is required for WSOW sources, particluarly in production areas, surface drainages and the burning ground area.

2. Nitroaromatics bind tightly to soil particles at the WSCP/WSRP. This was evidenced by the soil samples collected from the WSOW wastewater lagoon located just north of the WSCP. Nitroaromatic concentrations decreased from percent levels (0.3%) to less than the detection limits through eight feet of soil. This information will be used when designing the overall chemical soil characterization sampling plan.

3. Areas of nitrate and sulfate contamination appear to be related to WSOW processes and sources.

4. There appears to be low-level contamination by several metals including aluminum, antimony, barium, iron, lead, magnesium, manganese, nickel, vanadium and zinc. Isolated undetected areas of higher concentration may exist for these metals. Additional investigations are required to determine true background conditions and assess contaminant extent.

5. There do not appear to be any elevated concentrations of beryllium, cadmium, mercury, selenium or thallium in soils at the WSCP/WSRP.

6. Elevated asbestos levels are not present in surficial soils as a result of WSOW building demolition. Elevated levels of asbestos may be present near overhead piping in the WSCP.

7. There do not appear to be any significant on-site soil contamination areas contributing to groundwater contamination.

These conclusions will be used to guide further soil investigations as detailed in the Chemical Soil Investigation Sampling Plan. The data in this report will be factored into the overall soil contamination assessment and used in the Remedial Investigation Report.

APPENDIX B

DATA QUALITY

Throughout this sampling effort, analytical data quality was assessed through the use of duplicates and spikes. These additional analyses were performed for all analytical parameters.

All Quality Control Data is presented at the end of this appendix. Overall, no holding times were exceeded and the Quality Control Data is acceptable. Therefore, the analytical data presented in this report conforms to applicable standards of accuracy and precision and is representative of sample conditions at the time of collection.

All data presented in this report will be validated according to the procedures to be presented in the forthcoming Quality Assurance Project Plan (QAPP). This data will then be used to assess overall soil contamination.

1.0 INTRODUCTION

This study was initiated to investigate the possible exposure pathways of chemical and radiologic contamination to humans by ingestion of potentially contaminated fish and game from the presence of the former Weldon Spring Uranium Feed Materials Plant. Since the Weldon Spring Site (WSS) is surrounded by prime hunting and fishing habitat, (i.e. August A. Busch and Weldon Spring Wildlife areas), questions concerning the consumption of potentially contaminated animal tissue have been raised. Game animals that migrate on and off site are exposed to contaminated soils and water on site and to contaminated water leaving the site by natural drainage channels. Fish in the lakes and streams which receive this water are also a potential source of exposure to the public.

The interest in a bio-uptake study was generated in response to concerns expressed at the Draft Environmental Impact Statement (DEIS) public hearings. As a result, a draft bio-uptake sampling plan was submitted by the Department of Energy (DOE) to the Environmental Protection Agency (EPA Region VII) and the Missouri Department of Natural Resources for review (DOE, 1987d). Suggested changes and additions to the proposed scope of work were incorporated into the sampling plan where feasible, and field work began in November 1987.

This document is a report of the data and a discussion of the results obtained. A discussion of other biological sampling efforts and bio-uptake studies which have been performed by others prior to the current effort is included also. This study is not a comprehensive evaluation of all levels of the food chain. It is a screening process to identify the ranges of the concentrations of some chemical and radiological constituents within the few fish and mammal species that are eaten by humans. The purpose of this study was limited to evaluating only those tissues that are routinely consumed for food. Human

exposure through ingestion pathways is being determined as part of a risk assessment for EPA Remedial Investigation/Feasibility Study (RI/FS) documentation for the WSS.

1.1 SITE HISTORY AND ENVIRONMENTAL SETTING

The Weldon Spring Site is a DOE surplus facility located approximately 30 miles west of St. Louis in St. Charles County, Missouri. From 1941 to 1944, the U.S. Department of the Army (DA) operated the Weldon Spring Ordnance Works for production of trinitrotoluene (TNT) and dinitrotoluene (DNT). During this operation, small areas of the 17,000-acre site were contaminated by TNT process materials. In 1954, 220 acres of the Ordnance Works property were transferred to the U.S. Atomic Energy Commission (AEC). From 1957 to 1966, the AEC operated a uranium processing facility on the site. During the operation of the Uranium Feed Materials Plant, the buildings, equipment, and some terrain of the plant site became contaminated with radionuclides in the uranium transformation series.

After closure by the AEC, the Feed Materials Plant was reacquired by the Army in 1967. The Army partially decontaminated the buildings, dismantled some of the equipment, and began to convert the facilities for the production of herbicides. In 1969, prior to the Weldon Spring Chemical Plant (WSCP) becoming operational, the herbicide project was cancelled. In 1985, the custody of the WSCP was transferred from the DA to the Department of Energy (DOE). In conjunction with this transfer, the Weldon Spring Site Remedial Action Project (WSSRAP) was created as DOE Major Project Number 182.

1.2 SOURCES OF CONTAMINATION

Radiologically contaminated soils at the WSCP are generally confined to the north and south dump areas, Frog Pond drainage, and to areas immediately surrounding the buildings. Uranium

concentrations range from background levels of about 1 pCi/g to several thousand pCi/g. The majority of radium-226 and thorium-232 concentrations are at mean background levels (UNC, 1988). Therefore, sampling of small mammals on site was focused on those areas where the potential for radionuclide uptake was greatest. Contaminated soils in these areas are also the major source areas contributing to surface water runoff contamination.

Surface water runoff from the north and west sides of the WSS flows to Ash Pond (Figure 1-1). A significant portion of this runoff flows through the south dump area and enters Ash Pond. Water from Ash Pond flows to Lake 35 in the August Busch Wildlife Area, to Schote Creek and Dardenne Creek, and eventually to the Mississippi River (Figure 1-2). Since plant operations ceased in 1967, the discharge from Ash Pond has become an intermittent stream.

Lake 35 is the closest lake to Ash Pond that receives effluent from Ash Pond. Lake 35 is commonly used by the public for recreational activities such as fishing and limited boating.

Water from Ash Pond also discharges via underground connections to Burgermeister Spring, to Lake 34, to Dardenne Creek, and eventually to the Mississippi River (Dean, 1985). At present, there is no recreational use of Burgermeister Spring, but Lake 34 is used for recreational purposes similar to those of Lake 35. Lakes 34 and 35 are not used as drinking water or as irrigation sources (Figure 1-2).

Surface water runoff from the northeast portion of the WSS drains into Frog Pond. An intermittent stream running out of Frog Pond flows north to Lake 36. The outfall of Lake 36 discharges into Lake 35, to Schote Creek, to Dardenne Creek, and eventually to the Mississippi River. Lake 36, located in the Busch Wildlife Area, is the closest lake in an unrestricted area receiving effluent from Frog Pond. Lake 36 is also used for

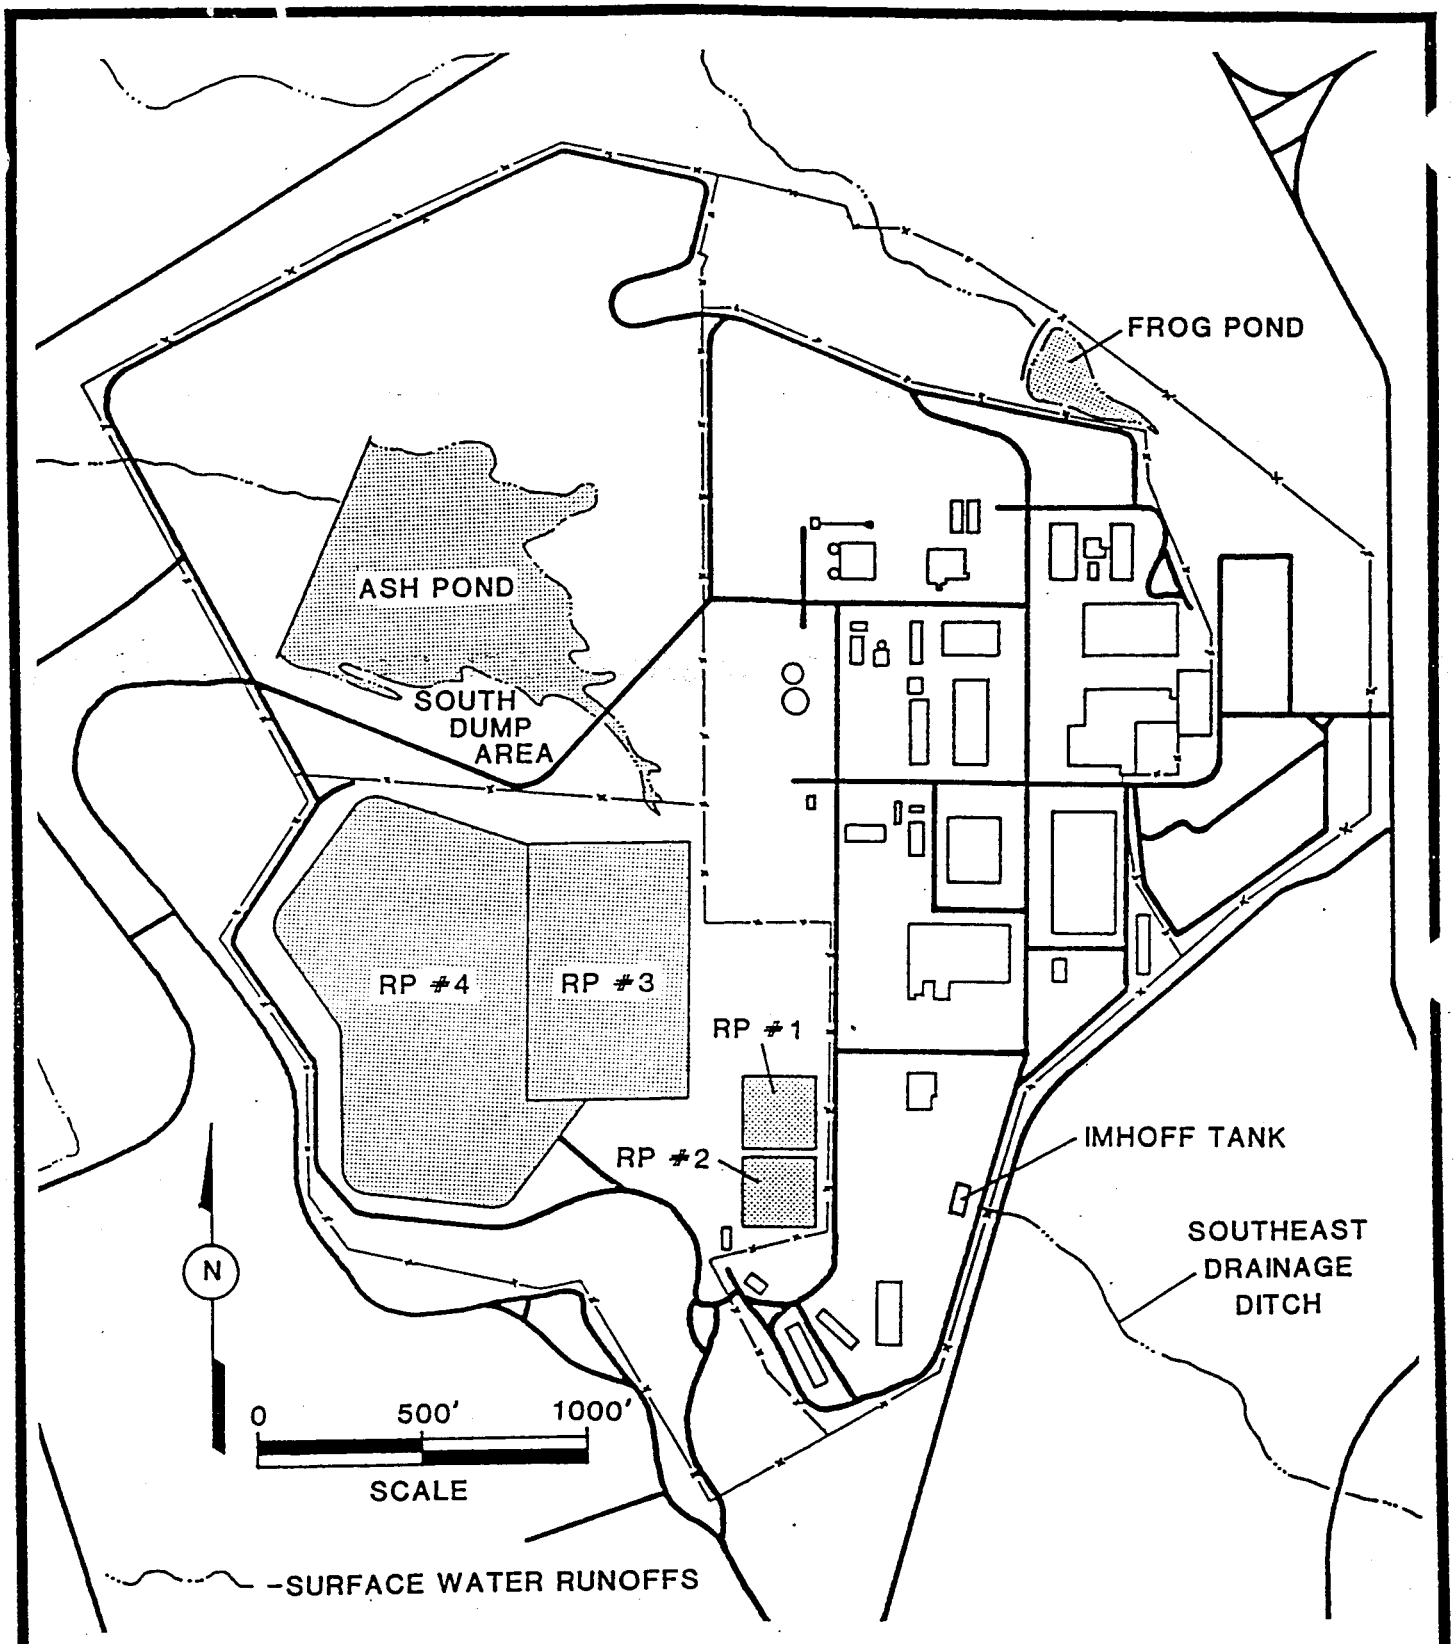

FIGURE 1-1

SITE MAP WITH ASH POND AND FROG POND DRAINAGES

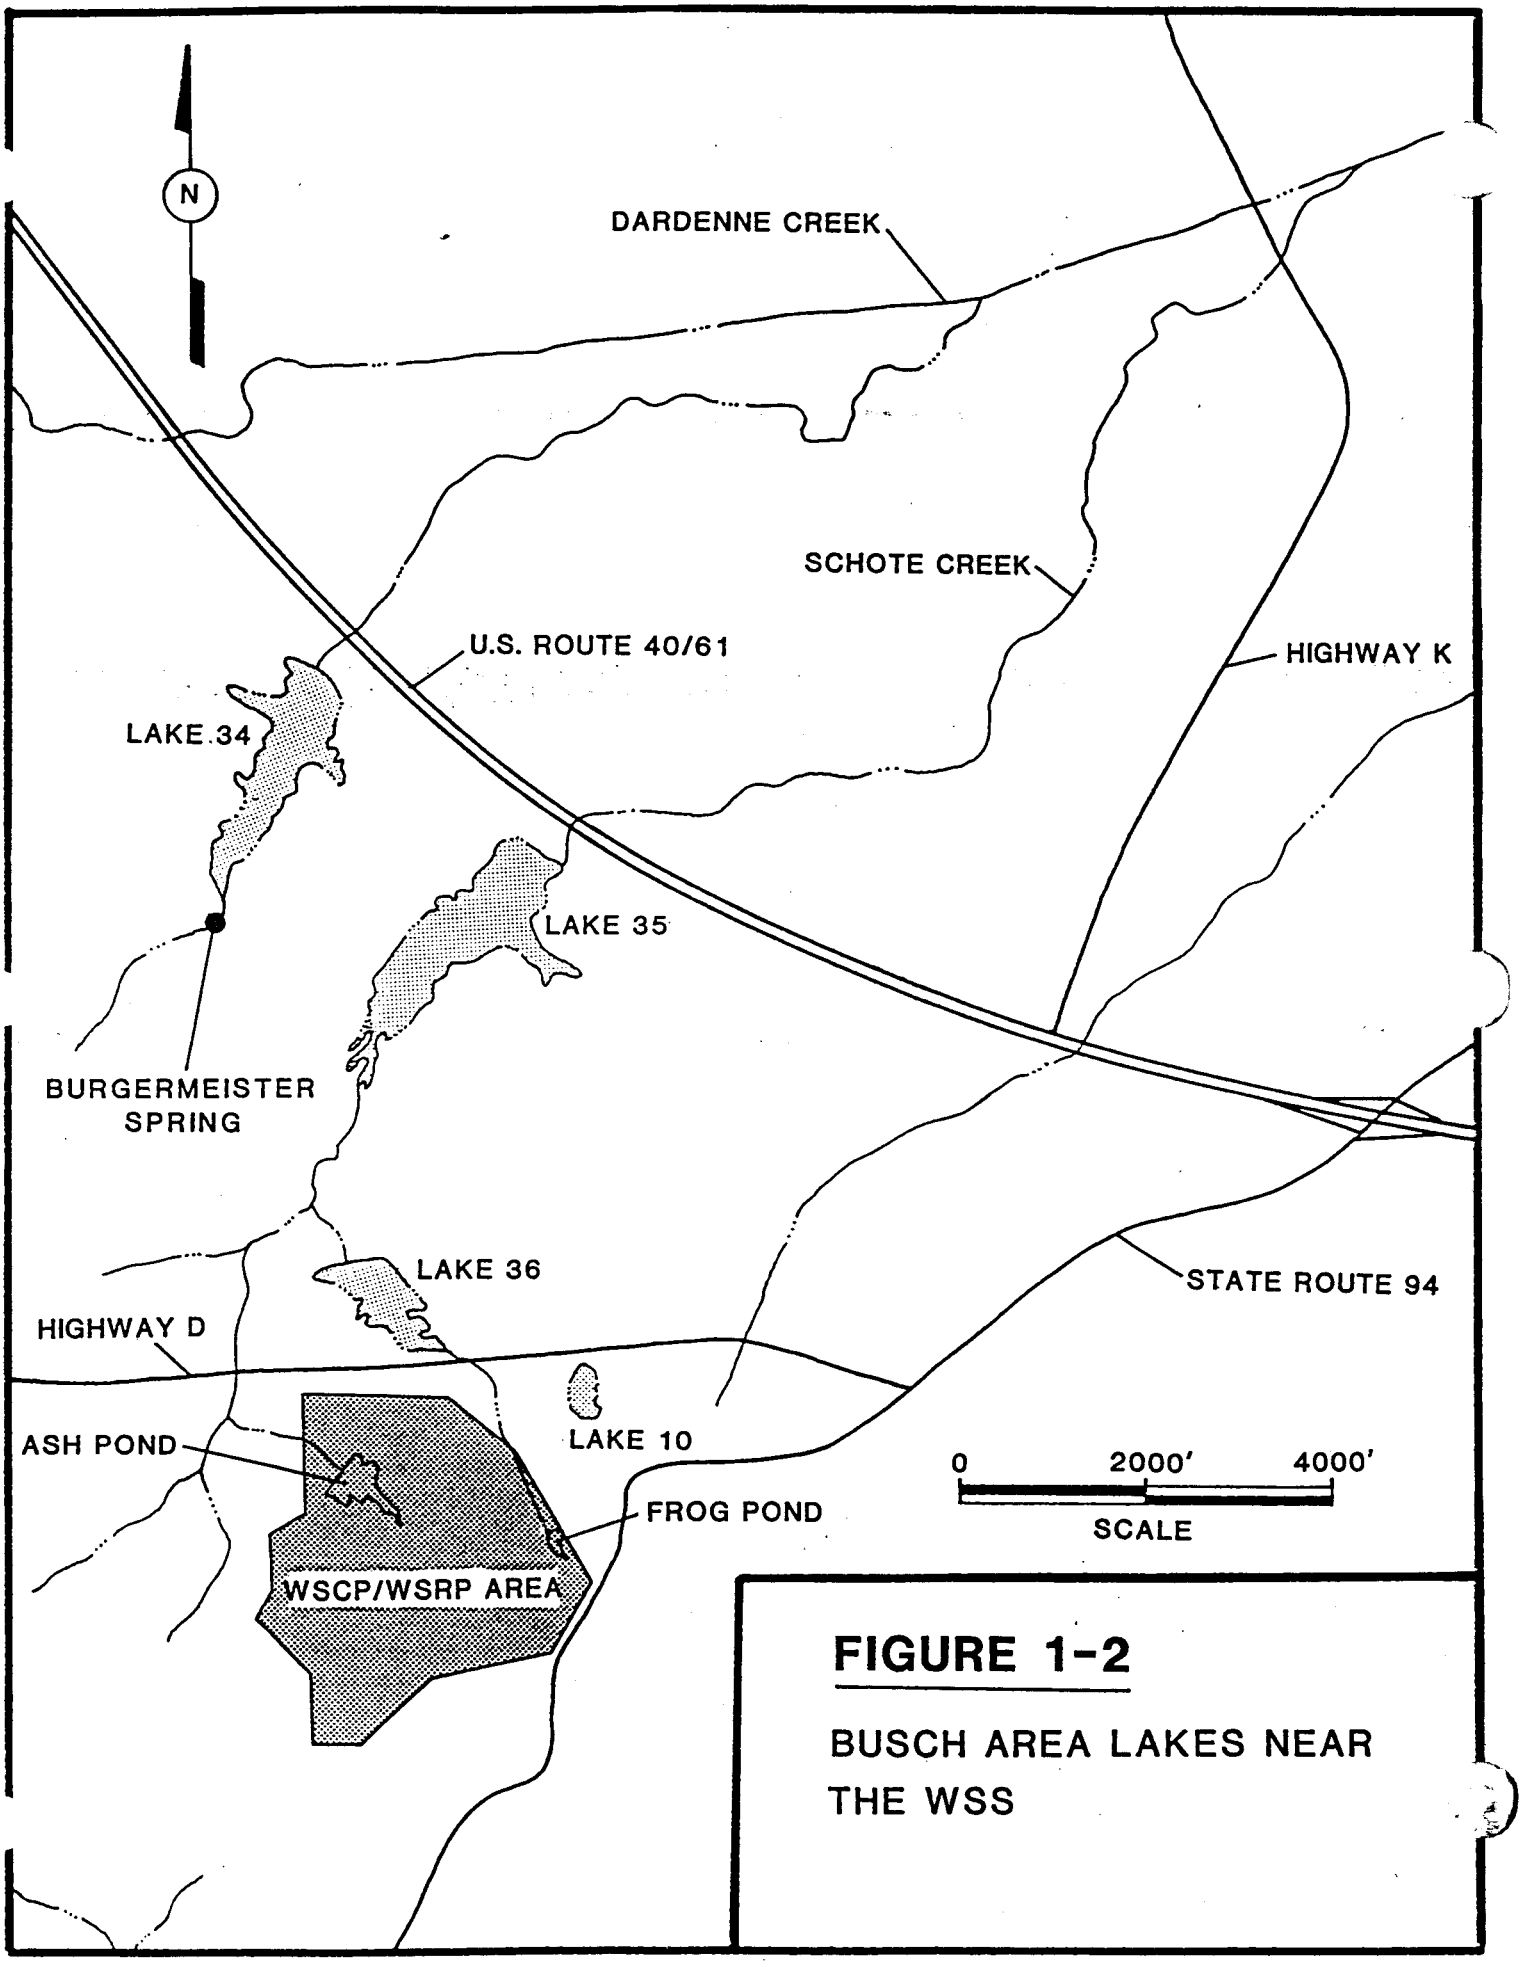

FIGURE 1-2

BUSCH AREA LAKES NEAR THE WSS

fishing and boating but not as a source of drinking water or as a source for irrigation.

On the southeast corner of the WSCP, the outfall from the Imhoff tank (the former WSCP sanitary sewage system) flows down a drainage ditch to the Missouri River. This drainage system contains areas of elevated radionuclide concentration. Currently, flow through the Imhoff tank results from the infiltration of storm water flowing into the sewer system. Sanitary wastes no longer enter the sewer system.

The Weldon Spring Quarry (WSQ) is approximately 4 miles south-southwest of the WSCP. Radioactive wastes were disposed of in the WSQ by the AEC from 1957 to 1966 (Figure 1-3) (U.S. DOE, 1987a). The DA also disposed of TNT process wastes into the WSQ. A large portion of the AEC radioactive wastes were from the Mallinckrodt Chemical Works' Destrehan Street Feed Plant in St. Louis. Materials from this plant were contaminated with radionuclides in the uranium transformation series.

The Femme Osage Slough is located in the Weldon Spring Wildlife Area, approximately 500 feet south-southeast of the WSQ (Figure 1-3). The slough is believed to be hydraulically connected to the quarry sump (U.S. DOE, 1987b). This slough is not used as a source of drinking water or for irrigation, but is used frequently for fishing.

Average radioactivity levels in surface water and runoff samples taken from in and around the WSS during 1987 are presented in Tables 1-1, 1-2 and 1-3. Figures 1-4, 1-5 and 1-6 illustrate the locations of these samples. Tables 1-1 and 1-2 present data from samples that were collected from surface water locations at quarterly intervals and averaged over the entire year. Table 1-3 presents data from surface water runoff samples collected monthly and averaged for the year. These runoff samples are collected monthly, following significant rainfall events, to

monitor contaminant concentrations leaving the WSSRAP as a result of surface runoff. These averaged values are also presented in the 1987 Environmental Monitoring Report (U.S. DOE, 1987c). The radiologic activity levels in surface water generally decrease with increased distance from the site, mainly due to dilution by lake and runoff water.

NPDES SURFACE WATER SAMPLING LOCATIONS

2.0 METHODS

Only terrestrial and aquatic animal specimens were included in the analyses for chemical and radiological uptake. Human consumption of plants from the contaminated areas is considered to be minimal. Although several sharecrop fields are operated by the Department of Conservation in the surrounding areas, they are used exclusively for wildlife forage. The nearest commercial farming areas or private gardens are several miles from the WSS. In addition, no indication of radiological contaminants has been found in any offsite areas used for plant production. Therefore, the present study has been focused on the animal tissue pathway.

2.1 FIELD METHODS

2.1.1 Aquatic Species

Aquatic sampling took place in October and November of 1987. Fish specimens were collected from surface waters impacted by contaminant releases from the WSS in order to determine the extent of radionuclide uptake by game fish. Specimens were collected using the electrofishing technique. Electrofishing utilizes a gas-powered generator to introduce an electric current into the water around the boat. Fish are temporarily stunned, then netted and placed in a water-filled tub in the boat. Fish samples were collected from Lakes 34, 35, 36, and 37 in the August A. Busch Wildlife Area and from the Femme Osage Slough on the Weldon Spring Wildlife Area. This work was accomplished with the cooperation of the Missouri Department of Conservation.

Fish specimens from Frog Pond were also collected by PMC personnel using the electrofishing technique. An attempt was made to collect samples from Raffinate Pits 3 and 4 and from the Quarry Sump. However, these bodies of water did not yield a

single specimen.

Lake 37 in the Busch Wildlife Area was chosen as a background location. Lake 37 is located at the western edge of the Busch Area in a small, isolated watershed which does not receive runoff from the WSS or the abandoned Army Ordnance Works.

According to the bio-uptake sampling plan (DOE, 1987d), five composite samples of fish were to be collected from each location. The five composites were to represent the following fish, prepared as specified:

1) sunfish, filleted
2) sunfish, cleaned (beheaded, scaled, and eviscerated)
3) bass, filleted
4) catfish, filleted
5) mixed species, filleted

The fish species chosen for sampling represented three different patterns of feeding and food preference. All three species are commonly consumed by the public as a result of recreational fishing at the Busch and Weldon Spring Wildlife Areas. Sunfish are omnivorous fish confined to shallow waters. Largemouth bass are predominantly piscivorous in the Busch Wildlife Area lakes. Catfish are predominantly omnivorous bottom feeders. Catfish were expected to be the species most likely to exhibit contaminant uptake due to their proximity to the potentially more contaminated lake sediments. The cleaned (beheaded, scaled, and eviscerated) sunfish composites represented fish commonly used to make "fish cakes", a common way of preparing this smaller fish.

Fish were cleaned and samples prepared either the same day they were collected or the morning following an evening collection. Each composite consisted of a minimum of three fish, totaling at least 800 grams. Samples were placed in plastic bags, weighed,

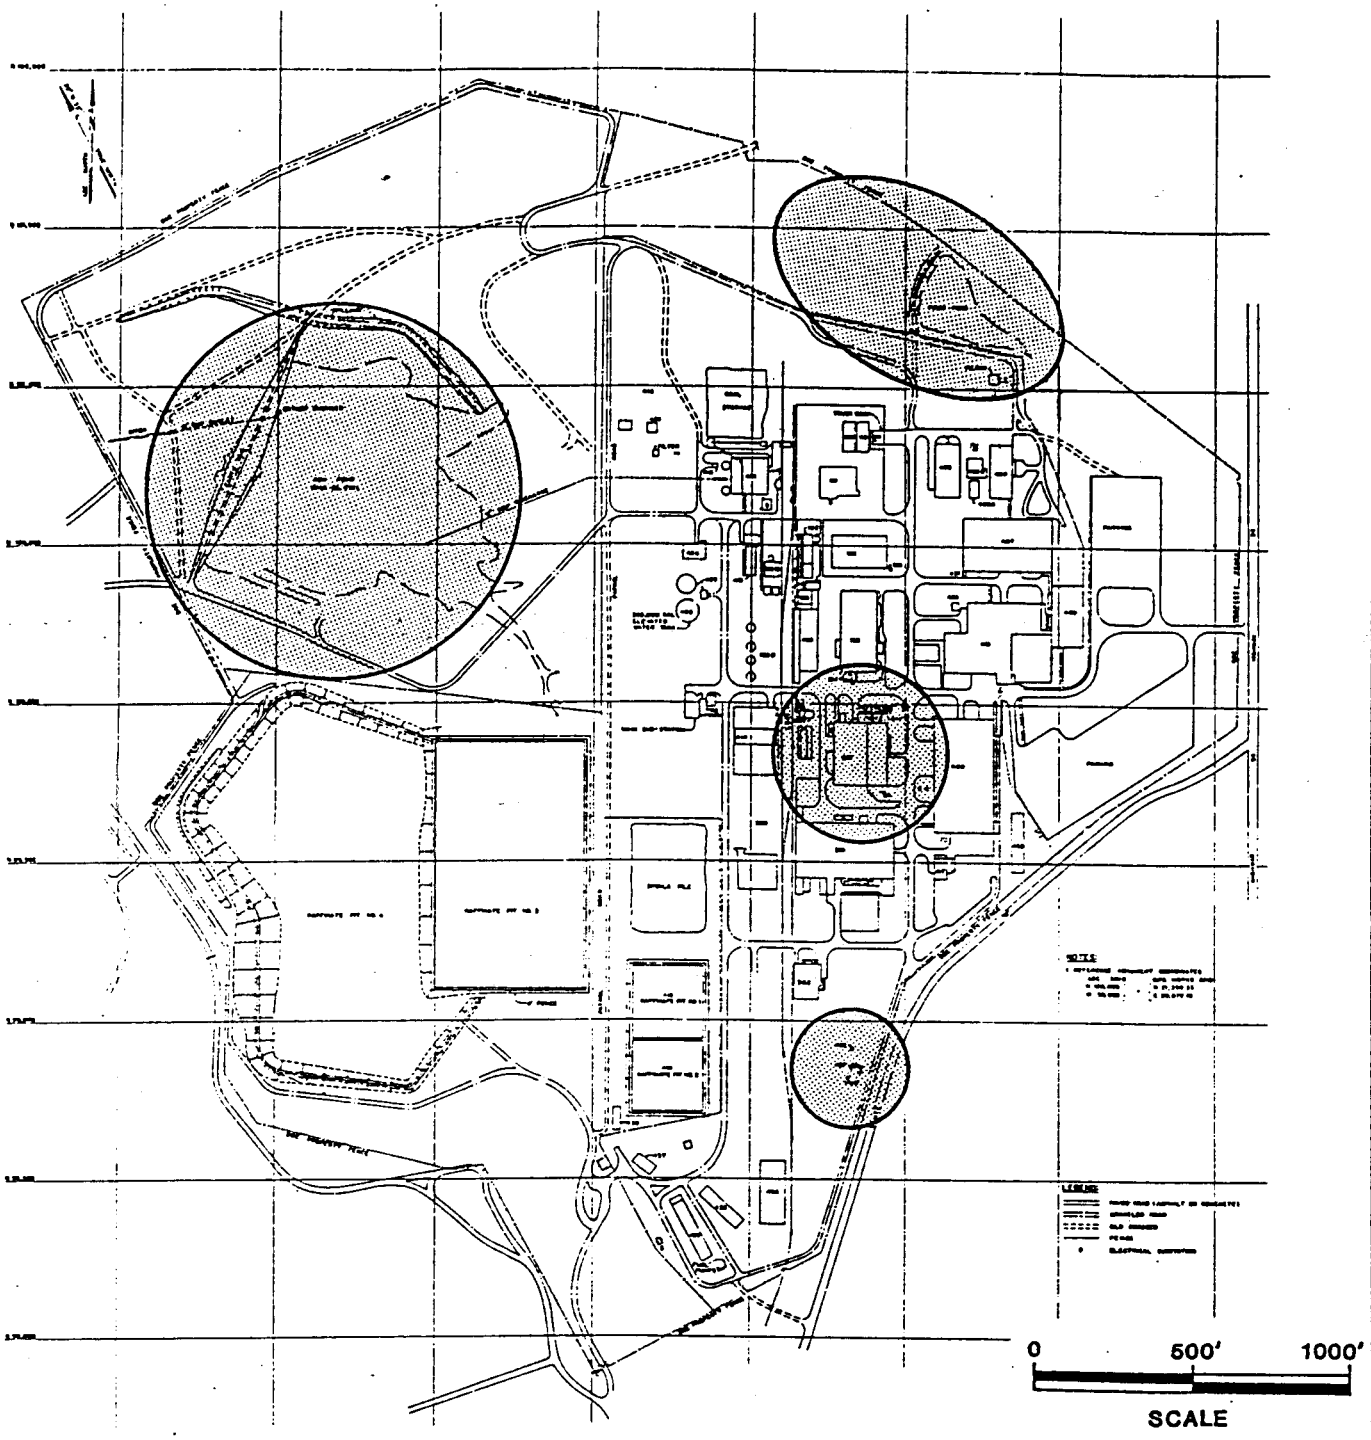
labeled, and immediately frozen. The frozen samples were sent for laboratory analyses within 48-72 hours of sample collection. The original sampling plan was followed whenever possible. However, at some locations substitutions were required due to species unavailability. For example, in Lake 35, crappie fillets were substituted for sunfish fillets. In the Femme Osage Slough, crappie replaced both sunfish composites; carp and largemouth buffalo were collected also because they were common within this body of water. At Frog Pond, sunfish were the only abundant fish and most of them were small in size. Therefore, only the cleaned sunfish composite could be collected.

The composite samples were sent to a subcontracted laboratory, metaTRACE, in Earth City, Missouri. The filleted composites were analyzed for natural uranium. The cleaned (scaled, beheaded, eviscerated) sunfish samples, representing fish that would be ground up to make fishcakes, were analyzed for thorium-230/232 and radium-226 as well as total uranium. The mixed fillet composites were analyzed for PCBs and CLP metals.

2.1.2 Terrestrial Species

Small game mammals (rabbits and squirrels) were collected from the Weldon Spring Chemical Plant (WSCP). Most of the samples were obtained by trapping with live traps using a variety of baits. However, this trapping was not as effective as anticipated, and samples were later obtained by hunting on site. A total of eight rabbits and three squirrels were collected from the WSS. Trapping was concentrated in two areas: the South Dump/Ash Pond area and the Frog Pond area. Hunting was utilized to obtain samples from areas around the chemical plant buildings. Figure 2-1 illustrates these areas.

Small mammal composite samples consisted of three individuals collected from each location. Specimens were cleaned on the day they were collected, placed in plastic bags, labeled, frozen,



SHADED AREAS INDICATE SAMPLING AREAS

FIGURE 2-1

SMALL MAMMAL SAMPLING AREAS AT WSS

and sent to the lab. At the lab, each composite was split into bone and tissue and analyzed separately for total uranium, thorium-230/232, and radium-226. The lab did not analyze for PCBs and metals since there were not enough individual specimens captured to provide the necessary volume of sample tissue.

Larger migratory game animals such as deer, turkey, geese, etc. were not sampled as part of the WSS bio-uptake study. Such animals readily migrate on and off site, spending an unknown proportion of their time on the WSS. An expansion of the bio-uptake study's scope to include larger migratory game animals was dependent upon the data obtained from the smaller terrestrial mammals. No small mammal samples were obtained from the quarry area since trapping in the WSQ area was unsuccessful.

2.2 ANALYTICAL PARAMETERS

The investigation focused primarily on the analysis for uranium in the biological specimens collected. In comparison with the other contaminants present in the WSS, uranium exists at the highest concentrations and quantities, and is one of the most water soluble. In addition, when introduced into the body, uranium is the most soluble of the radionuclides, incorporating into the soft tissues as well as into the bones. All samples were analyzed for total uranium except for the mixed fillet composites which were analyzed for PCBs and metals.

Surface waters at the WSS generally exhibit background concentrations of radium and thorium (DOE, 1987c). Radium and thorium are relatively insoluble and primarily incorporate into the bone. Therefore, only the cleaned sunfish composites which included bone were analyzed for these radionuclides. Small mammals were also analyzed for radium and thorium. Small mammal samples were split by the lab into tissue and bone subsamples and analyzed for all three radiological parameters.

The mixed species fish composites were analyzed for CLP metals and PCBs. Draft versions of the Biological Uptake Plan also included the analysis of biota samples for nitroaromatics, on the assumption that this analysis could be performed by the laboratory. Subsequent research indicated insufficient information concerning the uptake, biodegradation, and metabolism of nitroaromatic compounds by animals and humans, making it difficult to interpret analytical results. In addition, there are no accepted methodologies for the analysis of nitroaromatic compounds in biological tissue. Recovery of target compounds following extraction procedures was estimated to be extremely low. TNT and DNT degradation products in the samples would probably not be detected. The lower limits of detection would not be low enough to consistently detect the concentrations anticipated. Therefore, nitroaromatic analyses were not performed as part of this study.

Additional analyses of semi-volatile compounds were considered as part of the sampling plan, but were discounted because of the same factors discussed for nitroaromatics. Information concerning uptake, degradation and metabolism is considered inadequate, and acceptable analytical methodologies have not been developed.

2.3 ANALYTICAL METHODS

Laboratory analytical methods used for the bio-uptake study generally followed the same procedures as those used for water samples. The main differences were in the sample preparation procedures. Fish samples analyzed for radionuclides and CLP metals were first digested in concentrated hydrochloric acid and then diluted to one liter before analysis by the following methods: total uranium was analyzed according to EPA method 908.0, isotopic thorium by EPA 00/07, radium-226 by EPA 903.0, and metals by EPA CLP protocols. PCB (Aroclor) analyses also followed CLP methods but utilized fish tissue that was not

acid-digested.

Small mammal composite samples sent to the laboratory for analysis were split first into separate bone and soft tissue portions, and then prepared for analysis according to Eastern Environmental Radiation Facility procedures (USEPA, 1984). These procedures included ashing the samples at 550° C for 72 hours in a muffle furnace followed by treatment with various carriers, tracers, and acids prior to the actual analyses. Radionuclide analyses followed the same methods as listed above for the fish samples.

3.0 RESULTS

3.1 AQUATIC SAMPLES

Twenty-five (25) composite fish samples, representing a total of 184 fish, were sent to the laboratory for analysis. Results from the fish portion of the bio-uptake study are presented in Tables 3-1, 3-2, and 3-3. Table 3-1 presents the sample numbers, radiological results, and the number and type of fish collected from each location. All samples analyzed exhibited no radiological contaminants detected at the lower limits of detection indicated in Table 3-1. Values less than the detection limits for samples from Frog Pond are especially noteworthy in light of the water concentrations of nuclides shown in Table 1-1.

Table 3-2 presents the results of PCB analysis from the mixed species composites. No PCBs were detected in any of the four composite samples analyzed for these parameters with detection limits of 0.04 to 0.06 ug/g (ppm).

Table 3-3 presents the results of CLP metals analyses for the mixed species composites. Many metals naturally occur in biological tissues; therefore, careful comparison with the background location (Lake 37) is necessary in order to interpret these data. Most of the metals detected in the non-background samples occurred in concentrations similar to the background location. Only iron (Fe) concentrations were found to be higher in all samples when compared to Lake 37. Iron was detected in concentrations ranging from 11.7 to 50.7 ug/g compared to 4.89 ug/g at the background location. Elevated background iron levels are not unusual to this area, as evidenced by values for Dardenne Creek in the Phase I Water Quality Assessment Report (DOE, 1987b), (570 - 808 ug/l.)

Chromium was detected in one mixed species composite sample from

Lake 34 with a concentration above the detection limit.

The metals arsenic (As), mercury (Hg), potassium (K), thalium (Tl), and zinc (Zn) are also shown with concentrations above the limits of detection. Each of these chemical species is also detected in the samples from Lake 37 which is located outside of the drainage of the WSS. For this reason, these concentrations are considered to be natural levels for the metals in fish tissue in this setting.

The lead (Pb) concentrations in fish samples from Lake 36 and 34 are about a factor of eight higher than the detection limit. Lakes 36 and 34 have no point of commonality. They are part of separate drainage basins and have been shown not to be in hydraulic connection through subsurface flow conduits (Dean, 1985). Although lead was not used as part of the former Weldon Spring Uranium Feed Materials Plant, it was commonly used throughout the Army Ordnance Works as a spark-free metal. Lead was a minor component of the impurities contained within the yellowcake processed, and therefore is found at low levels in the raffinate pit sludges.

Reasons were examined to determine any significance and possible sources of the elevated lead levels in fish tissue. Importantly, Phase I Soils studies (DOE, 1988) indicated that no migration of lead has occurred beyond the raffinate pit containment. That same study also reported an average background level of lead naturally occurring in the soils surrounding the WSS of 29 ppm. It also demonstrated that elevated levels of lead in soils occurred onsite in highly localized deposits associated with the Ordnance Works sources.

Monitoring data from the Phase I Water Quality Assessment (DOE, 1987b) indicates that lead is below the level of detection of 5 ug/l in both surface and groundwater from and around the site. The only location where lead has been detected above detection

limits is in Dardenne Creek, downstream from the lakes in question and even further from the WSS.

The above information, combined with the apparent absence of lead in fish tissue from Lake 35 which is immediately downstream of Lake 36, imply that the source of the lead is probably localized and is not from the Weldon Spring Site. Several plausible mechanisms exist that individually or in concert provide explanation for the localized phenomenon of lead uptake into fish tissue. Lead shot has been known to be ingested by waterfowl. In routinely hunted areas, many waterfowl carry a large body burden of lead from hunting injury. Fish feeding on the contaminated carcasses of such fowl would evidence elevated concentrations of lead. Additionally, fish could ingest and digest individual lead pellets which in turn would be assimilated into the tissues and result in elevated lead concentrations. Use of lead materials in fishing equipment is widespread and common. Nationally, lead contamination of the environment is recognized as an issue of concern with lead coming from a wide variety of anthropogenic sources.

Another factor introducing variability into the lead concentration of different samples is based upon the nature of the composite samples themselves. Slightly elevated lead levels in fish tissues from Lakes 34 and 36 are presumed to be partly the effect of statistically variable samples of fish. In order to achieve the goal of the study, i.e., to examine the effect of species of concern to human diets, the metals analysis samples consisted of a composite of three different species of edible fish. Composite samples of 800 grams each were made from the catch that was obtained from each of the lakes. The guideline followed in determining the sample constituents was to incorporate as good a representative mix of these edible species as could be acquired from the catch at each lake. These composites consisted of the following proportions of fish:

- Lake 34
  - 1/2 of a bass
  - 4 crappie
  - 2 sunfish

- Lake 35
  - 2 bass
  - 4 sunfish
  - 6 crappie

- Lake 36
  - 2 ea 1/2 bass
  - 2 crappie
  - 2 sunfish

- Lake 37
  - 4 bass
  - 5 sunfish

Two important elements determined the mix of these samples. First, the samples were to be representative of species which humans eat, and second, the samples were to be representative of the catch obtained at each lake. While these samples represent the kind of variability that would reflect a human diet from the lakes, nevertheless they introduce some variability with respect to different species composition, as well as differences in age, sex, and possibly other factors.

The samplers tried to achieve as uniform a mix of fish as possible. One factor apparent between samples from Lake 34 and 36 is the small number of bass (larger fish had to be cut to achieve correct proportioning). Bass are on the top end of the fish food chain and, given the rule of thumb of 10 fold increase in bioaccumulation in each higher trophic level, these bass may have more lead than the other fish. Also, age is another factor in bioaccumulation. Since larger fish in a species group are

usually older fish, it appears older bass were caught in 34 and 36. For these reasons, it is believed that they may be contributing proportionally higher levels of lead.

Arsenic (As) levels about 14 times the lower detection limit were found in fish samples from Lakes 35 and 37. Arsenic is an element well known for its bioaccumulation capacities. It occurs naturally and also as a result of human activity. Naturally occurring arsenic concentrations on or around the WSS have an arithmetic mean of 6 mg/kg (DOE, 1988). Lake 37 is not influenced by the Weldon Spring Site and, therefore, accumulation of arsenic is clearly a result of other mechanisms. This finding is reinforced by a similar arsenic concentration in fish from Lake 35. This lake is downstream from Lake 36 where the fish did not show accumulations of arsenic above the levels of detection. The Phase I Water Quality Assessment reports all surface water and groundwater samples of the WSS had levels of arsenic below the detection limits (DOE, 1987b). Only water samples taken directly from the Raffinate Pits showed concentrations ranging from below the level of detection up to 38 ug/l, or part per billion concentrations. For these reasons, the arsenic accumulations in fish from Lakes 35 and 37 appear to be unrelated to the Weldon Springs facility.

Chromium (Cr) was detected only in the fish sampled from Lake 34 at slightly less than 3 times the detection limit. Chromium is a naturally occurring element in soils and waters of the area. Natural soil background concentrations at or around the WSS have an arithmetic mean of 24 mg/kg (DOE, 1988). It is found at detectable but low concentrations in all ground and surface waters with about 50 ug/l being a reasonable approximation of the background levels (DOE, 1987b). Chromium has been detected in fish tissues at or slightly above background concentrations in other studies (Wixson, 1982). With the ubiquitous nature of chromium, a single fish sample containing less than 3 times the

detection limit cannot be considered as significant nor can it be attributed to the WSS.

Concentrations of the metals calcium (Ca), potassium (K), and sodium (Na) were anticipated because these metals are essential constituents of living tissues. Their presence at varying levels as indicated in Table 3-3 was expected also.

3.2 TERRESTRIAL SAMPLES

A total of eight rabbits and three squirrels were collected from the Ash Pond area, three rabbits from among buildings at the WSCP, and two rabbits from around the Imhoff Tank drainage. Three squirrels were collected from the Frog Pond area. Table 3-4 presents the results of radiological analyses for these samples. No radiological contaminants were detected at the lower limits of detection as shown in Table 3-4.

No samples were collected off-site or from the quarry area. Trapping at the quarry was unsuccessful.

4.0 DATA INTERPRETATION

The principal objective of the biological sampling program was to establish the fate of the site contaminants in edible biota in the local environment so that their impact could be experimentally measured. The characterization design was based on the direct sampling of edible biota and the analysis of samples for contaminants. Assimilation of contaminants by biota is a complex phenomenon, especially in aquatic organisms that absorb contaminants directly from water as well as from food in their gastrointestinal tract. This section presents a determination of bioaccumulation factors of radionuclides for aquatic species so that a comparison with similar studies can be made. It does not present an analysis of the bioaccumulation for nonradiological chemical species.

The bioaccumulation factor of an organism or tissue is the ratio of a radionuclide in the whole organism or tissue to that in water. A variety of environmental factors can influence the assimilation of contaminants, and hence the bioaccumulation in organisms. For example, the calculation of a radiation dose to man from food chains usually requires that bioaccumulation factors be calculated only for the edible portion of the organism. Whole-body bioaccumulation factors may be quite different from those reported for muscle tissue. When a contaminant accumulates in the bone, its contribution to the whole body concentration is greater than its concentration in the muscle. Therefore, the actual radiation dose to man from the ingestion of the muscle may be much lower than the radiation dose calculated using the whole-body accumulation factor.

Several factors can significantly influence the organism bioaccumulation factors reported in the literature, including the method used to determine bioaccumulation factors, various environmental parameters, the chemical form of the contaminant, and characteristics of individual species. Because of the

uncertainties associated with bioaccumulation factors, there is a tendency to select values that are usually overestimates. It may be impractical to expect validation studies to show close agreement between many of the values found in literature and experimentally measured site-specific values. This conservatism needs to be noted when the data are interpreted.

4.1 PREVIOUS STUDIES

The National Council on Radiation Protection and Measurements (NCRP) has published a reference document on the application of radionuclide transport models from the point of discharge to the environment to the point of intake by man (NCRP Report No. 76, 1984). The report indicated that comprehensive studies of uranium, thorium, and radium in aquatic biota concerning their relative concentrations and their movement through aquatic food chains are not readily available. The report presented limited experimental data for the concentration of uranium and radium in freshwater biota (Table 4-1).

T.L. Gilbert (Argonne National Laboratory) et al. prepared a manual for the U.S. Department of Energy for implementing residual radioactivity guidelines (Gilbert et al., 1985). The manual included various food pathway factors used in deriving the environmental transport factors of residual materials. Table 4-2 lists these bioaccumulation factors for fish which are represented by the ratios of aquatic concentrations to the radionuclide concentration in fresh water.

Since models of aquatic dispersion of radionuclides released to water are very dependent on the exact local conditions of surface or underground flow and on absorptive capacities of prevalent biota, the NCRP and Gilbert documents were used as comparative references for the WSSRAP studies.

Two separate biological sampling studies have been performed at

the WSS prior to the data collection discussed in this report. Information gathered from these two studies has been used to estimate upper bounds for bioaccumulation factors for aquatic species. The previous studies are shown with values resulting from the current study in subsequent sections.

In 1977, a biological sampling program was initiated by a contractor for the Department of the Army at the WSCP. Ryckman/Edgerly/Tomlinson and Associates (RETA) performed the assessment (RETA, 1978). One hundred eighteen (118) terrestrial and 60 aquatic biological samples were collected from permanent bodies of water and contaminated land areas on-site, drainages, off-site bodies of water receiving drainage from the WSS, and background sites. Water and sediment samples were collected in coordination with biological samples to obtain correlative data on bioaccumulation.

The detailed analytical results of all biological samples taken by RETA are presented in the appendix to the Phase II report (RETA, 1977). The WSSRAP has been unable to locate this detailed data. A summary of that study is available in the Phase III report (RETA, 1978). The summary presents the general relationships between the contaminant levels in the food chain and the water bodies studied based on samples from the study. These relationships are roughly shown in Table 4-3. For comparative purposes, RETA listed numerical values indicating the ratio between the sample concentrations in a common unit, such as parts per million (ppm). As an arbitrary numeric value, an uranium concentration of 100 ppm in the sediment would suggest 1 ppm in water, 100 ppm in macrophyte roots, and 1 ppm in frogs. From these generalized relationships, it was evident during the sampling phase that there was no evidence of biomagnification of contaminants in these samples which are representative of the food-chain.

In 1983 and 1984, the Missouri Department of Conservation (MDOC)

collected samples of water, fish, and sediments from various water bodies near the WSS (deRoss, C. 1984). These locations were Lakes 9, 10, 34, 35, and 36, the Femme Osage Slough, and the Big Femme Osage Creek. Approximately ten fish (edible portions only) were composited per sample. Table 4-4 lists the results from the MDOC sampling effort for Lakes 34, 35, and 36, the Femme Osage Slough, and a background lake located north of Jefferson City, Missouri. Natural uranium concentrations in fish ranged from 0.002 to 0.06 pCi/g.

In 1985, an assessment was performed by Argonne National Laboratory (ANL) using the data from MDOC. In addition to the analytical data from the fish, the radiation doses received during recreational activities and from consuming the fish were assessed. Bioaccumulation factors were calculated by the WSSRAP from MDOC samples and analyses of routine water samples. The results ranged from 0.08 to 7.0 (uCi/kg wet weight to uCi/l in water). Higher bioaccumulation factors were seen for samples that were not filleted and submitted with bones in the sample.

Based upon measured concentrations of uranium in the water and fish tissue by MDOC, the detection limit of 0.01-0.05 pCi/g of natural uranium, Ra-226, Th-230, or Th-232 was chosen as an analytical detection limit goal. Also, the dose received under given assumptions by ingesting edible tissue at these concentrations was considered when choosing the detection limit. The radiation dose received by ingesting edible tissue at these concentrations is much less than 1.0 mrem/yr.

4.2 FACTORS INFLUENCING BIOACCUMULATION

The method used to determine bioaccumulation factors can have a significant influence on the calculated value. Although bioaccumulation factors are simple to calculate, compounded uncertainties can vary the results by several magnitudes.

Some of the factors responsible for this variation are:

- Physical state of the sample -- wet, dry or ash,
- Sampling variations,
- Analytical variations,
- Filtered vs unfiltered water,
- Tissue(s) being examined,
- Chemical state of the analyte,
- Habitat of the organism,
- Age and size of the organism, and
- Others.

Bioaccumulation factors are variously calculated using wet weight, dry weight, or ash weight of the biota. Conversion factors are available for converting dry weight to wet weight for most biota. Bioaccumulation factors based on dry weight are higher than those based on wet weight. The data based on samples collected for this study represent the wet weight of the biota.

Sampling and analytical errors can have significant influence in a sampling program. Laboratory error, number of samples, appropriate time scales for movement of biota, and acute releases of radionuclides into the environment are probably the greatest sources of error. The laboratory and sampling protocol used by the analyses herein are described in Section 3.

The use of filtered or unfiltered water samples in the analyses influences the bioaccumulation factor results. Since a

significant fraction of some elements in water may be in the suspended phase, bioaccumulation factors based on filtered samples may be much greater than those based on unfiltered samples. The water concentrations cited in this report represent unfiltered water samples.

The distribution of elements in tissues influences results. A reference to the specific tissue analyzed must be made because whole-body concentrations may be quite different than only muscle tissue concentrations. Tissues and organs have different metabolic requirements for certain elements. A description of samples submitted for analysis is presented in Section 3.

The chemical state of the radionuclide and the chemical composition of the water influence the bioaccumulation of the biota. Mineral content of the water, soluble forms, exchangeable sites, and stable states of the compound may influence the availabilities of contaminants to biota. Also, the location of water stratification and the nature of the habitat of the biota have effects. The feeding habits of an individual species may vary from ecosystem to ecosystem. Benthic feeding, changing food habits, age and size of biota, and seasonal variations of the habitat may have an impact on the data.

4.3 CALCULATED BIOACCUMULATION FACTORS

The bioaccumulation factor of an organism or tissue is the ratio of radionuclide concentration in the whole organism or tissue to that in water. The ratio of the equilibrium concentration of the assimilated nuclide in the organism or tissue to the average concentration of that nuclide in the water during the history of exposure is the theoretical bioaccumulation factor.

For the field study reported here, all analytical results for all radionuclides were less than the lower limit of detection.

Therefore, all calculated bioaccumulation factors represent a maximum which may be equal to or less than the numerical values indicated. A summary table (Table 4-5) presents the calculated maximum bioaccumulation factors for the WSS along with the model values (Gilbert, et al. 1985) and other values based on actual data (NCRP, 1984).

4.4 COMPARISON WITH STUDY RESULTS

The assimilation of an element by biota is calculated by using a single empirical relationship to represent the transfer of the element to an organism from consumption of contaminated foodstuffs and absorption of water. Calculated results from bioaccumulation factors published by the NCRP and Gilbert are compared with the experimental results from the current study. These results are listed in Table 4-6.

The current results, in general, indicate that maximum concentrations (i.e. at the lower limit of detection) are less than those calculated using the transfer factors provided by the Gilbert models. As indicated in the previous discussion, these models are conservative and are meant to be used as a guide for more complex calculational methodologies. Though no positive results were seen in the WSSRAP study, the limits of detection were well within the range of the values published by the NCRP and experimental values from the MDOC. Since the NCRP published complete data sets from biological studies, the current data seem to be more comparable to the values published by the NCRP than the model estimates.

5.0 CONCLUSIONS

This study was undertaken to determine the potential for biological uptake of contaminants either from, or related to, the WSS that may occur in the human food chain. It does not describe all possible bio-uptake routes in the complex aquatic and terrestrial food chains on or around the WSS.

Previous studies on the uptake of radioactive materials at the WSS were reviewed in Section 4. The RETA study conducted in 1978 was primarily a screening process to determine whether or not uptake of radioactive materials was taking place in selected organisms at or around the site. To accomplish this, the study examined a wide range of organisms and the organs and tissues of some animals. The results of that study indicate that measurable but very low levels of contamination were present. Many of the organisms and target organs examined in that study, however, would never significantly impact human health. For example, the RETA study looked for contamination by uranium, thorium and radium in algae, cattail roots, and arrowhead roots. Terrestrial organisms were also examined and low levels of uranium were found in smartweed, goldenrod and animal parts such as raccoon stomach, intestine contents, bones and kidneys. Slightly elevated uranium concentrations were also found in muskrat stomach contents. All positive results were at very low levels and in organs or organisms not considered part of the human diet.

In 1983-84, an additional study was conducted by the MDOC. The only organisms examined in this study were fish. Because the fish samples were filleted, it appears (though not stated in the report) that an attempt was being made to examine the impact of the fish upon the human population. Here, too, it was found that even though concentrations of radioactivity were detectable, these concentrations were very low.

The results of the MDOC study were later analyzed by Argonne National Laboratories to determine the amount of radioactivity that one could receive from eating fish from the area of the MDOC study. Calculations determined that if an individual ate the national average annual per-capita consumption of fish from these sources, the individual would receive only 1/1000 of the background level of radiation generally received by Missouri residents.

It is not surprising to find that the previous reports reviewed in Section 4 described low levels of contamination in some organisms. Plants or animals in intimate contact with the water and/or sludges in the raffinate pits, ash pond or other sites of known contamination generally will have slightly elevated levels of radioactivity caused by either primary or secondary contamination. Fish in some of the slightly contaminated lakes off-site also will acquire slight levels of radioactivity.

The most recent data collected for this report offer an advantage over the previous studies. The new data were acquired in compliance with the latest guidance for sampling and analysis, were handled according to the latest chain of custody requirements and were analyzed according to procedures and instruments that are more accurate than those of the former studies completed five and ten years ago, respectively. For these reasons, it is probable that the most recent data are a more accurate representation of the actual effects upon human health than were the data of former studies.

The following conclusions can be made:

- No significant biological uptake of radiological contaminants was detected in fish collected from the WSS or August A. Busch Wildlife Area, or the Weldon Spring Wildlife Area.

- Two conclusions on the chemical data can be drawn. The amount of bioaccumulation of metals from these lakes is generally small, and even these small variations are probably localized incidents. Other studies (Wixson, 1982) have shown similar low concentrations of chromium, arsenic, lead, and other metals in fish tissue at or slightly above the detection limits. In any case, concentrations of metals in fish tissues from this study are not believed to be due to contamination from the Weldon Spring Site.

- Bioaccumulation factors calculated using data from this study are low compared to factors developed from other investigations. Use of these other factors would result in a conservatively overestimated dose. However, exposures would still be negligible.

- No significant biological uptake of radiological contaminants was detected in small mammals collected from WSS.

- No PCBs were detected in any of the offsite fish samples collected.

APPENDIX A
QUALITY ASSURANCE

This study followed the same quality assurance (QA) guidelines set up for the Environmental Monitoring Program (US DOE, 1987c). However, no duplicate samples could be sent to the laboratory as a result of the small number of individual samples collected.

All samples were collected according to a site-specific sampling plan approved by EPA and DOE. These procedures were instituted to ensure consistency in sample collection. Samples sent to the laboratory were assigned unique identification numbers and documented by completion of chain-of-custody and laboratory authorization forms.

The laboratory receiving samples undergoes an EPA Laboratory Performance Evaluation and an internal laboratory evaluation annually. The laboratory also maintains an internal quality assurance program that involves routine instrument calibration, source and background counts, yield determinations, and replicate analyses to check precision.

AQUIFER CHARACTERISTICS DATA REPORT

This Aquifer Characteristics Data Report (ACDR) presents the results of investigations designed to physically characterize the hydrogeologic regime of the uppermost bedrock formation beneath the Weldon Spring Site chemical plant, raffinate pits, and vicinity properties (WSCP/RP/VP). Specifically, this report presents the results of slug tests and pumping and tracer testing. Slug tests and pumping tests were conducted as elements of hydrogeologic investigations sampling (MKF and JEG 1988b). Tracer tests were performed to complement physical aquifer characterization with respect to effective porosity and dispersivity.

The ACDR constitutes a portion of the Weldon Spring Site Remedial Action Project (WSSRAP) characterization program designed to support the Remedial Investigation/Feasibility Study (RI/FS) under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA).

If you have any questions please call Ken Lawver at (314)441-8978.

Sincerely,

Stephen H. McCracken
Project Manager
Weldon Spring Site
Remedial Action Project

Enclosure:
As stated

ABSTRACT

This report describes the procedures and methods used, and presents the results of physical testing performed, to characterize the hydraulic properties of the shallow Mississippian-Devonian aquifer beneath the Weldon Spring chemical plant, raffinate pits, and vicinity properties. The aquifer of concern is composed of saturated rocks of the Burlington-Keokuk Limestone which constitutes the upper portion of the Mississippian-Devonian aquifer. This aquifer is a heterogeneous anisotropic medium which can be described in terms of diffuse Darcian flow overlain by high porosity discrete flow zones and conduits. Average hydraulic conductivity for all wells tested is 9.6E-02 meters/day (3.1E-01 feet/day). High hydraulic conductivity values are representative of discrete flow in the fractured and weathered zones in the upper Burlington-Keokuk Limestone. They indicate heterogeneities within the Mississippian-Devonian aquifer. Aquifer heterogeneity in the horizontal plane is believed to be randomly distributed and is a function of fracture spacing, solution voids, and preglacial weathering phenomena. Relatively high hydraulic conductivities in deeper portions of the aquifer are thought to be due to the presence of widely spaced fractures.

Pumping tests conducted in the upper 12 meters (39 feet) of saturated bedrock provided values for transmissivity which ranged from 0.19 to 0.49 meters^2/day (15.5 to 39.9 gallons per day/foot). The average storativity determined from pumping tests is 4.9E-04. Results of pumping tests indicate a primary lateral anisotropy and poor hydraulic communication between pumped intervals and deeper portions of the Burlington-Keokuk Limestone. This suggests that appreciable upward leakage is unlikely from deeper portions of the aquifer to the test interval. Limited evidence of delayed yield may indicate double porosity effects.

Groundwater velocities average 1.1E-01 meters/day (3.6E-01 feet/day). Calculated groundwater velocities and travel times are consistent with observed contaminant distribution, although actual flowpaths are expected to exhibit nonlinear aspects resulting in significant variations in velocity.

Pumping and tracer tests did not intercept free flow zones, or conduits capable of supplying sustained pumpage in excess of 1.5 liters/minute (0.4 gallons/minute). However, slug testing indicates the existence of randomly distributed high porosity zones in the upper saturated portion of the formation. Additional pumping tests in these locations would provide information on discrete flow properties.

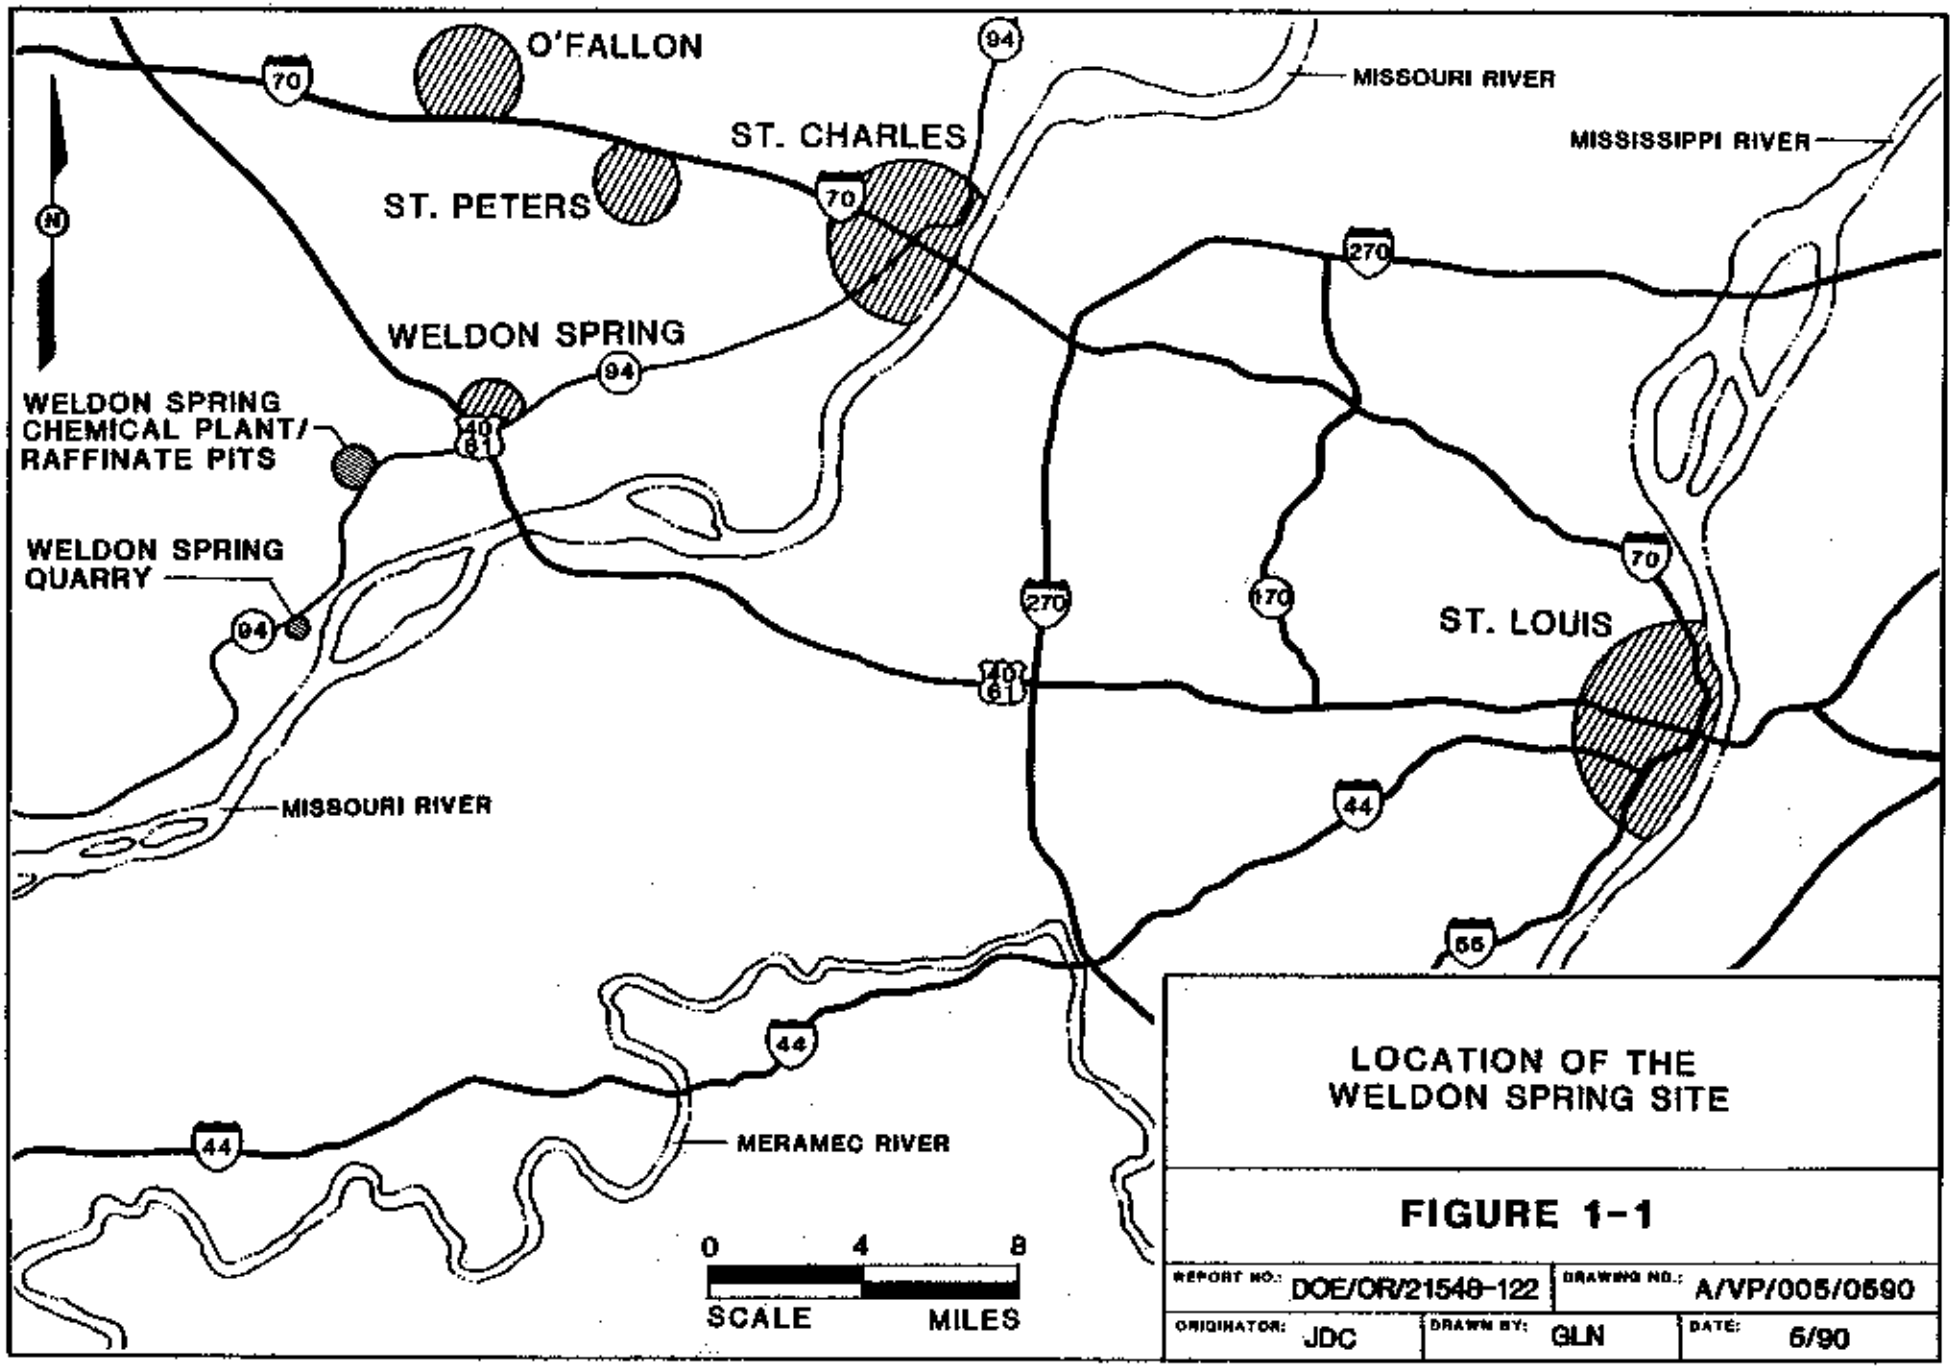
1 INTRODUCTION

This Aquifer Characteristics Data Report (ACDR) presents the results of investigations designed to physically characterize the hydrogeologic regime of the uppermost bedrock formation beneath the Weldon Spring Site chemical plant, raffinate pits, and vicinity properties (WSCP/RP/VP). Specifically, this report presents the results of slug tests and pumping and tracer testing. Slug tests and pumping tests were conducted as elements of hydrogeologic investigations sampling (MKF and JEG 1988b). Tracer tests were performed to complement physical aquifer characterization with respect to effective porosity and dispersivity.

The ACDR constitutes a portion of the Weldon Spring Site Remedial Action Project (WSSRAP) characterization program designed to support the Remedial Investigation/Feasibility Study (RI/FS) under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA).

1.1 Site Description

The chemical plant and raffinate pits are is located in St. Charles County, Missouri, approximately 48 km (30 mi) west of St. Louis and 23 km (14 mi) southwest of St. Charles as shown in Figure 1-1. The site is situated on Missouri State Highway 94 about 3 km (2 mi) southwest of the junction of Highway 94 with U.S. Routes 40 and 61. The site is surrounded by State and Federally owned lands. It is adjoined on the west by the Weldon Spring Training Area (WSTA) and on the east, north, and south by Missouri Department of Conservation (MDOC) lands.



LOCATION OF THE WELDON SPRING SITE

FIGURE 1-1

REPORT NO.: DOE/OR/21548-122	DRAWING NO.: A/VP/005/0590	
ORIGINATOR: JDC	DRAWN BY: GLN	DATE: 5/90

The community of Weldon Spring, with a population of approximately 700, is located approximately 3 km (2 mi) north of the Weldon Spring site (WSS). The metropolitan area of St. Louis, with a population exceeding 2.5 million, is within 48 km (30 mi) of the site.

1.2 Site History

The site history, including previous decontamination efforts from 1941 to 1987, is summarized below. A more detailed history of WSS operations is included in the WSSRAP Remedial Investigation/Feasibility Study Work Plan (ORNL 1988).

The land encompassing the WSS was privately held until April 1941 when the Department of the Army (DA) acquired 6,974 ha (17,232 ac) of land. From November 1941 through January 1944, Atlas Powder Company operated a trinitrotoluene (TNT) and dinitrotoluene (DNT) explosives production facility known as the Weldon Spring Ordnance Works (WSOW). After another production operation during 1945 and 1946 the WSOW was closed in April 1946 and declared surplus to Army needs. By 1949, all but approximately 809 ha (2,000 ac) had been transferred back to the State of Missouri (August A. Busch Memorial Wildlife Area) and the University of Missouri (agricultural land). Except for several small parcels of land transferred to St. Charles County, the remaining property became the WSTA.

Through a Memorandum of Understanding between the Secretary of the Army and the Atomic Energy Commission (AEC) in May 1955, 83 ha (205 ac) of the former WSOW were transferred to the AEC for the construction and operation of the Weldon Spring Uranium Feed Materials Plant (WSUFMP) to process uranium and thorium ore

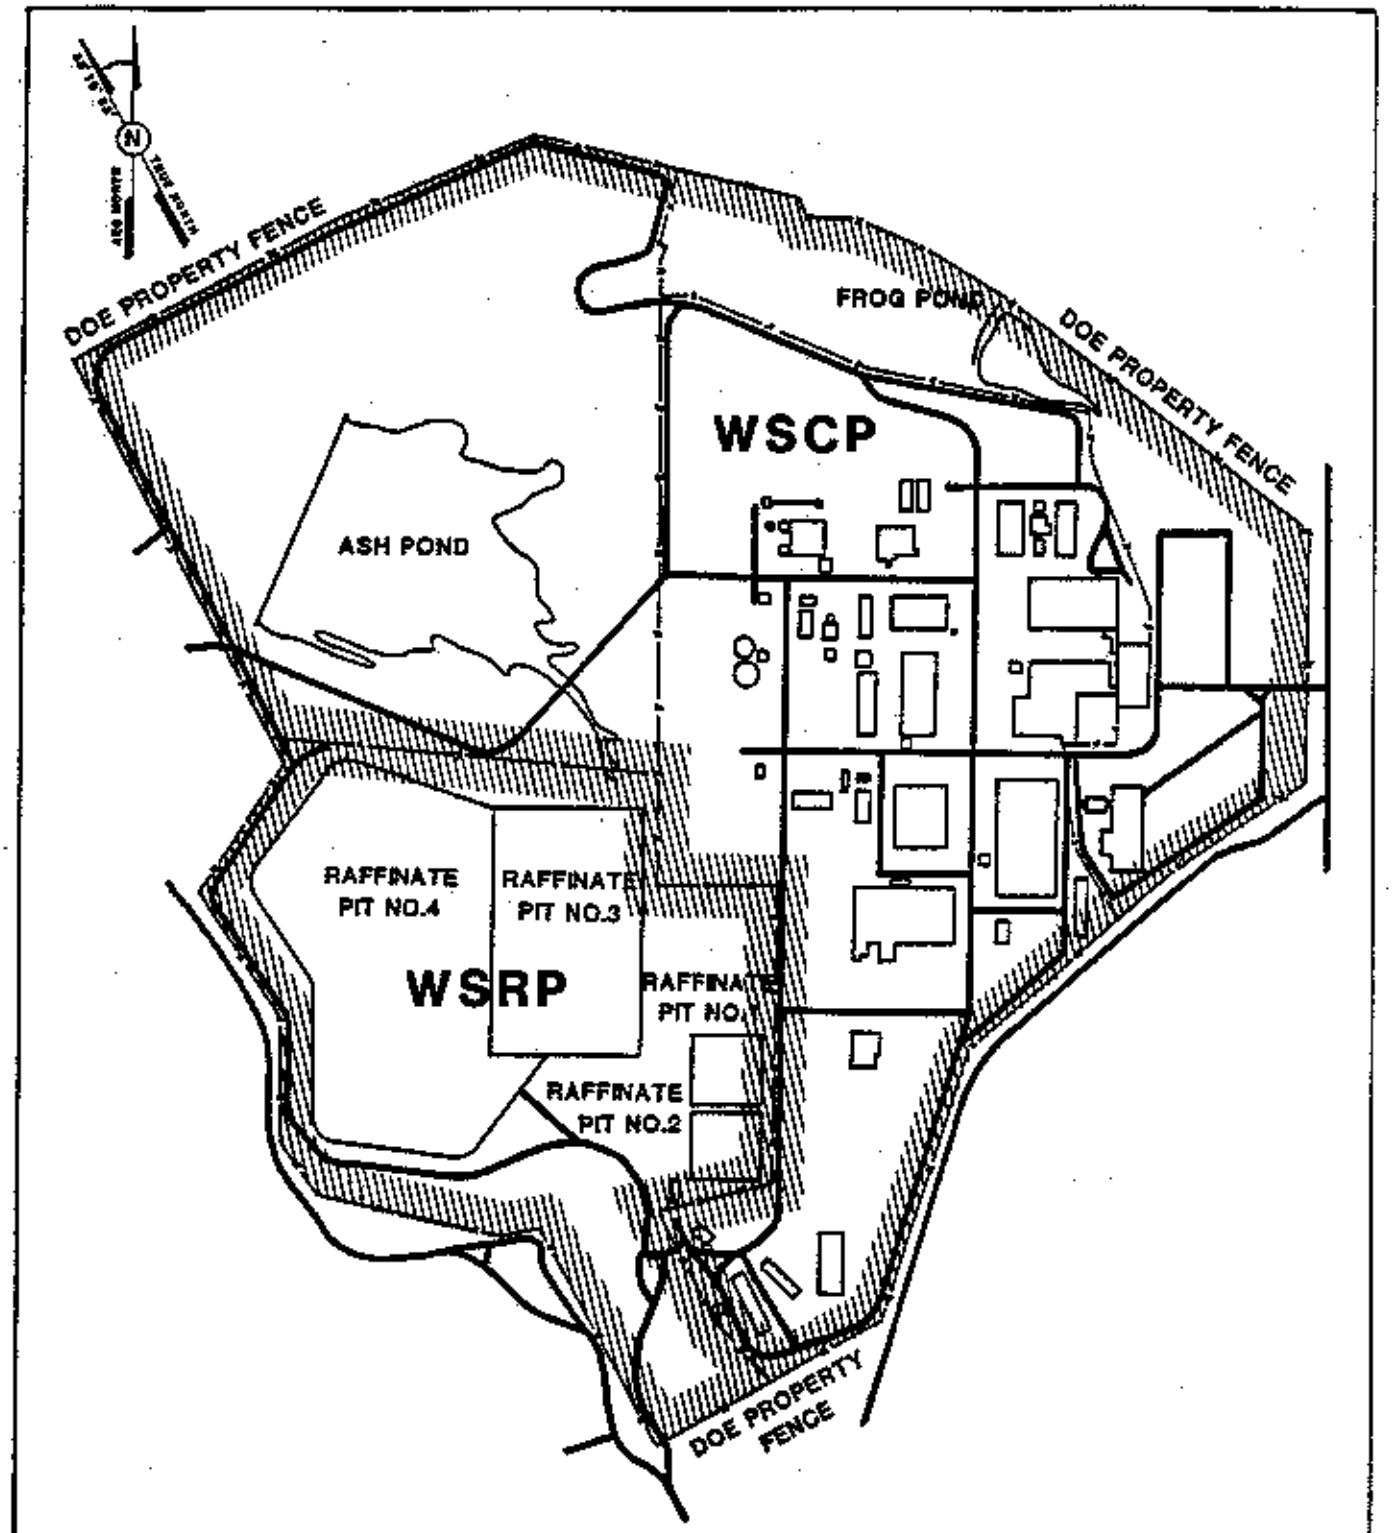
concentrates. The DA decontaminated a considerable portion of the WSOW before construction of the WSUFMP commenced (DA 1976).

The WSUFMP processed uranium and thorium ore concentrates from 1957 to 1966 with the Uranium Division of Mallinckrodt Chemical Works acting as the AEC operating contractor. This facility consisted of 13 major process buildings and approximately 30 support structures. The AEC closed the WSUFMP in December 1966.

On August 7, 1967, approximately 67 ha (166 ac) of the AEC facility were selected as the site for a herbicide production facility, later known as the Weldon Spring chemical plant (WSCP). The remaining 21-ha (51-ac) area, encompassing four process waste lagoons called the Weldon Spring raffinate pits (WSRP), remained under AEC control. Figure 1-2 is a site plan of the WSCP and WSRP. On December 31, 1967, 67 ha (166 ac) of property and improvements were transferred to the Kansas City District, U.S. Army Corps of Engineers, which was responsible for the design and construction of the herbicide facility.

Decontamination and dismantling operations were initiated in January 1968. Some progress was made in the decontamination of areas required for herbicide production equipment before the project was cancelled in February 1969. This cancellation was due in part to costs required to comply with the radiological contamination limits imposed on the facility and in part to a reduction of the DA's requirements for herbicide.

The herbicide project was cancelled before any production equipment was installed. However, the DA retained responsibility for the land and facilities at the WSCP.



MAP OF THE WSCP & WSRP

FIGURE 1-2

REPORT NO.: DOE/OR/21548-122	DRAWING NO.: A/CP/003/0590	
ORIGINATOR: JDC	DRAWN BY: GLN	DATE: 5/90

The AEC contracted with National Lead Company of Ohio (NLO) to visit the WSRP periodically for environmental monitoring and to maintain the pit embankments and perform maintenance and surveillance tasks as necessary. Bechtel National, Inc. (BNI) assumed management responsibility for the WSRP from NLO in October 1981 under contract to the U.S. Department of Energy (DOE) which succeeded the AEC.

In November 1984, the U.S. Department of Energy (DOE) was directed by the Office of Management and Budget to assume custody and accountability for the WSCP from the DA. This transfer occurred on October 1, 1985.

In February 1985, the DOE proposed designating control and decontamination of the WSS as a major project. Designation was effected by DOE Order 4240.1E dated May 14, 1985. A Project Management Contractor (PMC) for the WSSRAP was selected in February 1986. In July 1986, a DOE Project Office was established on site. The PMC, MK-Ferguson Company, assumed control of the WSS on October 1, 1986.

2 GEOLOGIC SETTING

This section presents background information on the regional and local geology based on information available from published reports, results of previous investigations, and data derived from Project Management Contractor (PMC) investigations.

2.1 Regional Physiography and Geology

The site lies at the southern edge of the dissected till plains of the Central Lowlands Physiographic Province, which is characterized by gently rolling hills in upland areas (ORNL 1988). South of the site, the topography changes dramatically as the dissected till plains give way to narrow ridges and valleys which characterize the Ozark Plateau Physiographic Province. The surface drainage divide between the Mississippi River to the north and the Missouri River to the south bisects the site from southwest to northeast.

The stratigraphy in the Weldon Spring area is composed of approximately 610 to 915 m (2,000 to 3,000 ft) of Paleozoic Era marine limestone, dolomite, sandstone, and shale. A detailed description of regional stratigraphy is given by BNI (1987) and MKF and JEG (1989b). The bedrock in the Weldon Spring area exhibits a regional strike of N601°W and a regional dip of approximately 1° to the northeast. Due to vertical crustal movements during the Paleozoic Era, rocks of the Central Stable Region, of which Missouri is a part, were deformed into broad basins and arches (Eardley 1951). The closest of these features, the northwest trending House Springs-Eureka anticline, is located about 6 km (4 mi) southwest of the site. The rocks on the northeast limb of the fold strike approximately N60°W and dip approximately 0.5° to 1° to the northeast.

Geologic mapping of the Weldon Spring 7.5-minute quadrangle by the Missouri Department of Natural Resources Division of Geology and Land Survey (MDNR-DGLS) shows an east-west trending normal fault located approximately 1.6 km (1 mile) north of the site. The fault is reported to display approximately 18 m (60 ft) of vertical displacement with the north block down (Whitfield et al. 1989).

2.2 Geology of the Weldon Spring Chemical Plant, Raffinate Pits, and Vicinity Properties

The Weldon Spring Chemical Plant/Raffinate Pits/Vicinity Properties (WSCP/RP/VP) extend over several distinct geologic units that are pertinent to this study. There are several distinguishable overburden units and two units in the uppermost bedrock. The following subsections describe the principal geologic units based on information contained in the Geologic Report on Weldon Spring Raffinate Pits Site (BNI 1984), Hydrogeological Characterization Report for Weldon Spring Chemical Plant (BNI 1987), and the Draft Remedial Investigation Report (MK-F and JEG 1989b).

2.2.1 Geology of Unconsolidated Material

Unconsolidated surficial materials at the site are composed of fill material, loess, interglacial sediment, glacial tills, and residuum. The thickness of the surficial units ranges from 5 to 18 m (15 to 60 ft) and is controlled both by surface erosional features and bedrock topography. The unconsolidated units are generally thickest in the north central portion and thinnest in the eastern third of the site. The unconsolidated materials have been divided into six distinguishable units based on physical

characteristics observed during sampling and laboratory testing (MK-F and JEG 1989b).

2.2.1.1 Topsoil/Fill

The uppermost soil unit is composed of topsoil or fill material. This unit ranges up to 9 m (30 ft) in thickness. The topsoil fraction is widespread on site and ranges up to 1 m (3.5 ft) in thickness. It is generally a black, organically rich clayey-silt to silty-clay. The fill portion of the unit varies greatly in thickness because of its use as construction material for the raffinate pit dikes and Ash Pond dike, and recontouring of low areas prior to construction of buildings. The fill composition varies but is primarily clayey silt which is believed to have originated on or near the site.

2.2.1.2 Loess

Underlying the topsoil/fill unit is an upper Pleistocene loess unit that is distributed sporadically on the site due to pre-depositional topography, post-depositional erosion, and extensive reworking of site soils during site preparation and construction. Subsurface data indicate that the loess ranges up to 3 m (10 ft) in thickness. The unit is a low plasticity silt to clayey silt with very minor amounts of sand.

2.2.1.3 Ferrelview Formation

A mid-Pleistocene interglacial sediment interpreted as being the Ferrelview Formation underlies the loess and is present across most of the site. The Ferrelview is described in detail by Howe and Heim (1968). The unit ranges up to 6.5 m (22 ft) in thickness and consists of a mottled gray and dark yellowish-

orange silty-clay to clayey-silt. The unit is generally stiff and plastic. Iron oxide nodules and manganese oxide (pyrolusite) precipitates are common. The unit commonly displays slickensides as a result of post-depositional compaction and consolidation. Also, irregular blocky fractures are sometimes encountered which continue through the underlying clay till. Blocky fractures are described as tight dry features which are often coated with calcium or manganese minerals of a powdery or concretionary nature. Laboratory tests for particle size distribution indicate mostly silt- and clay-sized particles in this unit with minor sand and fine gravel (MK-F and JEG 1989b).

2.2.1.4 Clay Till

The clay till unit is a lower Pleistocene glacial till which underlies the Ferrelview Formation and is the most areally extensive overburden unit on the site. The clay till ranges in thickness to 9 m (30 ft) and is found in almost all boreholes and trenches on site. This unit is composed of yellowish-brown silty-clay and clayey-silt with some sand and rounded pebbles of chert and igneous and metamorphic detritus. Material in this unit is very stiff and moderately to highly plastic. Blocky fractures coated with pyrolusite are abundant.

2.2.1.5 Basal Till

The basal till unit is the lowest member of the Pleistocene glacial till sediments found on the site. It underlies the clay till and is found mainly on the western and north central portions of the site. Deposition of the basal till unit may have been influenced by bedrock topography since the unit is generally thin or absent in areas of higher bedrock elevations, and is thicker where bedrock elevations are lower. The basal till

ranges in thickness up to 3 m (10 ft) and can generally be described as a yellowish-brown sandy, clayey, silty-gravel with angular chert in a poorly bound matrix.

2.2.1.6 Residuum

The residuum unit is located beneath the basal till and clay till unit where the basal till is absent. The residuum forms the base of the unconsolidated material and is interpreted to be a pre-Pleistocene weathering product of the underlying cherty argillaceous limestone. The unit varies in thickness up to 8 m (26 ft) and is highly heterogeneous, ranging from a typically gravel dominated matrix to a gravelly-clay to gravelly-silt. The gravel fraction is generally weathered chert fragments but also consists of minor weathered limestone. Sample recovery in this unit is very difficult due to the large gravel fraction. As such, the unit is hard to characterize without using in situ methods.

2.2.2 Bedrock Geology

The uppermost bedrock unit at the Weldon Spring site (WSS) is the Burlington- Keokuk Limestone. This is a fine- to coarse-grained, thinly to massively bedded argillaceous to crystalline limestone containing abundant chert as nodules and beds. From borehole stratigraphic data, the formation has been divided into two units based primarily on weathering characteristics. The upper division is referred to as the weathered limestone portion, and the lower division is referred to as the competent limestone.

Roberts (1951) reported two major joint sets present within the exposed bedrock in the Weldon Spring area; one set trends between N30°W and N65°W and the other set trends N30°E to N72°E.

Subsequent regional and site-specific joint studies have generally confirmed these orientations (BGA 1984, MK-F and JEG 1987 and 1988b). Bedrock topography exhibits erosional features interpreted as paleochannels, which coincide with observed joint set orientations (MKF and JEG 1989b). Additionally, present-day drainages within the Missouri River watershed are incised into bedrock and exhibit strong linearity coincident with joint set trends. Drainage trends within the Mississippi River watershed are more sinuous than those in the Missouri River watershed and do not exhibit linearity due to the presence of overlying, unconsolidated sediments.

2.2.2.1 Weathered Limestone

The weathered limestone ranges in thickness from 3 to greater than 15 m (10 to greater than 50 ft), and is typically a grayish-orange to yellowish gray, argillaceous limestone, commonly containing as much as 60% chert as nodules and interbeds. Minor interbeds of fossiliferous, finely crystalline limestone occur near the top of the unit in some cores. The unit is moderately to highly fractured, slightly to severely weathered, with abundant iron oxide staining and manganese oxide in the rock matrix and along fractures. Solution features are quite common in this unit, ranging from pinpoint vugs to small cavities up to 1.5 m (5 ft) in diameter (BNI 1987). Many of the smaller vugs are lined with calcite and drusy to euhedral quartz. The larger cavities in many cases appear to be at least partially filled with clay or silt/clay/chert/gravel mixtures. These cavities are generally reported as core loss in the boring logs. In some locations, recognition of top of bedrock was hindered due to alternating rock and clay-rich zones at or near the bedrock surface. Rock quality designations (RQD) are generally poor to very poor indicating a high degree of fracturing and/or

weathering. Core samples from angled boreholes indicate that fracturing in the weathered limestone is predominantly horizontal and loosely spaced, typically occurring along shaley interbeds, bedding planes, or chert interbeds (MK-F and JEG 1990b). Mineralization and clay deposition along fractures is common.

2.2.2.2 Competent Limestone

Underlying the weathered portion of the Burlington-Keokuk Limestone is the competent limestone, which is thinly to massively bedded, gray to light gray, finely to coarsely crystalline, stylolitic, and fossiliferous. The rock is slightly weathered to fresh, containing 20% to 40% chert. Cored material shows very little iron oxide staining and exhibits unaltered pyrite on some fracture surfaces. Both horizontal and vertical fracture densities are significantly lower in the competent limestone than in the weathered limestone (MK-F and JEG 1990b).

3 HYDROGEOLOGIC SETTING

This section presents background information on regional and local hydrogeology based on information available from published reports, results of previous investigations, and Project Management Contractor (PMC) derived data.

3.1 REGIONAL HYDROGEOLOGY

Three principal aquifer systems have been identified in the Weldon Spring area. These are the alluvial aquifers, the shallow bedrock aquifer system, and the deep bedrock aquifer system. Additionally, a leaky confining unit is recognized (Kleeschulte and Emmett 1987).

The major alluvial aquifers in western St. Charles County consist of saturated sands, gravels, and silts which compose the alluvium of the Missouri River and Mississippi River floodplains (Kleeschulte and Emmett 1986). Yields to wells from these aquifers range up to 9,800 lpm (2,600 gpm) along the major rivers (BNI 1987). Recharge to the alluvial aquifers occurs from infiltration of precipitation, increases in bank storage due to flooding, and as underflow in the form of regional discharge from bedrock aquifers. Fluvial recharge may also be induced in some locations due to pumping of large-capacity wells near the Missouri River (Kleeschulte and Emmett 1986).

The shallow bedrock aquifer system is composed of saturated Mississippian and Devonian aged rocks which range from 76 to 197 m (250 to 650 ft) in thickness and compose the uppermost bedrock units in the area. These units correspond to the Mississippian-Devonian aquifer system as depicted in Figure 3-1.

SYSTEM	SERIES	STRATIGRAPHIC UNIT	TYPICAL THICKNESS (ft)	LITHOLOGY	HYDROSTRATIGRAPHIC UNIT

GENERAL STRATIGRAPHY AND HYDROSTRATIGRAPHY OF THE WELDON SPRING AREA

FIGURE 3-1

REPORT NO: DOE/OR/21548-122	EXHIBIT NO.: A/PI/075/1190		
ORIGINATOR: JDC	DRAWN BY: GLN	DATE: 11/90	

In the Weldon Spring area the Mississippian-Devonian aquifer system includes formations from the Burlington-Keokuk Limestone through the lower part of the Sulphur Springs Group. Reported yields to wells from this aquifer range from less than 4 lpm to 190 lpm (1 gpm to 50 gpm) (BNI 1987), but typically are from 19 lpm to 55 lpm (5 to 15 gpm). The higher yield wells are those that intercept zones of extensive secondary porosity such as joints and solution openings. The Mississippian-Devonian aquifer system is recharged by direct infiltration of precipitation along fractures and bedding planes in outcrop areas, unsaturated flow through unconsolidated overburden, and losing stretches of streams encounter bedrock joints. Discharge occurs as springs, seeps, evapotranspiration, underflow to the deeper portions of the bedrock under downward hydraulic gradient conditions, and as water supply wells are pumped (Kleeschulte and Emmett 1986).

Examination of potentiometric data from the Weldon Spring area by Kleeschulte and Emmett (1987) indicates that a groundwater divide runs beneath the trend of the ridge which divides surface water drainage between the Missouri and Mississippi watersheds.

A leaky confining layer is present below the Mississippian-Devonian aquifer from the top of the Maquoketa Shale down through the Joachim Dolomite. These units correspond to the Ordovician leaky confining unit as depicted in Figure 3-1. Individual units or zones within the leaky confining layer may yield low to moderate amounts, 40 to 190 lpm (10 to 50 gpm), of potable water on a local basis. The confining sequence is approximately 121 m (400 ft) thick (Kleeschulte and Emmett 1986).

The Ordovician-Cambrian aquifer system is approximately 305 m (1,000 ft) thick and consists of Ordovician and Upper Cambrian formations, which include the St. Peter Sandstone through the Potosi Dolomite (Kleeschulte and Emmett 1987). These units correspond to the Ordovician-Cambrian aquifer system as depicted in Figure 3-1. Yields from this aquifer range from 40 to 1900 lpm (10 to 500 gpm) (BNI 1987). Recharge to the Ordovician-Cambrian aquifer occurs primarily as direct infiltration of precipitation where the Ordovician units outcrop southwest of the Weldon Spring area. Additionally, recharge occurs where losing stretches of streams penetrate the aquifer near the outcrop area, and as underflow from superjacent aquifers under conditions of downward hydraulic gradient. Discharge from the Ordovician-Cambrian aquifer occurs principally as underflow to the alluvial and Mississippian-Devonian aquifers under upward hydraulic gradient conditions, and as evapotranspiration and seepage to springs and streams where the aquifer crops out.

3.2 Hydrogeology of the Weldon Spring Chemical Plant/Raffinate Pits/Vicinity Properties

The following subsections provide background information about the hydrogeologic regime at the Weldon Spring site (WSS) based on information available from previous investigations.

3.2.1 Surface Water/Groundwater Interaction

Spring and seep surveys, seepage runs, and dye trace and water trace studies have been conducted in the area around the WSS by the Missouri Department of Natural Resources (MDNR) and U.S. Geological Survey (USGS).

The locations of known springs and seeps within various tributary drainage basins are shown on Figure 3-2. Springs in the vicinity of the site vary from small seeps at bedrock and clay interfaces to solution enlarged bedrock conduits and fractures having flow rates of 750 lpm (200 gpm) or more during precipitation events. Some of the springs are wet weather springs, flowing only in response to significant rainfall events. Wet weather flow may be quite heavy, but is usually of short duration (MKF and JEG 1988b).

Several tributaries around the WSS have losing segments which have been identified by the MDNR (Dean 1983, 1984a, 1984b, and 1985) and the USGS (Kleeschulte and Emmett 1986; Kleeschulte et al. 1986). The results of dye trace studies conducted by the MDNR in the 6000-series drainages (Mississippi River Basin) indicate a probable subsurface connection between the unnamed tributary of Schote Creek that drains Ash Pond and the raffinate pit areas and the Burgermeister Spring area. Results of dye trace studies conducted by the MDNR in the 5000-series drainages (Missouri River Basin) indicate that a groundwater divide exists north of the area, and water lost to the streambed in the southeast drainage easement stays within the drainage boundary. Furthermore, at least some of the flow lost in the upper reaches of the southeast drainage easement re-emerges through springs in the lower reaches (MDNR 1989).

3.2.2 Unconsolidated Materials

The unconsolidated materials at the site are, for the most part, unsaturated. Unsaturated flow is present locally as a result of direct infiltration, leakage from on-site storm water, sewer and water lines, and leakage from the raffinate pits. Saturated conditions also exist due to mounded and perched

SPRINGS AND SEEPS IN THE WELDON SPRING AREA

FIGURE 3-2

REPORT NO. DOE/OR/21548-122	EXHIBIT NO.: A/VP/053/1190	
ORIGINATOR: JDC	DRAWN BY: GLN	DATE: 11/90

groundwater. Mounded conditions are apparent beneath the raffinate pits due to leakage. Perched conditions occur where leakage or infiltration accumulates over low permeability clay-rich horizons and in discrete permeable lenses.

Hydraulic conductivities and moisture content values of unconsolidated materials as determined by laboratory methods are presented in the site Remedial Investigation (RI) report (MKF and JEG 1989b). The saturated hydraulic conductivity values are generally quite low. Slug tests were performed by the PMC in March 1987 on wells that monitor seasonally saturated portions of the clay till unit in the vicinity of the raffinate pits. The results of these tests indicate an average saturated hydraulic conductivity of 1.0E-05 m/d (3.4E-05 ft/d) for the clay till unit (Allan 1987). This value agrees well with laboratory test results presented in the site RI report (MKF and JEG 1989b).

Ten lysimeters are currently in place at three locations around the perimeter of the raffinate pits. The locations of the lysimeters are indicated in Figure 3-3. Lysimeters LY-3604, LY-3605, LY-3606, and LY-3607, located north of Raffinate Pit 3, monitor silty zones over clay layers. Soil moisture from this location is considered to be leakage from Raffinate Pit 3 due to the elevated concentrations of nitrate, sulfate, and total uranium detected in samples from that location. Lysimeters LY-3608, LY-3609, and LY-3610 are located near the northwest corner of Raffinate Pit 1. Lysimeter LY-3609 and LY-3610 have not detected any moisture since installation, although they maintain a vacuum. A sample taken from LY-3608 indicates that near surface moisture (1.7 m (6 ft) below ground surface) is leakage from Raffinate Pit 1 due to the high concentration of nitrate. Lysimeters LY-3601, LY-3602, and LY-3603 are located at the base of the west berm of Raffinate Pit 4 near a small seep. Analysis

of the seep water and soil moisture suggest that this seep is a local discharge for infiltration which is captured by the riprap on the west flank of the west berm of Raffinate Pit 4.

Previous exploratory drilling investigations at the WSS indicated areas of anomalously high groundwater elevations or perched groundwater in the vicinity of the raffinate pits (BGA 1984; BNI 1984; and UNC Geotech 1988). Details regarding monitoring efforts designed to characterize saturated conditions in the surficial soils are given in the site RI report.

Seismic refraction surveys performed by Weston Geophysical Corporation (BNI 1984) detected velocity zones of 1,515 m/s (5,000 ft/s) in the vicinity of Raffinate Pit 3 which may be indicative of saturated conditions. The geophysical data indicate that the subsurface soil beneath Raffinate Pit 3 may be saturated and that saturated soil may also be present beneath unsaturated materials on the east, west, and south sides of Raffinate Pit 3. Subsequent borings in the vicinity of the raffinate pits have confirmed that localized saturated conditions are present (MKF and JEG 1989b).

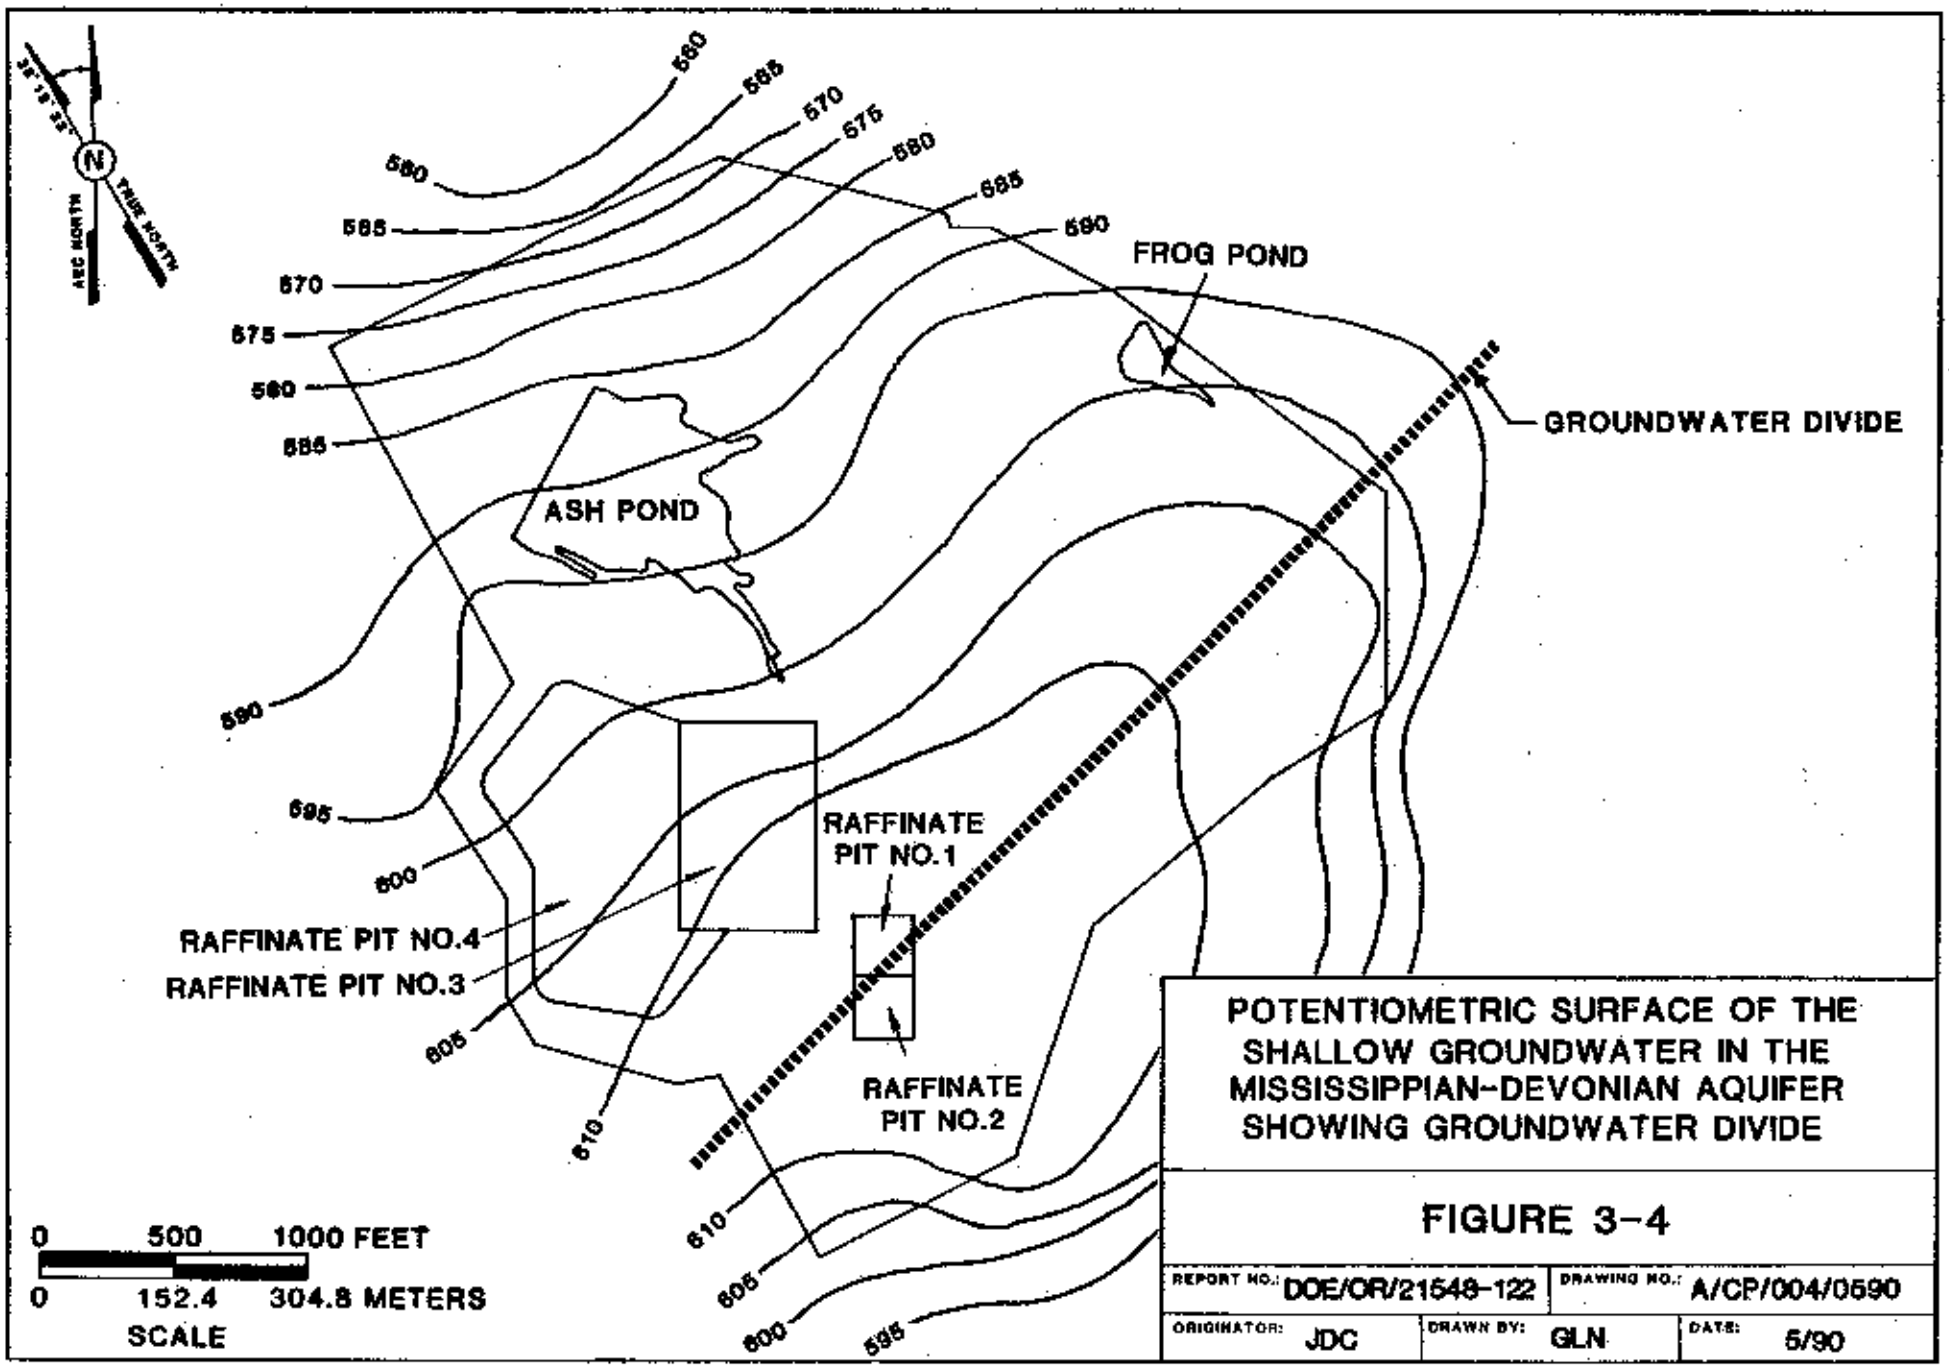
3.2.3 Mississippian-Devonian Aquifer System

The Mississippian-Devonian aquifer system is the uppermost aquifer present in the vicinity of the WSS. The upper portion of the aquifer consists of saturated rocks of the Burlington-Keokuk Limestone. As described in Section 3.1, this unit is subdivided on the basis of weathering in the vicinity of the site. At the WSS the lowermost unit in the Mississippian- Devonian aquifer system is the Bushberg Sandstone. Groundwater flow in the vicinity of the site is characterized by Darcian diffuse flow with conduit flow superimposed. The dynamics of groundwater flow

through the upper portion of the Mississippian-Devonian aquifer can best be described in terms of hydraulic head distribution. That is, groundwater flows from areas of high hydraulic head to areas of lower hydraulic head. Darcian principles may be applied to assess flow characteristics on a scale much larger than that of the spacing of individual fractures that have not been significantly enlarged by dissolution. Specific conduit flow pathways in the vicinity of the site have been defined from dye injection and water tracing performed by the MDNR (MDNR 1989).

Potentiometric data indicate the presence of a groundwater divide trending from the southwestern to northeastern portions of the site. Figure 3-4 is a potentiometric surface map based on data collected in December 1988 from shallow groundwater monitoring wells. Groundwater to the north of this divide flows northerly toward Dardenne Creek and groundwater to the south of the divide flows southerly toward the Missouri River.

Borehole packer testing of the saturated bedrock has revealed a general decrease in hydraulic conductivity with depth. Water quality data from the Weldon Spring chemical plant/ raffinate pits/vicinity properties (WSCP/RP/VP) monitoring well network indicate that although a downward hydraulic gradient exists between the shallower and deeper monitoring wells, the degree of communication is very limited (MKF and JEG 1989a). Contaminants detected in wells monitoring the shallower portion of the aquifer are generally present at lower concentrations or not at all in deeper monitoring wells. Vertical hydraulic conductivity is considered to be a function of vertical fracture spacing. Angle hole drilling indicates thatspacing of vertical fractures is sporadic, ranging from 0.75 m (2.5 ft) to 5.5 m (18 ft), and averages 3 m (10 ft). The ratio of horizontal to



POTENTIOMETRIC SURFACE OF THE SHALLOW GROUNDWATER IN THE MISSISSIPPIAN-DEVONIAN AQUIFER SHOWING GROUNDWATER DIVIDE

FIGURE 3-4

ORIGINATOR:	JDC	DRAWN BY:	GLN	DATE:	5/90

vertical fractures is approximately 20:1 or greater (MKF and JEG 1989b).

To provide insight into the degree of karst development and, consequently, the potential for conduit flow in the upper portion of the Mississippian-Devonian aquifer system, the following discussion of core recovery and drilling fluid loss is presented. Dissolution and weathering of the bedrock is indicated by poor core recovery in the upper 6 to 9 m (20 to 30 ft) of the bedrock in many locations; complete loss of circulation of drilling fluids during drilling of roughly half of the borings; dissolution features in cores; and low rock quality designation (RQD) values for the upper 3 to 15.25 m (10 to 50 ft) of bedrock cores (MKF and JEG 1990).

In general, core loss is concentrated in the top 6 to 9 m (20 to 30 ft) of bedrock with less than 1.5 m (5 ft) of core loss per boring. Notable exceptions include MW-4009 and MW-4010. MW-4009 experienced a total core loss of 7.6 m (24.9 ft) beginning at a depth of 17.1 m (56.2 ft) below ground surface and MW-4010 had 7.4 m (24.3 ft) of total core loss starting at a depth of 13.4-m (44 ft) below ground surface. These wells are located along the projection of the conduit traced from losing stream stretches that occur down-drainage from Ash Pond. A discussion of the effects of core loss and fluid loss during drilling is presented in the Report on Suitability of the Weldon Spring Site for Potential Location of a Disposal Facility (MKF and JEG 1990).

4 INVESTIGATION PROCEDURES

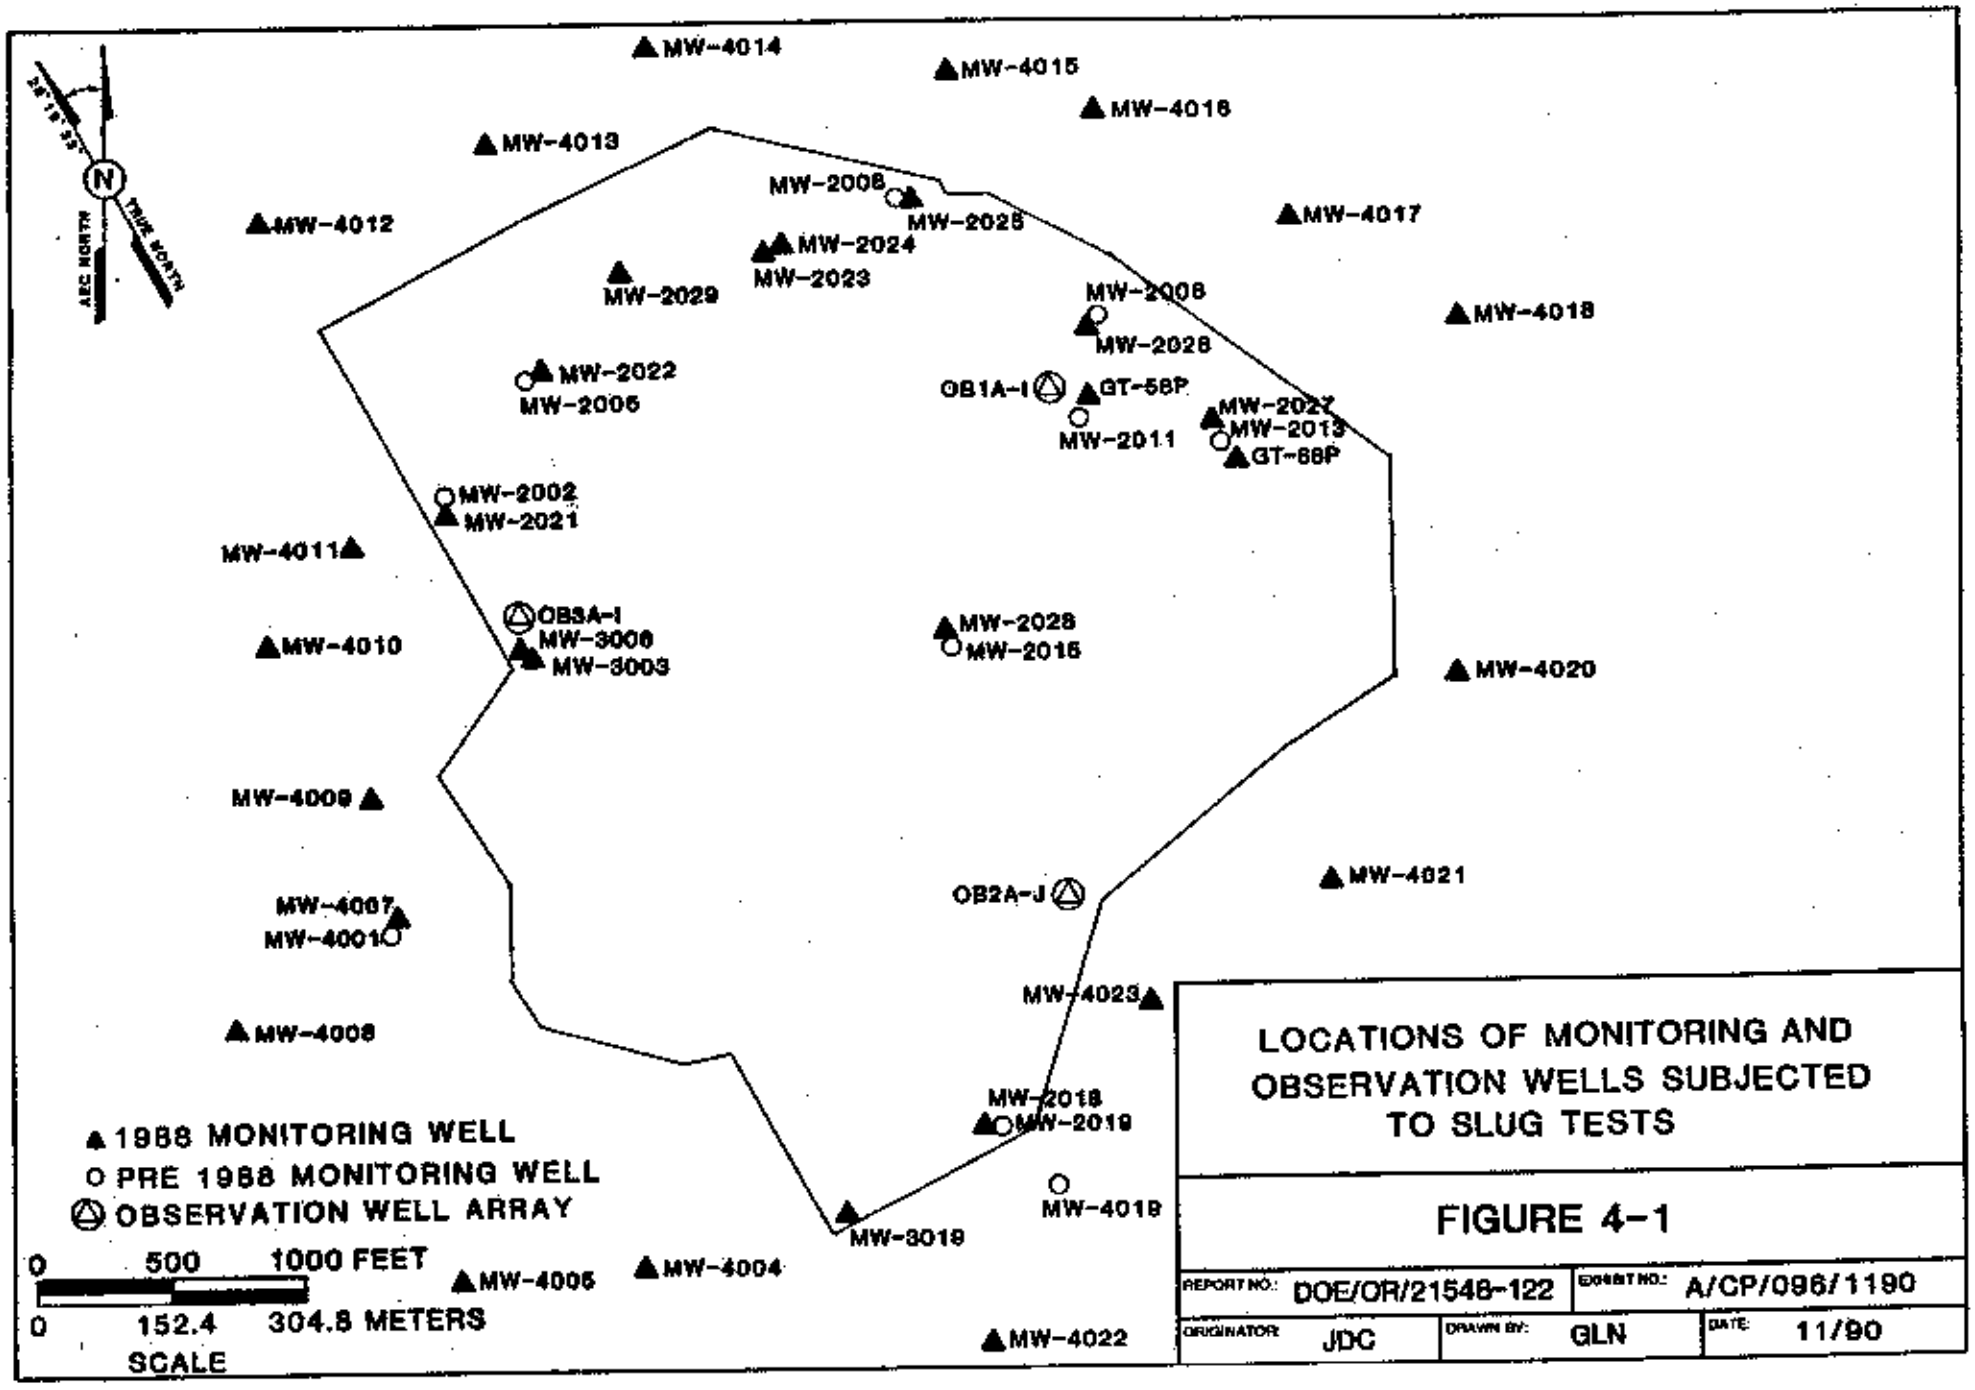
Three types of tests were performed to obtain the data included in this report: slug tests, pumping tests, and tracer tests. This section describes field procedures and the data management methods used for each type of test.

4.1 Slug Tests

Slug tests were performed on 39 monitoring wells, two geotechnical piezometers, and 28 observation wells between October 1988 and November 1989. The locations of wells and piezometers subjected to slug tests are presented in Figure 4-1. The testing was performed by Project Management Contractor (PMC) personnel in support of aquifer characterization efforts as detailed in the Hydrogeologic Investigations Sampling Plan (MKF and JEG 1988b). All of the wells selected for testing are screened within the Burlington-Keokuk Limestone which is the uppermost unit of the Mississippian-Devonian aquifer beneath the site. The results of these tests are expected to provide information on hydraulic conductivity and aquifer heterogeneity and anisotropy, and to complement pumping tests and water level and flow study data.

4.1.1 Field Procedures

Falling and rising head tests were conducted at each well using solid polyvinyl chloride (PVC) slugs attached to braided polypropylene rope. For 0.05 m (2 in.) inside diameter (ID) wells a 0.032 m (1.25 in.) diameter by 1.52 m (60 in.) long slug was used, and for 0.10 m (4 in.) ID wells a 0.076 m (3 in.) diameter by 1.52 m (60 in.) long slug was used. The 0.032 m



LOCATIONS OF MONITORING AND OBSERVATION WELLS SUBJECTED TO SLUG TESTS

FIGURE 4-1

ORIGINATOR: JDC	DRAWN BY: GLN	DATE: 11/90	

(1.25 in.) diameter slug created a vertical head displacement of approximately 0.61 m (2 ft) and the 0.076 m (3 in.) diameter slug created a vertical displacement of approximately 1.52 m (5 ft). Head data were collected using an Enviro-Labs Model DL-120-MCP programmable data logger equipped with a 0-to-25-pound/sq in. (psi) pressure transducer.

Well numbers, depths to static water level, pressure transducer installation depths, initial transducer heads, test types (rising or falling), and test times were recorded in the field log book by field personnel. Variable interval sampling frequencies were also developed and recorded in the field.

In general, tests were conducted as follows:

1. The depth to static water level was determined and recorded.

2. The pressure transducer was placed in the well to a depth of approximately 2.5 m (8 ft) or more below the static water level.

3. A falling head test was performed by simultaneously starting data acquisition (using the data logger) and quickly lowering the PVC slug within the well to a depth below the previously determined static water level. Data acquisition proceeded until transducer head values closely approximated pretest conditions.

4. After transducer head values indicated a return to static or near static conditions, a rising head test was conducted by simultaneously starting data acquisition and withdrawing the PVC slug, thereby causing an instantaneous decrease in the transducer head value.

5. Data acquisition proceeded until head values returned to static or near static conditions whereupon testing was terminated.

4.1.2 Data Management

All data were collected using the EL-120-MCP data logger and pressure transducer. Field data were periodically transferred to a portable computer for conversion to a LOTUS 1,2,3 compatible format using an Environ-Labs data conversion program. Individual test identification for data analysis was accomplished using HYCON, a LOTUS program developed at the Weldon Spring Site Remedial Action Project (WSSRAP) specifically for single well hydraulic conductivity data reduction and analysis.

4.2 Pumping Tests

The pumping tests were designed to provide data to be used in the calculation of the transmissivity, storativity, and areal anisotropy of the shallow bedrock aquifer beneath the Weldon Spring chemical plant and raffinate pits (WSCP/RP). Pumping tests began January 10, 1989 and continued through February 4, 1989. These tests were performed by Earth Scientists, Inc. of St. Louis, Missouri, on behalf of the PMC, at pumping and observation well networks installed specifically for performance of pumping tests. The locations of pumping and observation well networks are indicated in Figure 4-2.

The following subsections describe the rationale used to design testing, the procedures followed in the performance of the pumping tests, and the methods used to manage the data obtained during the testing.

4.2.1 Testing Rationale

As the pumping and observation wells were developed, step-drawdown pumping tests were performed. The results of these tests showed that it was likely that the pumping tests could be run concurrently to shorten the period of test performance. To monitor for possible interference between pumping wells, a staggered starting schedule was developed. According to the schedule, the initial pumping test would be run for a minimum of 48 hours. During that time, static water levels were observed so that any effects at other test locations could be identified. Assuming negligible effects at other locations, a concurrent pumping test could begin and the process could be repeated until completion of all testing.

Preliminary calculations indicated that up to 240 hours of pumping would be necessary at each pumping location to monitor potential effects of delayed yield under steady state conditions. However, contingency plans were made to end the pumping before this time limit if pumping could not be sustained. Maximum sustainable pumping rates were determined based on the results of step-drawdown pumping tests performed during well development.

4.2.2 Field Procedures

Before the first test was started, static water levels were observed to determine background conditions of the aquifer. Potentiometric observation began on January 10, 1989. Water level measurements were taken at two-hour intervals at the three pumping/observation well networks and selected monitoring wells near the pumping wells (Table 4-1). These measurements continued for approximately 96 hours.

During and after the testing, water levels were monitored at time intervals based on three schedules. These schedules are shown in Table 4-2.

Upon termination of pumping, recovery measurements were taken until the water level had returned to within 10% of the original static water level.

Water levels were monitored by two methods. The water levels in the pumping wells were monitored using pressure transducers. The information was recorded using data loggers manufactured by In Situ, Inc., Laramie, Wyoming. The electronic data were verified by obtaining water levels with an electric tape at periodic intervals. Electric tapes were also used to obtain all water levels in the observation and monitoring wells.

The pumping test at Well No. PW-2 began at 8:36 am, Friday, January 13, 1989 at a pumping rate of 1.5 lpm (0.4 gpm). Water level measurements continued at and around the other pumping locations. Pumping continued until 6:30 pm, Friday, January 20, 1989 -- a total of 178 hours. Pumping was terminated after the water level in the pumping well began dropping rapidly to near the level of the pump intake. Water level recovery was then monitored until 8:39 am, January 22, 1989, when the test was terminated.

The pumping test at Well No. PW-3 began at 1:42 pm, Wednesday, January 18, 1989 at a pumping rate of 1.1 lpm (0.3 gpm). Pumping continued until 10:25 am, January 26, 1989 -- a total of 189 hours. Pumping was terminated after the water level in the pumping well began dropping rapidly to near the level of the pump intake, approximately 36 hours after the well

reached steady state. After pumping, water level recovery was monitored until 9:23 am, January 30, 1989.

The pumping test at PW-1 began at 12:55 pm, January 24, 1989 at a pumping rate of 1.1 lpm (0.3 gpm). Pumping continued for the planned 240-hour duration until 1:13 pm, February 3, 1989. Water level recovery was monitored until 1:08 pm, February 4, 1989.

4.2.3 Data Management

Field measurements from the pumping tests included static water levels, pumping and recovery water levels, ambient air temperature, and barometric pressure. Barometric pressure and temperature were recorded from a mercury barometer and a thermometer at the pumping well.

All physical measurements collected by the subcontractor were recorded in field notebooks and were then transferred to LOTUS 123 spreadsheets. Calculations were made to convert the field elevations to elevations above mean sea level and to correct for changes in atmospheric pressure. The final data were then transmitted to the PMC in hardcopy and electronic form.

4.3 TRACER TESTS

The tracer tests were designed to aid in determining values of effective porosity and assessing dispersivity. The tracer tests were performed at the PW-2 and PW-3 networks. PW-1 was not considered suitable for tracer tests due to its susceptibility to freezing and proximity to known areas of nitroaromatic compound contamination. Figure 4-3 shows the location of the injection points at each test network. The following subsections describe

the procedures followed in the performance of the tests and the methods used to manage the data as it was collected.

4.3.1 Field Procedures

A converging-flow technique was selected in which an aliquot of conservative ion tracer solution was injected into observation wells and samples were collected from the pump discharge at preset intervals. Chloride and bromide salts were selected as tracers because they are environmentally safe, readily available, and could be easily analyzed on site at parts-per-million levels using a specific ion electrode. Tracers were prepared by dissolving 5 kg (11 lb) of potassium bromide or potassium chloride in 8-liters (2.1 gallons) of deionized water. Two tracer tests were conducted at each location using different ion solutions to determine effects of anisotropy on travel time. Preliminary estimates indicated that 100 to 150 hours would be required for the tracers to travel from the injection well to the pumping well under the anticipated pumping rates.

Samples were collected in 250 ml Nalgene bottles according to the schedule shown in Table 4-3. New bottles were obtained specifically for the tracer testing but were reused as necessary. Prior to each use, the bottles were triple-rinsed with deionized water and immediately before a sample was taken were triple-rinsed with water from the pump discharge. At each sampling time, a total of four samples was taken from each well. This gave duplicate samples for each tracer analysis.

Pumping for the tracer tests at PW-3 began at 3:45 pm, March 21, 1989. A saturated potassium chloride solution was injected into observation well OB3C on March 22 between 3:15 pm and

TABLE 4-3 Sampling Intervals During Tracer Testing

Time Since Tracer Injection (hours)	Time Interval Between Samples (hours)
0 - 24	No Samples Taken
24 - 96	4
96 - termination of test	2

4:20 pm. A saturated potassium bromide solution was injected into observation well OB3F between 4:40 pm and 4:55 pm. After the tracers were injected at each location, each injection well was surged with a bailer to mix the tracer within the water column. Then a total of 275 liters (73 gallons) of aquifer water from the pump discharge was injected incrementally as a "chaser" to drive the tracer into the formation. Sample collection at the pumping well began at 4:00 pm, March 22 and continued until the test was terminated at 4:40 pm, April 12.

Pumping for the tracer tests at PW-2 began at 4:40 pm, March 22, 1989. A saturated potassium chloride solution was injected into observation well OB2I on March 24 between 9:30 am and 9:50 am, and a saturated potassium bromide solution was injected into observation well OB2E between 2:30 pm and 2:42 pm. Surging and injection of chaser water followed the tracer injections in the same manner as at the PW-3 location. Sample collection at the pumping well began at 12:30 am, March 25 and continued until the test was terminated at 4:50 pm, April 12.

4.3.2 Data Management

The measurements taken during the tracer tests were the same as those taken during the pumping tests with the addition of tracer concentrations. The tracer concentrations were determined by analyzing the water samples taken from the pumping wells using specific-ion electrodes attached to an Orion meter. Meter calibration curves were generated using standards of 1 part per million (ppm), 10 ppm, and 100 ppm for bromide and 10 ppm, 100 ppm, and 1,000 ppm for chloride. The calibration curves and slope intercept equation were used to convert millivolt readings to parts per million.

5 METHODS OF ANALYSIS

Monitoring wells, pumping wells, and observation wells were utilized for aquifer testing at the Weldon Spring chemical plant/ raffinate pits/vicinity properties (WSCP/RP/VP) in support of the environmental documentation process. The primary objectives of testing were to define the hydraulic characteristics of the aquifer. This information will be of use in predicting contaminant migration and in assessing groundwater remediation alternatives. Slug tests were performed to provide information on areal variations in hydraulic conductivity in the uppermost aquifer. Pumping tests were performed to accurately determine transmissivity and specific yield and to allow assessment of the effects of pumping on groundwater flow patterns and contaminant levels. Tracer tests were performed to assess the effective porosity and dispersive properties of the formation. The methods of analysis used to evaluate the slug tests, pumping tests, and tracer tests are discussed in this section.

5.1 SLUG TESTS

Test data were analyzed using two analytical methods. A method developed by Hvorslev (1951) was used to determine hydraulic conductivity. This method allowed comparisons because it is widely used. A method developed by Bouwer and Rice (1976) was also used to derive hydraulic conductivity values.

Slug test head recovery data revealed three types of data configurations that required examination and editing prior to analysis. These data configurations were:

Harmonic distortion - This occurs when a pressure wave is created during slug deployment. Since the transducer used to collect

data converts pressure to hydrostatic head in units of length, the force of slug deployment results in variations in pressure (head) at the transducer. These variations may be either greater than or less than actual head differences due to differences in aquifer hydraulic conductivity. The pressure wave created during slug deployment was generally observed to dissipate within the first 5 to 10 seconds of the test. Harmonic distortion was easily recognized during data inspection because head values within the distorted data segment usually exceeded the possible range of head values caused by slug deployment. Data segments exhibiting harmonic distortion were not included during data analysis. The omission of early time data did not impact the quality of data analysis since early time data segments reflected filterpack influences in most cases.

Level shifts - Data sets that exhibited instantaneous (vertical) shifts in head level that were not consistent with the established recovery rate were examined. It was found that the vertical shifts always occurred at programmed changes in collection frequency. Level shifts were not common. Retesting usually yielded acceptable data; however, in a few cases, the data were smoothed manually to reflect the pre-shift and post-shift recovery rates.

Filterpack influence - Most tests exhibited a dramatic decrease in the rate of head recovery within the first 5 to 30 seconds of data recovery. The fast early time recovery rate is attributed to the permeability of the filterpack material surrounding the screen. These portions of the data are easily recognized upon inspection and were not utilized for data analysis.

5.1.1 Hvorslev Method

The Hvorslev method is the simplest interpretation of piezometer recovery data under unconfined conditions. The analysis assumes a homogeneous, isotropic medium of infinite vertical extent, where the medium and fluid are incompressible and the change in volume of fluid within the borehole is instantaneous.

In the Hvorslev method, linear regression is used on a plot of the log of the ratio of the difference in head at any time during the test to the head difference at the beginning of the test (ln [H-h/H-H0]) versus time to determine the basic time lag, T_o. Hvorslev defines T_o as the time required for equalization of the active head while maintaining the original rate of flow. Hydraulic conductivity is then expressed as follows:

$$K = \frac{r^2 \ln(L/R)}{2LT_o} \qquad (1)$$

where:

r = radius of the casing
L = length of the intake
R = radius of the borehole at the intake
T_o = basic time lag

The basic geometry and graphical determination of T_o for the Hvorslev method are presented in Figure 5-1.

5.1.2 Bouwer and Rice Method

The method developed by Bouwer and Rice is derived from a modification of the Thiem equation where:

$$Q = \frac{2\pi KLy}{\ln(R_e/r_w)} \qquad (2)$$

and the hydraulic conductivity is determined for an unconfined system by:

$$K = \frac{r_c^2 \ln(R_e/r_w) \ln(y_o/y_t)}{2Lt} \qquad (3)$$

where:

- K = hydraulic conductivity
- r_c = radius of well casing
- r_w = radius of borehole at the intake
- L = length of intake
- t = time
- R_e = effective radius over which y is dissipated
- y = the vertical distance between the water in the well at time zero (y_o) or any time during the test (y_t) and the potentiometric surface at equilibrium

Test geometry for the Bouwer and Rice analysis is illustrated in Figure 5-2.

The change in head, y, was plotted versus time, t, (see Figure 5-2) to determine the appropriate straight line portion of the data for analysis. Most of the data exhibited a double straight line effect wherein data within the first 5 to 7 seconds exhibited a sharp decline in head difference, followed by a flattening of the time-versus-head relationship. In all cases the second straight line portion of the data was considered to reflect aquifer response. The terms 1/t and y_o/y_t were determined graphically as suggested by Bouwer (1989). Data plots are contained in controlled files maintained at the WSS project office. The data files are available for review on request. The straight line data portions used for analysis typically encompass later time data (up to 780 seconds) than that addressed by Bouwer (1989) in his update. However, it should be kept in mind that head-recovery curves for low permeability aquifers seldom resemble the example data plots used to illustrate principles of hydraulic phenomena.

Head recovery data were considered to reflect conditions closely approximating a fully penetrating situation where D is effectively equal to the distance between the potentiometric surface and the bottom of the test interval (screen). Fully penetrating conditions were assumed due to a conceptual model of anisotropy within the Burlington-Keokuk where hydraulic conductivity in the horizontal planes (K_x and K_y) are considered to be much greater than hydraulic conductivity in the vertical plane (K_z).

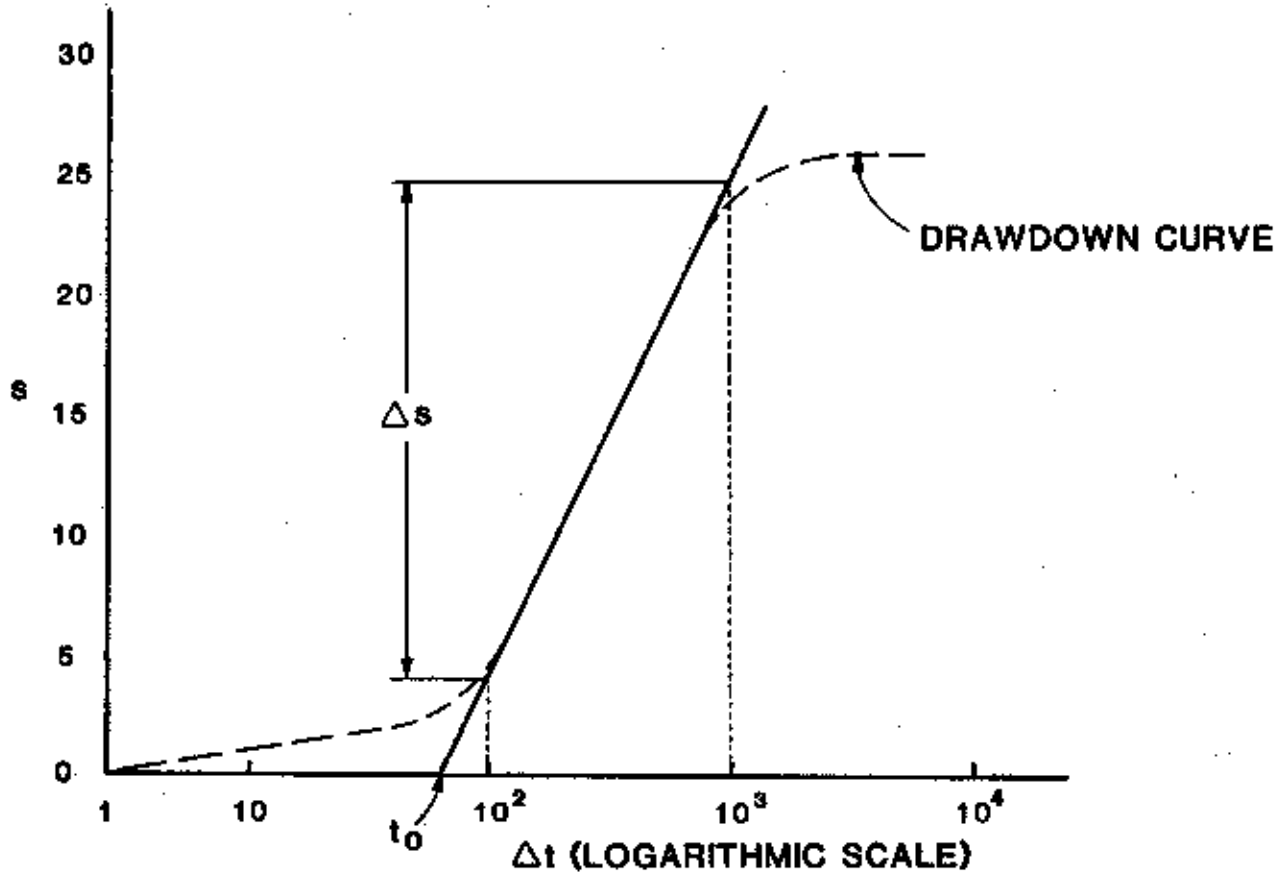
5.2 PUMPING TESTS

Pumping tests were designed to assess the reasonableness of the assumption that the shallow Mississippian-Devonian aquifer beneath the site can be modeled as an equivalent homogeneous porous medium exhibiting areal anisotropy in the horizontal plane.

Data obtained from the pumping tests were used to determine three properties of the upper portion of the Mississippian-Devonian aquifer beneath the WSCP/RP/VP: transmissivity, storativity, and lateral anisotropy. Values of transmissivity and storativity were obtained using the Cooper-Jacob (time-drawdown) semi-log method (Cooper and Jacob 1946). Anisotropy was determined using the Hantush method, which also yields values for transmissivity and storativity. Secondary objectives were to review the available data for evidence of other significant hydrologic phenomena, such as delayed yield due to gravity drainage, boundary effects, and leakage effects, which might provide insight into the presence and relative magnitude of double porosity as may be expected in an aquifer consisting of limited intergranular and fine fracture porosity coupled with larger aperture fractures and solution features.

In order to perform the Cooper-Jacob method, the data were plotted semi-logarithmically with drawdown on the y-axis and time plotted logarithmically on the x-axis. A line was then plotted through the straight line portion of the data and extended to find the intercept of the line of zero drawdown. Figure 5-3 is an example of the graphical determination of zero drawdown. The following equations were then applied.



EXAMPLE OF COOPER-JACOB GRAPHICAL METHOD OF PUMPING TEST ANALYSIS

FIGURE 5-3

REPORT NO.:	DOE/OR/21548-122	DRAWING NO.:	A/PI/013/0590		
ORIGINATOR:	JDC	DRAWN BY:	GLN	DATE:	5/90

$$T = 264Q/s \quad (4)$$

$$S = Tt_o/4800r^2 \quad (5)$$

where:

T = transmissivity (gpd/ft)
Q = pumping rate (gpm)
s = change in drawdown per log cycle (ft/cycle)
S = storativity (dimensionless)
t_o = x-intercept of straight line portion of curve (minutes)
r = distance from pumping well to observation well (ft)

The resulting values of T and S are average values for the formation in the area between the pumping well and the specific observation well. The values also overlap along the lines of the observation wells.

The Hantush method provides a measure of the lateral anisotropy of a formation. Intermediate steps in the method also provide storativity and minimum and maximum transmissivity values. A summary of the analysis follows (Hantush and Thomas 1966).

Values of transmissivity and storativity are obtained for each observation well using a standard technique, such as the Cooper-Jacob method. These values of transmissivity are then averaged to obtain an effective transmissivity, T_e, of the system. The drawdown values, s, at a given time, t_r, are then plotted, and for a given drawdown, an ellipse is contoured with major and minor axes, A and B, respectively. The orientation of the ellipse, Ø, can be found graphically (Figure 5-4). The principal values of the transmissivity in the major and minor

directions of the ellipse and the principal anisotropy can then be found from the following set of equations:

$$T_{max} = (a/b)T_e \quad (6)$$

$$T_{min} = (b/a)T_e \quad (7)$$

$$S = (4T_e t_f/ab)W^{-1}(4T_e s/Q) \quad (8)$$

$$\text{Principal Anisotropy} = T_{max}/T_{min} \quad (9)$$

where:

T_{max} = maximum transmissivity
T_{min} = minimum transmissivity
W^{-1} = inverse well function
Q = pumping rate

5.3 TRACER TESTS

Data obtained from the tracer tests were used to assess the effective porosity and dispersivity of the formation. Determination of the effective porosity was made using Darcy's law and the dispersivity was found by first using a common transport equation to find the hydrodynamic dispersion and then solving a direct relationship between hydrodynamic dispersion and dispersivity.

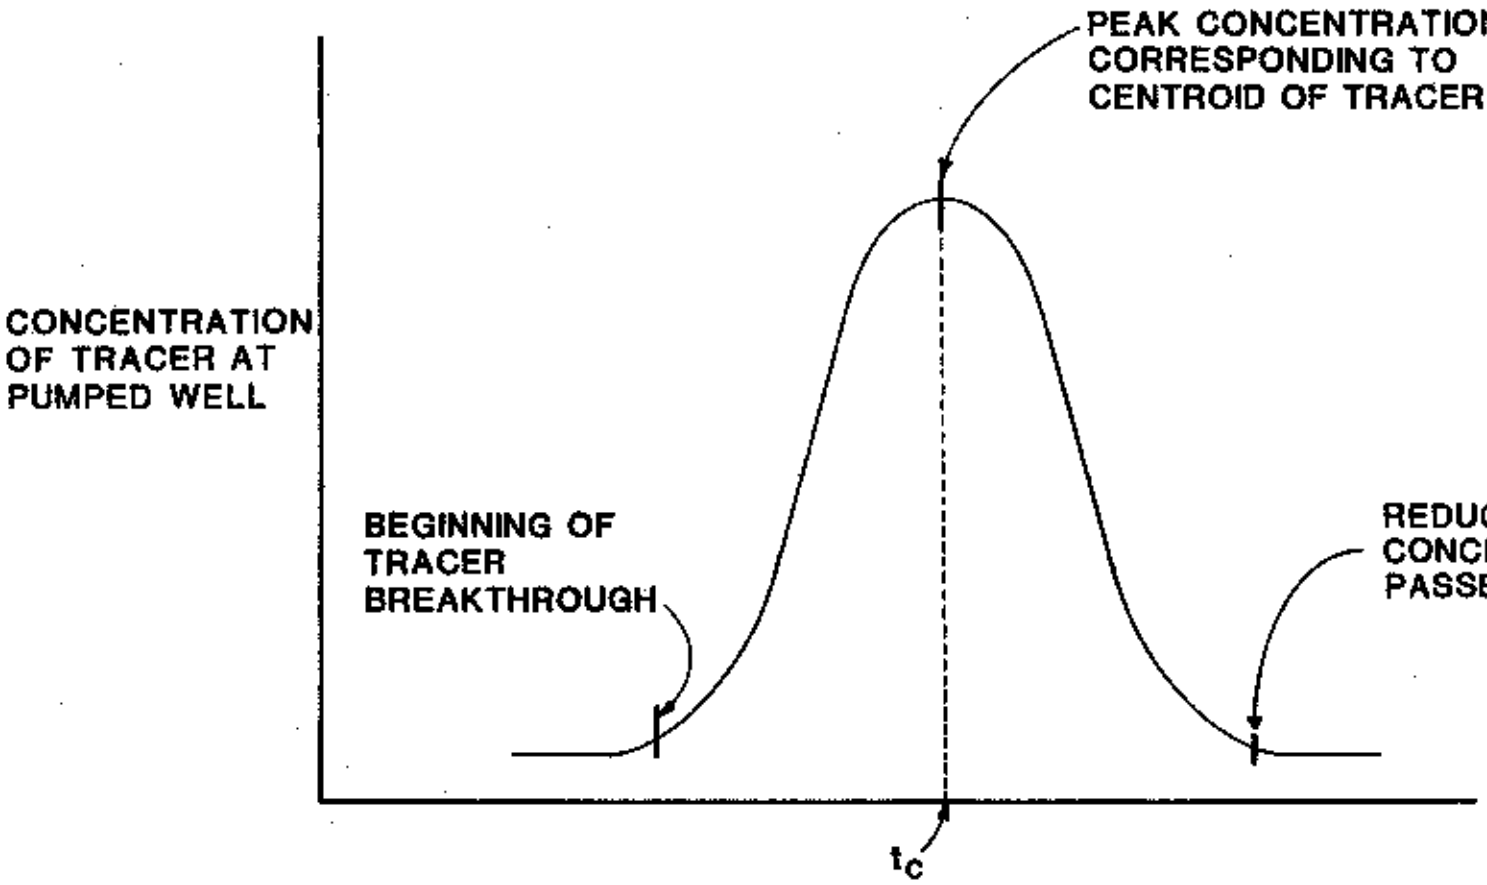
Darcy's law states that the specific discharge per unit area, q, of a formation is the product of the hydraulic conductivity, K, of the formation and the hydraulic gradient, i, across the formation. In order to obtain the effective porosity, n, the relationship $q = vn$, where v is the average linear velocity of the groundwater, must be substituted into Darcy's equation.

The hydraulic conductivity of the formation along the path of the tracer was found by dividing the transmissivity by the saturated thickness. In this case, the saturated thickness was taken to be the screened interval of the wells (40 feet). Equating saturated thickness to the screened interval is justified by the relative lack of vertical flow observed in the system (BNI 1987 and MKF and JEG 1989b). The transmissivity values that were used were estimated from the ellipses obtained in the Hantush analysis. The average hydraulic gradient between the injection well and pumping well, which is the value used in the calculation of effective porosity, is found by dividing the difference in hydraulic head between the injection and pumping wells by the distance between the two wells. Chloride and bromide ions are very conservative tracers, and therefore can be assumed to travel at the same velocity as the groundwater. Consequently, the average linear velocity can be determined by examining the breakthrough times of the tracers (Figure 5-5).

In order to find the dispersivity of the formation, the hydrodynamic dispersion, D_x, must first be determined. Hydrodynamic dispersion is found using the following transport equation (Bear 1972):

$$CA = \frac{M/n}{(4\pi D_x t)^{1/2}} \exp\left(\frac{(-x-Vt/n)^2}{4D_x t}\right) \qquad (10)$$

where: C = tracer concentration in sample
A = cross sectional area which the tracer originally occupies
M = original tracer mass
n = effective porosity of the formation
D_x = hydrodynamic dispersion



EXAMPLE OF TRACER BREAKTHROUGH CURVE FOR DETERMINATION OF AVERAGE LINEAR GROUNDWATER VELOCITY

FIGURE 5-5

REPORT NO.:	DOE/OR/21548-122	DRAWING NO.:	A/PI/015/0590		
ORIGINATOR:	JDC	DRAWN BY:	GLN	DATE:	5/90

t_c = ARRIVAL TIME OF CENTROID

t = time at which concentration, C, is determined

x = distance that tracer travels

v = average linear velocity of the groundwater

This equation is then rearranged to the form:

$$\frac{1}{D_x} \ln \frac{(M/n)}{(4\pi D_x t)^{1/2}} = - \frac{4t \ln(CA)}{(x-vt/n)^2} \qquad (11)$$

and D_x is found through iterative solutions of the equation.

Dispersivity is related to the hydrodynamic dispersion by the equation:

$$D_x = V\alpha_x + D^* \qquad (12)$$

where:

α_x = dispersivity

D^* = coefficient of molecular diffusion

Because the coefficient of molecular diffusion is several orders of magnitude smaller than the other terms, on the order of 10^{-10} (Freeze and Cherry 1979), it can be considered negligible and therefore can be omitted from the equation. Then, rearranging the resulting equation, dispersivity equals the coefficient of molecular diffusion divided by the average linear velocity.

6 RESULTS AND DISCUSSION

In the following sections the results of the slug tests, pumping tests, and tracer tests are presented and discussed.

6.1 Slug Tests

Statistical analyses of slug test results were performed to facilitate presentation of results. Figure 6-1 shows the distribution of results of slug test data analyzed by the Bouwer and Rice method for all monitoring wells and piezometers tested. Values for each observation well network are average values of all observation wells tested at each network location. A frequency histogram and summary statistics for all wells tested are presented in Figure 6-2. Individual slug test data for all wells tested are contained in controlled files maintained at the project office.

6.1.1 Monitoring Wells and Piezometers

Table 6-1 presents hydraulic conductivity values obtained by the Hvorslev and Bouwer and Rice methods for all monitoring wells and piezometers tested. Monitoring well designations are denoted by a MW prefix followed by a four-digit number, and piezometers are denoted by a GT prefix followed by a two-digit number and a P suffix.

Analysis by the Hvorslev method yielded results which ranged from a high of 1.4 m/d (5.3E-05 ft/s) for MW-4014 to a low of 1.4E-03 m/d (5.35E-08 ft/s) for MW-4011. A frequency histogram and summary statistics are provided in Figure 6-3.

FREQUENCY HISTOGRAM AND SUMMARY STATISTICS OF SLUG TEST RESULTS FOR MONITORING WELLS AND PIEZOMETERS (METERS/DAY)

FIGURE 6-3

REPORT NO.: DOE/OR/21548-122	DRAWING NO.: A/PI/017/0590	
ORIGINATOR: JDC	DRAWN BY: GLN	DATE: 5/90

Analysis by the Bouwer and Rice method yielded results which ranged from a high of 3.9 m/d (1.5E-04 ft/s) for GT-58P to a low of 1.5E-03 m/d (5.7E-08 ft/s) for MW-2029 and MW-4011. Summary statistics and a frequency histogram are presented in Figure 6-3. Data from piezometer GT58P was not suitable for analysis using the Hvorslev technique due to almost instantaneous equalization of that portion of the active head required for determination of the basic time lag. Use of a potable water slug to create a larger head displacement would probably eliminate this effect.

6.1.2 Observation Wells

Table 6-2 presents values obtained by Hvorslev and Bouwer and Rice methods for all observation wells tested. As with the monitoring well and piezometer data, values are either a mean or single test value depending on the integrity of the test data. Analysis by the Hvorslev method yielded results ranging from a maximum of 1.0E-01 m/d (3.8E-06 ft/s) for OB2I to a minimum of 8.1E-03 m/d (3.1E-07 ft/s) for OB2J.

Analysis by the Bouwer and Rice method yielded results ranging from a maximum of 4.4E-02 m/d (1.7E-06 ft/s) for OB3I and a minimum of 6.5E-03 m/d (2.5E-07 ft/s) for OB2J. Frequency histograms and summary statistics are presented in Figure 6-4.

6.1.3 Discussion

Calculated hydraulic conductivity values were compared by dividing the value obtained using the Hvorslev Method with the value obtained using the Bouwer and Rice Method. Ratios of Hvorslev to Bouwer and Rice values average 1.6 and range from 0.05 to 16.94. Individual ratios are included in Table 6-1.

Values for test data analyzed by the Bouwer and Rice method are generally lower than values determined by the Hvorslev method. This is because the Hvorslev method assumes that the effective radius of influence for the test (i.e. the radius over which head loss or gain is dissipated) is equal to the distance from the bottom of the well to the potentiometric surface. Bouwer and Rice determined a method of calculating the effective radius of influence, R_e, from equation (1) based on an electrical resistance network analog for different test geometries with the assumption that drawdown of the water table around the well is negligible, that capillary drainage can be ignored, head losses as water enters the well (well losses) are negligible, and the aquifer is homogeneous and isotropic (Bouwer and Rice 1976). With this in mind, the Bouwer and Rice method was used to analyze all data because it is considered to more closely simulate test conditions. The Hvorslev technique was also used because it is widely used, hence levels itself to comparisons with other data.

Analysis of slug test recovery data using the Bouwer and Rice Method was performed in general accordance with guidance supplied by Bouwer and Rice (1976) and Bouwer (1989). However, late time data was included in many cases so that it may appear that the data are not being treated in the manner prescribed by Bouwer and Rice, who suggest using straight line portions of the data which, in the examples, are displayed in early portions of the head recovery curve.

It should be noted that the examples in the literature are based on alluvial aquifer conditions where recovery occurs relatively rapidly, while conditions beneath the Weldon Spring site (WSS) more closely resemble aquitard properties in many instances. Almost all data exhibited fairly rapid early time recovery, which is considered to be indicative of filterpack or

annular influence. Future tests could use a potable water slug in order to minimize the effect of annular influence on recovery data. A water slug could be used to perform a falling head test by filling the well to the top of the casing with potable water. The active head would then be on the order of tens of feet rather than 2 to 5 feet. The larger active head would effectively exceed annular influence capacity (filterpack, developed zone), whereas most of the smaller active head (induced by relatively small solid slugs) is rapidly transmitted to the higher permeability filterpack and developed zone.

Figure 6-5 is a plot of the depth of the screened (mid-screen) interval below the top of bedrock on the vertical axis and hydraulic conductivity values increasing to the right on the horizontal axis. Plotted values are from all wells and were analyzed using the Bouwer and Rice method. The plot does not indicate any observable trend in hydraulic conductivity with respect to the depth of the screened interval below the top of bedrock. Hydraulic conductivity for MW-3006, one of the deepest wells tested, was significantly greater than the average and is probably a result of water-filled fractures at depth, as noted on the drilling log. Geochemical and contaminant data may be useful in determining whether water in this well is more like water in shallow wells than water in other deep wells.

While the lack of an observable trend with respect to the vertical distribution of hydraulic conductivity may seem to conflict with previous observations regarding a general decrease in hydraulic conductivity with increasing depth (BNI 1987), it should be noted that Bechtel conducted borehole permeability testing of both the unsaturated and saturated portions of the Burlington-Keokuk. It is well documented that the upper highly

weathered portion of the bedrock is a zone of poor core recovery and frequent drilling fluid loss which is indicative of highly porous material (MKF and JEG 1990). However, this portion of the bedrock is generally not included in the slug test data due to the usually unsaturated nature of the high porosity zones. Possible exceptions to this are GT-58P and MW-4014, which are considered to reflect saturated conditions within the weathered bedrock. The values for these wells compare favorably with values reported by Bechtel for the unsaturated bedrock.

Drilling logs from these locations note loss of circulation, bit drop, and core loss during drilling. MW-4014 was injected with one pound of pyranine on July 1, 1988 as part of the Missouri Department of Natural Resources (MDNR) dye tracing program. The tracer was not detected at any of the sampling locations as of December 1988. However, the amount of dye used for the injection may have been insufficient to produce a positive detection. Based on slug test results as well as core loss, fluid loss during drilling, and quick recovery during development and purging for groundwater sampling, the hydraulic conductivities of these wells are considered to be typical of saturated portions of the upper weathered Burlington-Keokuk Limestone.

Slug test values for the observation well networks did not reveal any heterogeneities such as those discussed above. This is probably due to the fact that the highly weathered upper portion of the Burlington-Keokuk is not saturated in the vicinity of the observation well networks. Results of pumping conducted at the PW-3 network suggest that OB3I may not be functional due to lack of drawdown. However, slug tests performed on this well did not indicate poor hydraulic function of the well.

6.2 Pumping Tests

The following subsections present the results of pumping test data analyses. Transmissivity and storativity were determined using the Cooper-Jacob method. The Hantush method was used to determine anisotropy, transmissivity, and storativity. Additionally, hydraulic conductivity was calculated from pumping test data for correlation with slug test results.

6.2.1 PW-1 Results

All of the observation wells in the PW-1 network responded to pumping of PW-1. Data from these wells and PW-1 provided 10 sets of data for analysis. Figure 6-6 shows a summary of these results.

The values of transmissivity and storativity that were obtained using the Cooper-Jacob method are presented in Table 6-3. The values of transmissivity range from 3.6E-02 m^2/d (2.9 gpd/ft) to 5.8E-01 m^2/d (46.6 gpd/ft) with a mean of 2.0E-01 m^2/d (16.3 gpd/ft) and storativity values range from 1E-4 to 6.8E-04 with a mean of 2.9E-4. The Hantush method provided maximum and minimum values of transmissivity around PW-1 equal to 3.5E-01 m^2/d (28.4 gpd/ft) and 1.8E-01 m^2/d (14.4 gpd/ft), respectively, and a mean storativity of 1.7E-4.

Analysis using the Hantush method indicates the maximum transmissivity has a bearing of approximately N72°W. Comparingthe maximum and minimum transmissivities, it is apparent that the anisotropy ratio is approximately 2:1.

* To convert transmissivity values from square meters per day (m^2/d) to gallons per day per foot (gpd/ft) multiply by 80.5.

** To convert hydraulic conductivity from meters per day (m/d) to feet per day (ft/d) multiply by 3.28.

Hydraulic conductivity values calculated from pumping and recovery data for the PW-1 array averaged 2.3E-02 m/d and 1.2E-02 m/d respectively.

6.2.2 PW-2 Results

Nine of the observation wells in the PW-2 network responded to the pumping of PW-2. Data from these wells and PW-2 provided 10 sets of data for analysis. Figure 6-6 summarizes these results. Deep observation well OB-2J (screened from 39.6-42.7 m [130-140 ft.]), at the PW-2 array did not respond to the pumping of PW-2.

The values of transmissivity and storativity obtained using the Cooper-Jacobs method are presented in Table 6-3. The values of transmissivity range from 2.8E-02 m^2/d (2.3 gpd/ft) to 8.7E-01 m^2/d (70.4 gpd/ft) with a mean of 4.9E-01 m^2/d (39.9 gpd/ft) and storativity values range from 3.3E-4 to 1.8E-3 with a mean of 8.1E-4. The Hantush method provided maximum and minimum values of transmissivity around PW-2 equal to 9.0E-01 m^2/d (72.4 gpd/ft) and 2.5E-01 m^2/d (20.5 gpd/ft), respectively, and an overall storativity of 1.3E-3.

Analyses using the Hantush method indicate the maximum transmissivity has a bearing of approximately N101°W. Comparing the maximum and minimum transmissivities, it is apparent that the anisotropy ratio is approximately 3.5:1.

Hydraulic conductivity values calculated from pumping and recovery data using the pumping and observation wells at the PW-2 location averaged 4.9E-02 m/d for pumping data and 3.3E-02 m/d for recovery data.

6.2.3 PW-3 Results

Eight of the nine observation wells at the PW-3 network responded to the pumping of PW-3. Data from these wells and PW-3 provided nine sets of data for analysis. A summary of results is presented in Figure 6-6. OB-3I did not show any response to the pumping of PW-3. A discussion of possible explanations for the lack of response at OB-3I is presented in Subsection 6.2.4.1.

The Cooper-Jacob analysis of the data from the PW-3 array provided many values of transmissivity and storativity (Table 6-3). The values of transmissivity range from 3.2E-02 m^2/d (2.6 gpd/ft) to 3.7E-01 m^2/d (29.9 gpd/ft) with a mean of 1.9E-01 m^2/d (15.5 gpd/ft) and storativity values range from 1.4E-4 to 1.0E-3, with a mean of 3.6E-4. The Hantush method provided maximum and minimum values of transmissivity around PW-3 equal to 3.0E-01 m^2/d (24.3 gpd/ft) and 1.8E-01 m^2/d (14.4 gpd/ft), respectively, and an overall storativity of 4.0E-4.

Analyses using the Hantush method indicate the maximum transmissivity has a bearing of approximately N12°E. Comparing the maximum and minimum transmissivities, it is apparent that the anisotropy ratio is approximately 2:1.

Hydraulic conductivity values calculated from pumping and recovery data using pumping and observation wells at the PW-3 locations averaged 2.1E-02 m/d for pumping data and 1.1E-02 m/d for recovery data.

6.2.4 Discussion

6.2.4.1 Pumping Test Data

The results of pumping test data analyses can be most readily compared by referring to Figure 6-6. Figure 6-6 shows that the major axis of transmissivity is aligned approximately north-south at the PW-2 and PW-3 networks. However, the effective transmissivity at PW-2 is approximately twice that for the vicinity of PW-3. Furthermore, the degree of anisotropy is greater near PW-2 than PW-3 and storativity was determined to be an order of magnitude higher near PW-2. Higher hydraulic properties for the PW-2 vicinity may be attributed to the fact that the PW-2 network is screened higher in the section and monitors a more highly weathered portion of the Burlington-Keokuk. Comparison of PW-2 results with those for PW-1 and PW-3 may indicate vertical anisotropy within the upper Burlington-Keokuk Limestone.

Figure 6-6 also shows that the major direction of anisotropy near PW-1 is aligned approximately parallel to the northwest trending observation well array, approximately 60° from the orientation of maximum transmissivity at PW-2 and PW-3. Note that the major axis of the apparent transmissivity tensor at PW-3 is oriented approximately parallel to the minor axis at PW-1. Also the values for transmissivity and storativity near wells PW-1 and PW-3 are approximately equal.

As noted previously, the current analyses have concentrated on observing and interpreting effects of lateral anisotropy. However, evidence of other phenomena has been observed in the test well data. Although quantification of such phenomena is

hindered by the quality of the data, the following statements can be made about some of the apparent phenomena:

- In general, the pumping test data were reviewed for evidence of short-term or long-term recharge effects, barrier-boundary effects, and hydraulic separation between pumped wells and observation wells.

- Although the data from wells near PW-1 showed evidence of recharge effects, as evidenced by declining rates of drawdown during the test, they also show increasing rates of drawdown during latter stages of the test. The variations in drawdown do not correlate to similar variations in pumping rates, indicating a likelihood of other hydraulic phenomena occurring. One possible explanation of the phenomenon would be classical delayed yield due to gravity drainage. This interpretation would be consistent with the very low values of storativity (1E-04 to 1E-03) calculated from earlier portions of the time-drawdown data, before the recharge effects began to be observed. However, the changes from declining to increasing rates of drawdown were generally more abrupt than would be expected from classical delayed yield effects, and the phenomena are not consistently observed for all three pumping well locations. An alternative interpretation might be recharge derived from draining a larger fracture or conduit near the pumping well, followed by barrier-boundary effects once the fracture has been locally drained.

For the vicinity of PW-2, recharge effects are generally observed only along the south-bearing ray of wells. This is also the approximate orientation of the major direction of

transmissivity. Along the other two rays, recharge effects are generally not observed, whereas barrier effects are definitely observed at two wells and possibly observed at two other wells. These results suggest that delayed yield may be due to a zone of discrete flow which parallels the south-bearing ray of wells. These results are consistent with possible recharge from fractures or conduits along the south-bearing ray, with no such features along the northwest- and northeast-bearing rays.

The fact that OB2J did not respond to pumping, yet lies along the principal axis of anisotropy, suggests that discrete flow influences present along the south-bearing ray do not extend to the depth of the screened interval of OB2J.

In the vicinity of PW-3, recharge effects are commonly observed and evidence of late time barrier effects is lacking. This again suggests that delayed yield is not a predominant phenomenon. This effect would, however, be consistent with more generalized dual-permeability conditions near PW-3. In this interpretation, diffuse-flow permeability, which is reflected in the calculated aquifer parameters, would provide the major response of the aquifer to pumping, with discrete-flow permeability providing generalized recharge later in the test. The diffuse-flow permeability could be attributed to intergranular or fine-fracture flow, with discrete-flow permeability resulting from larger, more widely spaced fractures or conduits.

In addition to the potential recharge effects described above there is also some evidence of short-term effects consistent with a dual-permeability aquifer. In data from several wells, there was a short-time rise in water levels, or brief flattening of the drawdown curve, which would be consistent with temporary recharge

from a fracture or conduit, followed by cessation of recharge consistent with drainage of the fracture. Such effects are seen in wells PW-1 (500 minutes), OB1A and OB1G (200-350 minutes), and possibly OB1I (400-500 minutes); note that wells OB1A and OB1G are aligned approximately parallel to the inferred major direction of anisotropy at PW-1. Since such effects are seen in all nine observation wells, this may partially explain the generally higher transmissivities and storativities inferred from data at PW-2 than from the other two wells. Similar short-term recharge effects are not readily observed in data from PW-3 observation wells indicating that the cone of influence for PW-3 is dominated by diffuse flow permeability.

Isolated evidence of barrier-boundary effects was also occasionally observed, notably in wells OB2C, OB2G, and OB3F, and possibly in test wells PW-2 and PW-3. Wells OB2C, OB2G, and PW-2 are aligned generally parallel to the direction of minimum transmissivity near PW-2 indicating a lack of discrete-flow permeability along this orientation.

Two observation wells did not readily respond to production from nearby pumping wells: OB2J and OB3I. OB3I is located about 18 m (60 ft) from PW-3 along ray 3, and is screened at an elevation comparable to that of PW-3. Slug test data indicate that OB3I responds in a manner similar to other observation wells near PW-3, so it does not appear to be hydraulically isolated due to any well construction or well development difficulties. A possible explanation could be the presence of a filled fracture (as have been observed during site drilling activities) lying between OB3H and OB3I. However, no boundary effects were seen in the drawdown curve of OB3H.

Well OB2J is located approximately 6 m (19 ft) from PW-2, but is screened within a much deeper interval of the limestone 40-43 m (130-140 ft) below ground surface for OB2J compared to approximately 14-26 m (45-85 ft) below ground surface for the other observation wells at PW-2). The lack of response at this well suggests a degree of hydraulic separation between shallower and deeper parts of the aquifer, consistent with the results of in situ aquifer tests and water-level observations. The hydraulic separation may be due to strong vertical anisotropy due to the layered nature of the aquifer, a general decline in hydraulic conductivity with depth due to smaller apertures and more widely spaced fractures, or a combination of such factors.

The drawdown data were reasonably consistent with the constraints of the Hantush approach for analyzing data in the presence of areal anisotropy. It was possible to readily match the observed drawdown distributions with families of ellipses having more-or-less parallel major and minor axes. Furthermore, it was generally possible to obtain reasonably consistent transmissivity estimates from different observation wells utilizing different analytical techniques (Jacob time-drawdown, Hantush time-drawdown, Jacob distance-drawdown, and Hantush distance-drawdown). Exceptions to this general conclusion are discussed above.

In general, many of the observation wells exhibited evidence of significant recharge in the later portion of the tests. This is consistent with classical delayed yield due to gravity drainage, leakage from overlying or underlying beds, or possibly to double porosity relationships such as could readily occur in a fractured rock with some degree of intergranular or fine-fracture porosity. The calculated storativity is relatively low, consistent with that of a classical confined, homogeneous

aquifer. Since the estimates of storativity are derived largely from early-time data during each test, this low storativity could be consistent with classical delayed yield. Observation wells at PW-1 exhibit some indication of a possible late-time return to a Theis curve, which is also typical of a delayed yield effect. On the other hand, the very-late-time return to an apparent Theis curve is more abrupt than would be expected from classical delayed yield theory. Since this phenomenon is not generally observed at the PW-2 and PW-3 observation wells, delayed yield does not appear to be a major cause of the observed drawdown behavior.

Leakage from overlying or underlying strata is not expected. The pumping and observation wells were designed to be completed in the uppermost saturated interval of the aquifer, so that overlying source beds generally do not exist. Perched groundwater zones are known to exist in the vicinity of the raffinate pits; however, drilling performed for installation of observation wells and pumping wells did not encounter perched conditions. Furthermore, the lack of response at well OB2J suggests that there is relatively little hydraulic connection between the depth interval tested and deeper portions of the Burlington-Keokuk; thus, significant upward leakage is unlikely.

Double porosity effects are quite possible at the site. As noted in previous site reports (MKF and JEG 1989b, BNI 1987), the Burlington-Keokuk Formation is generally expected to exhibit some aspects of both intergranular and fracture porosity. The low transmissivities and storativities observed would be consistent with a very fine-grained, low-permeability granular aquifer, or an aquifer with very fine interconnected fractures which behaves as an equivalent porous medium. The recharge effects would be consistent with secondary fracture porosity zones capable of

supplying recharge to the intergranular aquifer as water levels are drawn down. There is evidence in the drawdown data from some observation wells of temporary recharge effects, which might be consistent with the draining of relatively isolated fracture zones. There is also evidence in the data from a few wells of possible barrier-boundary effects, which might suggest poor lateral communication between wells such as might be expected under aquitard conditions.

Radii of influence were determined for each of the test networks (ESI 1989). In general the radii are on the order of 60 m (200 ft). However, along OB1G, OB1H, and OB1I the distance where zero drawdown occurs is 275 m (900 ft). This ray of wells lies in the same direction as the primary direction of fractures in the formation (MKF and JEG 1989b). Therefore, a fracture may be transmitting the effects of pumping farther than expected.

Hydraulic conductivity values calculated from pumping and recovery data correlate well with values determined from slug testing. Table 6-4 presents a comparison of mean hydraulic conductivity values determined from pumping and observation wells and slug tests.

Anisotropic analyses of transmissivity indicated orientations of N72°W for PW-1, N10°W for PW-2 and N12°E for PW-3. In Figure 6-7, the orientations of maximum transmissivity are compared to fracture orientations observed in bedrock exposures in the vicinity of the Weldon Spring site. The orientation of maximum transmissivity at PW-1 coincides with a major fracture set whereas the orientations of maximum transmissivity at PW-2 and PW-3 are coincident with minor fracture features. This suggests that groundwater flow is controlled by lateral anisotropy in the form of horizontally oriented fractures and that vertical

fracture orientation has little impact on orientation of lateral anisotropy.

6.2.4.2 Recovery Data

Recovery data were evaluated by the subcontractor, Earth Scientists, Inc. (ESI), using semi-logarithmic plots of elapsed recovery time versus residual drawdown to obtain values of transmissivity and storativity. A verification of the accuracy of the subcontractor recovery results was conducted to determine whether the recovery data warranted reevaluation. The verification process involved construction of time-recovery plots of observation wells to determine storativity values and construction of residual drawdown plots of pumping and observation wells to determine transmissivity. The time-recovery plots and residual drawdown plots were constructed according to Driscoll (1986). Results of the recovery data verification are compared to ESI's reported values in Table 6-5. The verification process did not indicate a significant difference in aquifer property values which could be attributed to the methods of recovery data evaluation.

6.3 Tracer Tests

The following sub subsections present the results of tracer test data analysis. The values obtained from the tracer test data were verified using RESSQ, a two-dimensional advection-adsorption contaminant transport modeling program (Javandel et al. 1984). Values of porosity and induced flow velocity were used to determine a calculated travel time.

Tracer tests were performed at the PW-2 and PW-3 locations which exhibited the upper and lower range, respectively, of

hydraulic properties determined from pumping tests. Tracer tests were not conducted at PW-1 since the hydraulic properties for this location were considered to be similar to those at PW-3.

6.3.1 PW-2 Results -- Chloride Tracer

Using Figure 6-8, the tracer centroid arrival time was determined to be 125 hours after injection. Application of Darcy's law yielded an effective porosity of approximately 0.003 in the formation between OB2I and PW-2. Applying the transport equation and the relationship between dispersivity and hydrodynamic dispersion, the dispersivity was found to be approximately 0.049 m (0.16 ft).

6.3.2 PW-2 Results -- Bromide Tracer

Using Figure 6-9, the tracer centroid arrival time was determined to be 260 hours after injection. Application of Darcy's law yielded an effective porosity of approximately 0.015 in the formation between OB2E and PW-2. Applying the transport equation and the relationship between dispersivity and hydrodynamic dispersion, the dispersivity was found to be approximately 0.025 m (0.081 ft).

6.3.3 PW-3 Results -- Chloride Tracer

Using Figure 6-10, the tracer centroid arrival time was determined to be 190 hours after injection. Application of Darcy's law yielded an effective porosity of approximately 0.002 in the formation between OB3F and PW-3. The dispersivity was found to be about 0.014 m (0.047 ft).

6.3.4 PW-3 Results -- Bromide Tracer

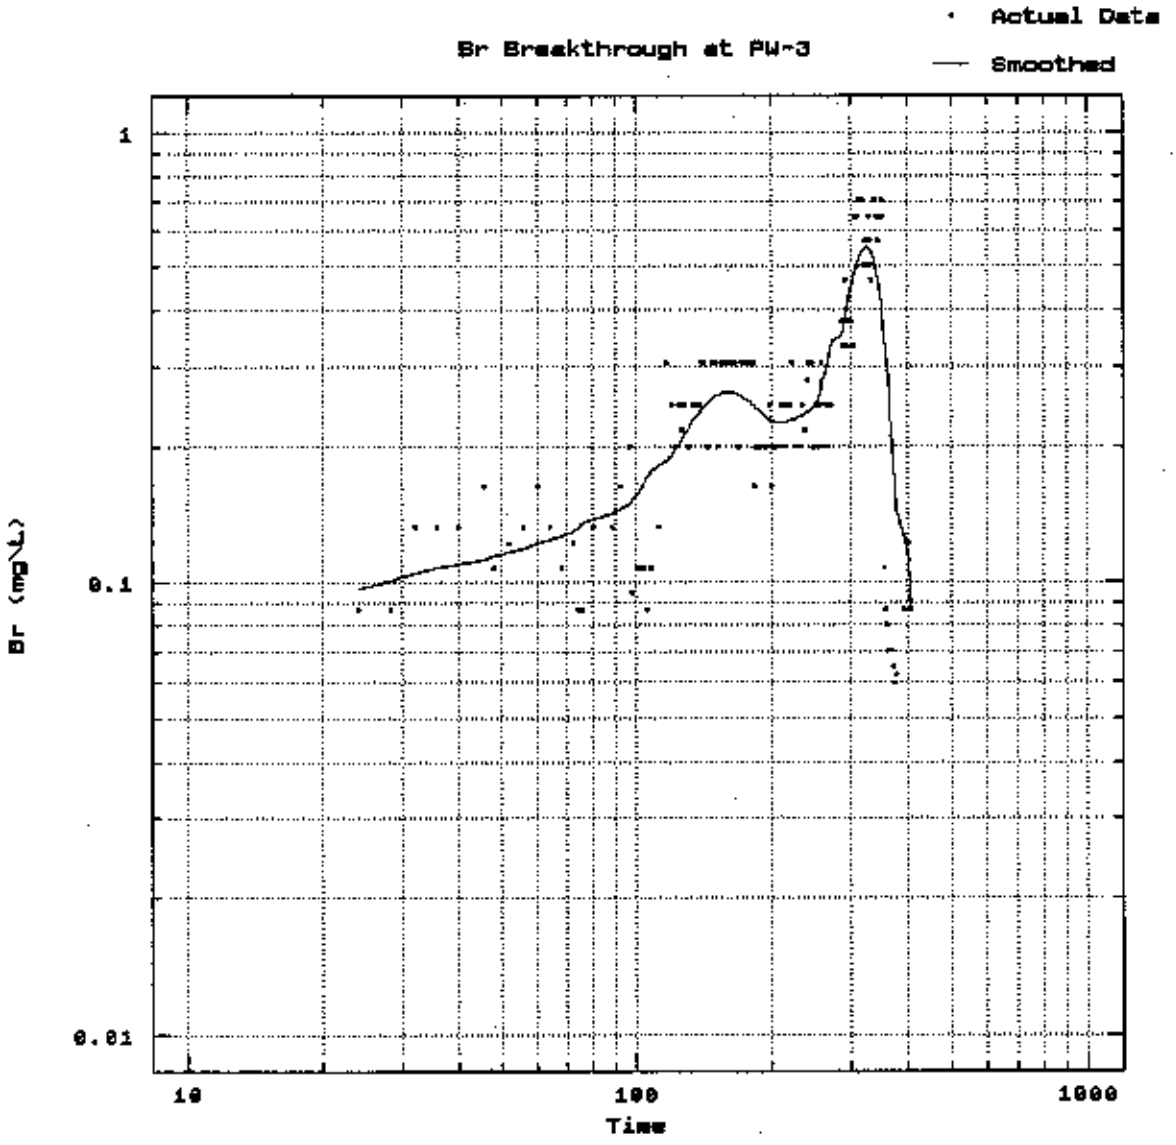
Using Figure 6-11, the tracer centroid arrival time was determined to be 320 hours after injection. Application of Darcy's law yielded an effective porosity of approximately 0.006 in the formation between OB3C and PW-3. The dispersivity was found to be about 0.0088 m (0.029 ft).

6.3.5 Discussion

Figures 6-8, 6-9, 6-10, and 6-11 are plots of time versus tracer concentration. A simple moving average technique was used to obtain a smoothed time-series vector for each tracer concentration data set.

The preinjection concentration of chloride at PW-2 was approximately 40 mg/l. From inspection of Figure 6-8 it appears that initial tracer breakthrough occurred prior to sample collection at PW-2. Peak concentration was determined to be at 125 hours. The asymmetric shape indicates dispersion of the tracer front under the induced gradient and a prompt return to preinjection concentrations after arrival of the tracer centroid. The tail dispersion may have been suppressed by the 275 liter chaser used to drive the tracer into the formation. The chaser may have diluted tail concentrations, while accentuating the centroid. The shape of the curve also suggests the tracer behaved as a single slug.

The concentration of bromide with time at PW-2 is shown in Figure 6-9. Preinjection concentrations for bromide were about 0.4 mg/l. While the tracer centroid was determined to have arrived 260 hours after injection, inspection of the data indicates initial breakthrough of peak concentration at



PLOT OF BROMIDE TRACER CONCENTRATION VERSUS TIME AT PW-3

FIGURE 6-11

approximately 88 hours after injection. The 88-hour time value for bromide breakthrough is not unreasonable considering the distance necessary for the bromide tracer to travel between OB-2E and PW-2, compared to the distance necessary for the chloride tracer to travel between OB-2I and PW-2. Additionally, if the orientation of maximum transmissivity is considered to be parallel to the bromide travel path, then a lower breakthrough time value is expected for the bromide tracer, given that bromide and chloride have essentially the same degree of conservativeness. The curve for bromide also exhibits a degree of oscillation in the centroid which may be the result of discrete tracer fractions traveling somewhat different travel paths (fractures), and therefore having different arrival times due to the relative distance of each travel path. The bromide concentrations did exhibit a sharp decline as with the chloride tracer.

Figure 6-10 is a plot of chloride versus time at PW-3. The preinjection concentration of chloride at PW-3 was about 6 mg/l. Concentrations of chloride at PW-3 were much lower in general than those at PW-2. The lower tracer concentrations may be the result of forcing the tracer into the formation where the bulk of the tracer entered fracture travel paths which were either of longer distance than that which could be evaluated with the available time, or were not connected to flow paths which intersected the pumping well. Centroid arrival was determined to be 190 hours after injection. The data also indicate a possible peak concentration at about 110 hours which may be due to tracer slug fractionation. Chloride concentrations decline sharply to below preinjection concentrations beginning at 200 hours and remain low for the remainder of the monitoring period. The rapid decline to preinjection levels may be due to dilution by the chaser water.

Bromide concentrations at PW-3 (Figure 6-11) were also lower than at PW-2. The preinjection bromide concentration was approximately 0.1 mg/l. Dispersion of the tracer front and dilution after the peak concentration is evident on the plot. Bromide also exhibited dual peaks, possibly due to tracer fractionation, similar to what was observed for chloride at PW-3 and bromide at PW-2. Use of the chaser seems to have diluted tail dispersion in a manner similar to what was observed at other locations.

The values of effective porosity obtained from the tracer tests are approximately one order of magnitude higher than the storativity values found from the pumping test data. It is believed that values obtained using the tracer test method are more reliable than values derived from pumping well drawdown data since tracer test values are a result of observed tracer travel times. As with the transmissivity, effective porosity was expected to be low. Results show that it ranges between 0.002 and 0.015. Local variations of the effective porosity, seen around both networks of wells, can be related to the directional variations in lateral anisotropy within the formation as determined by the Hantush analysis of pumping test data.

Dispersivity is a measure of the amount of mechanical mixing that occurs in a contaminant mass as it travels through a porous media. Causes of mixing include velocity differences within the pores and differences in the length of the pore channels through which the contaminant molecules move. Mixing causes some of the contaminant molecules to travel faster and some slower than the average linear groundwater velocity. Therefore, dispersivity causes the contaminant plume to grow in size as time increases. Dispersivities ranging from a minimum of 0.0088 m (0.029 ft) to a maximum of 0.049 m (0.16 ft) were determined from the tracer test

data. These values are relatively low and may indicate that a contaminant plume in the aquifer would increase in size very slowly. Correspondingly, contaminant concentrations may decrease, assuming that retardation mechanisms are negligible. The low values also indicate that the tested portions of the aquifer can, in a general sense, be treated as an equivalent porous medium since lower values would be indicative of fracture flow with less mixing.

Field-scale dispersivities are also considered to be proportional to the scale of the transport path under investigation (Fetter 1980). Since the tracer tests were applied to a rather small portion of the aquifer volume it is implicit that observed dispersivity values are smaller than what would be observed during a larger-scale test in more porous media. Consequently, it is difficult to make substantive inferences regarding the relative magnitudes of intergranular and fracture flow based solely on tracer test data. From inspection of tracer tests, it was determined that secondary porosity effects are evident as pulses in tracer concentration due to differential velocity through fractures. In the test horizon, primary porosity (intergranular) is considered to be very low while secondary porosity can be expected to exhibit a range of values. The lower end of this range is represented by tracer test data obtained during pumping. The upper end is represented by high slug test values (MW-4014 and GT-58P).

In order to increase confidence in the values for effective porosity derived from the tracer tests, the advection-adsorption contaminant transport model RESSQ was used to simulate tracer transport and verify initial arrival times of the tracers. RESSQ is normally used to simulate both contaminant transport from sources (e.g., injection wells, leaky tanks, or impoundments) to

sinks (e.g., extraction wells or natural groundwater discharge locations) and variations in contaminant concentrations with time. However, the program is considered applicable for verification of tracer travel times where the observation wells used for tracer injection are considered to represent sources and the pumped wells represent concentration sinks.

RESSQ was run for each tracer test using the effective porosities derived from each test. These values are reported in Section 6.3. Additional parameters required to run RESSQ include flow direction (which in this case was the bearing between the observation well used for tracer injection and the pumped well), average linear velocity due to pumping, aquifer thickness, and the adsorption capacity of the host media. Average linear velocity due to pumping ranged from 7.8E-03 m/day (2.5E-02 ft/day) for the chloride tracer traveling between OB-3F and PW-3, to 2.5E-02 m/day (8.2E-02 ft/day) for the bromide tracer traveling between OB-2E and PW-2. Aquifer thickness was assumed to be 12.5 m (41 ft) for all cases and adsorption capacity was considered to be zero for all cases.

Travel times determined using RESSQ ranged from 16 to 45 days, while actual travel times ranged from 8 to 10 days.

The differences in the range of observed tracer travel times and those determined using RESSQ are considered to be sufficiently small with respect to the validity of tracer-derived values for effective porosity. This is demonstrated by the observation that input porosity values for RESSQ would only decrease by a factor of four in order to obtain an RESSQ travel time equal to that seen in the tracer tests.

7 FLOW DYNAMICS

This section presents determinations of hydraulic gradients and calculations of groundwater velocities for selected flow paths using input values based on the results of slug tests and tracer tests.

7.1 Hydraulic Gradients

Horizontal hydraulic gradients were determined for six potential flow paths, four in the shallower portion of the Burlington-Keokuk Limestone and two in the deeper portion of the same formation. Flow paths were chosen to obtain values for average linear groundwater flow velocity under diffuse Darcian conditions. The horizontal flow paths were chosen to obtain a range of values for flow in a number of directions. The choice of deep flow paths is limited directionally due to the distribution of deep wells at the site. The selected flow paths do not suggest preferred flow paths. For horizontal flow situations, the hydraulic gradient is a measure of the slope of the potentiometric surface of the groundwater within an aquifer. It is defined as:

$$i = \frac{dh}{dl} \qquad (13)$$

where:

dh = difference in potentiometric head between two points
dl = distance between the two points.

The gradients that were obtained along the selected flow paths are presented in Table 7-1.

The vertical flow component has been inferred to be very low. The Phase II Groundwater Quality Assessment for the Weldon Spring Chemical Plant, Raffinate Pits and Vicinity Properties (MKF and JEG 1989a) suggests that there is poor communication between the upper and lower portions of the aquifer. This inference is based on vertical distributions of contaminants. Also, results of the pumping test at the PW-2 network showed that OB2J did not respond to pumping. This indicated that there is little or no communication between the upper (weathered) and lower (competent) portions of the aquifer.

Observed hydraulic gradients at well pairs exhibited a range of values from approximately 0.6 for MW-2018 and MW-2019 to 0.009 for MW-3006 and MW-3003. This range of observed gradients, along with the lack of response in OB2J during pumping, probably reflects the limitations of an equivalent porous medium approach, where diffuse flow, occurring within fine fractures, and a strong horizontal anisotropy inhibit vertical flow which can be assessed through Darcian principles. Some variation in vertical gradient may be due to the relative proximity of the various well pairs to widely spaced vertical fractures. Distributions of contaminant levels in paired deep and shallow wells do not correlate well with values of observed hydraulic gradients. For example, the vertical gradient between MW-3003 and MW-3006 is 0.009, which suggests relatively good hydraulic communication. However, nitrate concentrations reported in the 1989 Annual Site Environmental Report (MKF and JEG 1990b) ranged from 312,000 mg/l to 1,885 mg/l for MW-3003. The range for nitrate in MW-3006 during the same time period was 188.0 mg/l to undetected which,

on the basis of contaminant distribution, suggests poor hydraulic communication.

7.2 Groundwater Velocities

7.2.1 Results

Determination of effective porosity from the tracer test data allows for the calculation of natural average linear groundwater velocities. The average linear velocity is determined using Darcy's law in the form:

$$v = \frac{Ki}{n} \qquad (14)$$

where:

v = average linear groundwater velocity
K = hydraulic conductivity
i = hydraulic gradient
n = effective porosity (0.007 as determined from tracer tests)

Groundwater velocities were calculated for the five potential flow paths described above. These flow paths refer to the path that a molecule of water follows from point A to point B assuming an equivalent porous medium approach; they do not account for velocity anomalies due to free flow conditions (heterogeneities), or horizontal anisotropy (i.e. the calculation assumes a homogeneous isotropic flow media). Figure 7-1 shows the selected shallow flow paths and Figure 7-2 shows the deeper flow paths.

ORIGINATOR:	JDC	DRAWN BY:	GLN	DATE:	5/90

Average hydraulic conductivities of wells along the selected flow paths were used. Values of the hydraulic gradients and hydraulic conductivities and the resulting velocities along each flow path are presented in Table 7-1.

Using hydraulic conductivities determined by the Bouwer and Rice method, average linear velocities ranged from a minimum of 0.022 m/day (0.072 ft/day) between OB2F and MW-4021 to a maximum of 0.12 m/day (0.39 ft/day) between MW-2018 and MW-4022. Using hydraulic conductivities determined by the Hvorslev method, average linear velocities ranged from a minimum of 0.033 m/day (0.11 ft/day) between OB2F and MW-4021 to a maximum of 0.44 m/day (1.40 ft/day) between MW-2018 and MW-4022.

7.2.2 Discussion

To verify the values of average linear velocity presented in Section 7.2.1 and the underlying assumption that Darcian diffuse flow principles can be applied to assess contaminant transport, a comparison of calculated travel times to observed contaminant distribution can be made. Using the concentrations of nitrate along the flow path from MW-3003 to MW-2002 as presented in the Phase II Groundwater Quality Assessment for the WSCP/WSRP/WSVP (MKF and JEG 1989a), a travel time of about 30 years can be used to delineate the time since raffinate wastes were first introduced into the holding pits. Seepage rates for the raffinate pits (BNI 1986) and isopach thicknesses for the overburden of 12 m (40 ft) were used to calculate a velocity and travel time, assuming a hydraulic gradient of 1, and a porosity of 0.36 (BNI 1987).

The calculated travel time for nitrate to reach the phreatic surface is about 13.5 years, without taking into account initial

unsaturated flow which would conceivably lengthen travel time. This leaves a balance of 16.5 years for contaminants to reach their present distribution. The estimated travel time for flow from the middle of Raffinate Pit 3, the approximate center (and source) of the nitrate plume, to MW-2002, near the edge of the plume, is about 21 years using average hydraulic conductivity values obtained along the flow path between MW-3003 and MW-2002. Combining the time required for nitrate to reach the phreatic surface and the time required for the plume to reach its present horizontal extent yields a total estimated travel time of about 35 years. While these values are admittedly only rough estimates, the fact that they are fairly close corroborates the calculated values for hydraulic conductivity (Section 6.1) and average linear velocity (Section 7.2.1).

From Table 7-1 it can be seen that the calculated velocities in the flow paths in the deeper portion of the Burlington-Keokuk are not substantially lower, as might be expected for flow in the unweathered bedrock, than the velocities calculated for the shallower flow paths. This is probably because observed gradients between the deep wells imply the existence of a direct lateral connection, which may not be the case. In fact flow paths in the shallow and deep portions of the aquifer are probably not linear as assumed in the derivation of horizontal hydraulic gradients, but probably exhibit some degree of tortuosity which would result in lower hydraulic gradients and velocities. Therefore, the velocities presented in Section 7.2.1 represent maximum average linear velocities.

Conduit flow is considered to be limited to the highly permeable portion of the weathered Burlington-Keokuk Formation. No effort was made in this study to determine conduit flow velocities. However, results of surface injection dye tracing

studies conducted by the Missouri Department of Natural Resources indicate that dye lost to conduit flow in the subsurface had flow velocities ranging from 0.4- to 0.7-m/min (1.5 to 2.2 ft/min) (MKF and JEG 1989b).

8 FINDINGS AND CONCLUSIONS

Findings and conclusions resulting from slug tests, pumping tests, and tracer tests performed to characterize the shallow Mississippian-Devonian aquifer in the vicinity of the WSS are presented below.

8.1 Findings

8.1.1 Slug Tests

- The average hydraulic conductivity value for all wells tested was 7.4E-02 m/day as determined by the Hvorslev technique and 9.6E-02 m/day as determined by the Bouwer and Rice method.

- Piezometer GT-58P yielded the maximum value for hydraulic conductivity, which was 3.9 m/day as determined by the Bouwer and Rice method.

- Groundwater velocities calculated using hydraulic conductivity data obtained using the Hvorslev method yielded an average value of 1.8×10^{-1} m/day.

- Groundwater velocities calculated using hydraulic conductivity data obtained using the Bouwer and Rice method yielded an average value of 1.1×10^{-1} m/day.

8.1.2 Pumping Tests

- Mean transmissivity values were determined to be 2.34E-06 m^2/s (16.3 gpd/ft) for PW-1, 5.74E-06 m^2/s (39.9 gpd ft) for PW-2 and 2.23E-06-m^2/s (15.5 gpd ft) for PW-3.

- The average storativity determined by pumping tests was 4.9E-04.

- Hantush analysis yielded maximum apparent transmissivity tensor orientations of N72°W for PW-1, N10°W for PW-2, and N12°E for PW-3.

- Comparison of maximum and minimum transmissivity values yielded anisotropy ratios of 2:1 for PW-1 and PW-3, and 3.5:1 for PW-2.

- The radius of influence due to pumping is, generally, approximately 60 m (200 ft). However, along the line of OB1G, OB1H, and OB1I, the projected distance to zero drawdown was 275 m (900 ft).

- Hydraulic conductivity values determined from pumping tests averaged 2.3E-02 m/day for PW-1, 4.9E-02 m/day for PW-2 and 3.1E-02 m/day for PW-3.

8.1.3 Tracer Tests

- Effective porosities determined by tracer tests ranged from 0.002 to 0.015.

- Dispersivity values determined by tracer tests ranged from 8.8E-03 m for PW-3 (bromide) to 4.9E-02 m at PW-2 (chloride).

- Breakthrough curves for tracers did not exhibit double porosity effects.

8.2 Conclusions

Results of slug tests, pumping tests, and tracer tests conducted at the Weldon Spring site (WSS) have yielded valuable information about the shallow bedrock aquifer underlying the site. The results presented herein represent a substantive body of data which will be useful for remedial planning, assessing aquifer restoration alternatives, feasibility assessments and/or further monitoring programs, and groundwater modeling. With these applications in mind, the following conclusions are offered:

- The aquifer of concern at the Weldon Spring site, is composed of saturated rocks of the Burlington-Keokuk Limestone which constitute the upper portion of the Mississippian-Devonian aquifer. The aquifer of concern is a heterogeneous anisotropic medium which can be described in terms of diffuse Darcian flow overlain by high porosity discrete flow zones and conduits.

- Pumping and tracer tests did not intercept free flow zones or conduits capable of supplying sustained pump discharge yields in excess of approximately 1.5 liters/minute (0.4 gpm).

- Slug tests performed on wells GT-58P, MW-4014, and

MW-4013 had high hydraulic conductivity values relative to the average which was 9.6E-02 m/day (Bouwer and Rice Method) for all wells tested. These values are considered to be representative of discrete flow in the fractured and weathered zones found in the upper Burlington-Keokuk Limestone and indicate heterogeneities within the upper Mississippian-Devonian aquifer. Aquifer heterogeneity in the horizontal plane is believed to be distributed randomly and is a function of fracture spacing, solution voids, and preglacial weathering phenomena. The relatively high hydraulic conductivities that may be encountered in deeper portions of the aquifer (e.g., MW-3006 with a hydraulic conductivity of 2.3E-01 m/day) are thought to be due to the presence of widely spaced fractures.

- Piezometer GT-58P is a good location in which to consider an additional pump test because it has the highest hydraulic conductivity value of all wells tested. All indications suggest that flow at this location is discrete and, as such, sustained yields may be substantially in excess of rates required for the pumping tests addressed in this report (0.75-1.5 l pm [0.2-0.4 gpm]).

- Results of pumping tests indicate a primary lateral anisotropy and poor hydraulic communication between the pumped interval and deeper portions of the Burlington-Keokuk; thus, there is not likely to be significant upward leakage.

- Calculated groundwater velocities and travel times appear to be consistent with observed contaminant distribution due to diffuse Darcian flow, although flow paths may exhibit nonlinear aspects resulting in significant variations in velocity.

- Limited evidence of delayed yield such as that observed near PW-1 may indicate double porosity effects.

- Results of pumping tests, tracer tests, and slug tests indicate limitations to an assessment of hydrologic phenomena within the Burlington-Keokuk Limestone using an equivalent porous medium approach. Additional pumping tests of high hydraulic conductivity features such as GT-58P may provide insight toward how heterogeneous features influence the saturated zone.

ABSTRACT

Environmental monitoring continued at the Weldon Spring Site in 1989. Numerous exposure pathways were monitored in 1989, including groundwater, surface water, and air. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are being used to calculate exposure doses (where applicable) so the impact of the site on potentially exposed populations can be assessed.

Off-site exposures did not dramatically increase in 1989 over exposures calculated in previous years. Contaminated groundwater did not affect private water supplies or the St. Charles County Well Field. Surface water containing elevated uranium activity continued to impact the Femme Osage Slough and several lakes in the August A. Busch Memorial Wildlife Area. Elevated radon exposures at the Weldon Spring Quarry continued in 1989 due to the unusually dry conditions. Off-site gamma, radon and air particulate exposures remained indistinguishable from background. Off-site monitoring demonstrated that exposure at the Francis Howell High School, the Busch Wildlife Area Headquarters, and the Weldon Spring Training Area is indistinguishable from background levels. No spills occurred at the Weldon Spring Site in 1989.

1 INTRODUCTION

This report presents the findings of the environmental monitoring program conducted at the Weldon Spring Site (WSS) in 1989. Annual environmental monitoring reports have been prepared for this site (or portions thereof) since 1981. The WSS is part of the Department of Energy (DOE) Surplus Facilities Management Program (SFMP), one of the remedial action programs under the direction of the Office of Environmental Restoration and Waste Management. The WSS is comprised of the Weldon Spring Raffinate Pits (WSRP), the Weldon Spring Chemical Plant (WSCP), and the Weldon Spring Quarry (WSQ). These areas encompass 20.7, 67.2 and 3.6 hectares (ha) (51, 166, and 9 acres), respectively. The WSRP and WSCP areas are contiguous. The WSQ is approximately 6.4 kilometers (km) (4 miles) to the south-southwest.

When custody of the WSCP was transferred in 1985 from the Department of the Army (DA) to the DOE, the WSCP became part of the WSS. In conjunction with this transfer, the Weldon Spring Site Remedial Action Project (WSSRAP) was created as DOE Major Project Number 182 (DOE Order 4240.1E - 05/14/85). Consistent with the DOE mission under SFMP, the WSSRAP will eliminate potential hazards to the public and the environment and make surplus real property available for other uses.

During the years 1981 through 1985, the WSRP and WSQ were under DOE caretaker status. The WSCP was controlled by the DA. The DOE conducted environmental monitoring programs during this period to identify changes (if any) in the radiological levels in and around the WSRP and WSQ. The DA did not collect environmental monitoring data in and around the WSCP. When the WSCP was transferred to the DOE in 1985, the DOE began revision of the overall Environmental Monitoring Program to more

adequately determine the levels of contamination in and around the WSCP, WSRP, and the WSQ. A description of the WSS environmental monitoring program for 1989 is provided in Section 1.4 of this report.

DOE Order 5400.1 requires that an environmental radioactivity monitoring program be maintained at existing sites and, as determined on a case-by-case basis, at certain former sites to determine:

- Background levels and site contribution of radioactivity and other pollutants from DOE operations to the site environs.

- Compliance with applicable and appropriate environmental standards for radioactivity and other pollutants specified by the DOE and the U.S. Environmental Protection Agency (EPA).

- Compliance with environmental commitments in official documents such as environmental impact statements and Federal Facility Agreements (FFA).

This DOE Order also requires a listing of environmental permits. The only permit in effect at the WSS in 1989 was the National Pollutant Discharge Elimination System (NPDES) - Storm Water Runoff Permit Number MO-0107701. Compliance with this permit is discussed in Section 2.2.1 of this report.

This Annual Site Environmental Report is the DOE's vehicle for documenting the results of its extensive monitoring program at the WSSRAP. The report provides the public and concerned regulatory agencies with summary level discussions regarding the

routine environmental monitoring program. It explains how the WSSRAP environmental monitoring program meets the requirements of the NPDES program and compares the measured contaminant levels to applicable standards. Further, the report indicates whether changes are occurring in contaminant distribution or contaminant source conditions on and around the site--changes which might equate to variations in potential exposure scenarios to the public or environmental receptors.

Environmental monitoring is the WSSRAP's most effective means by which to assess the impacts from the site. The data and evaluations contained in the report provide the summary of that monitoring for 1989. Section 2 reports results of the contaminant level measurements and compares the environmental levels of radioactivity and chemical contaminants released from the site with applicable standards. Quarterly data is presented in Appendix A.

In addition to the routine environmental monitoring conducted in 1989, a number of related activities and special studies were performed. These activities and studies are directly applicable to the assessment of the overall impact of site operations on the environment. Therefore, these activities are described and the results are discussed in Section 3.

Section 4 presents the results of calculations, based on the 1989 sampling results, of the maximum radiation dose to a hypothetical maximally exposed individual at the WSCP/WSRP and WSQ areas. Calculations of the doses to the general population in the vicinity of the WSS are also reported.

For definitions of selected terms used in this report, the reader may consult Appendix B. Although each acronym used in

this report is defined when it is first used in each main section, a list of all abbreviations used is provided in Appendix C. Appendix D contains a description of the quality assurance methods that are applied to sampling and analysis activities in this monitoring program. Appendix E presents a discussion of the environmental guidelines that apply to the monitoring program. Appendix F provides a useful conversion table, and Appendix G the distribution list for this report.

1.1 Location and Description

The WSS is located in St. Charles County, Missouri, about 48 km (30 mi) west of St. Louis. The WSRP and WSCP areas are reached from Missouri State Route 94, 3.2 km (2 mi) southwest of the junction of Route 94 and U.S. Route 40/61. The WSQ is also reached from Route 94, 6.4 km (4 mi) south-southwest of the WSRP and WSCP areas. The Missouri River is located approximately 2.4 km (1.5 mi) southeast of the WSRP and WSCP areas and 1.6 km (1 mi) east of the WSQ. The Mississippi River lies approximately 22 km (14 mi) northeast of the WSRP and WSCP areas and roughly 29 km (18 mi) northeast of the WSQ. The general locations of these properties are illustrated in Figure 1-1.

Uranium and thorium residues, waste materials, and contaminated rubble are stored at the WSS. In addition to environmental monitoring, engineering activities are being conducted to minimize the migration of contaminants from these facilities into surface water and groundwater.

Additional characterization activities have been conducted at the WSCP and WSRP during 1989. These activities provide information on the types and magnitudes of the contamination. The complete picture of characterization information will be

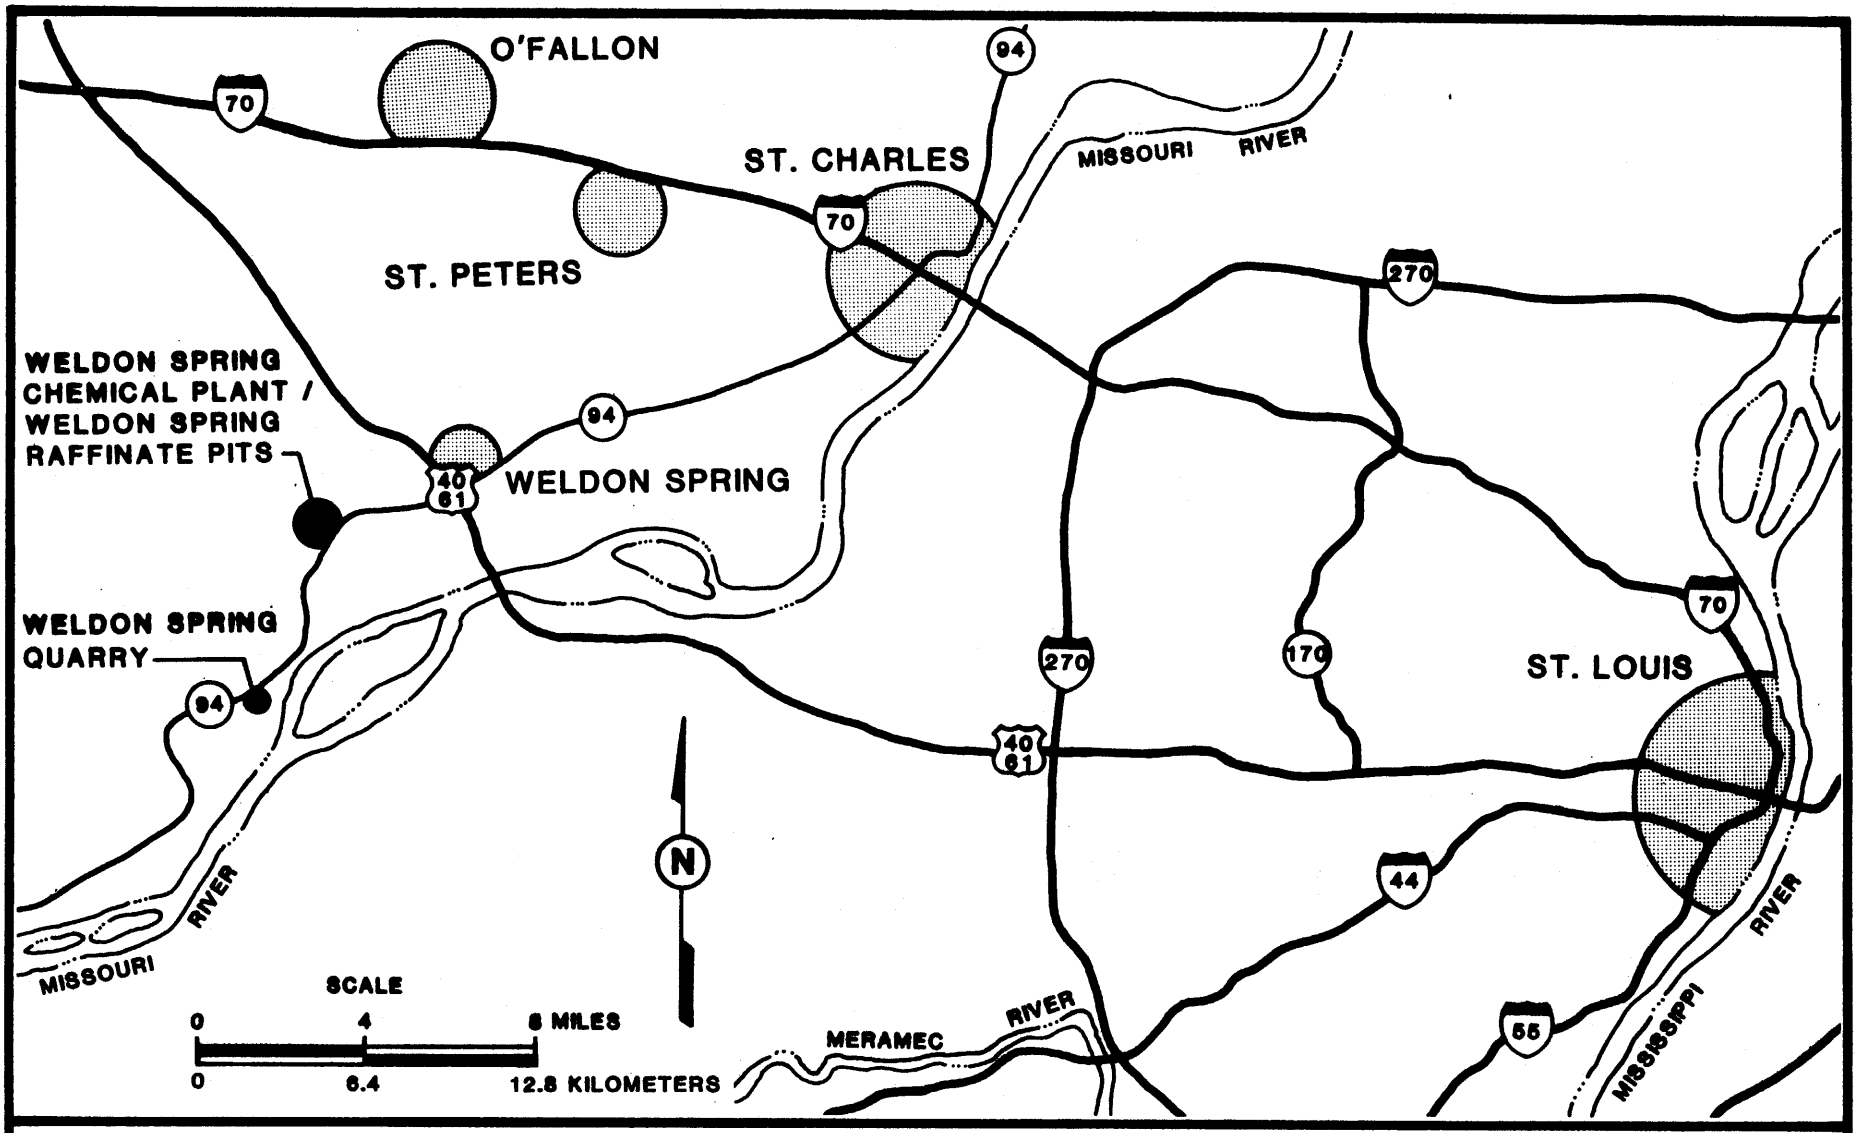

FIGURE 1-1

LOCATION OF THE WELDON SPRING SITE

presented in a Remedial Investigation (RI) report scheduled to be completed in 1990 and this information will be used to evaluate the course of remedial actions.

Brief descriptions of each major area of the site are given below.

Weldon Spring Raffinate Pits

Figure 1-2 is an aerial view of the WSRP area with part of the WSCP in the background. The 20.7-ha (51-acre) area includes four pits that cover approximately 10.5 ha (26 ac) (see Figure 1-3). The raffinate pits were constructed by excavating into the existing clay soils and using the removed clay for construction of dikes. These pits contain radioactive residues (raffinates) from uranium and thorium processing operations at the former Weldon Spring Uranium Feed Materials Plant (WSUFMP) which is now the WSCP.

Access to the area is controlled by a 2.1-meter (m) (7-ft) high fence that encloses the DOE property. In addition, each pit is enclosed by a fence at least 1.3 m (4 ft) high. All drains and transfer lines from the pits to the WSCP process sewer have been sealed (Ficker, 1981). During the 1989 monitoring year, surface water covered the vast majority of the residues in the pits.

Weldon Spring Chemical Plant

The 67.2-ha (166-ac) WSCP is located to the north and east of the WSRP area (Figure 1-3). The WSCP, which operated as the Weldon Spring Uranium Feed Materials Plant until 1966, comprises 13 major buildings and 27 smaller buildings. Of the former, five

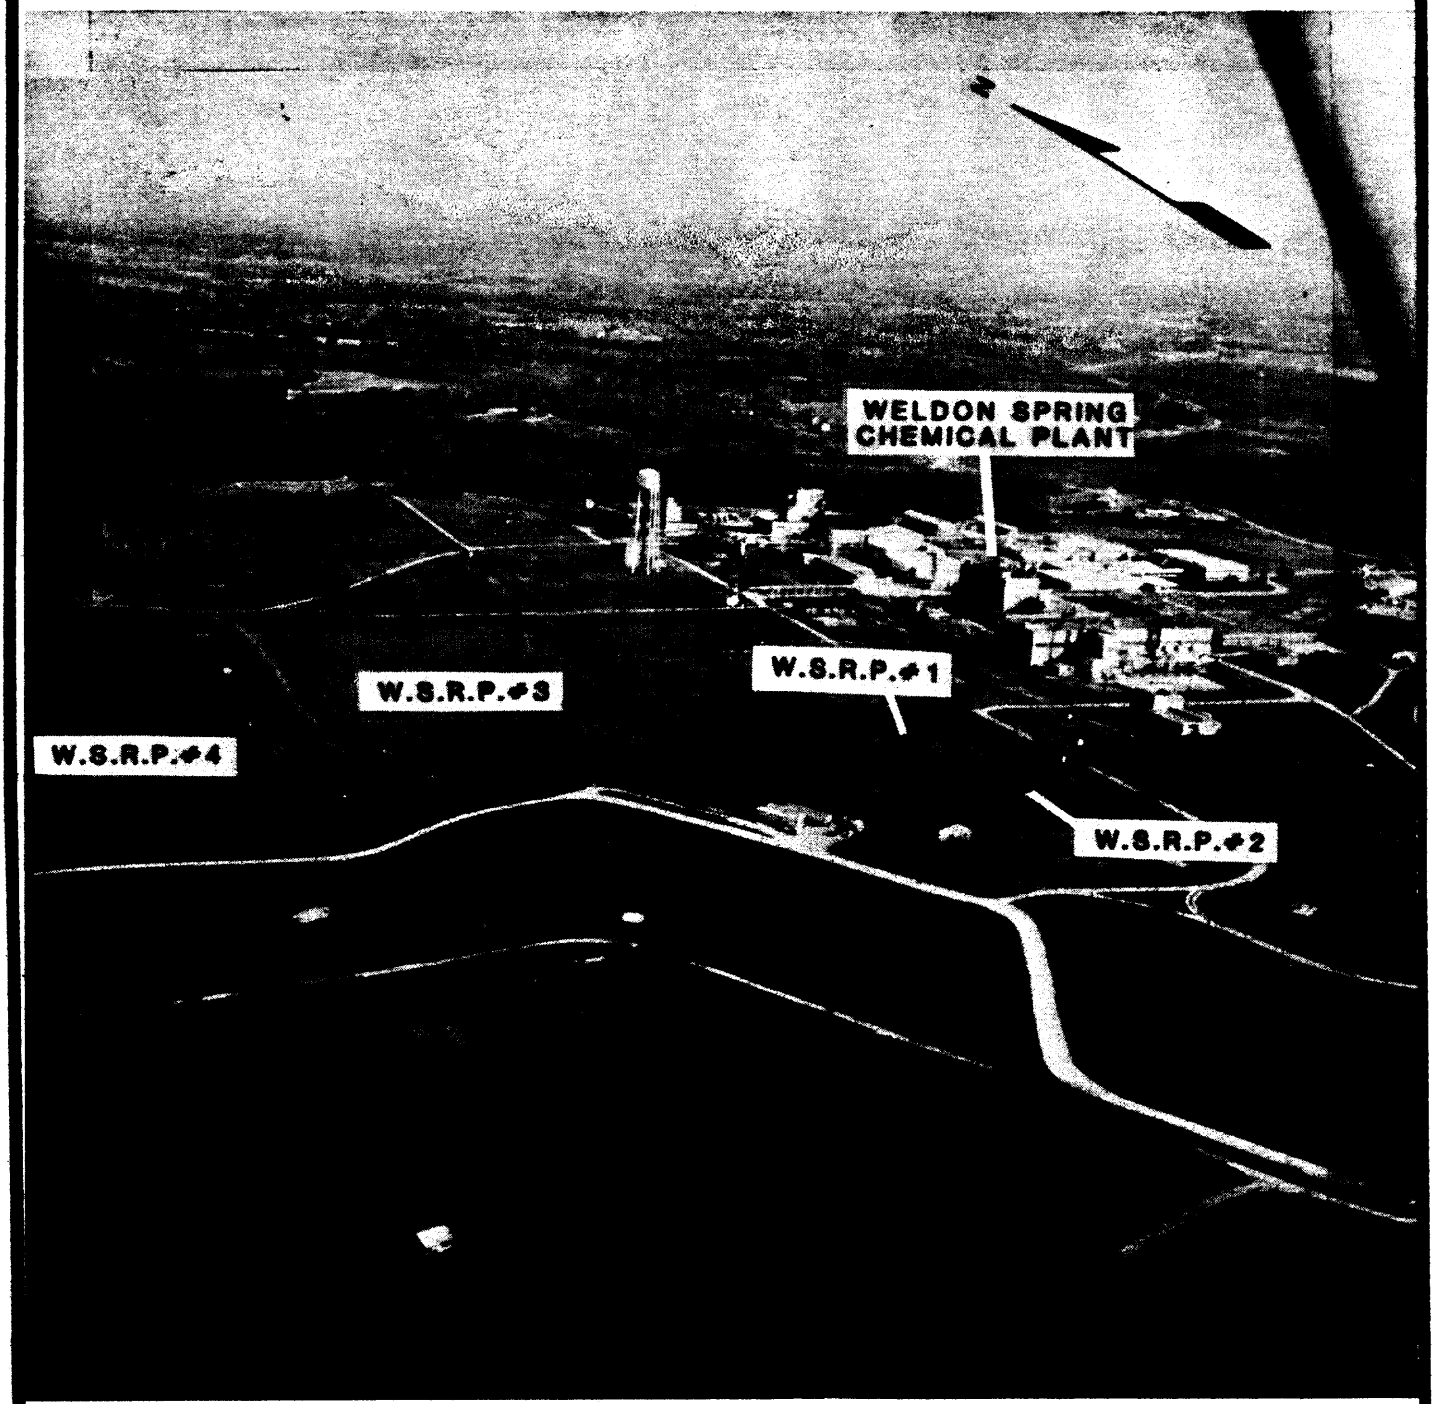

FIGURE 1-2

AERIAL PHOTOGRAPH OF THE WSRP AREA

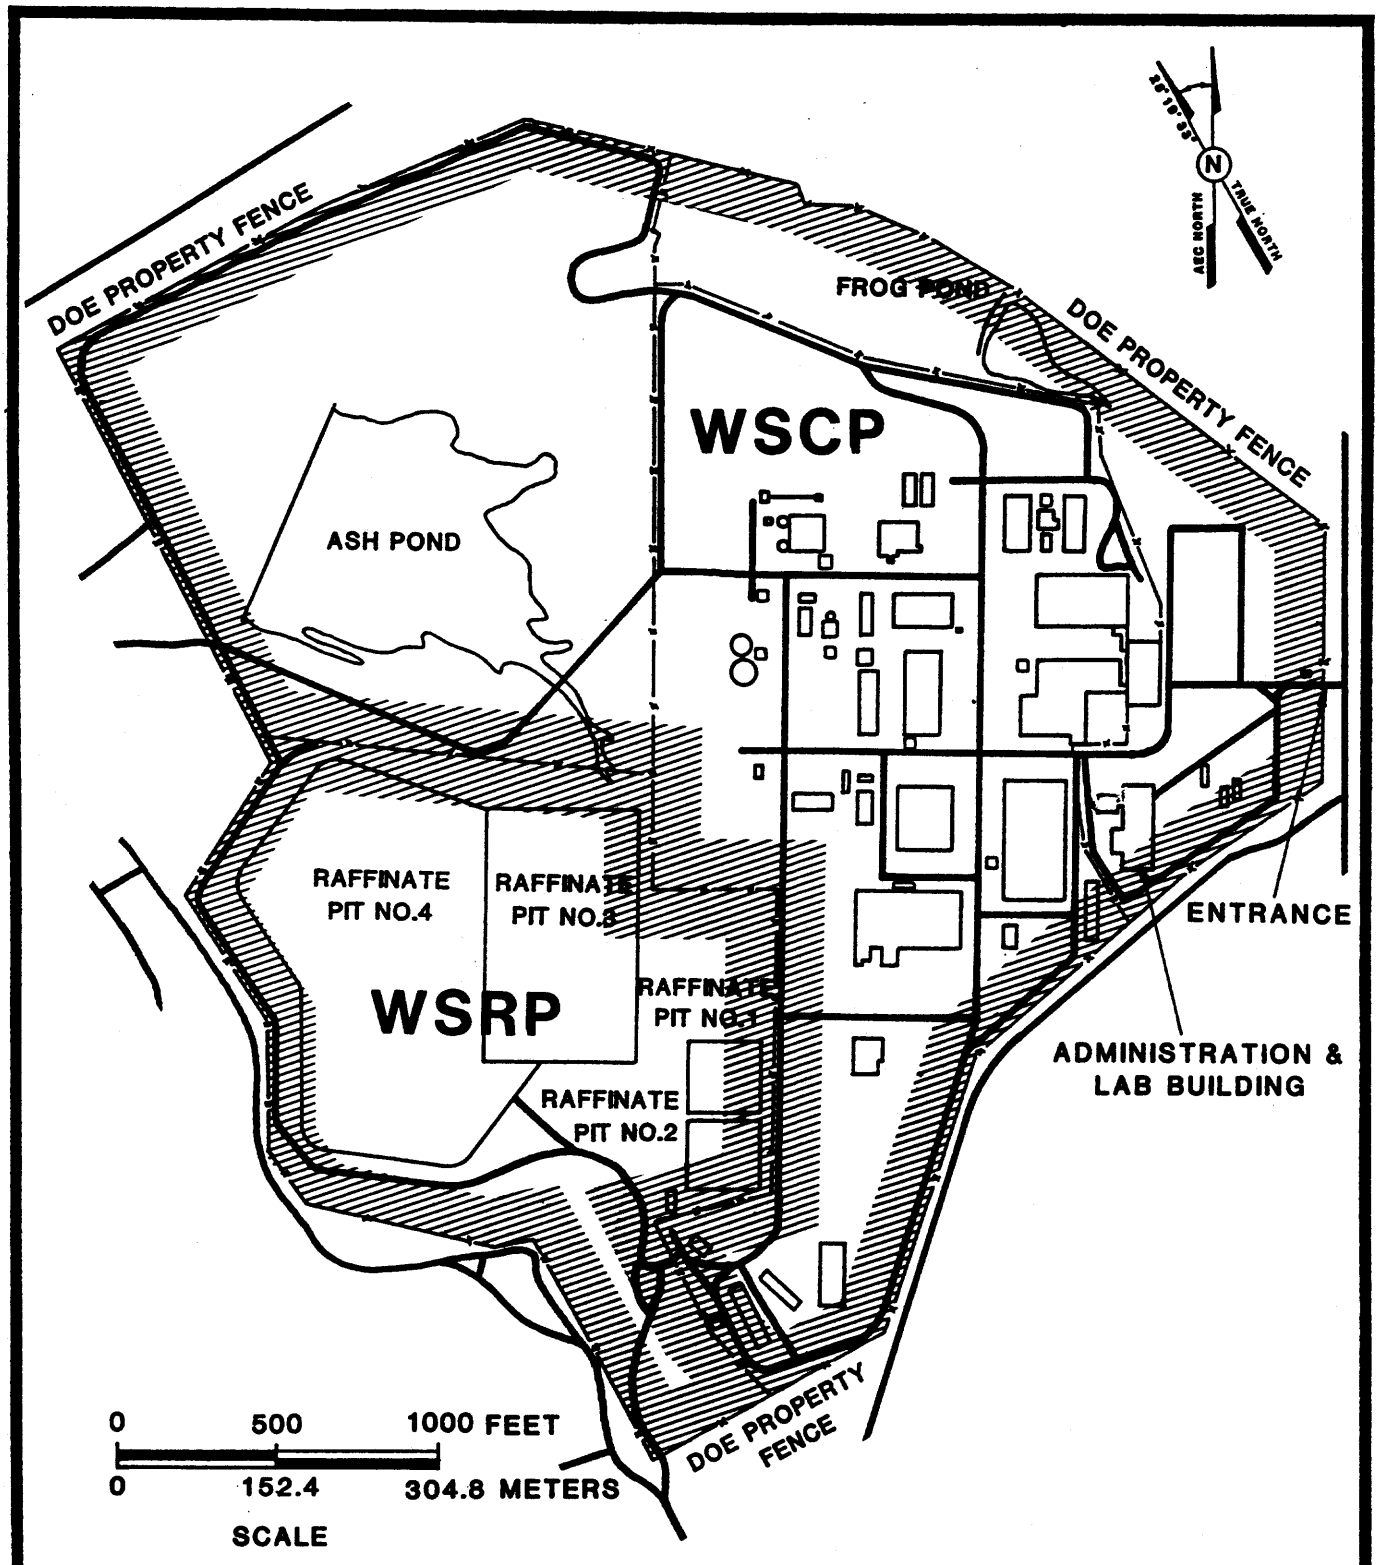

FIGURE 1-3

MAP OF THE WSCP & WSRP

were used as process buildings, and eight were major support buildings. The entire site is fenced. Access is controlled at a manned gate-house and site security continues to be maintained by guards periodically patrolling the site 24 hours per day.

The interiors of the eight major support buildings are heavily contaminated with uranium that is mostly "fixed" on surfaces. The rest of the buildings contain only small quantities of uranium contamination.

Surface water runoff from the WSCP drains primarily along three corridors. These include the natural drainageways leading to Ash Pond and Frog Pond, and the complex of tributaries which exits the site to the southeast. Surface water drains into these ponds and drainageways where it transports uranium off-site. These drainageways are more thoroughly discussed in Sections 1.3 and 2.2.

Small quantities of chemically hazardous substances are also present both in the buildings and as contamination in the soil in several areas of the site. These substances include asbestos, polychlorinated biphenyls (PCBs), dinitrotoluene, ammonia, hydrofluoric acid, sulfuric acid, and nitric acid. The data on these substances and their impacts to the environment will be detailed in the previously mentioned RI report.

Weldon Spring Quarry

The WSQ, an abandoned 3.6-ha (9-ac) limestone quarry, is located approximately 6.4 km (4 mi) south-southwest of the WSRP/WSCP area. Figure 1-4 is an aerial photograph of the WSQ. As shown in Figure 1-5, the WSQ is accessible at both the upper and lower levels from Missouri State Route 94. An unused

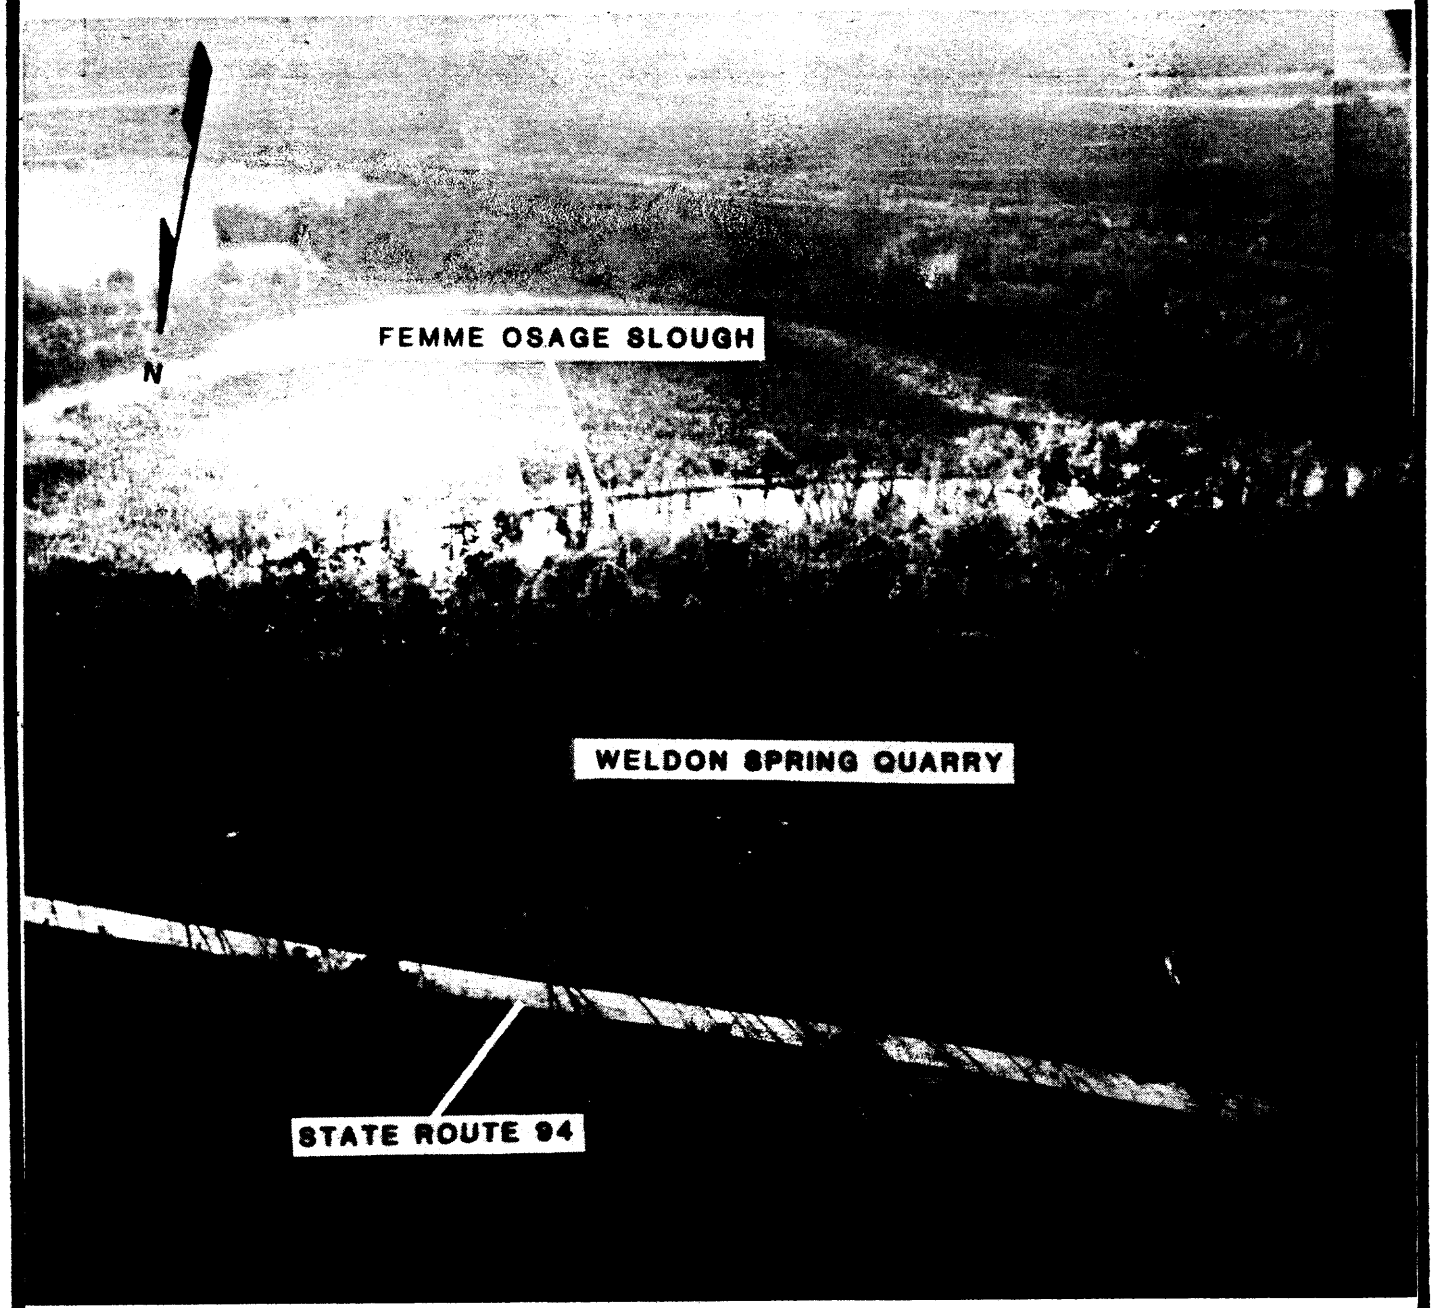

FIGURE 1-4

AERIAL PHOTOGRAPH OF THE WSQ

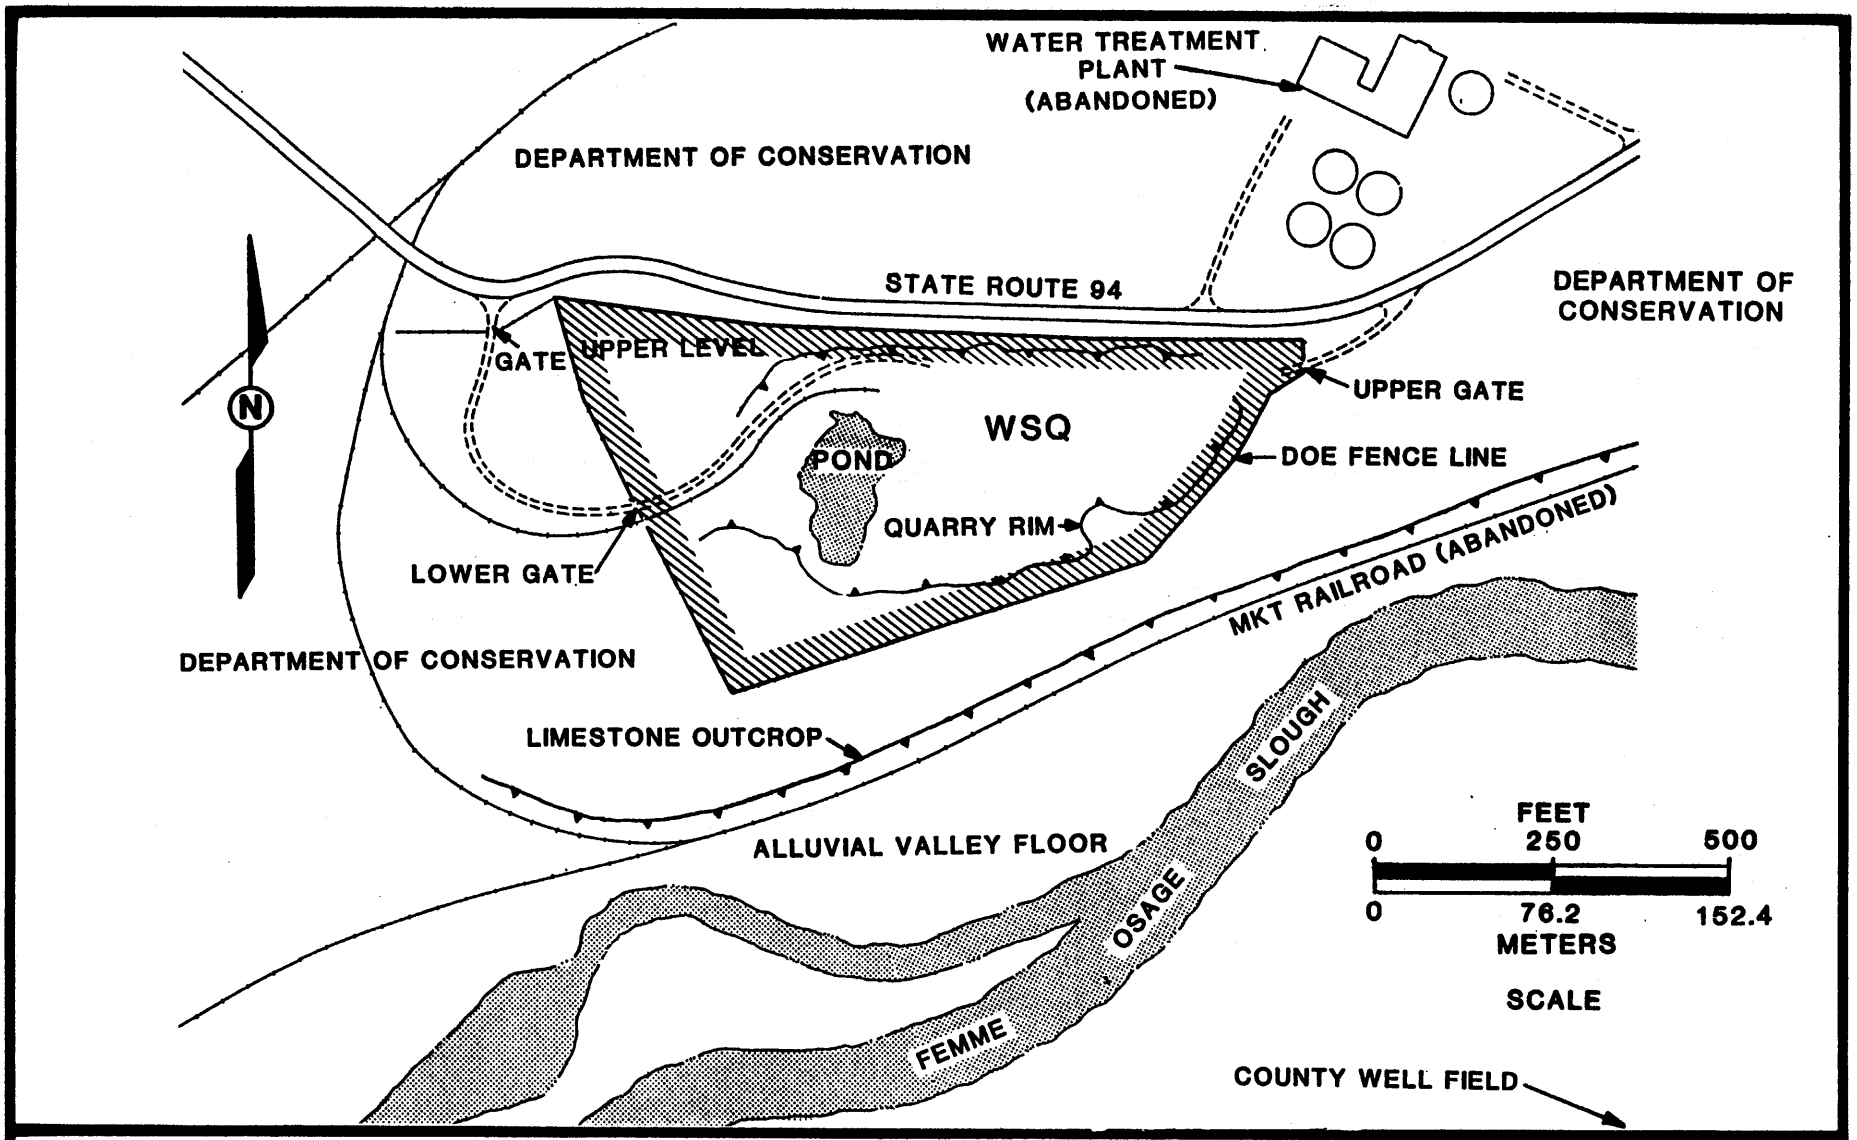

FIGURE 1-5

MAP OF THE WSQ

railroad spur enters the site at the lower level and extends approximately one-third of the way into the WSQ. The WSQ is essentially a closed basin; surface water within the rim flows to the quarry floor and into a pond which covers approximately 0.2 ha (0.5 ac). The pond contains approximately 12 million liters (3 million gallons) of water and is 6.1 m (20 ft) deep at its deepest point. The amount of water in the pond varies according to seasonal variations in precipitation and evaporation.

The only structures at the WSQ site are a small storage shed and a sampling platform in the pond area. Access to the site is restricted by a locked, 2.1-m (7-ft) high chain link fence. The amounts and types of wastes in the WSQ are summarized in the Remedial Investigation Report for Quarry Bulk Wastes (MKF and JEG, 1989b).

1.2 Site History

The WSS has a complex history of production processes within its boundaries. Between 1941 and 1944, the Department of Army (DA) occupied the property (Weldon Spring Ordnance Works--WSOW) and located four of its 20 explosives production lines across the WSS area (the remaining 16 production lines were distributed across an adjacent property which is now referred to as the U.S. Army's Weldon Spring Training Area). The WSOW produced dinitrotoluene and trinitrotoluene (DNT and TNT) for the Allied Forces during World War II.

In 1955, 83 ha (205 ac) of the former ordnance works property was transferred to the Atomic Energy Commission (AEC) for construction of the Weldon Spring Uranium Feed Materials Plant (WSUFMP). Until 1966, the AEC operated an integrated facility for the conversion of processed uranium ore concentrates

to pure uranium trioxide, intermediate compounds and uranium metal. A small amount of thorium was also processed. The wastes generated from these operations were stored in four raffinate pits on the site property.

In 1958, the AEC acquired title to the WSQ from the DA. The WSQ had been used earlier by the DA for disposal of TNT-contaminated rubble during the operation of the WSOW. The AEC used the WSQ as a disposal area for a small amount of thorium residue, but most of the material disposed of there consisted of uranium- and radium-contaminated building rubble and soils from the demolition of a uranium ore processing facility in St. Louis.

In February 1985, the DOE proposed designating the control and decontamination of the WSRP, WSCP, and WSQ as a major project. Designation was effected by DOE Order 4240.1E dated May 14, 1985. A Project Management Contractor (PMC) for the Weldon Spring Site Remedial Action Project (WSSRAP) was selected in February 1986. In July 1986, a DOE project office was established on site. The PMC, MK-Ferguson Company, assumed control of the WSS on October 1, 1986. The WSQ was placed on the Environmental Protection Agency's National Priorities List (NPL) in July 1987. The WSCP/WSRP was added to the NPL in March 1989.

Remedial investigations were conducted at the WSCP/WSRP area in 1988 and 1989. The investigations included characterization of the groundwater, on-site soil contamination, contaminated sediments in off-site surface drainages and lakes, surface water, and springs; the chemical and radiological characteristics of the raffinate wastes; and other smaller scale efforts. The results of each of these investigations are presented in stand-alone documents on the respective efforts and are brought together and

summarized in the RI report for the WSCP/WSRP, which is in the final stage of production following agency review.

Several small-scale actions have been conducted to mitigate or eliminate conditions that pose immediate or potential threats to worker safety, public health or the environment. These have included removal of exposed friable asbestos and overhead piping, power pole and wire removal, nonprocess-building demolition, Ash Pond isolation, and containerized chemical consolidation. Section 3.2 of this report details the interim response actions (IRAs) in process or completed during 1989.

The WSSRAP evolved from a National Environmental Policy Act (NEPA) authority decommissioning and cleanup project in 1986 into a remedial action project under combined NEPA-Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) authority requiring a Remedial Investigation/Feasibility Study (RI/FS) and complete environmental documentation as of autumn of 1987. In 1989, the environmental documentation process necessary to begin the excavation of the bulk waste from the WSQ was completed. The residual contamination within the quarry confines can be characterized when the excavation is completed.

A more detailed presentation of the production, ownership and waste history of the WSS is available in the Remedial Investigation reports for the WSQ and the WSCP/WSRP prepared by and available from the DOE Project Office.

1.3 Environmental Setting

The environmental setting of the WSCP/WSRP and the WSQ are described briefly below. A more detailed description is provided in the RI/FS-EIS Work Plan for the WSS (MKF and JEG, 1988a). The

WSRP/WSCP area is located on the Missouri- Mississippi River surface-drainage divide. The topography is gently undulating and generally slopes northward toward the Mississippi River. To the southeast are bluffs that overlook the Missouri River floodplain. Though the bedrock under the site is fractured, it is overlain by low permeability clays ranging from 1 to 9 m (3 to 30 ft) thick.

Burlington-Keokuk cherty limestone is the first bedrock unit and the first aquifer underlying the WSCP/WSRP. Bedrock topography varies in elevation from about 178.3 m (585 ft) National Geodesic Vertical Datum (NGVD) to 193 m (635 ft) NGVD.

The Burlington-Keokuk limestone is vertically fractured with two primary joint sets trending between N30°E and N72°E and between N30°W and N65°W (Roberts, 1951) and is susceptible to natural solution processes. Burlington-Keokuk solution features normally develop along fractures and bedding planes. Most solution features are small (up to several centimeters wide) and may or may not be clay filled.

Most surface water runoff from the WSCP/WSRP area discharges either through an intermittent stream in the Army Reserve Training Area or through the Ash Pond diversion structure on the WSCP property to Schote Creek. An additional surface drainage system reaching Schote Creek exits the WSCP area along the Frog Pond drainage. That drainageway carries storm water from most of the plant area where concrete surfaces drain into a storm water sewer system. The Frog Pond drainageway also carries runoff from the northeastern portion of the WSCP. Drainage from the southern portion of the WSCP property travels southeast to the Missouri River.

Schote Creek combines with Dardenne Creek and flows northeast to the Mississippi River. Schote Creek and several of its tributaries are impounded on the August A. Busch Memorial Wildlife Area. Dardenne Creek, portions of Schote Creek, and lakes on the August A. Busch Memorial Wildlife Area support aquatic life and are accessible to the public for recreational activities, such as fishing.

The WSQ is located on the northern bluff of the Missouri River valley. The unconsolidated upland material overlying bedrock consists of up to 10 m (30 ft) of silty clay soil developed from loess deposits. A residual soil is present in some areas between the silty clay and bedrock.

Sediments along the Missouri River vary from clays and silts through sands, gravels, cobbles, and boulders. The maximum alluvium thickness near the WSQ is approximately 30 m (100 ft). The alluvium "pinches out" at the base of the bedrock bluffs along the now-abandoned Missouri-Kansas-Texas (MKT) rail line. The alluvium thickness increases dramatically as distance from the Missouri River valley wall increases and then levels out.

Approximately 210 m (700 ft) to the south of the WSQ, toward the Missouri River, lies a 2.4 km (1.5 mi) section of the original Femme Osage Creek that was dammed at both ends between 1960 and 1963 by the University of Missouri. This section is now called the Femme Osage Slough. Southwest of the slough lies the area of floodplain alluvium from which St. Charles County draws its drinking water. Eight production wells are in this area, of which only five usually operate at one time. Average production from the well field is about 40 million liters (10 million gallons) per day.

Figure 1-6 shows silts and clays with minor amounts of sand as the primary sediments between the bluff and the Femme Osage Slough. The water-producing sands and gravels, 15 to 20 m (50 to 60 ft) thick, appear to pinch out southeast of the slough near the WSQ.

The WSQ bedrock consists of three distinct Ordovician formations. In descending order, they are the Kimmswick Formation, the Decorah Formation, and the Plattin Formation. The Bushberg Formation (the lowermost Mississippian formation in the area of the WSS) overlies the Kimmswick Formation to the north, west, and east of the WSQ at higher elevations but is not present at the WSQ.

With the exception of the Missouri River floodplain to the south, the topography of the WSQ area is rugged. Surface drainage in the area flows to the Missouri River, 1.6 km (1 mi) to the east, through the Femme Osage Creek and Little Femme Osage Creek (Figure 1-7).

Groundwater Occurrence

Groundwater in the vicinity of the WSRP and WSCP areas occurs in two separate zones: perched lenses and the underlying bedrock. Perched groundwater is present in small, isolated deposits of coarse-grained glacial drift.

A groundwater divide at the WSCP/WSRP trends roughly northeast to southwest through the eastern portion of the plant. Groundwater in the Burlington-Keokuk Formation flows to the northwest and to the southeast on opposite sides of the divide. Groundwater contamination sources include the raffinate pits, Ash and Frog ponds, and losing streams draining the site. The

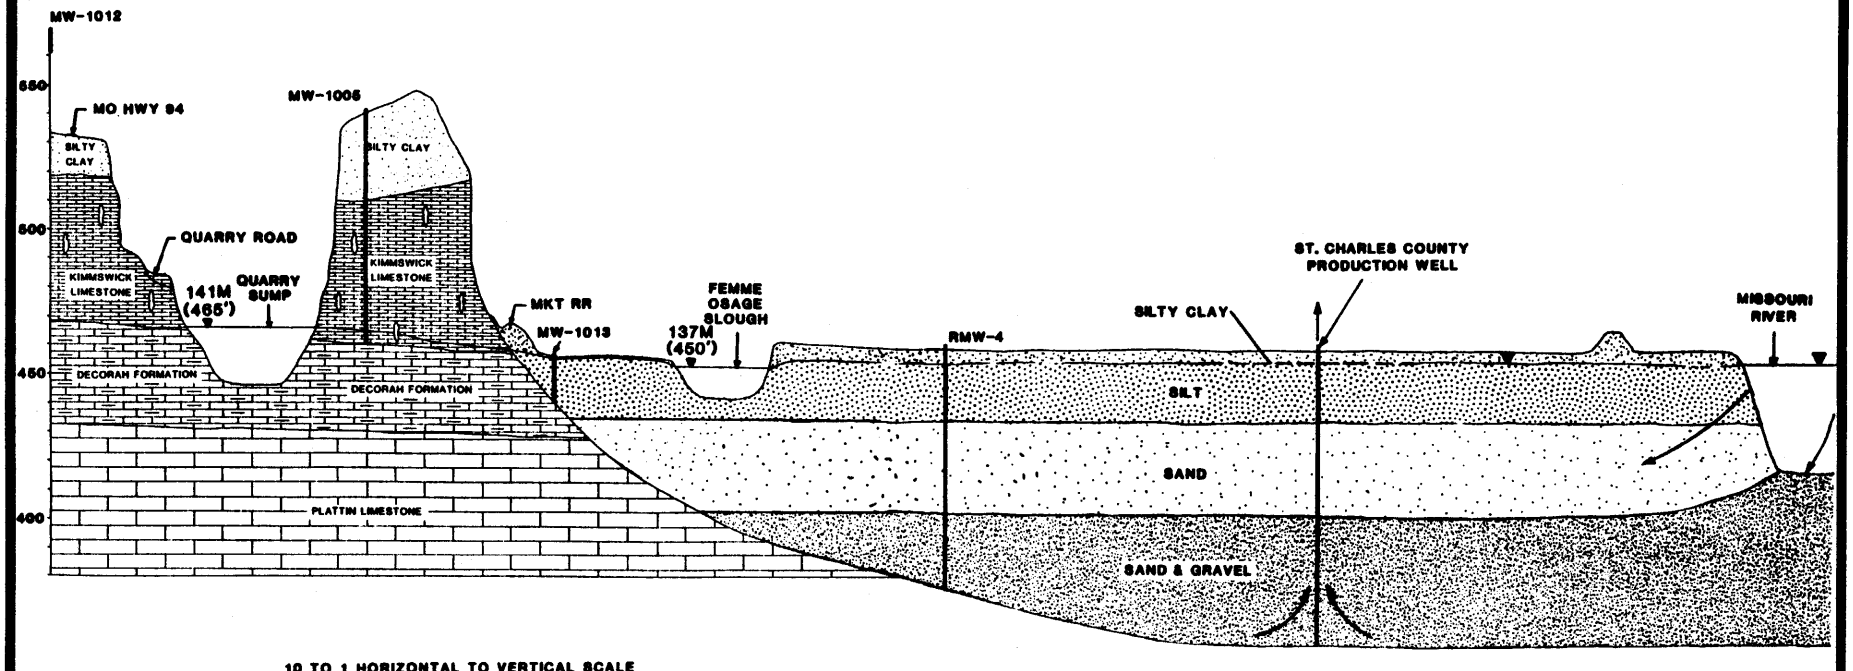

FIGURE 1-6

TYPICAL HYDRO-GEOLOGIC CROSS-SECTION OF WSQ AREA

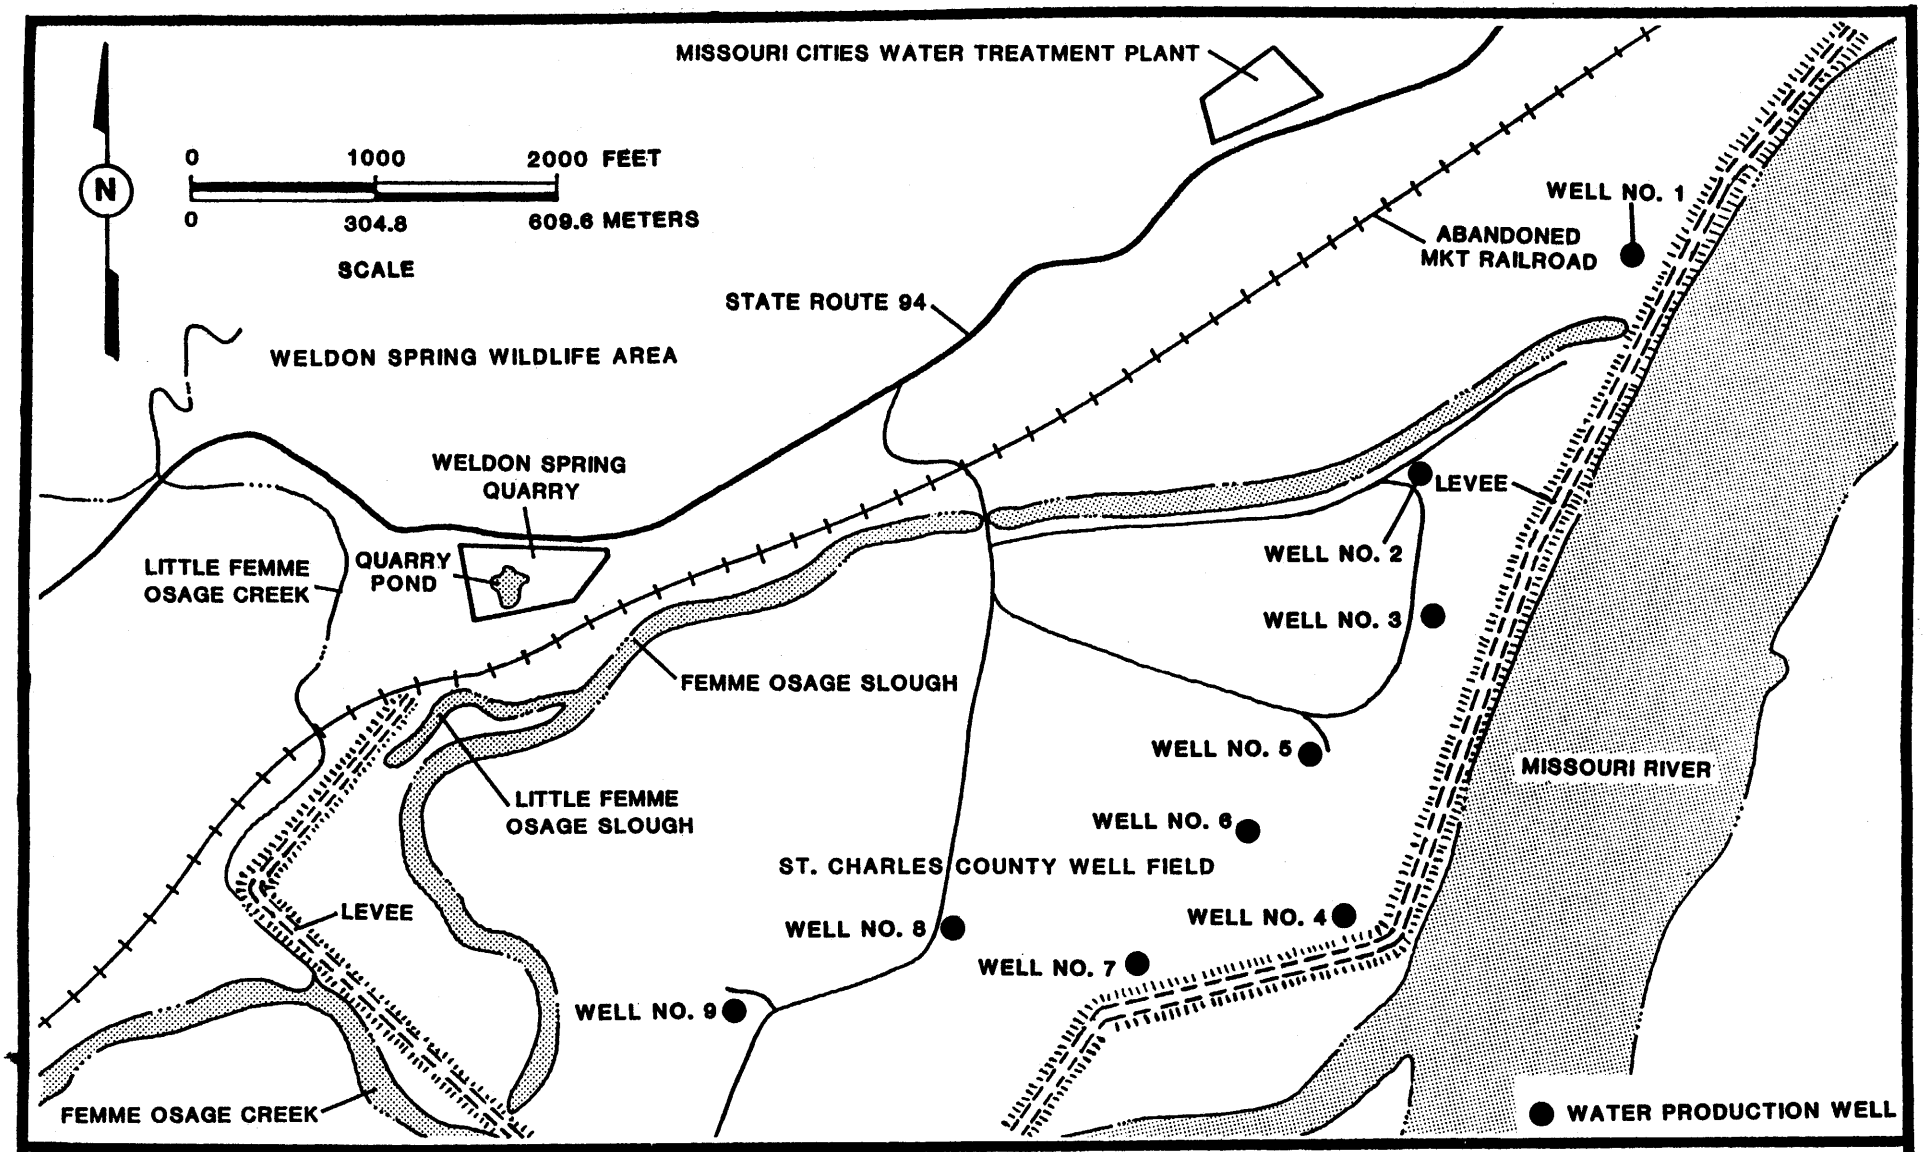

FIGURE 1-7

WELDON SPRING QUARRY & ST. CHARLES COUNTY WELL FIELD

Burlington-Keokuk Formation is not a heavily utilized aquifer, but private wells do supply households in rural areas. No private wells are currently utilized in the Burlington-Keokuk Formation within 2 km (1.25 mi) of the WSCP/WSRP.

Groundwater in the WSQ vicinity occurs both in bedrock and Missouri River alluvium (Figure 1-6). Groundwater flow near the WSQ is influenced by the Missouri River and pumpage from the St. Charles County well field, and varies with river stages and pumping rates. These production wells are controlled and monitored under public drinking water regulations. No additional active water supply wells are completed in the alluvial aquifer near the WSQ.

Local Climate Summary

The climate in the WSS area is continental, with moderately cold winters and warm summers. Alternating warm/cold, wet/dry air masses converge and pass eastward through the area almost daily. Normal annual precipitation in the area is approximately 85 centimeters (cm) (39 in.), with the heaviest rainfall occurring in spring and early summer. The total measured precipitation at the WSCP in 1989 was 72 cm (28.5 in.). The average temperature is 13° C (56° F). Prevailing winds in the vicinity of the WSS are from the south during the summer and fall. Wind speeds during these months average 13.9 km/h (8.7 mph). Winds during the winter months are from the northwest and west-northwest, averaging 17.6 km/h (11 mph) (GRC, 1985).

1.4 Summary of 1989 Environmental Monitoirng Activities

The 1989 Environmental Monitoring Program was carried out in order to identify, characterize and monitor release pathways for

both radiological and chemical constituents. Following the extensive characterization efforts conducted in 1988 as part of the remedial investigations of the site, an expanded quarterly monitoring program was instituted to collect additional data to allow for evaluation of seasonal or time based trends in contaminant concentrations. Groundwater sampling locations were added to the previous year's monitoring program to include the extended monitoring well network.

The surface water monitoring program was modified to include three additional locations on the Missouri River, one location at the west end of the Femme Osage Slough and additional on-site surface water bodies. Samples were collected quarterly at each location.

The program is dynamic, changing to meet the monitoring needs of the site as new physical and analytical data are assimilated and as release pathways are better understood. These release pathways include groundwater (via subsurface migration), surface water (via storm-water runoff), and air.

In 1989, 91 monitoring wells were sampled, compared with 50 wells sampled in 1988. This includes 59 wells installed at the chemical plant and raffinate pits, and 32 wells at the WSQ.

Surface water samples were collected from a total of 45 locations where measurable impacts from drainage originating at the Weldon Spring Site might be detected. These samples include 39 quarterly sampling locations and samples of storm water runoff from the six permitted outfalls at the WSCP and WSRP as required by the National Pollutant Discharge Elimination System (NPDES) Permit (storm water) for the Weldon Spring Site. The 39

quarterly sampling locations include 13 around the WSQ and 26 around the WSCP and WSRP.

A total of 22 locations were monitored quarterly for radon gas and external gamma exposure. Duplicate radon gas detectors were installed at each location to improve the precision and accuracy of the measurements. Four additional off-site monitoring locations were used to determine annual average background gamma exposure rates and radon concentrations near the WSSRAP.

Air particulate sampling for radiological parameters at the site perimeter continued on a weekly basis through 1989. Two new sampling stations were installed at the WSQ perimeter. A third station was installed one-half mile west (up prevailing wind direction) to provide background measurements. The air was monitored at these locations to establish ambient baseline data and to monitor for potential off-site releases. Data from this program will also be used to assess the effectiveness of engineering controls at the site during future remedial action activities.

1.5 Compliance Summary

The PMC is responsible for the management of hazardous waste at WSSRAP including the characterization, consolidation, inventory, storage, transportation, and disposal of hazardous and other wastes that remained on-site after closure of the WSUFMP and for wastes generated during remedial action activities. All WSSRAP waste management activities are performed in accordance with the Resource Conservation and Recovery Act and the Toxic Substances Control Act (RCRA and TSCA), as well as Occupational Safety and Health Act, (OSHA), Department of Transportation (DOT)

and Missouri regulations concerning the storage, labeling, transport and disposal of hazardous materials, and DOE Order 5820.2A, Radioactive Waste Management.

Compliance issues were determined through continuing internal evaluation and a series of audits conducted by the DOE and the PMC. These issues, their resolution and status are presented in Table 1-1 and the open issues explained in more detail in the text. Those issues identified as closed in Table 1-1 are considered closed by the PMC/DOE WSSRAP Office. Only four of 19 compliance issues remain open at this time. These issues should be resolved in 1990; they are described in the following subsections.

1.5.1 Improper Storage of PCB Contaminated Materials (40 CFR 761.65)

Issue: All non-radiologically contaminated PCB articles have previously been removed and appropriately disposed of by off-site treatment, storage, and disposal facilities. Except for the capacitors in Building 301, the remaining PCB-contaminated equipment has been placed in proper storage, labelled, and inspected weekly. The capacitors in Building 301 are stored in a cabinet and offer minimal threat of release.

Corrective Action: The capacitors are labelled and inspected monthly, and are scheduled for removal during the first half of 1990 through the ongoing chemical containerization interim response action at WSSRAP (Section 3.2.5).

TABLE 1-1 Regulatory Compliance Summary

Issue	Regulation	Resolution/Date	Status
Inadequate separation of wastes	40 CFR 264.177(o)	Proper storage in Bldg 434 - 04/90	Closed
Run-on into waste storage area	40 CFR 264.175(b)(4)	Proper storage in Bldg 434 - 04/90	Closed
Inadequate aisle space	40 CFR 264.35	Proper storage in Bldg 434 - 04/90	Closed
Inadequate characterization of wastes	40 CFR 264.13(a)(1)	Wastes are being characterized - 05/90	Closed
Waste Analysis Plan inadequately describes methods	40 CFR 264.13(a)	Waste Analysis Plan revised - 05/90	Closed
Inadequate inspection records	40 CFR 264.15(d)	Procedure revised 11/89	Closed
Contingency Plan did not address emergencies	40 CFR 264.52	Plan revised 04/90	Closed
Improper storage of PCB contaminated RCRA liquid	40 CFR 761.65	Containment Structure built 11/89	Closed
Improper storage of PCB contaminated materials	40 CFR 761.65	Routine inspection/ labelling-Removal planned for 1990	Open
Storage of PCB contaminated material in excess of 1 year	40 CFR 761.61a	Removal scheduled for 1990	Open
Annual PCB Report not completed by July 1	40 CFR 761.180	Report submitted 11/89	Closed
PCB items not inspected every 30 days	40 CFR 761.65(c)(5)	Inspections performed 09/89	Closed
PCB items not properly labelled	40 CFR 761	Items properly labelled	Closed
Radionuclide emission monitoring not confirmed by EPA as suitable for NESHAP	40 CFR 61.93	Under discussion with EPA	Open
Inadequate water supply for RCRA storage	40 CFR 264.32(d)	Sprinkler system in Building 434	Closed

TABLE 1-1 Regulatory Compliance Summary (Continued)

Issue	Regulation	Resolution/Date	Status
Receipt of improper radiological shipment	49 CFR 172.20, .300, .400, 173.400	Vehicle surveyed; no contamination	Closed
Offsite release of radionuclide	Clean Water Act (CWA) Section 311(b)(1)	CWA satisfied. Ongoing remedial action (Ash Pond Diversion 05/89)	Closed
Offsite release of nitroaromatic compounds	Clean Water Act Section 311(b)(1)	CWA satisfied. Ongoing remedial action	Closed
Storage of PCB and land ban wastes beyond 1 year	40 CFR 761.65(a) and 268.50(a)	Destruction scheduled for 1990	Open

1.5.2 Storage of PCB Contaminated Material in Excess of the One Year Limit (40 CFR 761.61a)

Issue: Remaining PCB capacitors and equipment have been stored for more than one year. These items remained from WSUFMP operation and were recently identified and characterized.

Corrective Action: All PCB contaminated capacitors and equipment currently in temporary storage are properly labelled and inspected weekly. They are scheduled to be radioactively decontaminated and removed during the first half of 1990 as a part of the chemical containerization interim response action.

1.5.3 Storage of PCB and Land Ban Wastes Beyond the One Year Storage Requirement (40 CFR 761.65(a) and 40 CFR 268.50(a))

Issue: There are approximately 7,400 gallons of tributyl phosphate (TBP) stored at WSSRAP which is RCRA and TSCA regulated as well as being contaminated with radionuclides. The TBP remains stored in the same two tanks it was placed in during the late 1960s.

Corrective Action: WSSRAP is addressing this issue in three ways. The primary effort involves dialogue with the Oak Ridge Gaseous Diffusion Plant (ORGDP) to have the TBP prioritized for destruction by their permitted incinerator. In October, the WSSRAP resampled the material to verify that it meets ORGDP's analytical acceptance criteria, and the results were forwarded to ORGDP in eary 1990.

Another approach has been to reply to an ORO request for input seeking a nationwide extension for storage of

radiologically contaminated land ban waste. Also a request to EPA Region VII for a variance from the storage requirements for radiologically contaminated land ban and PCB wastes was submitted in eary 1990.

1.5.4 Radionuclide Emissions Monitoring that is Currently Conducted at Weldon Spring Does Not Meet the Requirement for the Radionuclide NESHAPS (40 CFR 61.93)

Issue: The WSSRAP is currently using an environmental monitoring network which monitors the source (the entire WSS). However, the WSSRAP is not in strict compliance with NESHAPS requirements since it does not measure "annual air concentration where a maximally exposed individual resides."

Corrective Action: On March 18, 1989, WSSRAP personnel met with EPA Region VII personnel to outline the off-site Radionuclide Monitoring Plan. EPA Region VII agreed that the proposed monitoring plan would meet the requirements of 40 CFR 61, and the regional EPA staff will brief EPA Headquarters. Region VII will then convey Headquarters' comments to the WSSRAP during 1990. If the Radionuclide Monitoring Plan is acceptable, the PMC will issue the proposed monitoring plan in writing for EPA approval. This written plan will be completed and reviewed by the WSSRAP DOE in 1990.

2 ENVIRONMENTAL MONITORING RESULTS

Environmental monitoring is the first line of defense in protecting the public and environmental health and safety. Additionally, environmental monitoring is done to ensure that any potential public exposure is documented and quantified, and to demonstrate compliance with applicable legal and regulatory requirements; to confirm adherence to the U.S. Department of Energy (DOE) environmental protection policies; and to support environmental management decisions.

This portion of the report presents monitoring results and includes discussions about the environmental conditions at the Weldon Spring Site (WSS). The Weldon Spring Remedial Action Project (WSSRAP) is moving toward compliance with DOE Order 5900.2 by presenting parenthetically the standard international (SI) units following the more commonly used unit for these measurements. The WSSRAP is phasing into full compliance by the year 1992 as DOE Order 5900.2 requires.

2.1 Groundwater Monitoirng

All Weldon Spring Chemical Plant/Raffinate Pits/Vicinity Properties (WSCP/WSRP/WSVP) and Weldon Spring Quarry (WSQ) monitoring wells were sampled at least annually during 1989. Wells installed during 1988 or wells of particular importance or interest were sampled quarterly. Through routine monitoring and investigations at the site, an understanding of groundwater quality and hydrogeology has been established over the past several years. Therefore the groundwater monitoring program has been changed since earlier years and made more efficient by avoiding unnecessary or redundant sampling and analysis. Through

these modifications, a high quality program which effectively assesses the groundwater quality has been maintained.

The WSSRAP continues to monitor for uranium, inorganic anions (nitrate, sulfate, chloride, fluoride), and nitroaromatic compounds in the groundwater. Six nitroaromatic compounds have been associated with the WSOW; 1,3,5-trinitrobenzene, 1,3-dinitrobenzene, nitrobenzene, 2,4,6-trinitrotoluene, 2,4-dinitrotoluene and 2,6-dinitrotoluene.

Data tables of all laboratory analytical results presented in this section contain annual concentrations calculated from data generated during 1989 where more than one analysis was conducted. These values are usually compared to background concentrations and/or to U.S. Environmental Protection Agency (EPA) or DOE guidelines. The guidelines are for discussion purposes and may not be strictly applicable. The annual concentration is stated in each column with a fraction in parentheses adjacent to that value. The numerator is the number of samples used to calculate the annual concentration. If only one sample was collected, it was reported as the annual concentration. The denominator is the number of times that particular well was sampled during 1989. An "ND" indicates "Not Detected" and appears only if a particular parameter was not detected above the detection limit in any analyses done on samples obtained from that well during 1989. If the analytical laboratory reported an "ND" for a particular parameter for a particular sampling event, the ND was not used to calculate the annual concentration. Individual quarterly results are presented in data tables in Appendix A.

Groundwater quality trend analyses are presented in this report. Chemical and radiological concentrations for each monitoring well included in the monitoring program in 1987, 1988,

and 1989 are presented graphically. Uranium, nitroaromatic compounds, nitrate, and sulfate data were analyzed for trends at both the WSCP/WSRP/WSVP and the WSQ areas, and are presented in this section.

Groundwater monitoring wells are grouped in the trend analyses by location on the horizontal axis of the graph while parameter concentrations are listed on the vertical axis. Symbols representing the annual concentrations for 1987, 1988, and 1989 are plotted for each well. For each well sampled, a symbol appears on the graph at a point intersecting the vertical location line and the horizontal concentration line for that year. The graphic analysis enables the reader at a glance to see consistencies or fluctuations over time.

2.1.1 Groundwater Monitoring at the Weldon Spring Chemical Plant/Raffinate Pits

Groundwater at the WSCP/WSRP became contaminated as a result of the Weldon Spring Ordnance Works (WSOW) operations during World War II and operations at the Uranium Feed Materials Plant during the 1950s and 1960s. The Phase I Water Quality Assessment Report (MKF and JEG, 1987) reported that: "groundwater near the raffinate pits contains elevated amounts of uranium; nitroaromatic compounds are present at low to high levels over much of the site; and relatively widespread nitrate and sulfate contamination problems are the result of leaking raffinate pits and other sources." The Phase II Groundwater Quality Assessment Report (MKF and JEG, 1989a), an expanded, comprehensive evaluation of groundwater quality at the WSCP/WSRP/WSVP area during the third quarter of 1988, is essentially in agreement with the Phase I report. Two notable exceptions are that the nitrate plume has been more clearly defined and that the original

sulfate plume reported in the Phase I Water Quality Assessment is actually several isolated plumes, and its source is not exclusively the raffinate pits. These exceptions were detected as a result of additional monitoring well installations.

The groundwater monitoring network consists of 59 wells, 28 at the WSCP, eight at the WSRP, and 23 at the WSVP. Figure 2-1 shows the locations of individual wells in the WSCP/WSRP/WSVP monitoring well network. All of these wells are screened in the uppermost unconfined aquifer. The wells are completed in a range of depths in order that the entire uppermost aquifer is monitored. Detailed well construction information for individual wells is available in the 1990 Environmental Monitoring Plan (MKF and JEG, 1990a).

2.1.1.1 Radiological Results

The upper bound for natural uranium background concentrations in groundwater at the WSCP/WSRP/WSVP was determined to be 3.4 pCi/l (0.125 Bq/l) (MKF and JEG, 1989a). EPA has not yet established drinking water standards for uranium; however studies leading to proposed rulemaking are using uranium in the 10 to 40 pCi/l (0.37 to 1.48 Bq/l) range (MKF and JEG, 1989a). The DOE has a derived concentration guideline (DCG) of 550 pCi/l (20.35 2Bq/l).

Each groundwater monitoring well was sampled and analyzed for total natural uranium during 1989. Table 2-1 provides the annual concentrations.

Forty-five of the groundwater monitoring wells have total uranium concentrations below the upper bound for natural background. Eight monitoring wells--MW-2003, MW-2020, MW-2028,

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

* Detection Limit

@ Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1989. For example, 2.00 (2/4) indicates that 4 samples were taken in 1989, 2 of which average 2.00 and the other 2 samples were ND.

MW-3002, MW-3008, MW-3019, MW-4010 and MW-4016--show annual concentrations above background but below 10 pCi/l. Four wells, MW-2017, MW-3003, MW-4020 and MW-4021 have annual concentrations of uranium in the 10 to 40 pCi/l range. Monitoring wells MW-3009 and MW-4004 have the highest annual concentrations, 50 and 70.50 pCi/l (1.85 and 2.59 Bq/l), 9% and 12% of the DCG respectively. Figure 2-2 highlights those wells with above background (3.4 pCi/l) annual natural uranium concentration. These results are generally consistent with 1988 monitoring and characterization results.

WSCP/WSRP/WSVP URANIUM TREND ANALYSIS

The annual average uranium concentrations reported in previous monitoring reports and this report are displayed for comparison in Figure 2-3. Since 1987, groundwater uranium concentrations generally has not varied dramatically. The exceptions to this are MW-2020 and MW-3009 each of which has both decreased and increased concentrations of uranium with time. The source of uranium contamination in these wells has not yet been removed; therefore it might be expected that concentrations of uranium in groundwater will continue to fluctuate until remedial action removes the source. Monitoring Well 2017 is the only well that continually increased from 1987 to 1989. The cause of this increase is not known. All monitoring wells, with the exception of MW-3009, which is adjacent to the raffinate pits, had annual concentrations of uranium below 40 pCi/l during this three-year period. Overall, increases of uranium concentrations have not been observed.

ANNUAL URANIUM CONCENTRATIONS WSCP/RP/VP GROUNDWATER 1987-1989

2.1.1.2 Analytical Results for Nitroaromatic Compounds

No primary or secondary drinking water standards have been promulgated for any of the six nitroaromatic compounds previously listed. However, standards set by the Clean Water Act-Federal Ambient Water Quality Criteria may be utilized as a reference for discussion. The criteria for 2,4-DNT is 0.11 µg/l based on a lifetime 10^{-6} cancer risk. For nitrobenzene, the criteria is 30 µg/l based on toxicity. Both 2,4-DNT and 2,6-DNT are suspected carcinogens. Nitroaromatic compounds are not naturally occurring; therefore any concentration detected indicates contamination of the groundwater system.

Each groundwater monitoring well was sampled and analyzed for nitroaromatic compounds during 1989. Table 2-2 provides a summary of the results. Nitroaromatic compounds were not detected in 28 monitoring wells. Twenty-four monitoring wells exhibited a cumulative annual nitroaromatic compounds concentration above ND, but below 10 µg/l. Six wells exhibited annual concentrations greater than 10 µg/l. They are MW-2006, MW-2013, MW-4001, MW-4006, MW-4009, and MW-4013. Figure 2-4 shows the locations of these wells and their respective annual concentrations.

Six groundwater monitoring wells--MW-2003, MW-2008, MW-2013, MW-3001, MW-4001 and MW-4006--exhibited annual concentrations of 2,4-DNT above the ambient water quality criteria (0.11 µg/l). Figure 2-5 highlights the locations of wells exhibiting annual concentrations of 2,4-DNT above these criteria. No monitoring wells contained annual concentrations of nitrobenzene exceeding 30 µg/l. Overall the nitroaromatic results are consistent with past environmental monitoring and characterization studies.

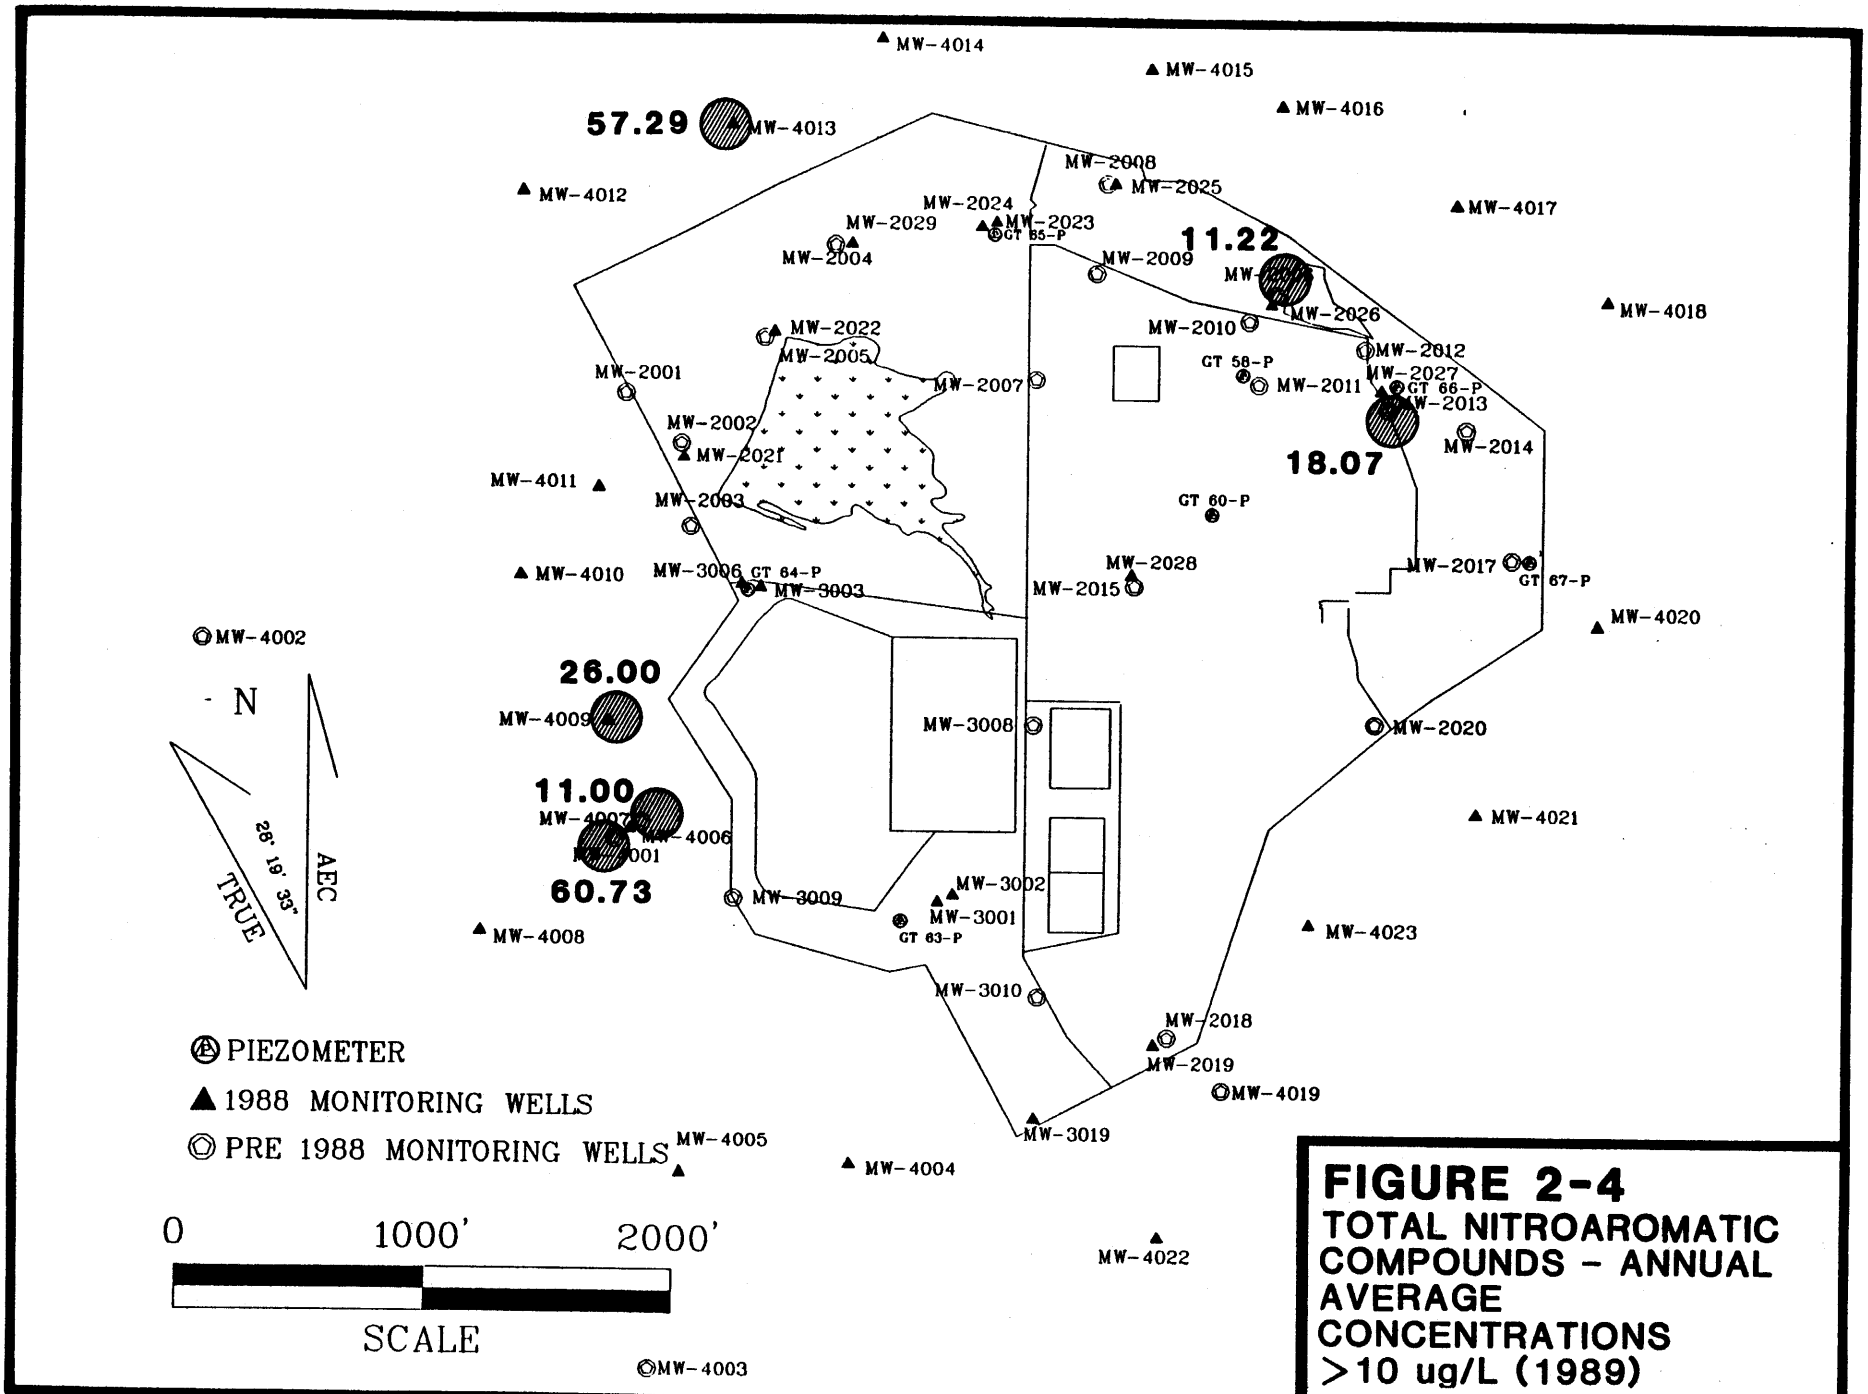

FIGURE 2-4
TOTAL NITROAROMATIC COMPOUNDS - ANNUAL AVERAGE CONCENTRATIONS >10 ug/L (1989)

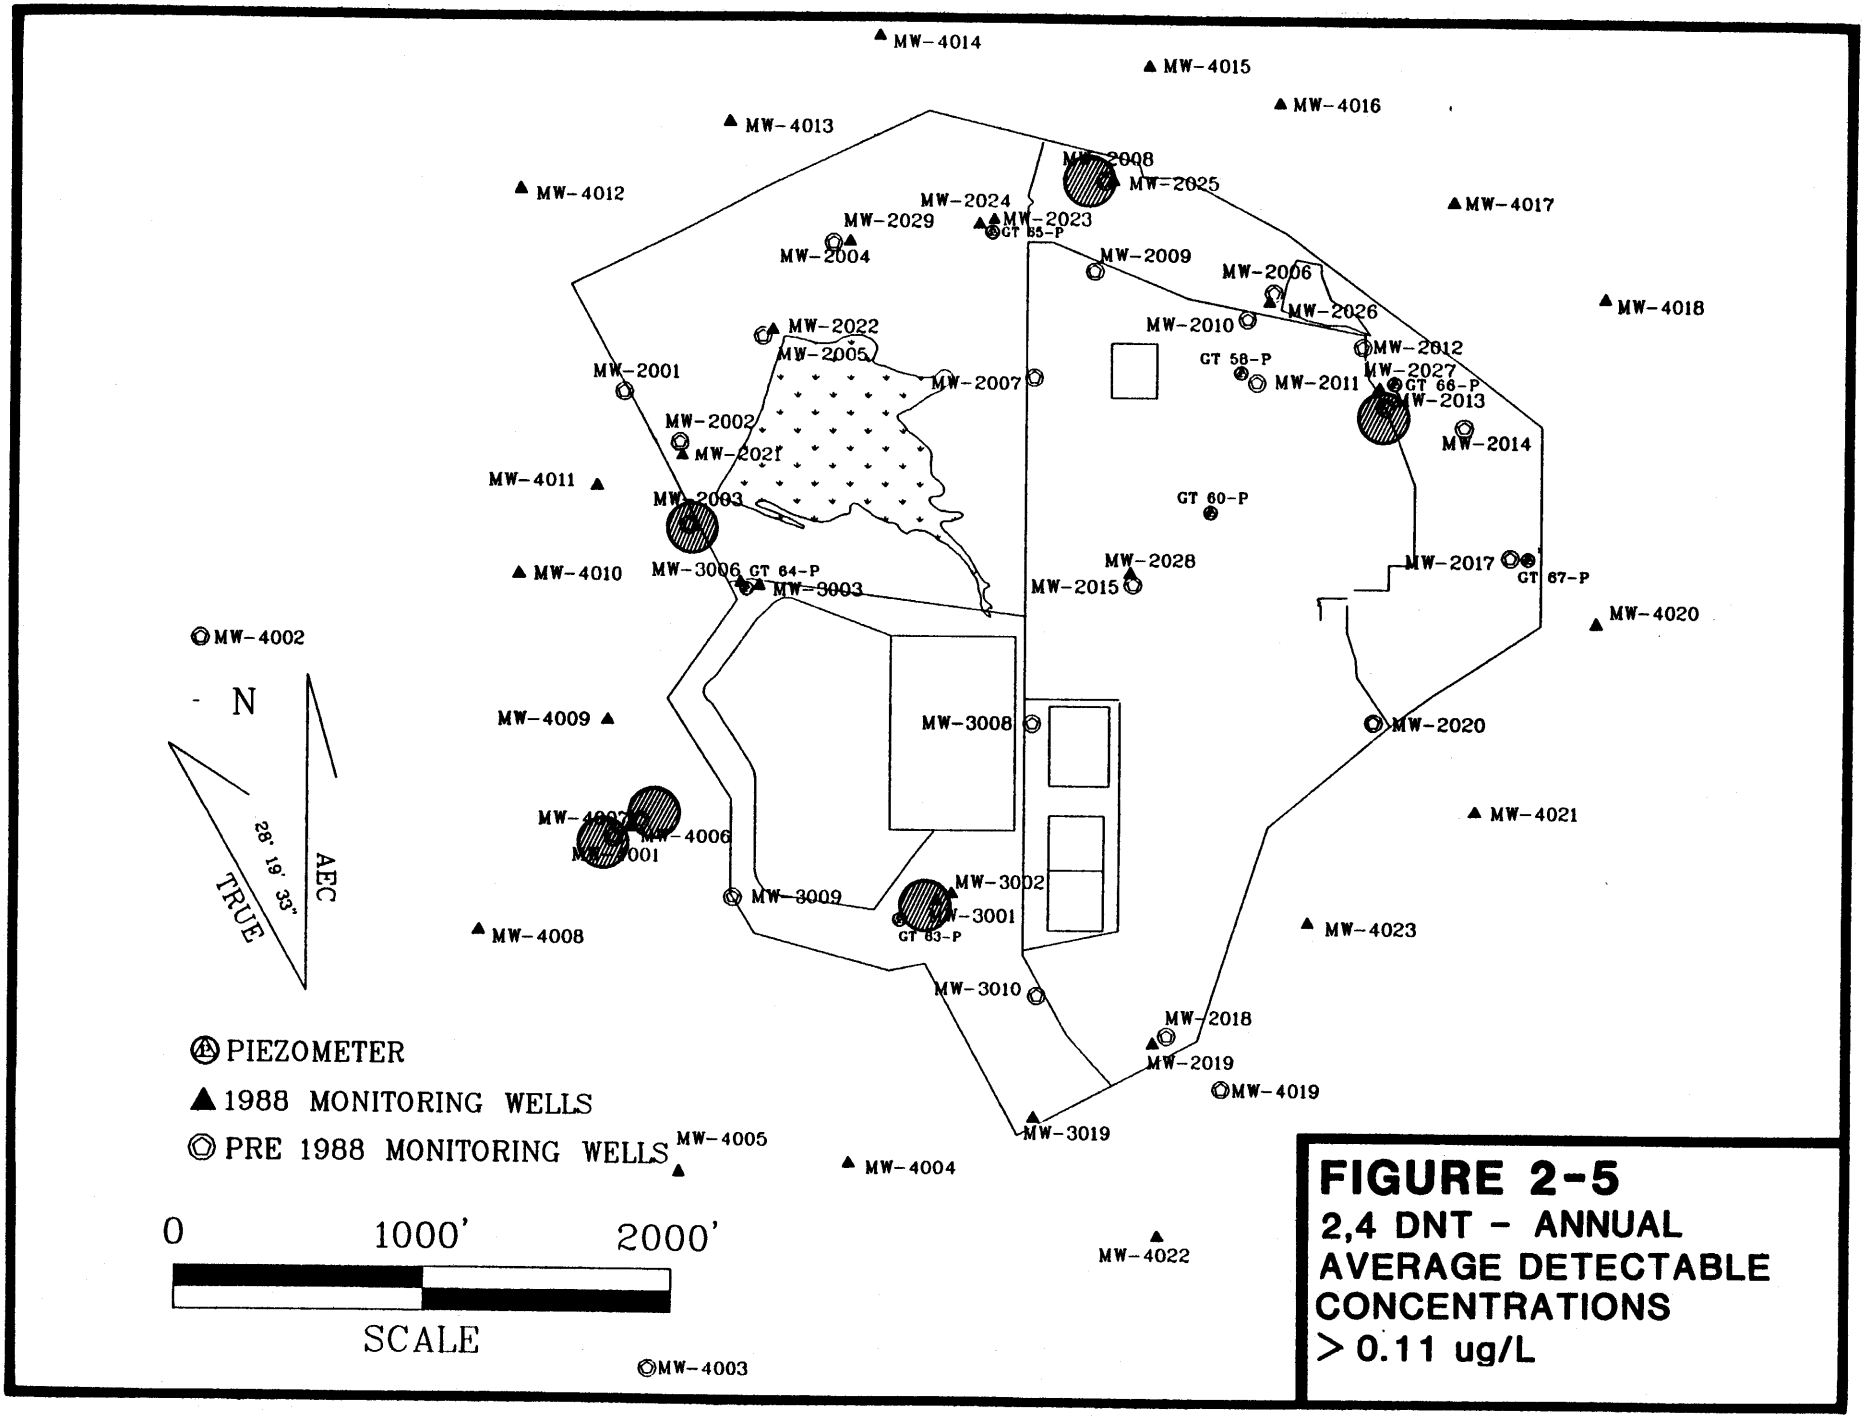

FIGURE 2-5
2,4 DNT - ANNUAL AVERAGE DETECTABLE CONCENTRATIONS > 0.11 ug/L

WSCP/WSRP/WSVP TOTAL NITROAROMATIC COMPOUNDS TREND ANALYSIS

The annual concentrations of total nitroaromatic compounds reported in previous monitoring reports and this report are displayed for comparison in Figure 2-6.

Monitoring wells within the section of the graph labeled "General WSCP/WSRP/WSVP Wells" show a very uniform, relatively low total nitroaromatic compound concentration history. Wells located within the northeast portion of the WSCP historically have had the highest concentrations of total and individual nitroaromatic compounds. Total nitroaromatic compounds concentration in all of these "northeast portion" wells, with the exception of MW-2012, have continually decreased in the period since 1987. MW-2012 had higher concentrations in 1988 than 1987. The cause of this general decrease is not known but may be due to drilling activities in 1988 and 1989.

Groundwater monitoring wells located on the Weldon Spring Training Area (WSTA) generally have displayed consistent levels of nitroaromatic compounds. MW-4001 remained the well with the highest total nitroaromatic compound concentration on the WSTA in 1989.

2.1.1.3 Inorganic Anions Results

As previously discussed, nitrate, sulfate, chloride and fluoride are included in the WSSRAP environmental monitoring program. Table 2-1 displays the annual concentrations of inorganic anions for 1989 at the WSCP/WSRP/WSVP area.

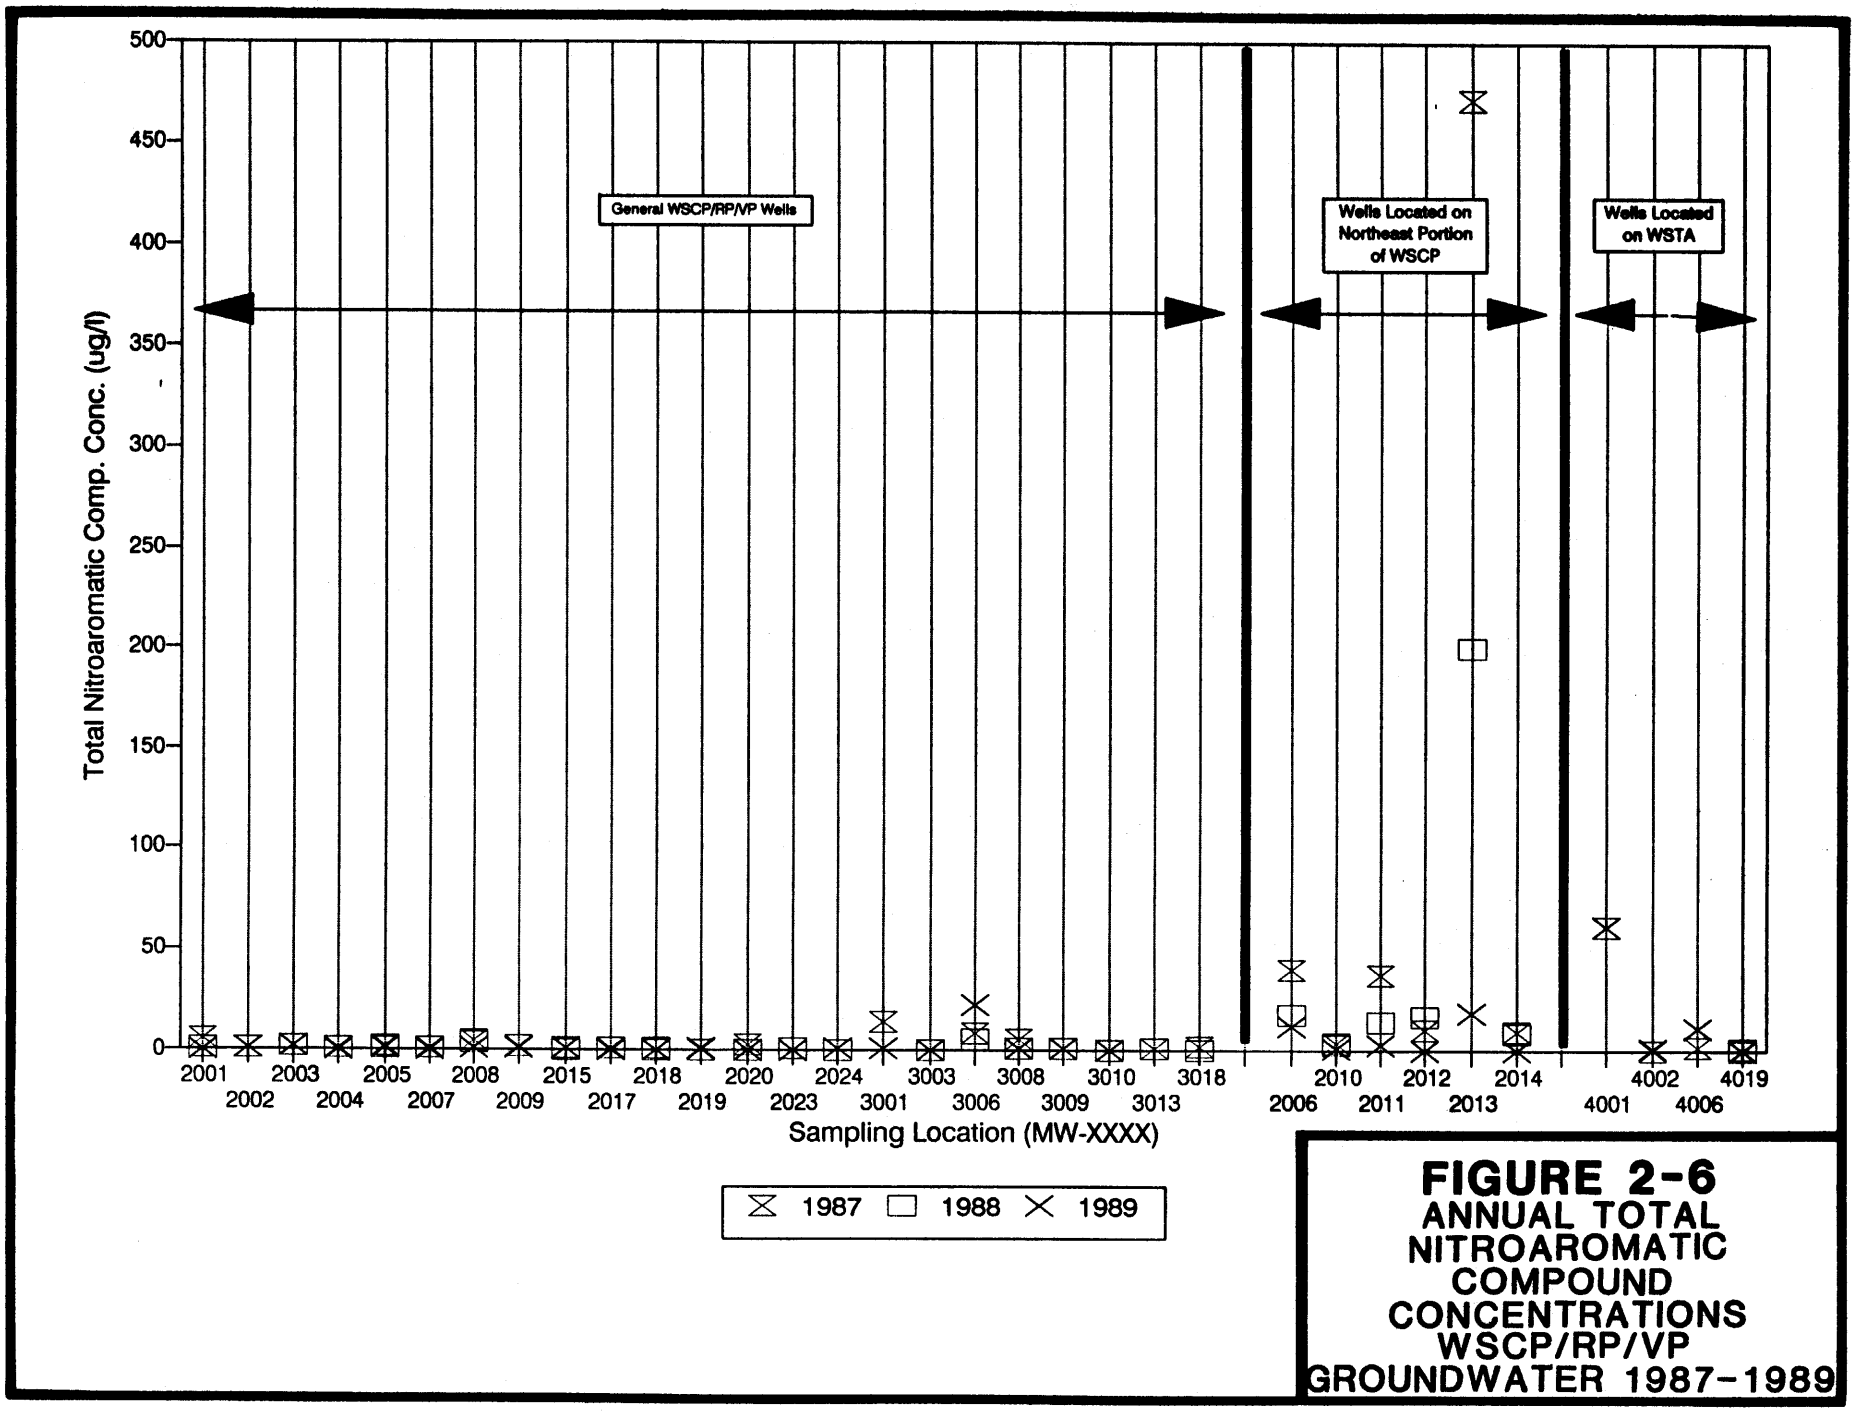

FIGURE 2-6
ANNUAL TOTAL NITROAROMATIC COMPOUND CONCENTRATIONS WSCP/RP/VP GROUNDWATER 1987-1989

NITRATE

The standard issued in the Safe Drinking Water Act for nitrate as nitrogen is 10 mg/l. Converted, this standard is 45 of nitrate. Background nitrate concentrations are below 14.43 mg/l (MKF and JEG, 1989a). During 1989, concentrations exceeding the standard occurred in 12 groundwater monitoring wells. The range of values for these wells is 50.20 mg/l in MW-2001 to 3330.00 mg/l in MW-2003. Figure 2-7 shows the locations of these wells at the WSCP/WSRP/WSVP area.

WSCP/WSRP/WSVP NITRATE TREND ANALYSIS

The nitrate concentrations reported in the previous monitoring reports and this report are displayed for comparison in Figure 2-8. Groundwater monitoring wells in the general WSCP/WSRP/WSVP area have consistently had nitrate concentrations below the drinking water standard of 45 mg/l from 1987 through 1989.

Monitoring wells shown on Figure 2-8 under "Wells at or near WSRP" are located adjacent to or closer to the raffinate pits than the general WSCP/WSRP/WSVP wells discussed above. Generally, they display a trend of increasing nitrate concentration with time. Because the raffinate pits provide hydraulic head to the groundwater system, and because they are a source of nitrate, this increasing concentration of nitrate in groundwater may be expected to continue with time, until the source is eliminated. The size of the nitrate plume does not appear to be changing, indicating that the groundwater velocity is slow.

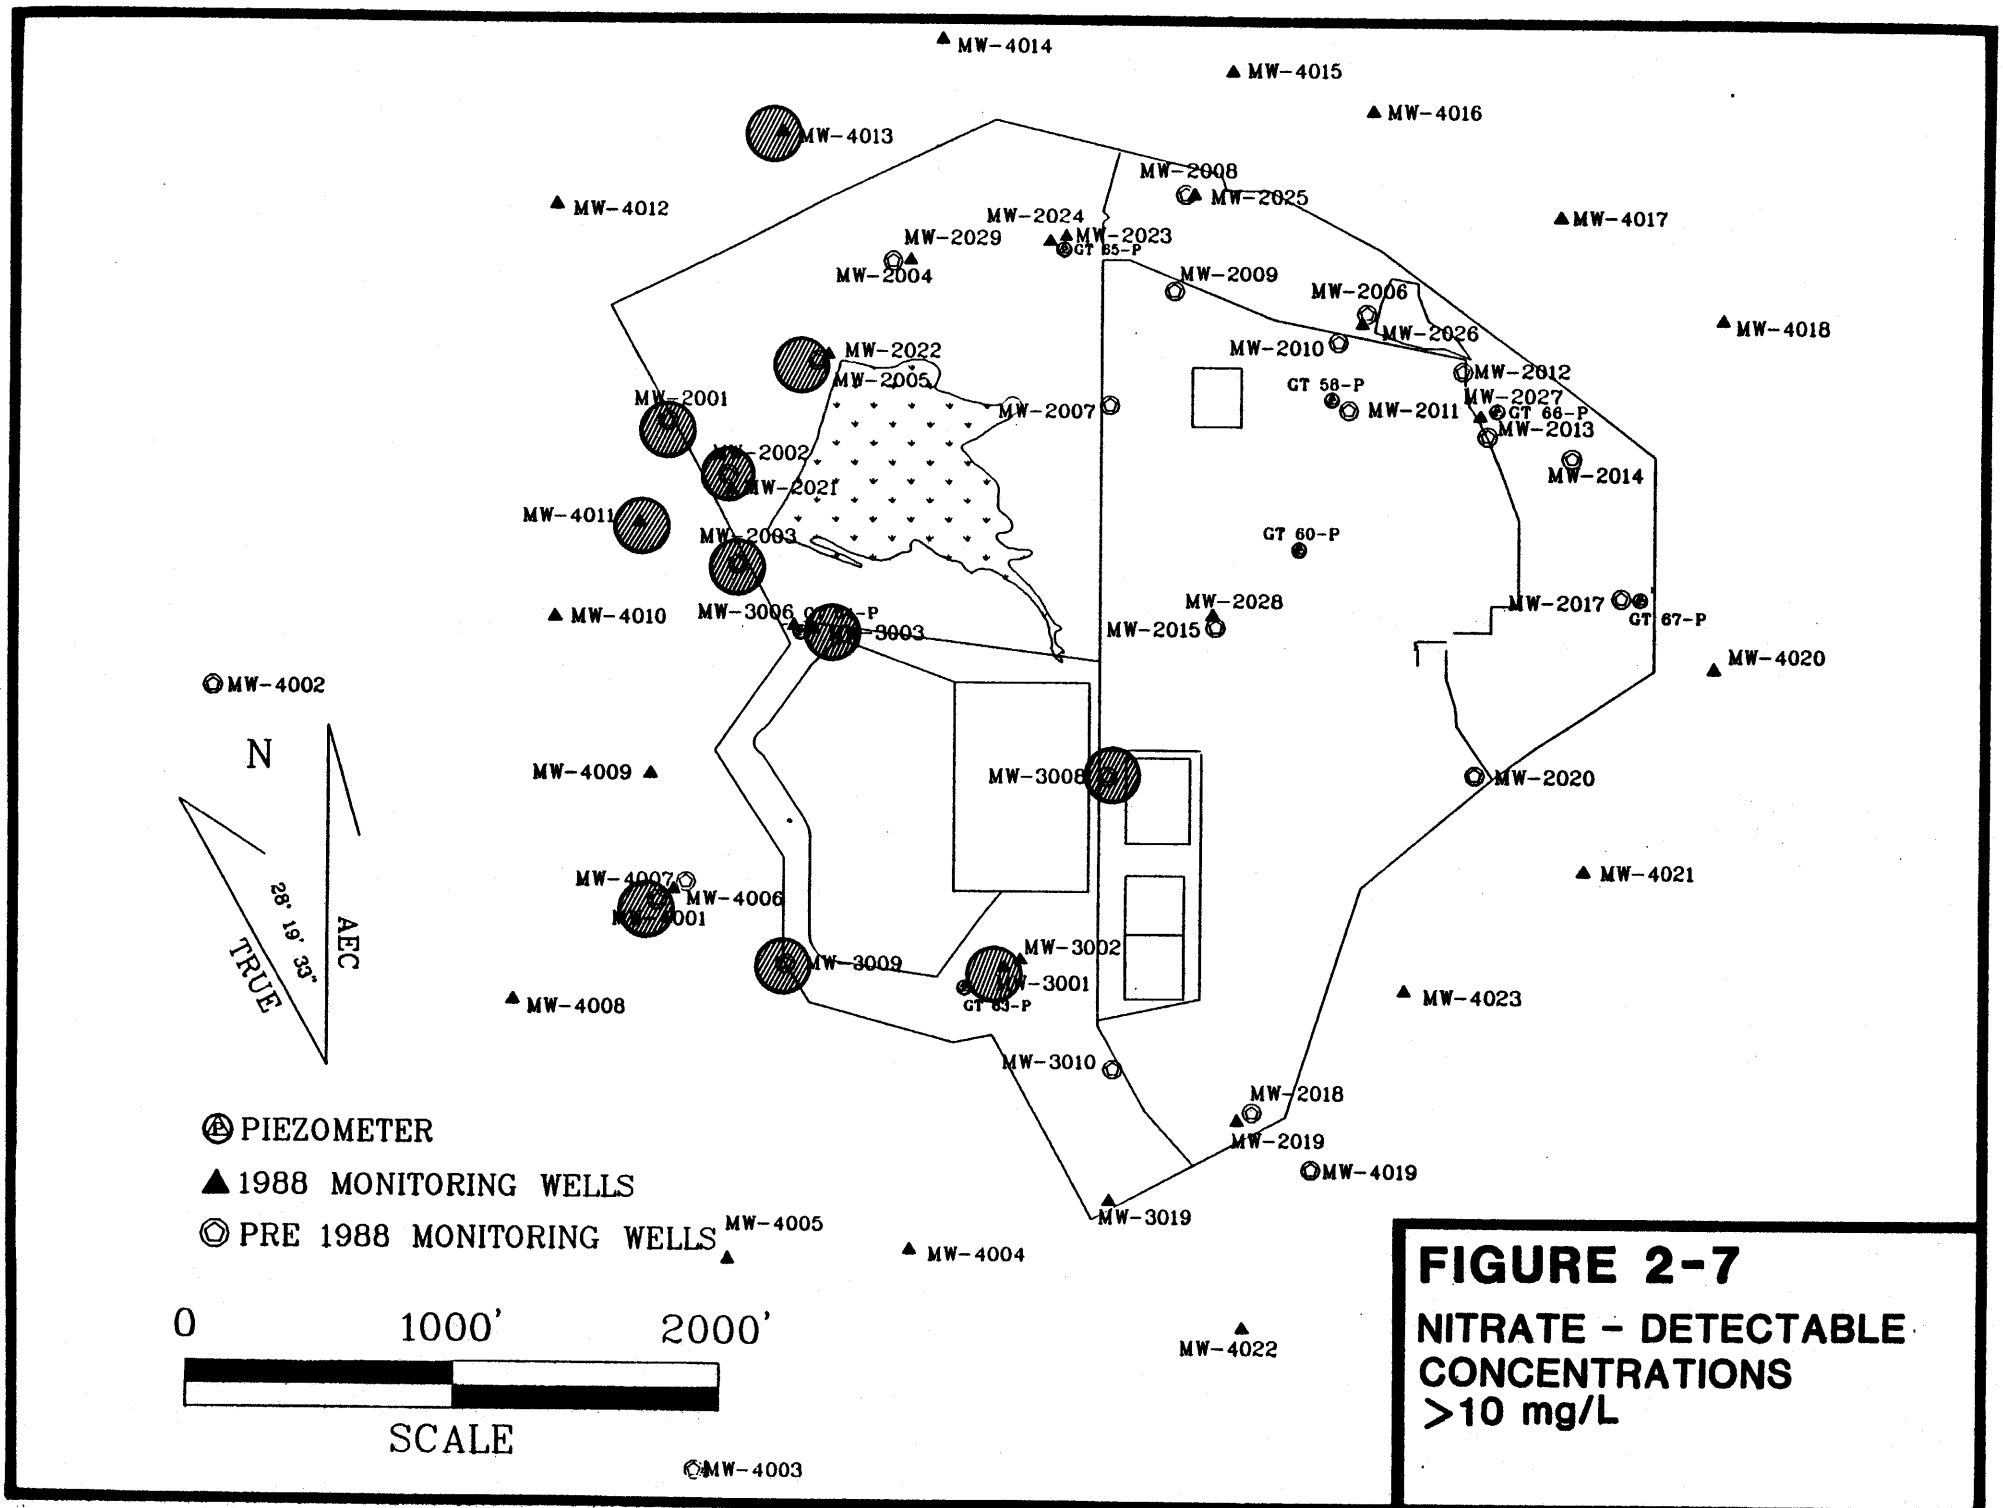

FIGURE 2-7

NITRATE - DETECTABLE CONCENTRATIONS >10 mg/L

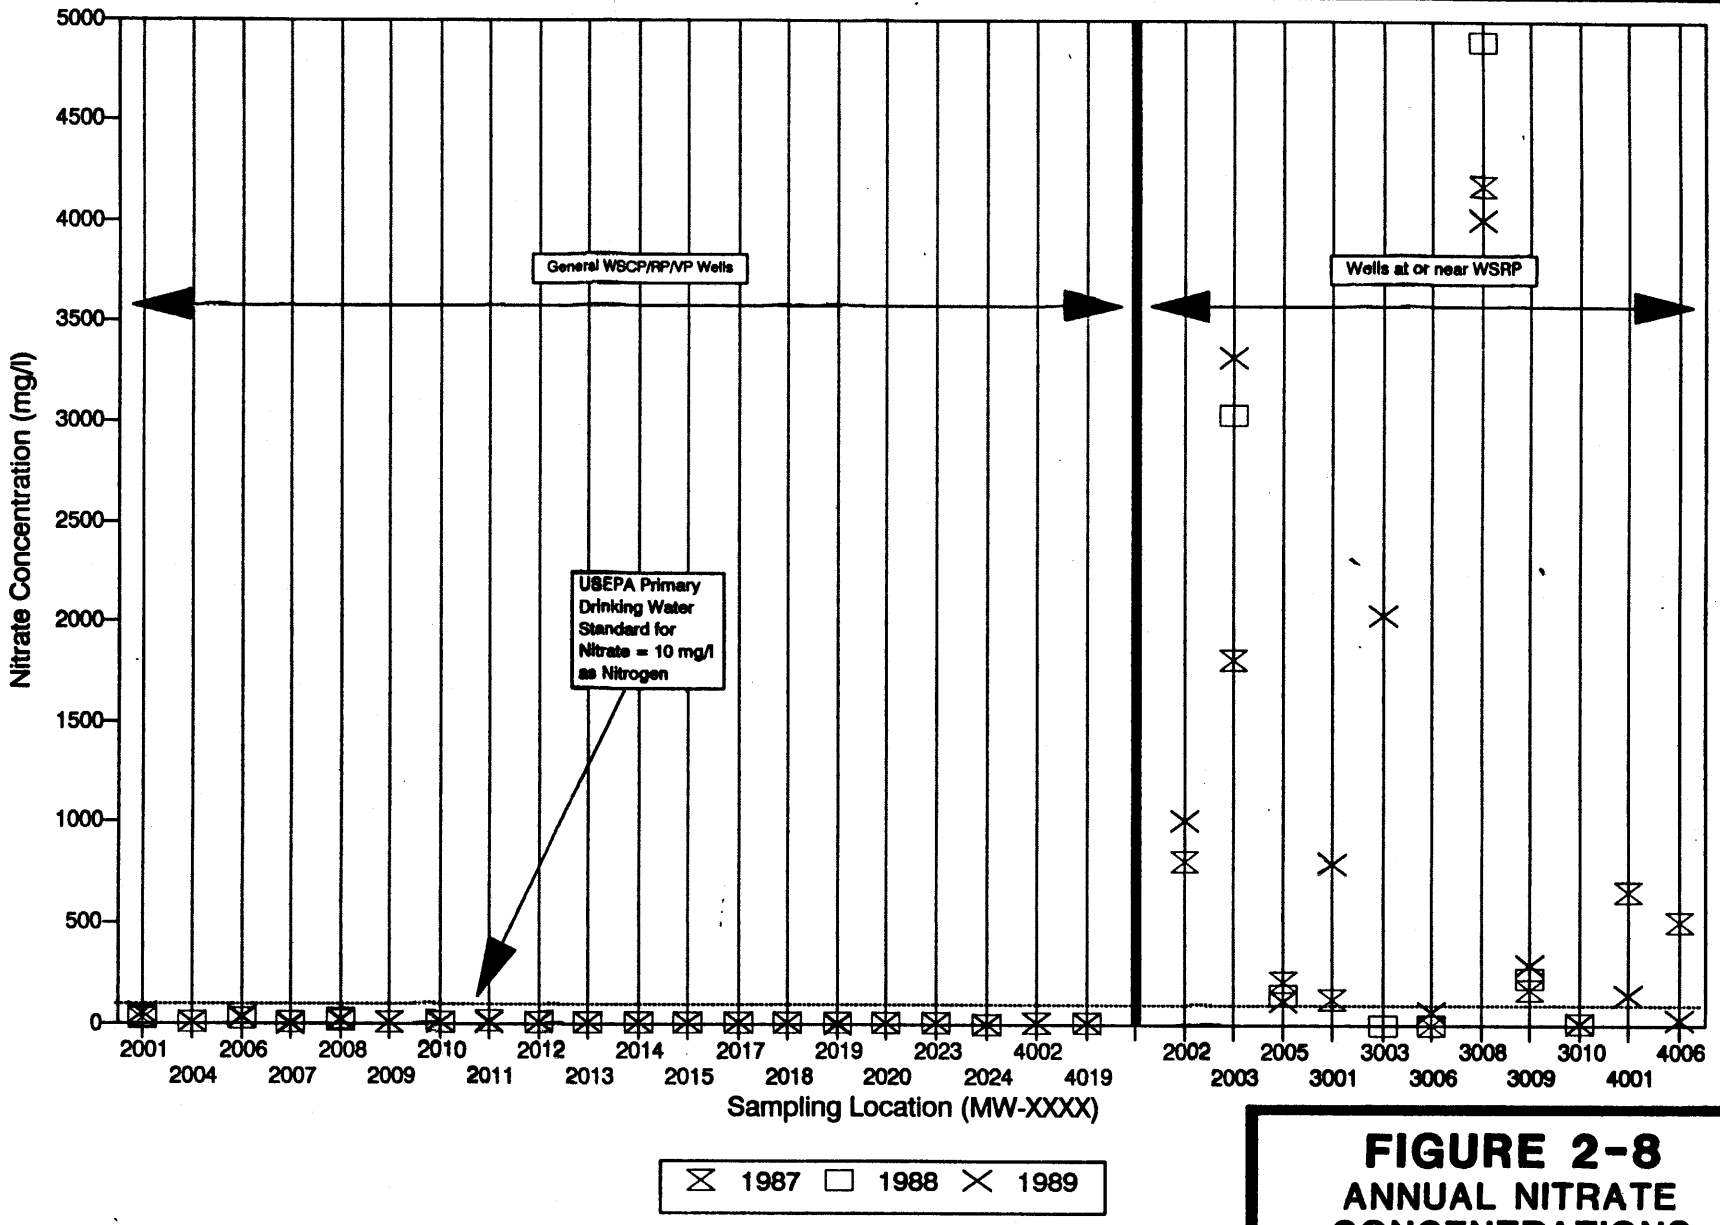

FIGURE 2-8
ANNUAL NITRATE CONCENTRATIONS WSCP/RP/VP GROUNDWATER 1987-1989

SULFATE

The upper bound of natural background sulfate concentrations in the aquifer at the WSCP/WSRP/WSVP was determined to be 50 mg/l (MKF and JEG, 1989a). The EPA secondary drinking water standard for sulfate is 250 mg/l. Twelve wells--MW-2009, MW-2015, MW-2020, MW-2028, MW-3003, MW-3006, MW-3009, MW-4001, MW-4013, MW-4020, MW-4022, and MW-4023--have annual sulfate concentrations between the upper bound of background and the EPA secondary drinking water standard. Four groundwater monitoring wells--MW-2003, MW-2012, MW-2017, and MW-4021--have an annual sulfate concentration higher than the EPA secondary drinking water standard. Figure 2-9 shows locations of wells with annual concentrations either above background and/or above the EPA secondary drinking water standard. The Phase II Groundwater Quality Assessment established that former WSOW processes were the primary source of these areas of sulfate contamination.

WSCP/WSRP/WSVP SULFATE TREND ANALYSIS

The annual concentrations of sulfate reported in previous monitoring reports and this report are displayed for comparison in Figure 2-10. The majority of groundwater monitoring wells on the "General WSCP/WSRP/WSVP Wells" portion of the graph have consistently yielded concentrations of sulfate below the EPA secondary drinking water standard of 250 mg/l during the years 1987 through 1989. The single exception to this is MW-2012, which was sampled during the second quarter of 1989 and contained 415 mg/l sulfate. This may be related to the increase in nitroaromatic concentrations in this well. One well, MW-2017, located in the southern portion of the WSCP, has exhibited

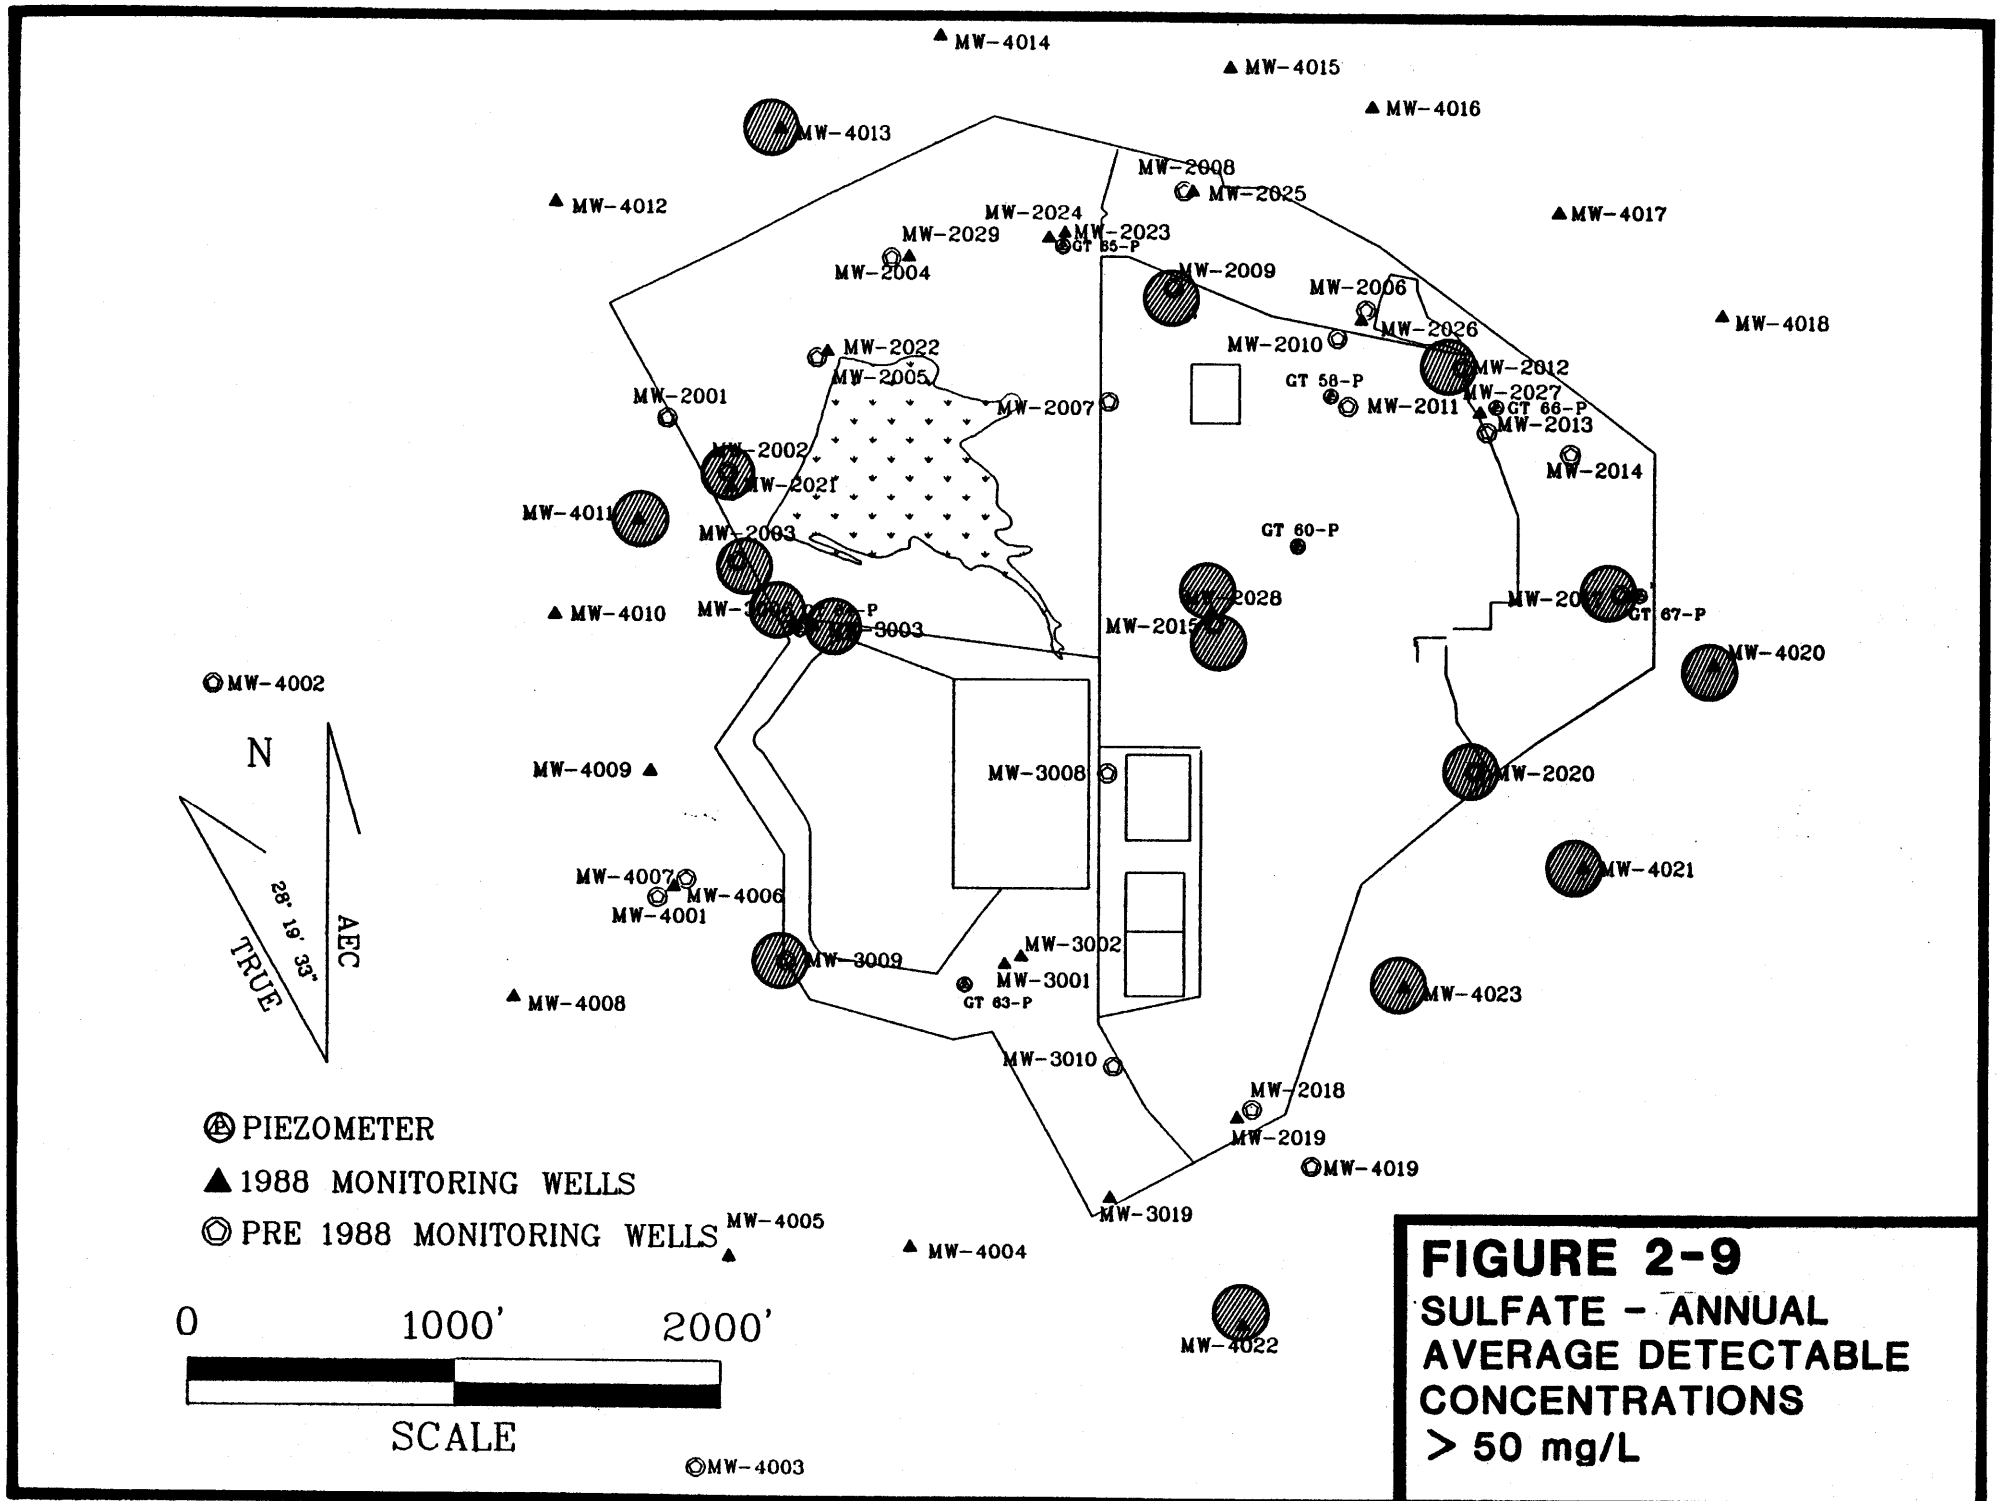

FIGURE 2-9
SULFATE - ANNUAL AVERAGE DETECTABLE CONCENTRATIONS > 50 mg/L

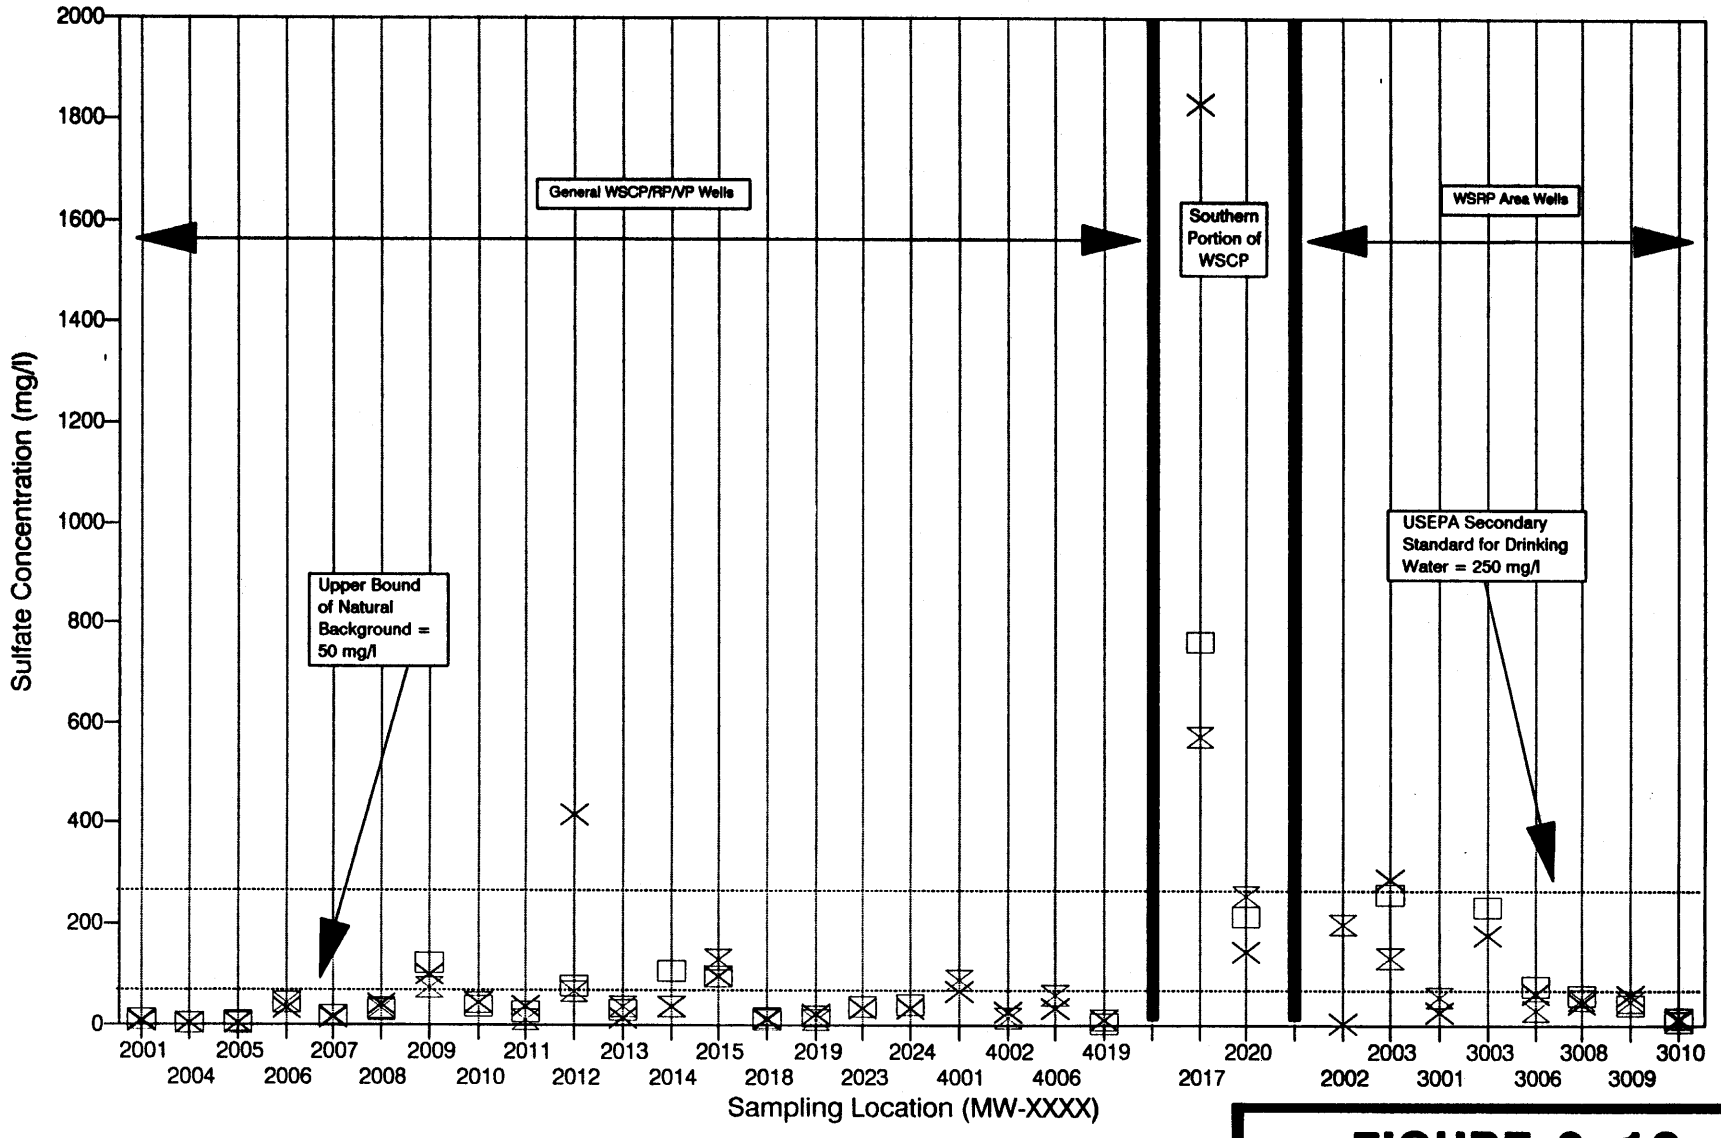

FIGURE 2-10
ANNUAL SULFATE CONCENTRATIONS WSCP/RP/VP GROUNDWATER 1987-1989

increased sulfate concentrations since 1987. Further complicating the picture, a nearby well (MW-2020) considered to be positioned in the same sulfate plume as MW-2017 (MKF and JEG, 1989a), has decreased in sulfate concentration since 1987. The cause of these fluctuations is not known. Another noticeable trend is the increase in nitrate and sulfate concentrations at well MW-2003 and the decreasing concentrations in MW-2002. The cause of these fluctuations is not known but they demonstrate consistency.

CHLORIDE

The upper limit of background concentration of chloride in groundwater at the WSCP/WSRP/WSVP area is 22 mg/l (MKF and JEG, 1989a). The EPA secondary standard for chloride in drinking water is 250 mg/l. Four wells-- MW-2008, MW-2010, MW-2012, and MW-2014-- exhibited annual detectable concentrations of chloride above natural background. Groundwater taken from one well only, MW-2006, exceeded the EPA standard with an annual average detectable concentration of 278.00 mg/l. All five of these wells are located adjacent to a surface drainage that drains a salt (sodium chloride) depot of the Missouri Highway Department off Highway 94. All of these wells have exhibited elevated chloride concentrations in the past.

FLUORIDE

Background fluoride concentrations are below 1 mg/l. The maximum contaminant level (MCL) for fluoride is 4.0 mg/l. A secondary MCL is 2.0 mg/l. No samples exceeded background concentrations. This is consistent with previous monitoring.

2.1.2 Groundwater Monitoring at the WSQ

Groundwater near the WSQ has become contaminated as a result of contact with or migration from the radioactive and hazardous substances present in the WSQ. Twenty-six DOE groundwater monitoring wells located at or near the Weldon Spring Quarry were sampled and analyzed during 1989 to monitor for the presence of WSQ related contaminants. Figures 2-11A and 2-11B show the locations of the groundwater monitoring wells. Groundwater samples were analyzed for natural uranium, nitroaromatic compounds, and inorganic anions. The groundwater monitoring wells are screened in a range of geologic formations from the Ordovician-aged Plattin Limestone, upsection to and including the unconsolidated Quaternary-aged Missouri River alluvium. Samples from four monitoring wells screened in the Missouri River alluvium and owned by St. Charles County were also analyzed during 1989. During 1988 and 1989, samples of groundwater were taken from a private water well which produces from the Missouri River alluvium and is located several miles upstream of the WSQ and St. Charles County well field. These samples were analyzed for a suite of parameters including total uranium, metals and inorganic anions. Four separate uranium analyses were run on samples from this background well and the results ranged from 4.8 pCi/l to 9.0 pCi/l with an average value of 6.8 pCi/l. Although not a comprehensive background study, it appears that values in the range of 5 pCi/l or slightly above can constitute background concentrations in the Missouri River alluvium.

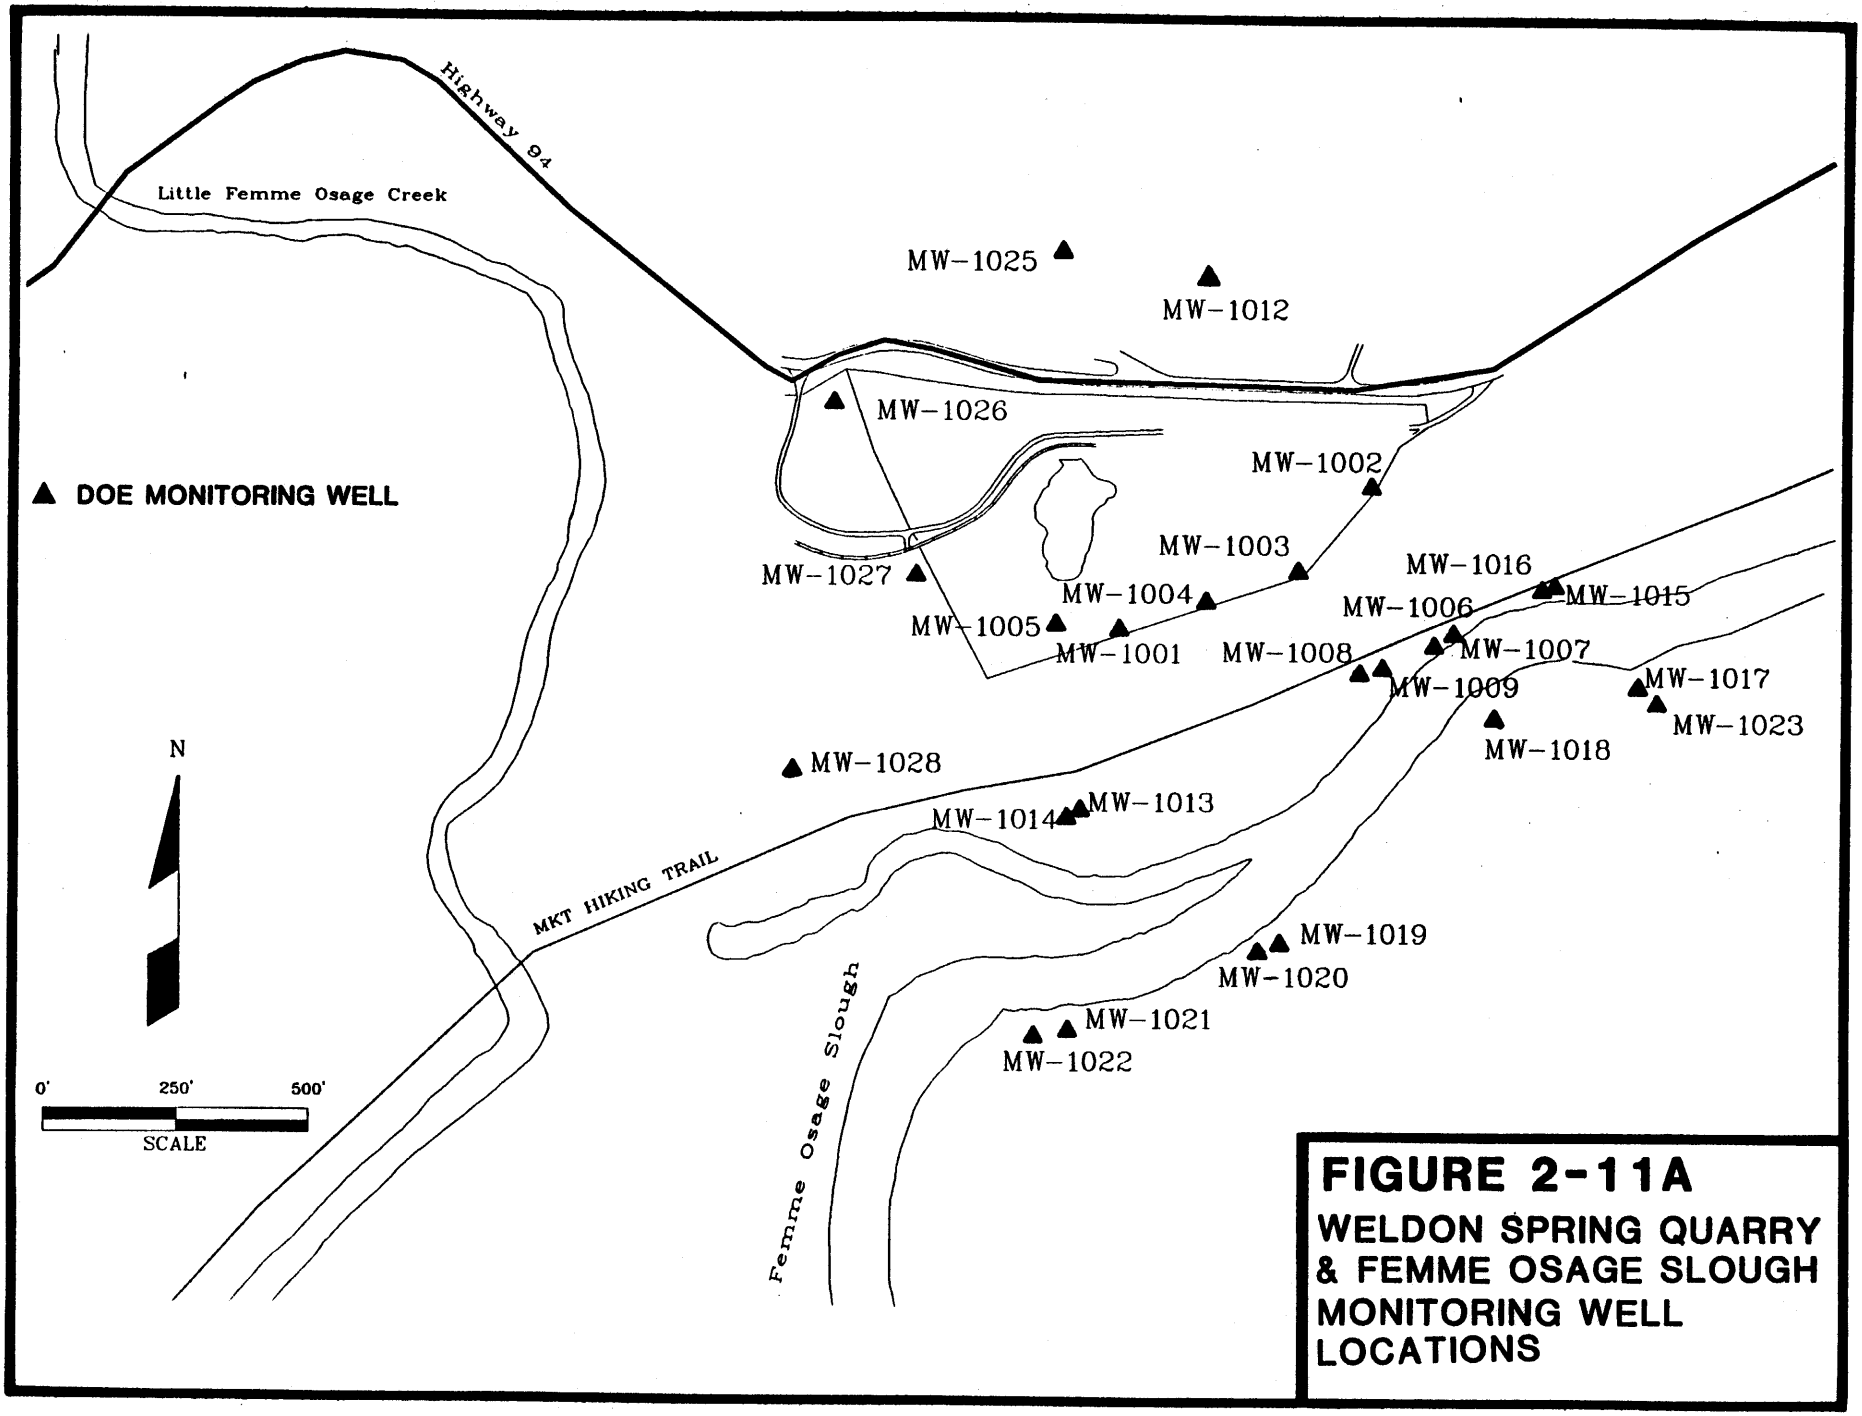

FIGURE 2-11A
WELDON SPRING QUARRY & FEMME OSAGE SLOUGH MONITORING WELL LOCATIONS

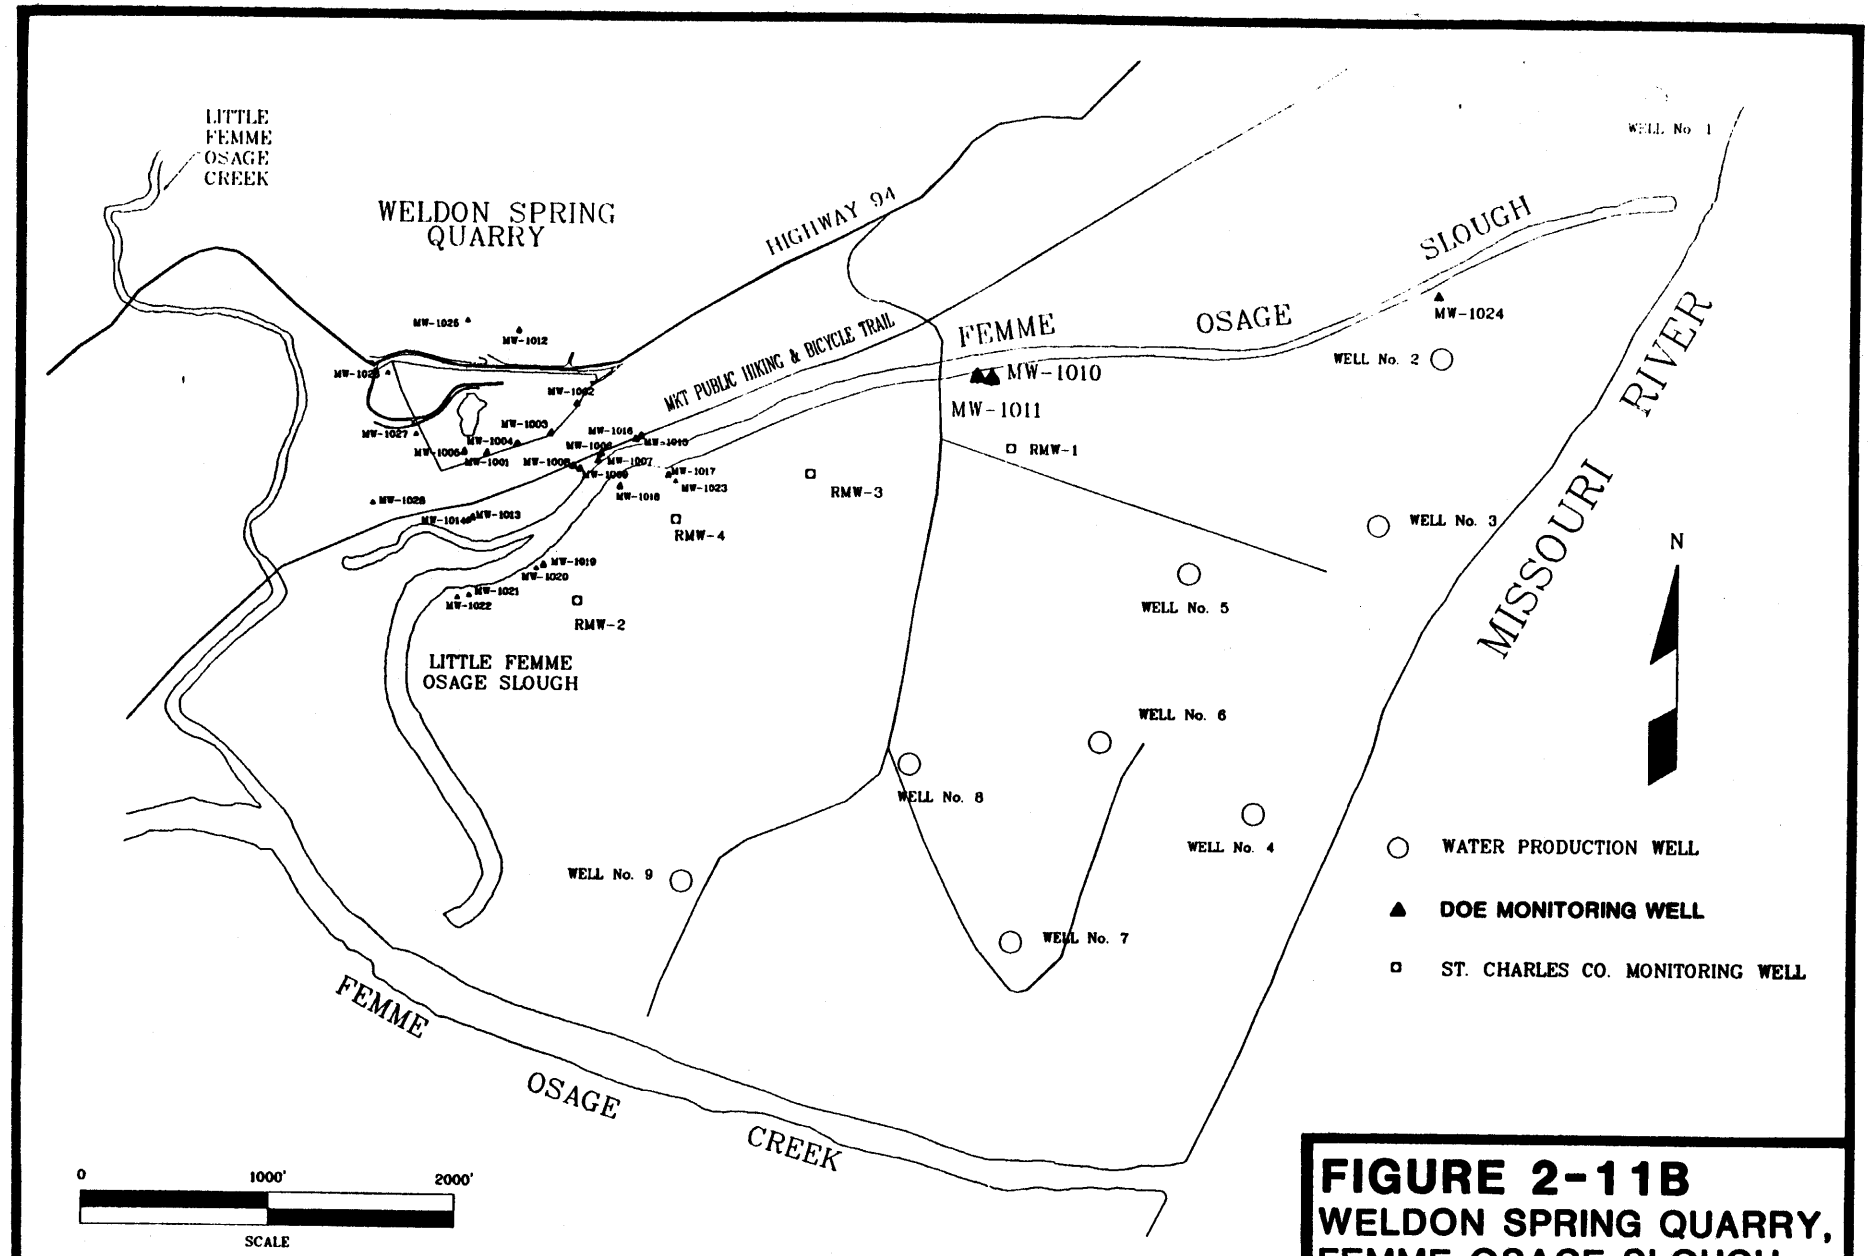

FIGURE 2-11B
WELDON SPRING QUARRY, FEMME OSAGE SLOUGH, & ST. CHARLES CO. WELL FIELD MONITORING WELL LOCATIONS

2.1.2.1 Radiological Results

Groundwater samples from 26 DOE monitoring wells and the four St. Charles County monitoring wells were analyzed for total uranium during 1989. Table 2-3 presents the results of these analyses. The results of the 1989 monitoring near the WSQ indicate that, although uranium concentrations have changed in individual wells, elevated uranium levels remain isolated to the bedrock adjacent to the quarry and the alluvium on the north side of the Femme Osage Slough. Samples from monitoring wells south of the slough exhibited average concentrations below 5 pCi/l. Elevated uranium levels north of the slough ranged from 260 pCi/l at MW-1016 to 4400 pCi/l in MW-1004, immediately adjacent to the quarry waste. Figure 2-12 highlights the wells with above-background uranium concentrations.

Groundwater samples from five wells--MW-1012 and the four St. Charles County groundwater monitoring wells--were analyzed for radium-226, thorium-230 and thorium-232. All analyses for these radionuclides indicated that the levels were below the minimum detection limit with the exception of MW-1012 (with a history of measurable thorium-230) which averaged 1.2 pCi/l thorium-230.

WSQ URANIUM TREND ANALYSIS

The concentrations of uranium at the WSQ reported in previous monitoring reports and this report are displayed for comparison in Figure 2-13. This figure illustrates that uranium is not and has not been present in elevated levels in DOE groundwater monitoring wells located south of the Femme Osage

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

* Detection Limits

@ Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1989. For example, 2.00 (2/4) indicates that 4 samples were taken in 1989, 2 of which average 2.00 and the other 2 samples were ND.

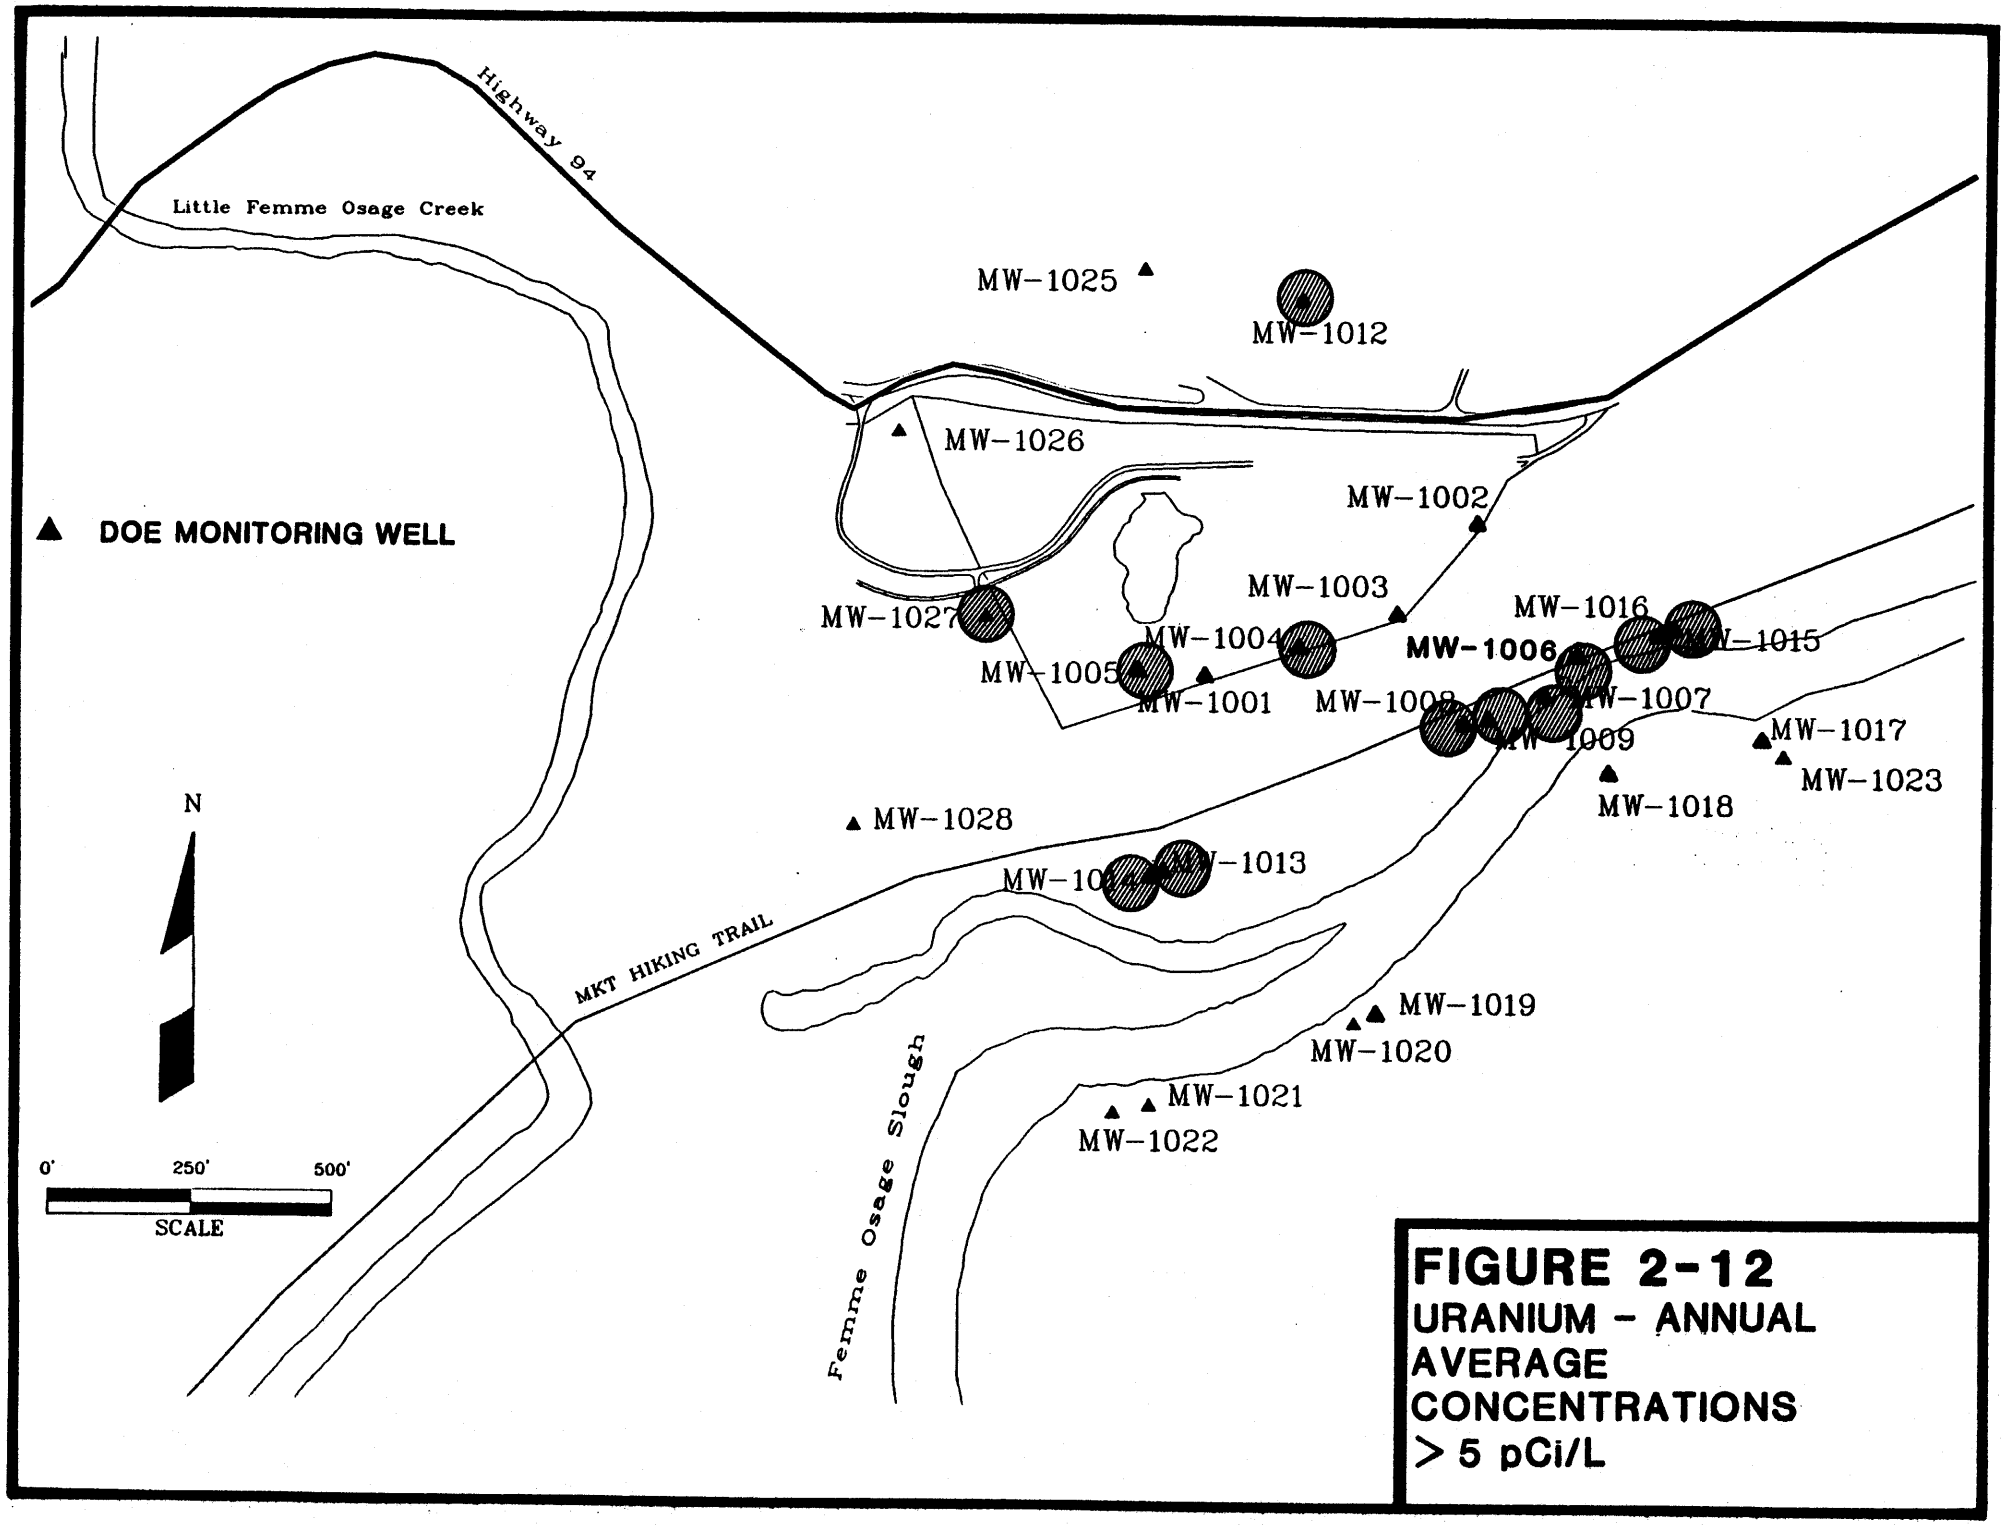

FIGURE 2-12
URANIUM - ANNUAL AVERAGE CONCENTRATIONS > 5 pCi/L

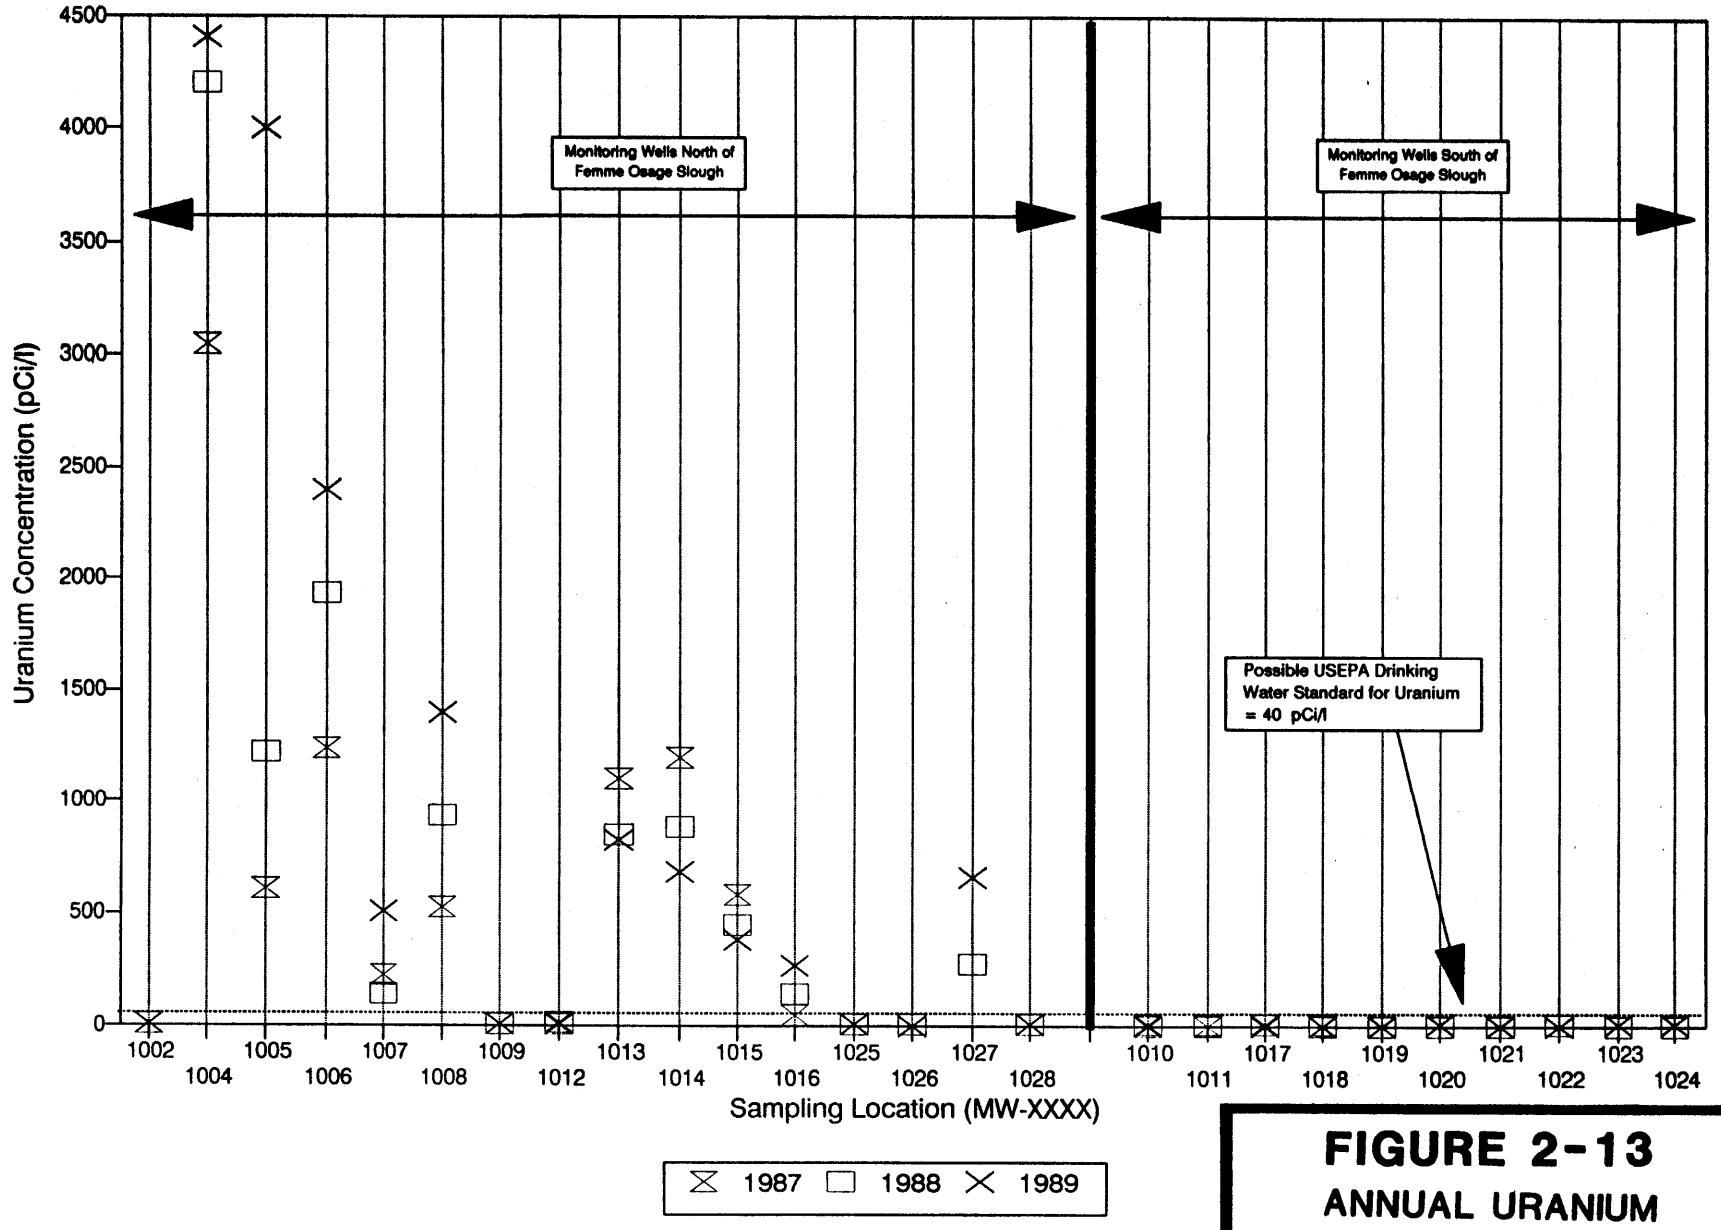

FIGURE 2-13

ANNUAL URANIUM CONCENTRATIONS WSQ GROUNDWATER 1987-1989

Slough. These wells south of the slough each have shown concentrations of uranium within the range of background since 1987.

Wells to the north of the slough and those adjacent to the WSQ display varying degrees and directions of change from 1987 to 1989. The most notable changes and trends have occurred as increases of uranium concentrations in the groundwater monitored by wells MW-1004 and MW-1005 along the WSQ rim and MW-1006 and MW-1008 in the Missouri River alluvium. Other small to moderate concentration variations occurred, both increases and decreases, in the wells in the WSQ area as presented in Figure 2-13. Although the increasing trends in uranium concentrations at select wells call for heightened awareness and review of the groundwater situation, the data continues to indicate no cause for immediate concern for the integrity of the St. Charles County well field and water supply.

2.1.2.2 Analytical Results for Nitroaromatic Compounds

During 1989, samples from the WSQ wells were analyzed for nitroaromatic compounds. Eleven monitoring wells yielded no detectable concentrations of any of the six nitroaromatic compounds during 1989. Analytical results are presented in Table 2-4. Figures 2-14A and 2-14B are maps of the WSQ area annotated with the annual average concentrations of total nitroaromatic compounds.

The 1,3,5-TNB concentrations in monitoring wells MW-1017 through MW-1023 are the result of laboratory contamination based on contamination of the blank sample. No monitoring wells south of the slough showed detectable concentrations of nitroaromatic compounds during 1989.

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

* Detection Limits

@ Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1989. For example, 2.00 (2/4) indicates that 4 samples were taken in 1089, 2 of which were ND and the other 2 samples average 2.00.

** No analysis was performed for this parameter at this location during 1989.

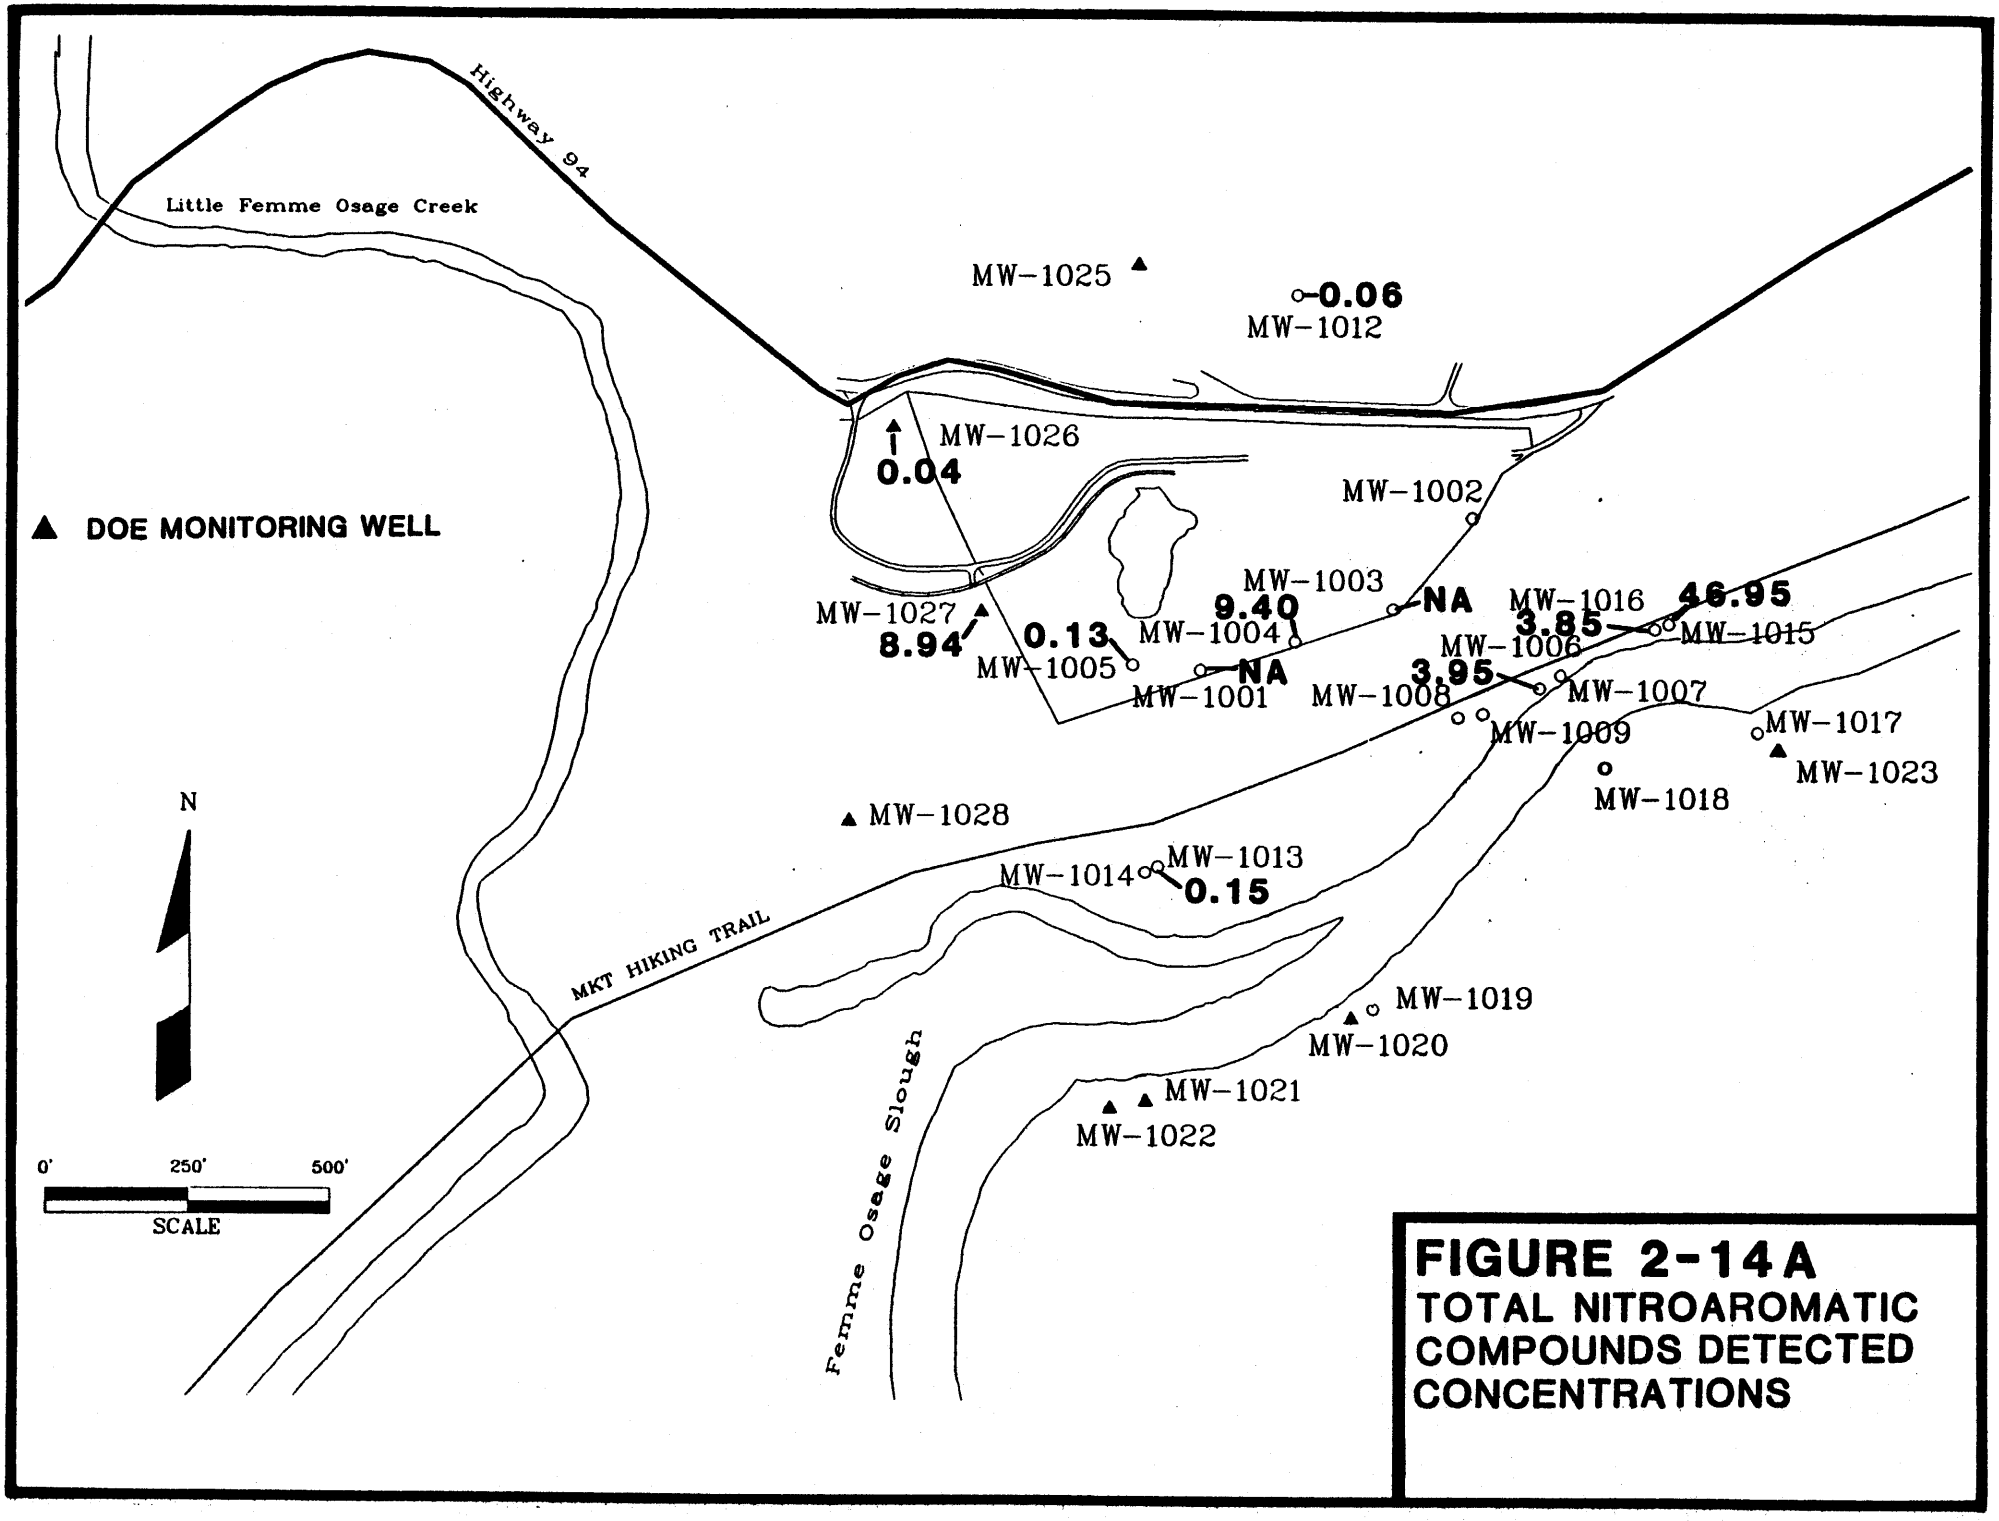

FIGURE 2-14A
TOTAL NITROAROMATIC COMPOUNDS DETECTED CONCENTRATIONS

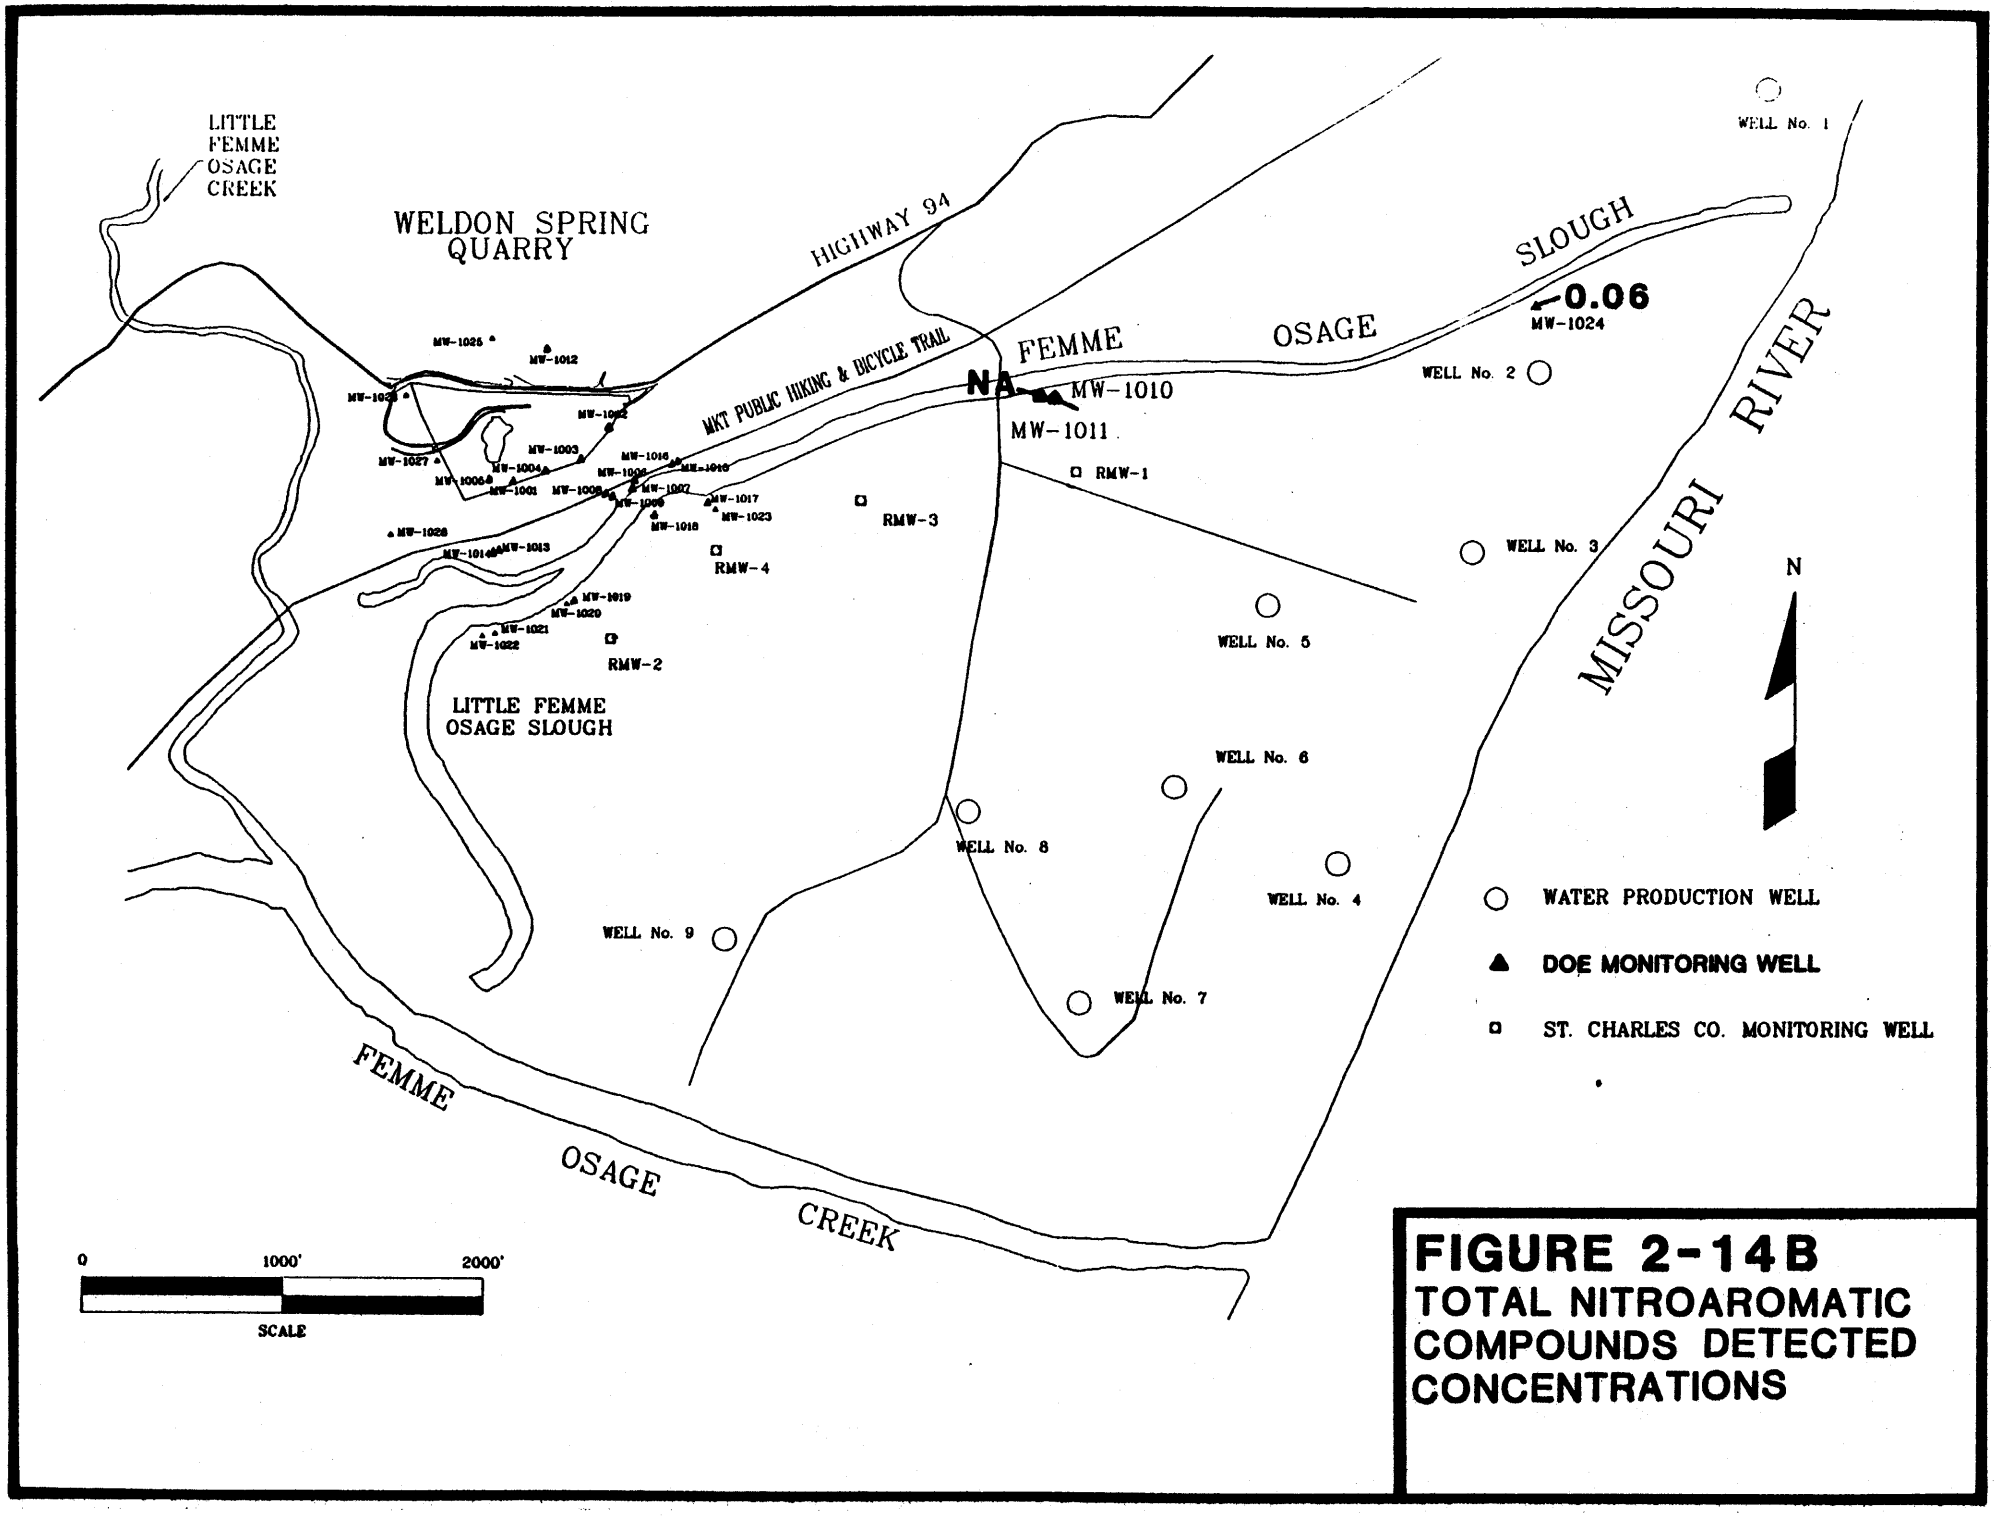

FIGURE 2-14B
TOTAL NITROAROMATIC COMPOUNDS DETECTED CONCENTRATIONS

CONCENTRATIONS OF TOTAL NITROAROMATIC COMPOUNDS IN GROUNDWATER - TREND AT THE WSQ

A comparison of data for years 1989, 1988, and 1987 suggest that concentrations of nitroaromatic compounds in groundwater are generally constant over the three years.

Figure 2-15 plots the historical averages of total nitroaromatic compounds in the WSQ groundwater. No particularly noteworthy trends in contaminant distribution or concentration were detected.

2.1.2.3 Inorganic Anions Results

Monitoring wells were sampled once in 1989 for inorganic anions. Previous WSS annual environmental monitoring reports and characterization sampling events have detected elevated inorganic anion levels in the groundwater in the vicinity of the WSQ. Four inorganic anions--nitrate, sulfate, chloride and fluoride--were targeted for study. Table 2-3 displays the 1989 annual concentrations of inorganic anions for the WSQ area. Inorganic anion results from 1989 are consistent with data reported in both the 1988 and the 1987 environmental monitoring reports. In 1988 and 1989, groundwater samples collected from the upgradient background well referenced in Section 2.1.2.1 provided some limited data on inorganic anions showing background nitrate and sulfate in the alluvial groundwater of <0.1 mg/l and 95 mg/l, respectively.

NITRATE

Table 2-3 presents the measured nitrate levels in the groundwater near the WSQ. The groundwater samples continue to

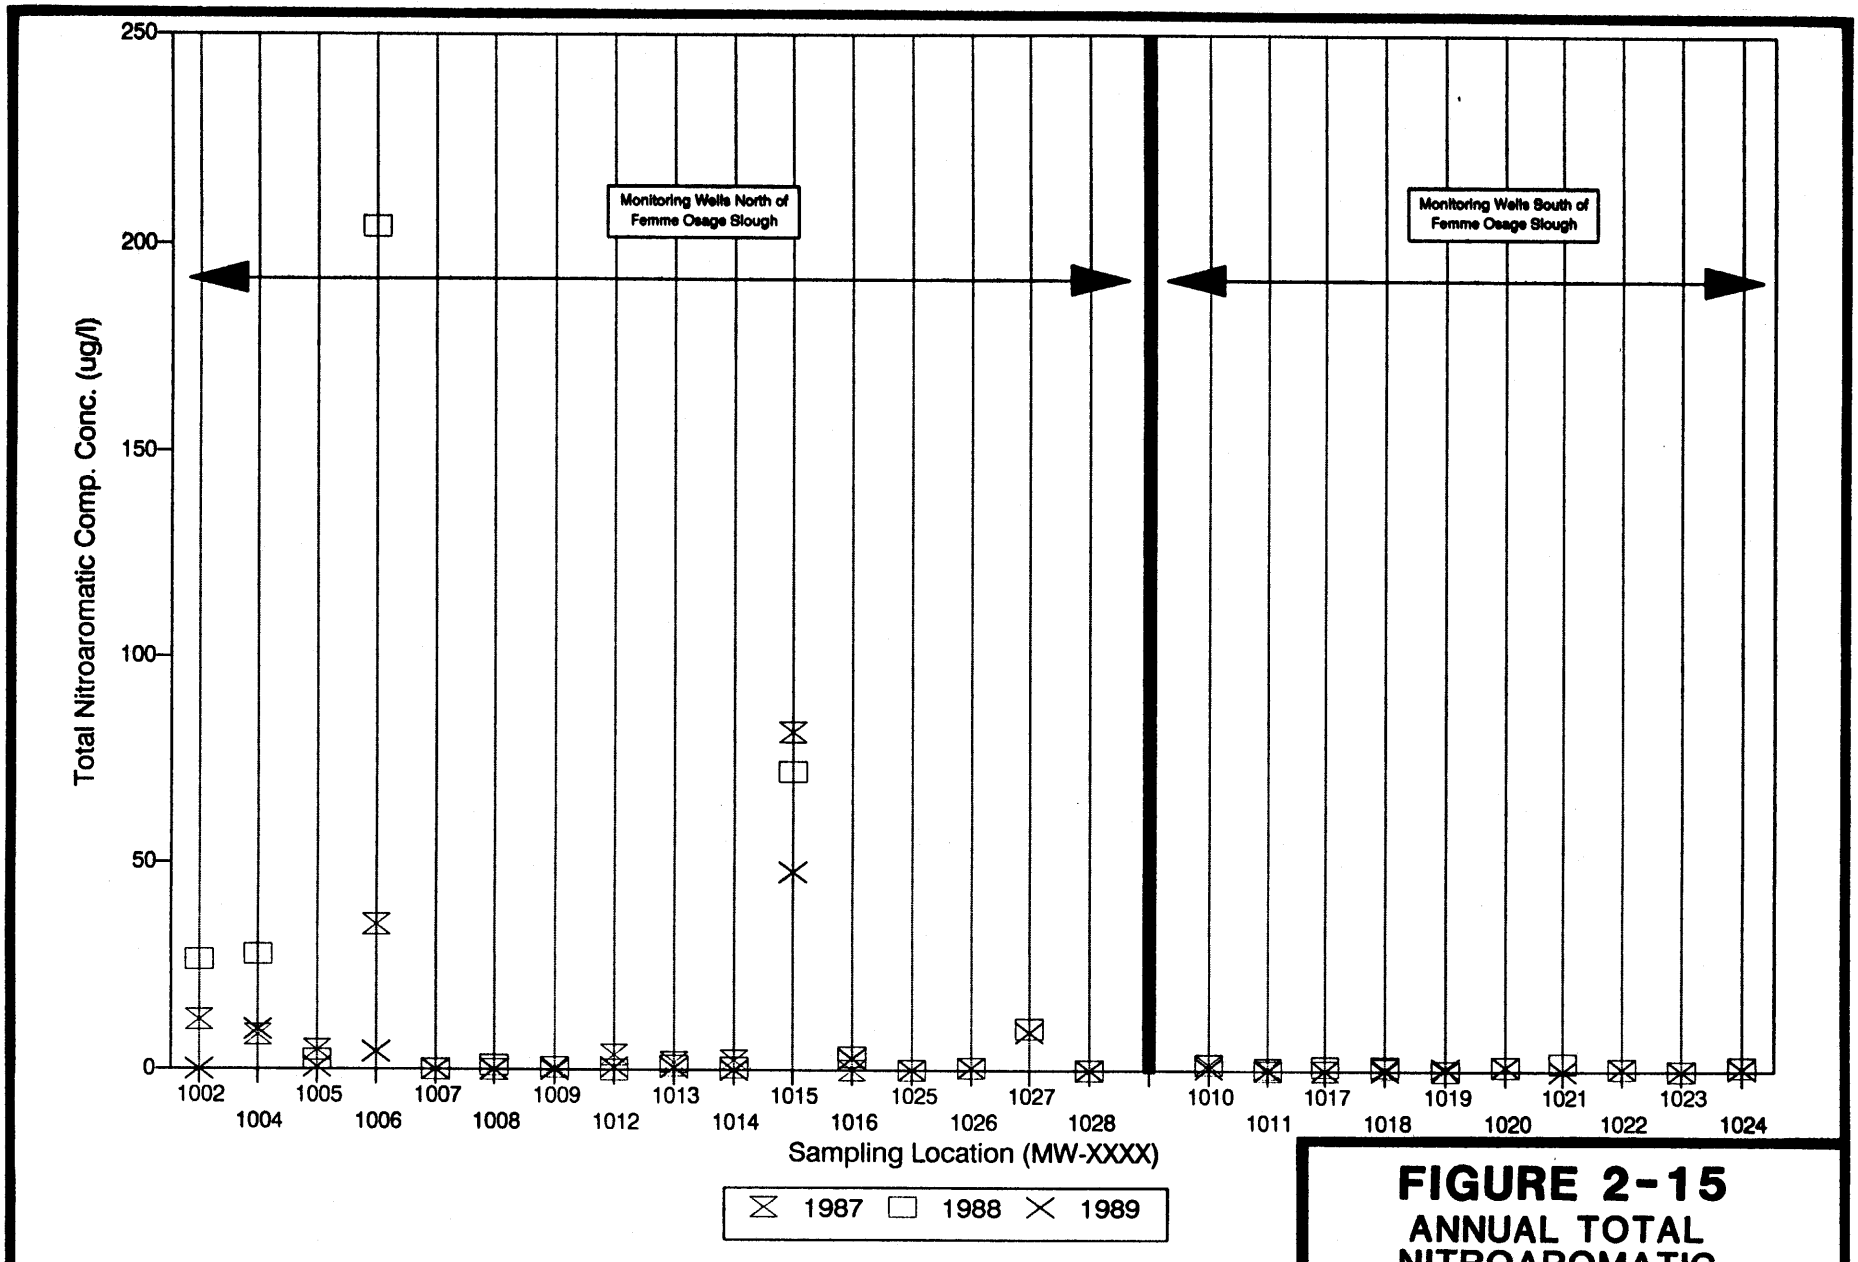

FIGURE 2-15
ANNUAL TOTAL NITROAROMATIC COMPOUND CONCENTRATIONS WSQ GROUNDWATER 1987-1989

indicate no notable groundwater contamination by nitrate, with the highest measured level observed at MW-1002 adjacent to the WSQ. This value is not attributed to contaminant migration from the WSQ, however, since the levels of nitrate in the quarry pond indicate little impact by nitrate from the quarry wastes. Further, the uranium levels in the water of MW-1002 show little impact from quarry migration. Nitrate does not constitute a particular threat to the groundwater system near the WSQ.

WSQ NITRATE TREND ANALYSIS

The annual concentrations of nitrate in groundwater near the WSQ reported in previous monitoring reports and this report are displayed for comparison in Figure 2-16. Overall, nitrate concentrations in individual wells from 1987 to 1989 remained nearly constant.

SULFATE

As will be discussed further in Section 2.2 of this report, the quarry bulk waste is a source of sulfate contamination to the surface water in the WSQ pond and subsequently to the groundwater surrounding the quarry. Sulfate levels in most of the wells adjacent to the WSQ and in the alluvium north of the Femme Osage Slough appear to be elevated as a result of migration from the quarry. The highest 1989 sulfate value of 1,000 mg/l was measured at MW-1004. Wells to the south of the slough remain at background concentration levels.

WSQ SULFATE TREND ANALYSIS

The concentrations of sulfate at the WSQ reported in previous monitoring reports and this report are displayed for

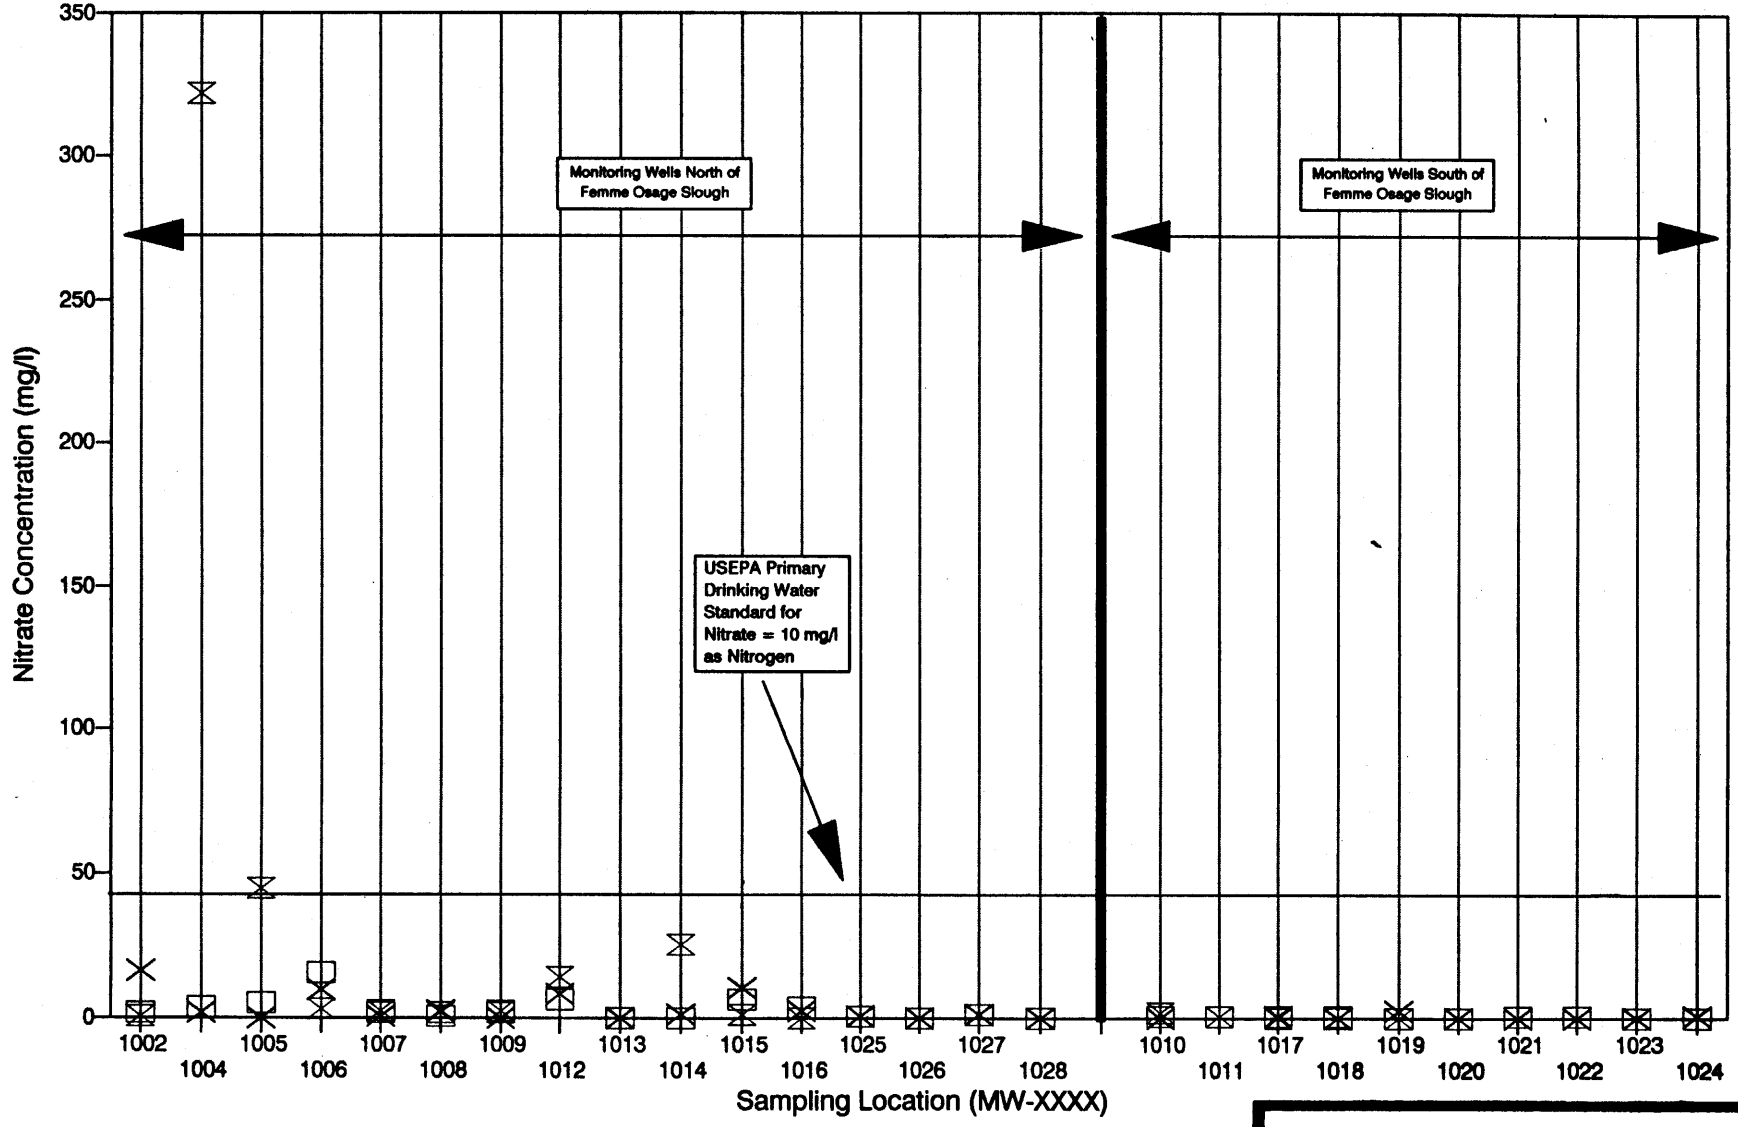

FIGURE 2-16

ANNUAL NITRATE CONCENTRATIONS WSQ GROUNDWATER 1987-1989

comparison in Figure 2-17. Evaluation of the historical sulfate data from samples from near the WSQ indicate a slight but consistent upward trend in concentration. The groundwater between the WSQ and the slough appears to have increased slightly in sulfate content from 1987 to 1989. This trend is consistent with the trend for uranium activity in the groundwater in that same area.

CHLORIDE

Chloride levels were measured once in 1989 from the WSQ monitoring wells. Those data are also presented in Table 2-3. The upper limit for background chloride levels in the bedrock aquifer near the WSCP/WSRP was established in the WSSRAP's 1988 Environmental Monitoring Report at 22 mg/l and it appears from the data from Missouri River alluvial water samples that the background for the alluvium is similar. Based upon comparison with background, chloride levels in the groundwater near the WSQ are slightly elevated in some alluvial wells north of the Femme Osage Slough. The elevated chloride levels remain well below the EPA secondary drinking water standard of 250 mg/l for chloride. Further, the measured chloride levels in groundwater south of the slough remain at background and show no evidence of contaminant migration beyond the slough.

FLUORIDE

Fluoride levels ranged from 0.1 mg/l to 0.6 mg/l in the groundwater near the WSQ. No noteworthy fluoride concentrations were detected, as compared to the EPA's maximum contaminant level of 4.0 mg/l.

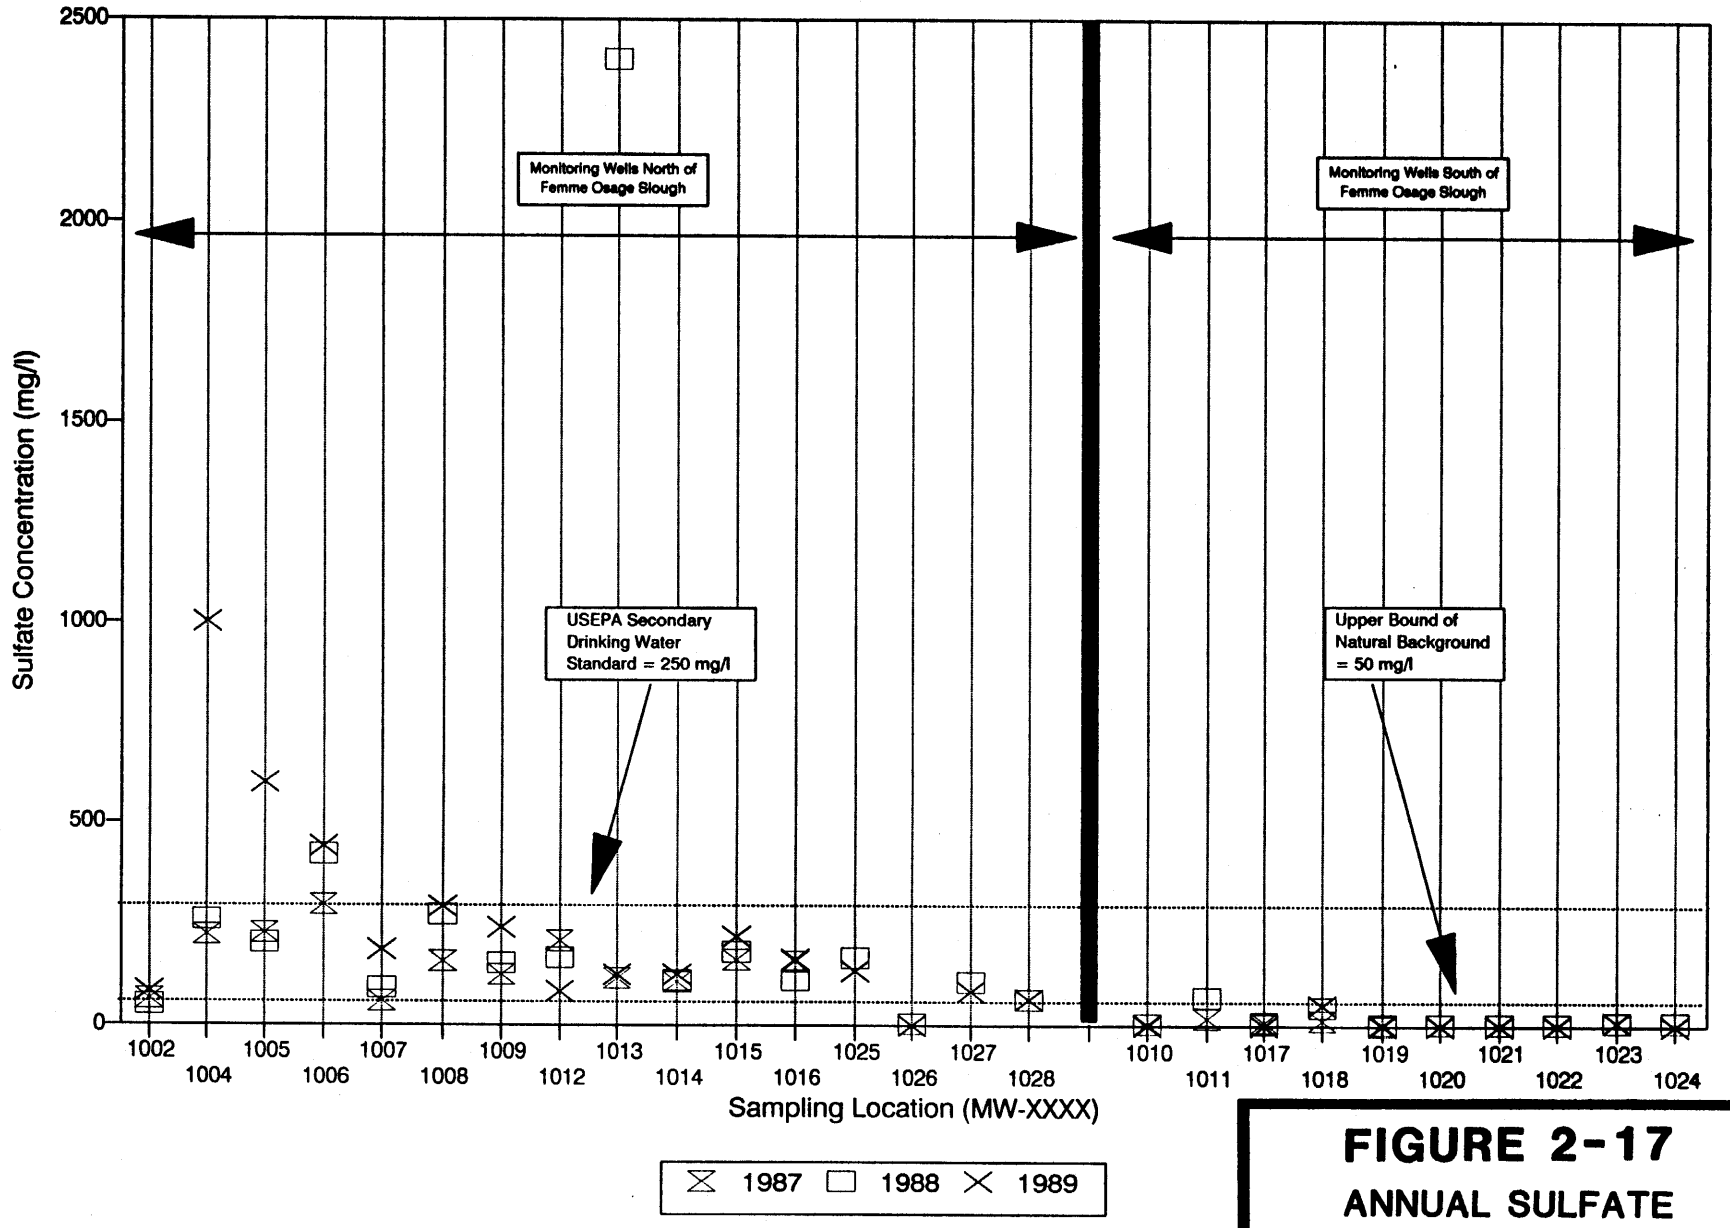

FIGURE 2-17

ANNUAL SULFATE CONCENTRATIONS WSQ GROUNDWATER 1987-1989

CONCLUSIONS OF WSQ GROUNDWATER MONITORING

Groundwater in the vicinity of the WSQ was sampled and analyzed for uranium (and other radiological species at certain wells), nitroaromatics and inorganic anions. The results indicate a slight but consistent increase in the concentrations of the contaminants in the groundwater between the WSQ bulk waste and the Femme Osage Slough. The results further indicate that the integrity of the alluvial groundwater south of the slough remains intact. Overall, the current data indicate that the groundwater contamination present near the WSQ does not pose an imminent threat to the St. Charles County water supply source.

2.2 Surface Water Monitoirng

Surface water samples were collected during 1989 under two distinct programs at the WSS. In one program, samples were collected at the WSCP boundary to monitor the off-site discharge of contaminants via surface water runoff. These samples were collected in compliance with the WSS's National Pollutant Discharge Elimination System (NPDES) permit, issued in November 1988, for storm water runoff and wastewater discharges. The permit requirements and 1989 analytical results are discussed in Section 2.2.1.

In the second program, routine samples were collected quarterly from both on-site and off-site locations where measurable impacts might be detected as part of the WSS Environmental Monitoring Program. This program was designed to fulfill the environmental surveillance requirements of DOE Order 5400.1. Environmental monitoring quantifies and documents any potential public exposure via the surface water pathway and ensures, through detection and implementation of response

measures, the protection of the public's health and safety. All surface water samples collected are analyzed without filtering unless a specific comparison of dissolved versus total contaminant concentrations is desired.

2.2.1 Effluent Monitoring Results

The Weldon Spring Site (WSS) NPDES Permit No. MO-0107701 requires monitoring of five stormwater discharge locations (NP-0001 to NP-0005) and one sanitary wastewater treatment plant discharge (NP-0006). These locations are illustrated in Figure 2-18. A summary of the permit requirements including monitoring parameters and frequencies is presented in Table 2-5. Currently, only discharges from outfall NP-0006, the administration building sanitary wastewater treatment plant, have limitations placed on them. The other five outfalls have monitoring requirements only.

Annual averages of analytical results for the stormwater locations are presented in Table 2-6. This table presents an annual summary of the individual sampling events. Tables presenting analytical results for the individual NPDES sampling events for each outfall may be found in Appendix A.

2.2.1.1 Radiological Analysis

Annual average uranium levels ranged from 6.5 pCi/l (0.241 Bq/l), about 1% of the DCG at the minimum concentration discharge point (NP-0004) to 368 pCi/l (13.62 Bq/l), about 61% of the DCG at the maximum concentration discharge point (NP-0001). The highest average uranium concentration was measured at the off-site discharge of the abandoned sanitary and process sewer outfall (NP-0001). Uranium concentrations measured at NP-0001

* These values were present in a single sample obtained in January. All other values at NP-0003 for lithium and settleable solids were ND and <0.1, respectively.

ranged from 120 to 590 pCi/l (4.44 to 21.83 Bq/l) during 1989. Flows from the process and sanitary sewer outfall (NP-0001) combine with surface runoff from the southeast portion of the WSCP (NP-0005) and discharge into the southeast drainage easement. Uranium concentrations measured at NP-0005 exhibited similar levels with an annual average of 347 pCi/l, 58% of the DCG, and a range of 95 to 570 pCi/l (3.52 to 21.09 Bq/l).

Frog Pond's off-site discharge (NP-0002) exhibited an annual average uranium concentration of 145 pCi/l (5.36 Bq/l), 26% of the DCG. Individual monthly measurements ranged from 25 to 400 pCi/l (0.93 to 14.8 Bq/l). Off-site runoff from the area of Raffinate Pit 4 (NP-0004) exhibited an annual average uranium concentration of 6.5 pCi/l (.24 Bq/l) 1% of the DCG with a range of individual measurements from 3 to 9.7 pCi/l (0.11 to 0.36 Bq/l).

Results for the four NPDES outfalls discussed above are consistent with previous years' monitoring results. In contrast, uranium concentrations measured at Outfall NP-0003, the off-site discharge of the Ash Pond drainage, exhibited a marked decrease compared to previous years' data. The 1988 annual average uranium concentration for this outfall was 1,178 pCi/l (43.59 Bq/l), 214% of the DCG. The 1989 annual average is 280 pCi/l (10.36 Bq/l), 51% of the DCG with an individual sample range from 16 to 1,000 pCi/l (0.59 to 37.0 Bq/l). This marked decrease can be attributed to the completion of the Ash Pond Isolation Project in April 1989 (MKF and JEG, 1990b). This Interim Response Action (IRA) was designed and constructed to divert surface runoff around contaminated areas (South Dump and Ash Pond) thereby decreasing the off-site discharge of uranium at Outfall NP-0003. This IRA is discussed in more detail in Section 3.2.4.

Annual average gross alpha levels generally followed the same pattern as the natural uranium results. The generally good correlation between the average uranium and gross alpha values indicates that virtually all of the offsite radionuclide release is in the form of soluble uranium. However, gross alpha measurements are biased low, probably due to measurement interference from dissolved solids.

If it is assumed that the entire annual precipitation runoff is discharged from these points and that the discharge from each point is proportional to the portion of the site that each point drains, an upper bound estimate of the total uranium released off-site during 1989 can be calculated. The results of these calculations are presented in Table 2-7.

2.2.1.2 Chemical Analysis

The annual average total settleable solids (ml/l) and total suspended solids (mg/l) were highest at the off-site discharge of the Ash Pond drainage (NP-0003). These elevated average values were primarily caused by high values from a sample taken in January. Total settleable solids and suspended solids for that month were measured at 8.0 ml/l and 7,018 mg/l, respectively. Lithium was also detected at 0.061 µg/l, slightly above the detection limit. During that time, the Ash Pond Isolation Project was underway in the Ash Pond drainage causing increased erosion during storm events. Additional erosion control measures were implemented in response to these high values.

The other NPDES locations also exhibited the highest suspended solids concentrations during January. Surface water runoff and resulting flows off-site were highest in January when the site received over four inches of rainfall. Settleable

* = SEE FIGURE 2-18
** = ESTIMATED

solids measurements were less than 0.1 ml/l at all other storm water monitoring locations. Lithium was not detected at any of the other outfalls during 1989.

Annual average nitrate values ranged from a low of 1.87 mg/l at Outfall NP-0002 to a high of 32.23 mg/l at Outfall NP-0005. These values are generally consistent with the analytical results from 1988.

Outfall NP-0006 is the discharge for the site administration building wastewater treatment facility. The NPDES permit has placed limits on discharges from this outfall for biochemical oxygen demand (BOD) and total suspended solids of 15 and 10 mg/l, respectively. Samples were analyzed quarterly for these parameters by the subcontractor operating this facility. NPDES Permit limitations for the outfall were not exceeded at any time during 1989. Results are presented in a table in Appendix A.

2.2.2 Quarterly Surface Water Monitoring at the WSCP/WSRP Area

Surface water samples were collected quarterly from the eleven locations shown on Figure 2-19 in an effort to maintain a current understanding of site-related contaminant concentrations in potentially affected off-site surface water features. Five of those locations are within or upstream of lakes on the August A. Busch Memorial Wildlife Area. Many of these locations have been sampled by the WSSRAP for three consecutive monitoring years and are considered to be the most representative for monitoring contaminants that may pose a risk to the public health or the environment. The samples were analyzed for radiological species at all locations and for nitroaromatic compounds and inorganic anions at select locations.

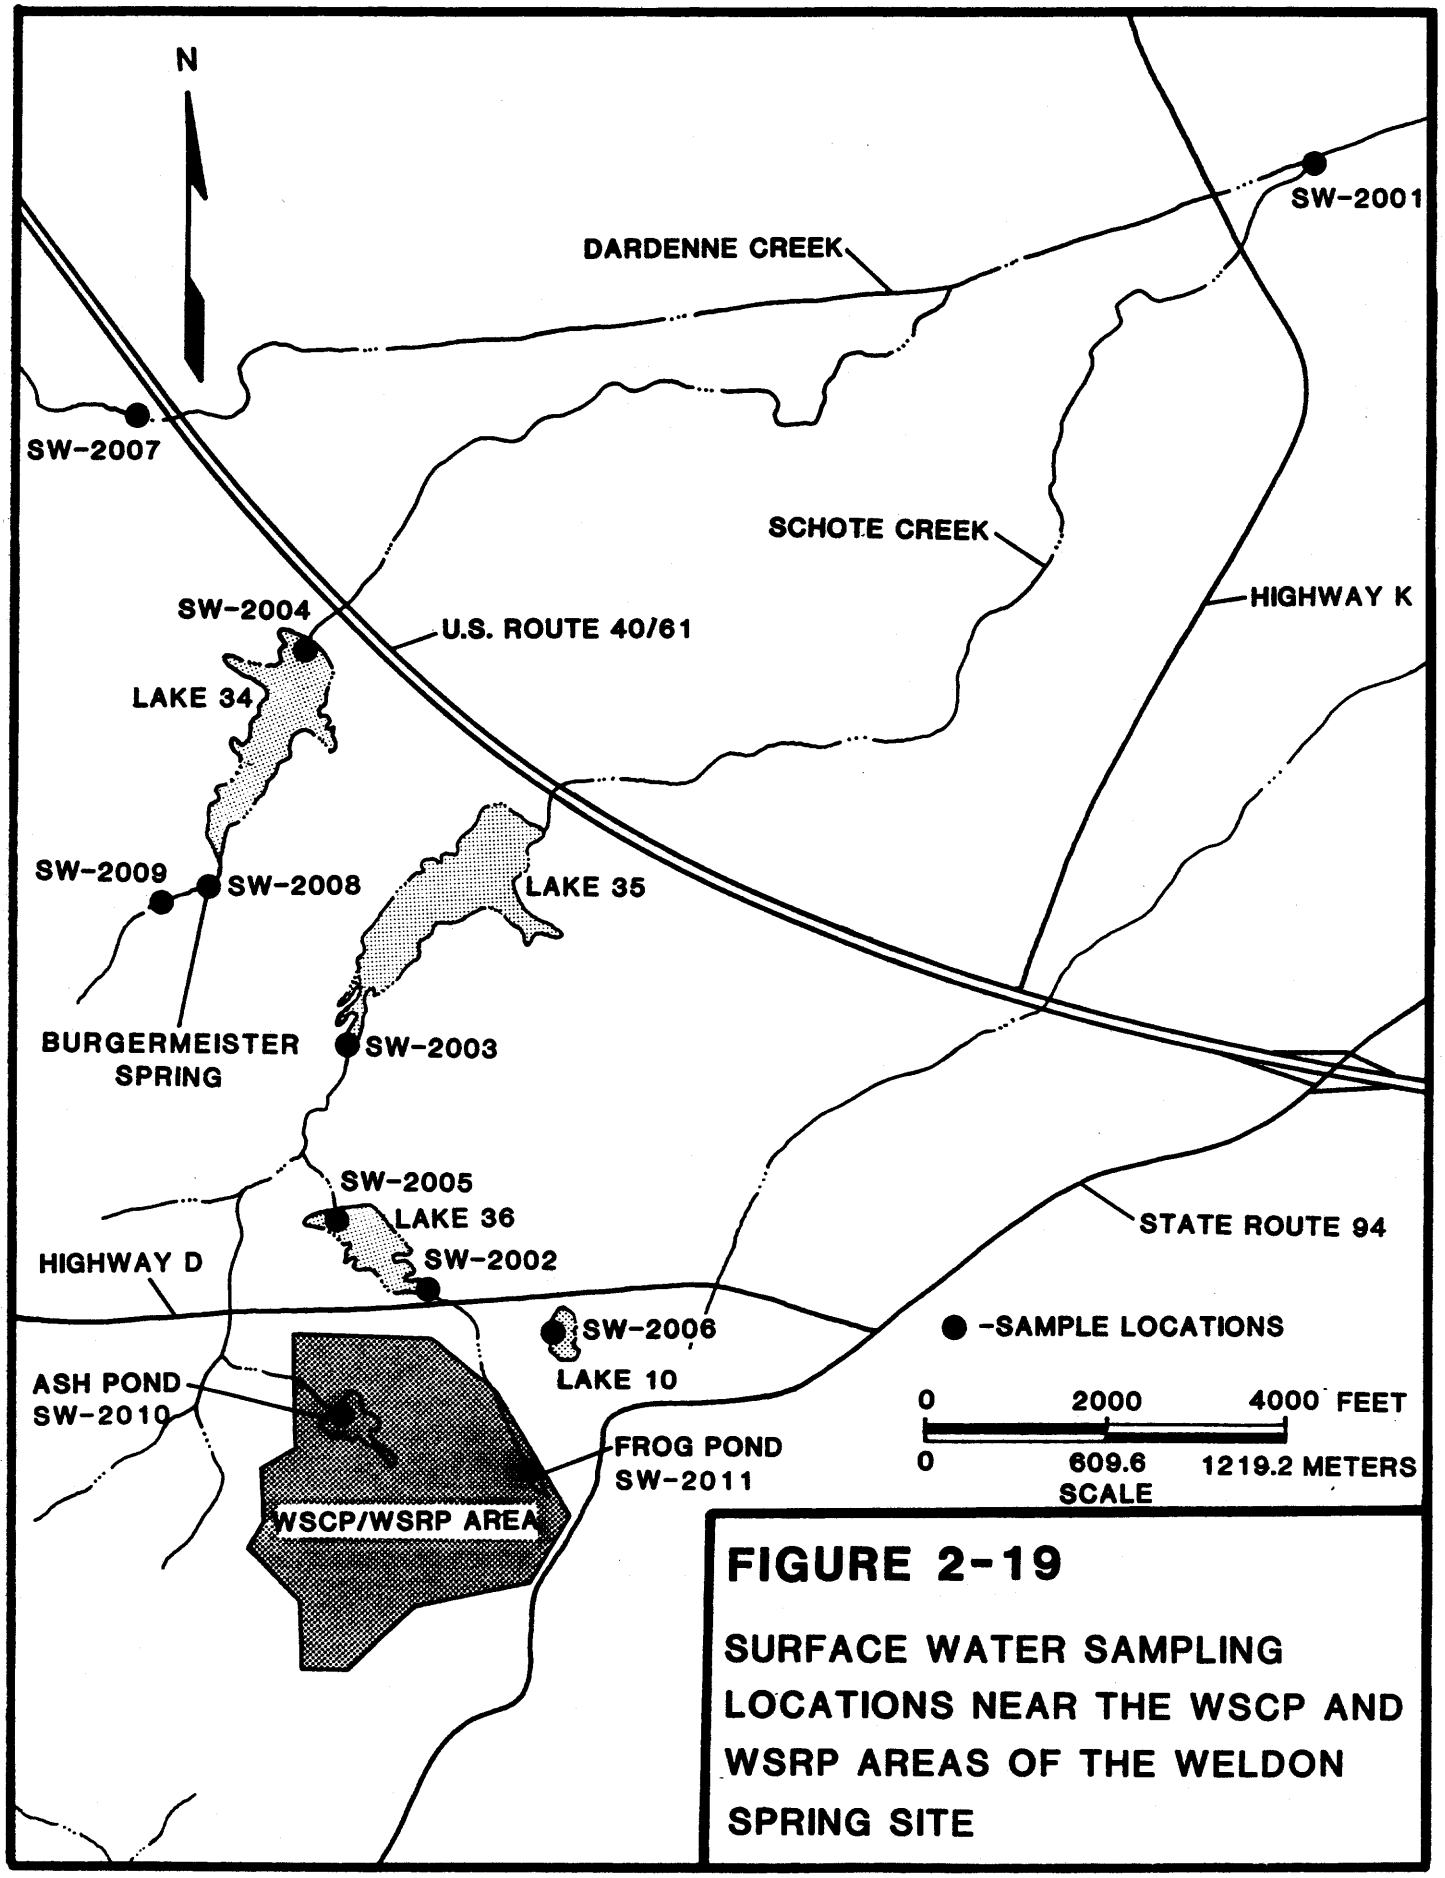

FIGURE 2-19

SURFACE WATER SAMPLING LOCATIONS NEAR THE WSCP AND WSRP AREAS OF THE WELDON SPRING SITE

2.2.2.1 Radiological Results

URANIUM MONITORING

The total uranium activities at off-site locations ranged from below the detection limit of 1 pCi/l (0.037 Bq/l) up to 240 pCi/l (8.88 Bq/l) at Burgermeister Spring. The on-site surface water impoundments, two of which were added as sampling locations to the routine monitoring program in 1989, measured levels up to 3,200 pCi/l (118.4 Bq/l).

No significant changes were observed between the average measured values of 1988 and 1989 at any of the quarterly locations. At the furthest downstream location SW-2001 (the confluence of Schote and Dardenne creeks) the average of the quarterly measurements remained unchanged from 1988 while the maximum value declined only slightly. All of the quarterly measured values for that furthest location were within the range of background. No notable pattern in the values was observed relative to time of year.

The quarterly sampling results indicate that uranium continues to migrate from the site at relatively low levels in surface water along known discharge pathways. The concentration (activity) of the dissolved total uranium is reduced by dilution and natural processes to the point that the level falls to within the range of natural background at the measurement location SW-2001.

A substantial reduction in the concentration of uranium leaving the NP-0003 outfall was achieved with the completion of the diversion structure. Refer to Section 3.2.4 for a full

description of the diversion structure and its environmental protection benefits.

The on-site surface water bodies that were monitored quarterly include the four raffinate pits, the Ash Pond and Frog Pond. The radiological results from those locations are presented in Table 2-8. The highest measured uranium value in the 1989 surface water monitoring program came from Ash Pond at 3,200 pCi/l (118.4 Bq/l). It is important to note that after April 1989 the only on-site surface water body that released directly to off-site surface water pathways was Frog Pond.

THORIUM, RADIUM ISOTOPE MONITORING

Other radiological species (radium and thorium) were monitored in 1989 at the raffinate pits only. Historically, no other monitoring locations have detected elevated levels of those species. The raffinate pits were sampled once in 1989 to maintain a baseline on the radioisotope levels.

According to the 1989 measurements, the quarry pond water contains no radium-226 or thorium-232 above 1 pCi/l (0.037 Bq/l), and thorium-230 activities were measurable at the detection limit of 1 pCi/l (0.037 Bq/l) during two quarters.

2.2.2.2 Chemical Results

The environmental monitoring program for chemical constituents in surface water was slightly expanded from 1988 in the number of monitored locations, but was reduced in the frequency of analyses for selected parameter categories. These changes were made based upon the detailed information available from findings of past investigations at the site. During the

* Detection Limits (in mg/l)

1989 program, inorganic anions were measured at all locations annually. Nitroaromatic compounds were monitored once at locations that have historically indicated the presence of those compounds.

INORGANIC ANION ANALYSES

The inorganic anions of interest at the Weldon Spring Chemical Plant include chloride, fluoride, nitrate and sulfate. The following sections detail the results and implications of the anion analyses. Annual average results of these analyses are presented in Table 2-8.

CHLORIDE

The chloride levels measured in the eight off-site surface water locations ranged from a low of 1.9 mg/l at SW-2001 (Schote and Dardenne creeks) to 77 mg/l at SW-2002 (the head of Lake 36). SW-2002 and SW-2005 are directly downstream of the Missouri Department of Transportation's maintenance facility, adjacent to the site where road de-icing salt is stockpiled. The SW-2011 sampling location (Frog Pond) also receives direct discharge from the salt storage areas and shows the highest concentration of chloride of all the monitored locations (368 mg/l). Location SW-2011 yielded the only concentration level that exceeded the EPA's secondary drinking water standard of 250 mg/l for chloride.

These results indicate that the chloride levels off-site do not pose a threat to health or safety. No standards exist for protection of aquatic life or biota.

FLUORIDE

The measured fluoride concentrations at all off-site sampling locations remained below the detection limit of 0.25 mg/l. The concentration measured highest in Ash Pond at 0.5 mg/l which remains well within the EPA's maximum contaminant level (MCL) of 4 mg/l for fluoride. Fluoride does not constitute a major contamination problem at the WSCP/WSRP.

NITRATE

Nitrate concentrations ranged from below the detection limit of 1.0 mg/l to a quarterly high at Burgermeister Spring of 124 mg/l. Two distinct categories of nitrate concentrations are apparent in the measurements from 1989. At locations SW-2001 through SW-2007, and SW-2010 and SW-2011 the nitrate levels ranged from below the detection limit up to 4.2 mg/l. The Burgermeister Spring concentrations consistently are measured at approximately ten times that level. These findings are consistent with the 1988 Environmental Monitoring Report (EMR) and reinforce the conclusion drawn in the 1988 WSS EMR that contaminated groundwater is apparently contributing to the elevated nitrate levels in the Burgermeister Spring. At most locations, the levels of nitrate that are present in the surface water are below drinking water standards and therefore constitute no particular threat to human health or the environment, but they do provide valuable information on the mechanics of contaminant migration from the WSS. Further discussion regarding Burgermeister Spring contamination is presented in Section 2.2.2.3 of this report.

SULFATE

The sulfate measurements made under the surface water monitoring program yielded levels ranging between 9 mg/l at SW-2001 and 56 mg/l at SW-2011.

The pattern of high sulfate values is similar to that of the chlorides migrating from the Highway Department Facility with relative highs at Frog Pond and Lake 36. In addition, however, relatively elevated sulfate levels were detected at Ash Pond and Burgermeister Spring during 1989. These results suggest the presence of an on-site surface source for sulfates within the Ash Pond drainage. Also the sulfate value of 45 mg/l at Burgermeister Spring might suggest a component of sulfate-contaminated groundwater discharging at that point. The measured levels are well below the EPA's secondary drinking water standard of 250 mg/l for sulfate.

The WSSRAP measurements of inorganic anions in the surface water medium around the WSS indicated consistently elevated nitrate, sulfate and chloride levels. The nitrates and sulfates can in most instances be attributed to an on-site source on the WSS; the source for chlorides is located on the adjacent state highway department property. None of the measured anion levels exceeded existing water quality criteria and inorganic anions around the WSS pose no particular environmental or health and safety threat.

NITROAROMATICS MONITORING

The monitoring program for nitroaromatics in 1989 involved annual sampling at each of the off-site locations SW-2001 through SW-2008 (SW-2009 was dry) and quarterly monitoring of the on-site

locations at Ash Pond (SW-2010) and Frog Pond (SW-2011). No monitoring for nitroaromatic compounds was performed during 1989 at the raffinate pit locations (SW-3001 through SW-3004).

The monitoring results confirm what has been detected historically at the off-site monitoring locations. Nitroaromatics were detected at levels above the detection limits only at Burgermeister Spring. A possible positive result was indicated at Lake 34 downstream of Burgermeister Spring; however, a duplicate analysis of the sample did not confirm that result.

The analyzed sample from Lake 10 on the Busch Wildlife Area did indicate a low-level positive result for two nitroaromatic compounds during the second quarter. However, no confidence is placed in those positives since there have been no previous detections in Lake 10, there are no known source areas upstream of that lake, the lake is isolated from subsurface conduit flow influences, blank samples were also contaminated, and at these low quantifiable limits the analyses have proven to be susceptible to false positive results. The positive results in Lake 10 are therefore dismissed as false and Lake 10 is not considered to be contaminated with nitroaromatics. The 1990 sampling and analytical program will include Lake 10 for nitroaromatics to verify the presence or absence of those compounds.

Mixed results were obtained from Frog Pond and again the positive detection of nitroaromatic compounds is questionable. At the Frog Pond, two samples collected during 1989 indicated no nitroaromatic compounds above the detection limit; however during second quarter, relatively high positive levels were detected for three of the six compounds monitored. The pattern of results suggests that again the second quarter positive results probably

constitute laboratory contamination or false positive interpretation. This is substantiated by the contamination of blank samples. Analyses for nitroaromatic compounds will continue at Frog Pond to verify the absence or presence of these contaminants.

2.2.2.3 Spring Monitoring

Other surface water features monitored under the environmental monitoring program are various springs near the WSCP/WSRP area. Some of the springs that are routinely monitored are known to issue contaminated water while others are located geographically so that contamination could reach the spring. Monitoring provides a baseline for establishing that connection. Figure 2-19A displays the spring sampling locations in the WSS area.

The results of the 1989 monitoring of springs in the WSS area are presented in Table 2-9 and indicate no change in the distribution or levels of contaminants at the springs of concern. The highest levels of uranium issue from SP-5301 through SP-5304 in the southeast drainage easement at annual averages ranging from 377 pCi/l (13.95 Bq/l) to 135 pCi/l (4.99 Bq/l). Burgermeister Spring and the estavelle spring (SP-6301 and SP-6302) remain within their historical range at an annual average of 98 pCi/l (3.63 Bq/l) and 90 pCi/l (3.33 Bq/l) respectively. (Note: Location SP-6301 and location SW-2008 are both Burgermeister Spring as they were sampled under two separate programs. That location will be assigned SP-6301 designation exclusively in 1990.)

* Detection Limit

An inconsistently high quarterly sulfate measurement at SP-5302 drove the 1989 annual average for sulfate up to a level unusual for local springs. The source for this unusually high quarterly measurement is uncertain; however laboratory error is suspected. None of the other springs connected to that same flow system, either upstream or downstream, indicated similarly high levels. All of the measured levels remain below the EPA's secondary drinking water standard of 250 mg/l.

At 68 mg/l, the chloride levels at SP-5203 remain elevated, as was documented in the Phase I Spring and Seep Study (MKF and JEG, 1988b). The source for these elevated chloride levels is hypothesized to be the stockpiles of sodium chloride (de-icing salt) at the highway department maintenance facility adjacent to the WSS. No other chloride levels in springs were noteworthy.

The fluoride measurements lay well within the range established as background for fluoride during the Phase I study. No quarterly values were noteworthy.

Nitrate levels above the maximum calculated background level of 14.5 mg/l were detected at three springs--SP-5203, SP-6301 and SP-6303. The highest quarterly nitrate level was detected at Burgermeister Spring (SP-6301) at 124 mg/l with an annual average of 59 mg/l. The annual average for nitrate at Burgermeister Spring is slightly above the EPA's primary drinking water standard equivalent for nitrate of 45 mg/l. It is important to note that Burgermeister Spring does not serve as a regular drinking water/tap water source to which primary drinking water standards apply; however the standard serves as an effective health-based numerical comparison for the purposes of this document. These elevated values indicate contaminant influences to the groundwater system feeding those springs. It is currently

not known whether the sources for the nitrates issuing from these springs is similar or disparate. Spring SP-6301 water contains low-level nitroaromatics, uranium and nitrates; SP-6303 contains higher nitroaromatics, no uranium, and elevated nitrates, and SP-5203 contains high anions and no nitroaromatics or uranium.

In summary, the conditions influencing the resurging water at local springs appear to be remaining constant with no notable variations in contaminant levels or distribution.

2.2.3 Quarterly Surface Water Sampling at the WSQ Area

The nine surface water locations in Figures 2-20 and 2-21 were sampled quarterly and analyzed for uranium, with select locations analyzed additionally for radium-226, thorium-230, thorium-232, nitrate, sulfate, chloride, and fluoride. These locations were chosen for routine monitoring to investigate and document the possibility that surface waters near the WSQ might pose a risk to human health or the environment.

Locations SW-1001 and SW-1002 monitor the Little Femme Osage Creek at points upstream and downstream of the WSQ. Five sampling locations--SW-1003 through SW-1005, SW-1009 and SW-1010--are distributed along the Femme Osage Slough west of, adjacent to, and east of the WSQ. Location SW-1008 monitors the ponded water within the WSQ. The samples from this location permit a rough determination of the concentrations of the various contaminants in the ponded surface water that may migrate to groundwater. Locations SW-1011, SW-1012, and SW-1013 were added to the monitoring program in 1989 to provide baseline water quality data from the Missouri River. SW-1011 is the Missouri River location furthest upstream above any potential influences

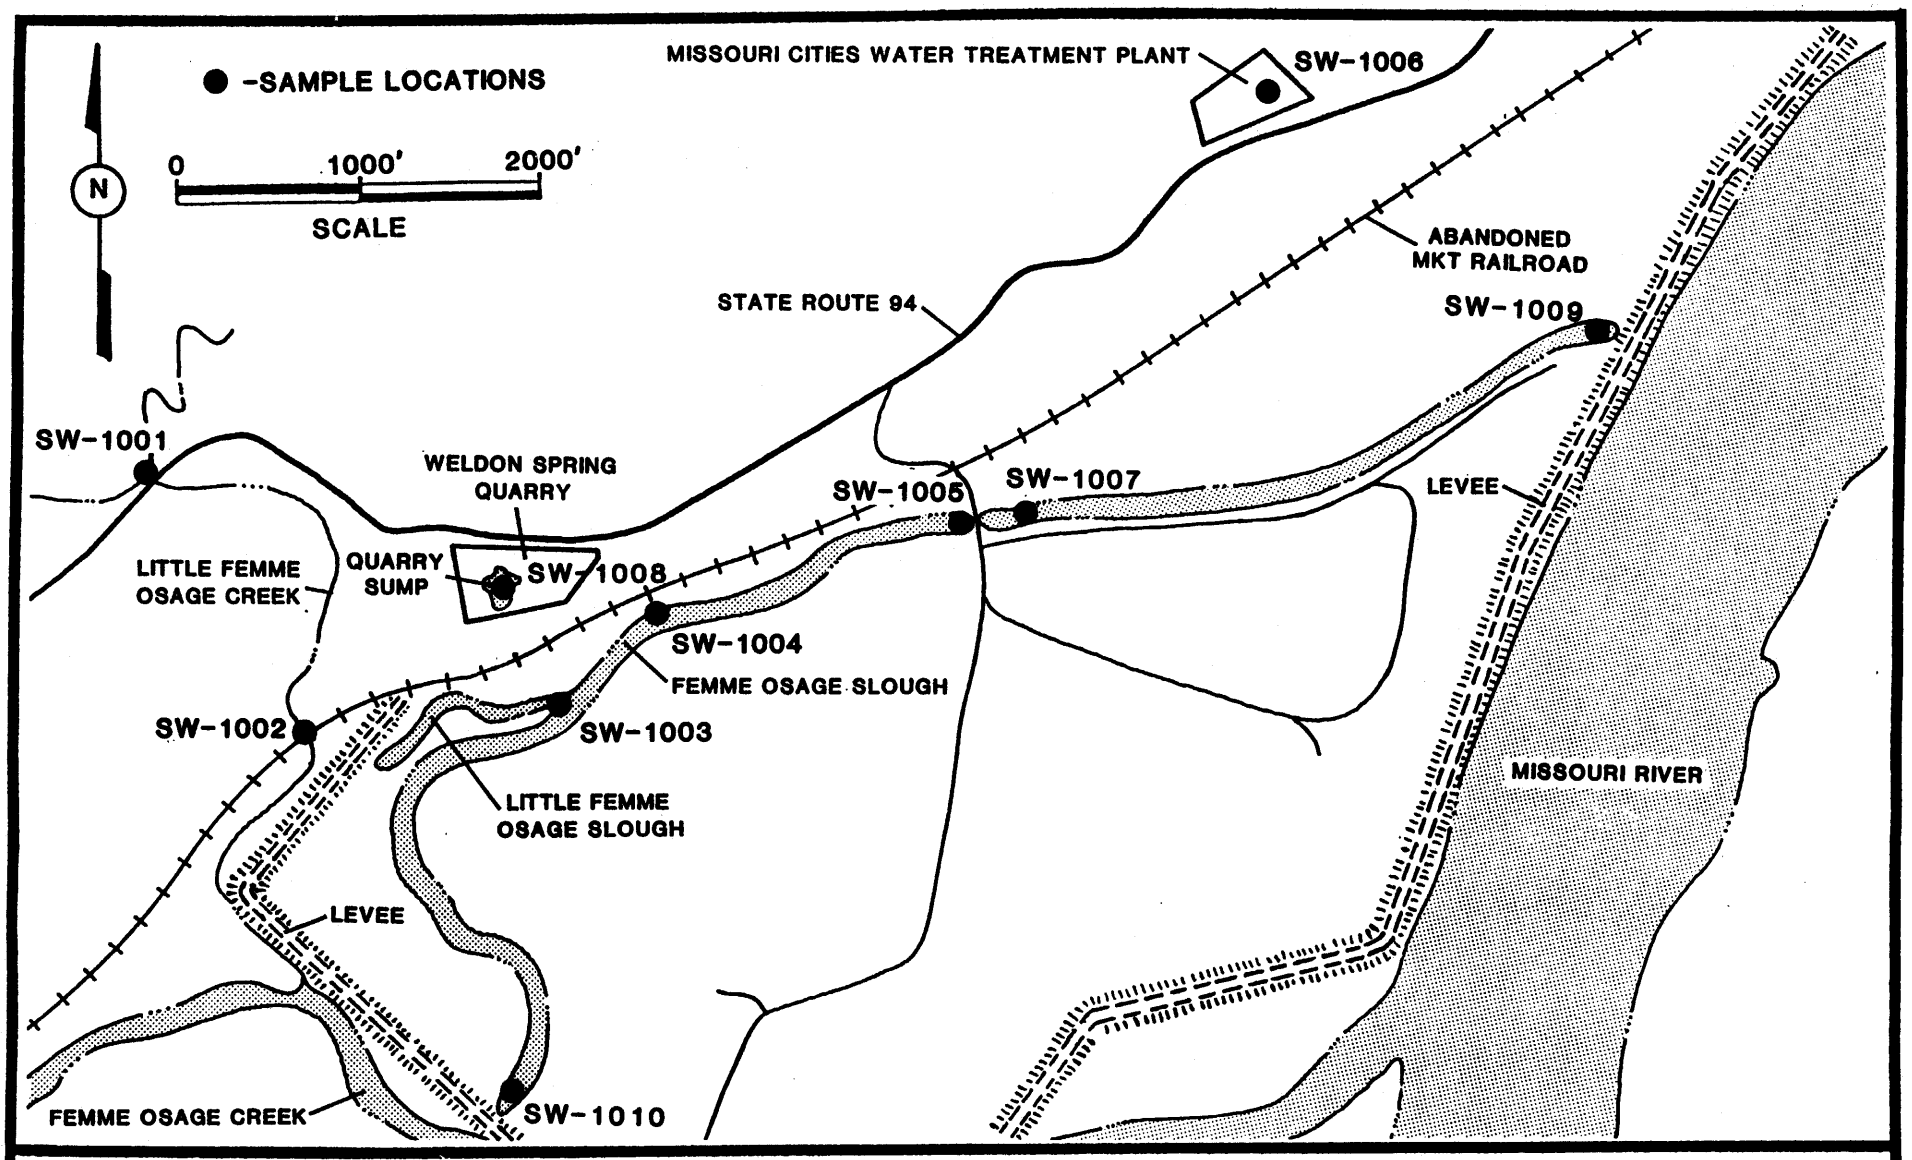

FIGURE 2-20

SURFACE WATER SAMPLING LOCATIONS NEAR THE WELDON SPRING QUARRY

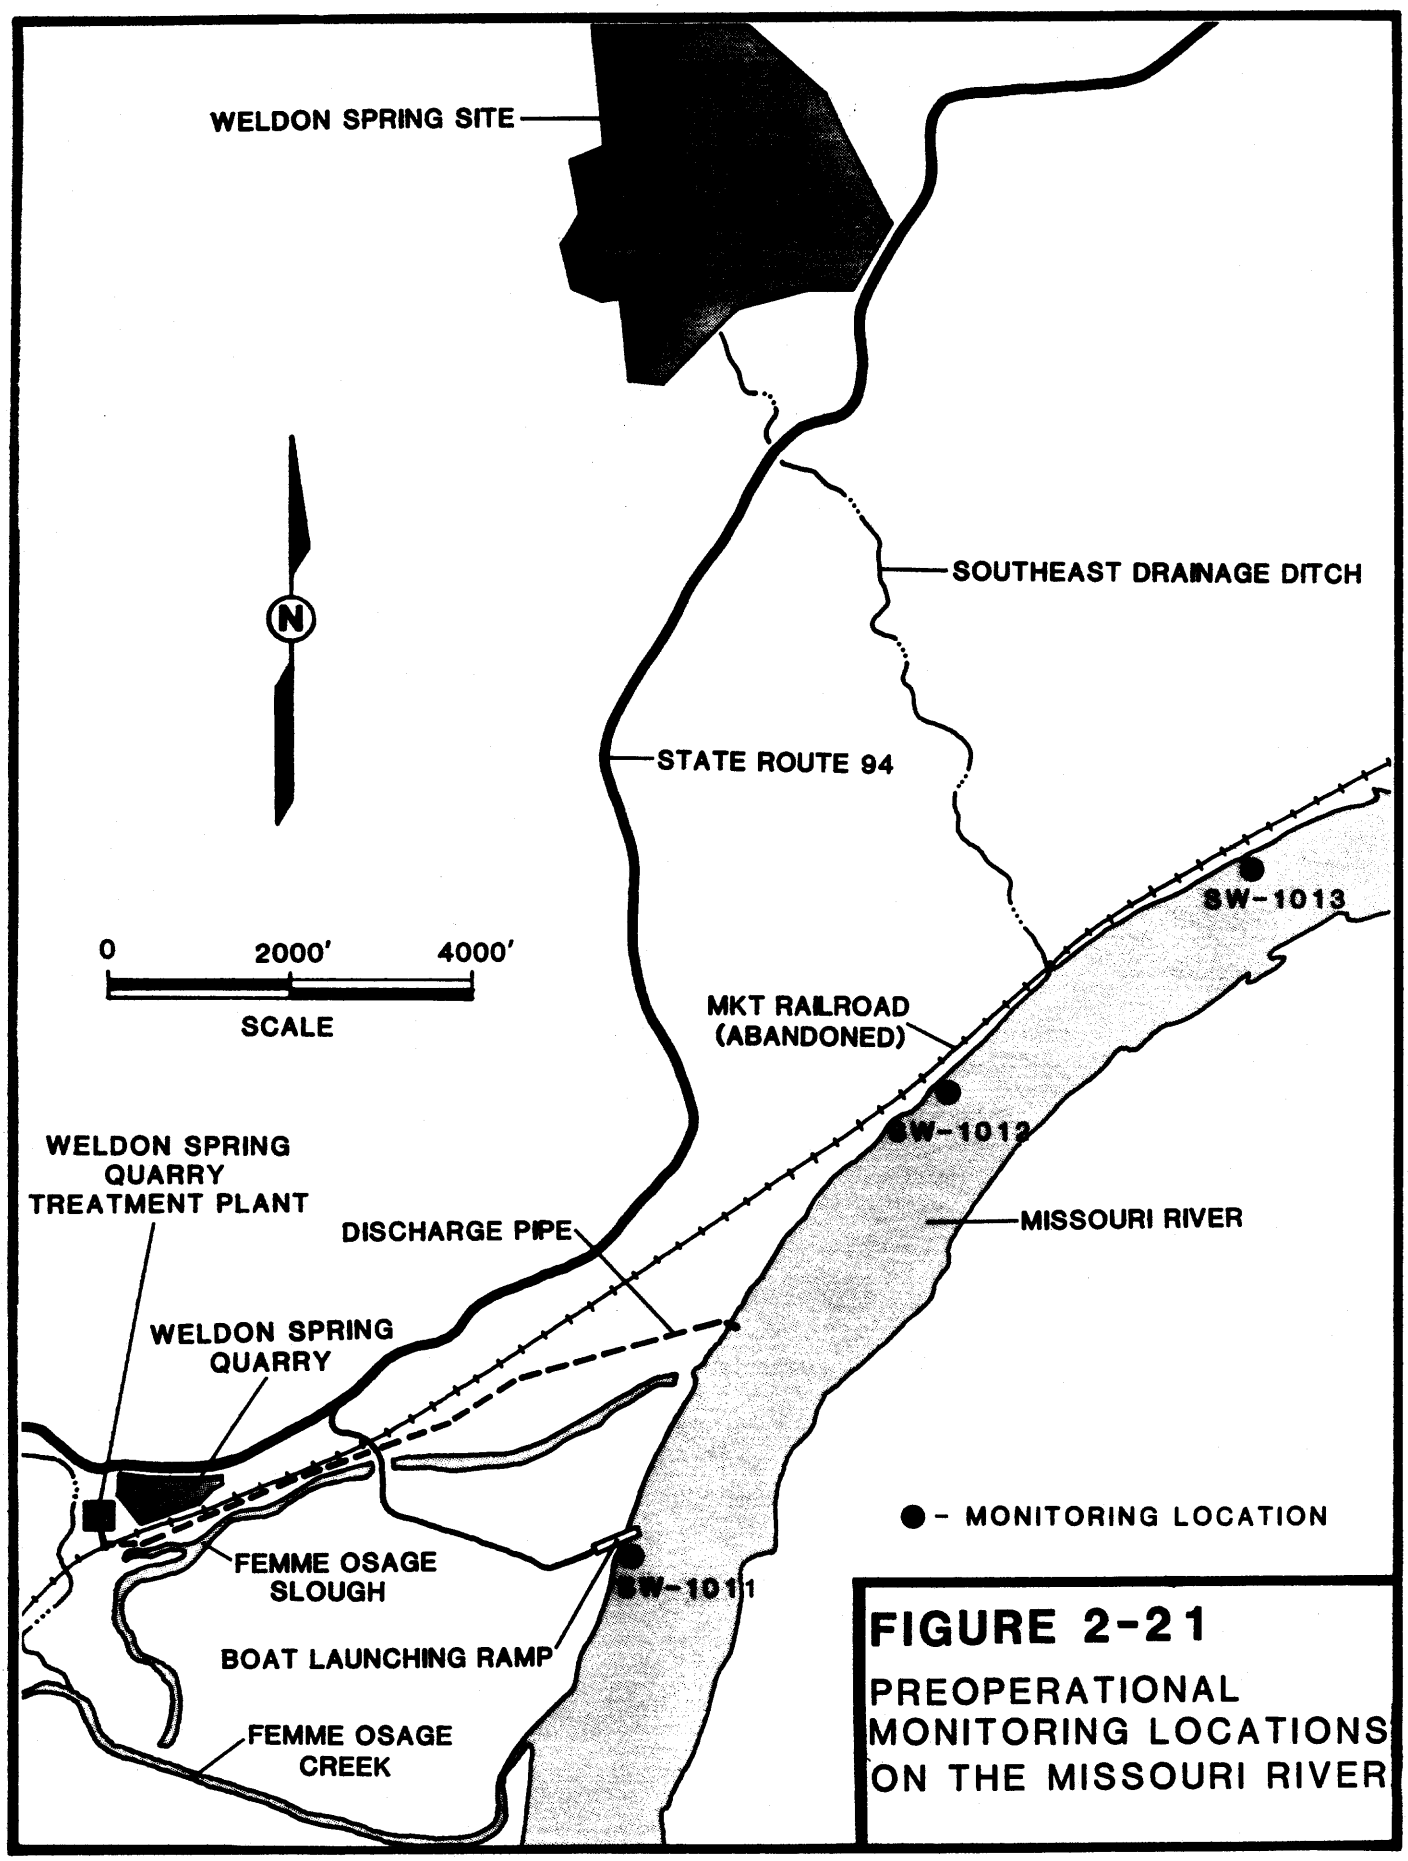

FIGURE 2-21

PREOPERATIONAL MONITORING LOCATIONS ON THE MISSOURI RIVER

from WSS contamination, while SW-1013 is furthest downstream below the outfall point of the southeast drainage easement.

2.2.3.1 Radiological Results

URANIUM

All surface water monitoring locations were sampled quarterly for uranium. Select locations including SW-1008, SW-1011, SW-1012, and SW-1013 were also analyzed for radium-226 and two thorium isotopes once during the monitoring year.

The primary radionuclide of concern at the WSQ and surrounding area is uranium, which was detected at levels ranging from below the detection limit of 1 pCi/l (0.037 Bq/l) to a high of 2,400 pCi/l (88.8 Bq/l) in the quarry pond water within the access-controlled area.

As has been determined in previous monitoring years, no elevated uranium activities were detected in the waters of the Little Femme Osage Creek either up or downstream of the quarry.

The Femme Osage Slough, which is the former channel of the Femme Osage Creek prior to rerouting that stream course, is a nearly unmoving water body. The slough has been known for several years to be receiving uranium contamination from the contaminated groundwater in the bedrock and alluvium to the north. In 1989, the average uranium activities ranged from 18 pCi/l (0.67 Bq/l), 3% of the DCG at SW-1009 to 161 pCi/l (1.68 Bq/l), 29% of the DCG at SW-1004. The annual average results for SW-1003 and SW-1004 were influenced by apparently elevated uranium levels in these portions of the slough. The levels returned to the usual range for those locations by third

quarter. This departure is atrributed to uranium contaminated groundwater discharging to the slough from the north side. The interception of this contaminated groundwater by the slough with evidence of no continued migration south of the slough is consistent with the DOE's data that show the slough has been acting as a barrier to contamination. With uranium activity measured at SW-1010 it is believed that the west end of the slough receives contaminants as water flows westward up the slough during periods of high river stage. The 1990 monitoring program will concentrate on this situation to attempt to characterize the mechanism and define the potential impacts.

Locations SW-1011 to SW-1013 are spaced along the north bank of the Missouri River to provide samples of river water for water quality testing in preparation for effluent discharge from the WSQ water treatment plant. The results of the measurements yielded average uranium activities which ranged from 2.9 pCi/l (0.107 Bq/l) at SW-1013 (downstream) to 4.4 pCi/l (0.16 Bq/l), less than 1% of the DCG, at SW-1011 (upstream). The values are virtually the same when considering the average counting error at plus or minus 1.0 pCi/l (0.037 Bq/l). The highest measured uranium activity in the Missouri River was detected during the first quarter of 1989 at 6.3 pCi/l (0.23 Bq/l).

Finally, the quarry pond water (SW-1008) was monitored quarterly during 1989 for uranium. The average measured uranium activity was 1,830 pCi/l (67.71 Bq/l), 332% of the DCG, which is similar to the levels measured in 1988 at an average of 1,300 pCi/l (48.1 Bq/l), or 236% of the DCG. The quarry pond remains within the access-controlled area of the quarry and poses little direct threat to the public health.

2.2.3.2 Chemical Results

INORGANIC ANION RESULTS

Inorganic anions were analyzed on an annual basis in samples from locations SW-1001 through SW-1010 (except SW-1006) and more frequently on samples from the quarry pond and on Missouri River water samples (SW-1011 to SW-1013). The inorganic anions category includes chlorides, fluorides, nitrates and sulfates. The results of the analyses are presented below. Table 2-10 presents the annual averages for each parameter measured.

CHLORIDE

The highest measured chloride values were detected in the three Missouri River water samples at annual averages ranging from 23 mg/l at SW-1013 to 29 µg/l at SW-1012. All other measured levels remained well below the Missouri River background concentrations.

The levels measured in 1989 at SW-1001 to SW-1009 have decreased or remained very nearly the same. The relatively slight variations were of a magnitude that can be accounted for by natural dilutional effects.

FLUORIDE

Fluoride levels remained below the detectable limit of 0.25 mg/l at eight of the 12 monitored locations. At the quarry pond, the annual average was 0.57 mg/l while the Missouri River ranged from 0.49 mg/l at SW-1011 to 0.55 mg/l at SW-1013 during the fourth quarter of 1989.

TABLE 2-10 Summary of Analytical Results for 1989 Surface Water Monitoring Locations Near the Weldon Spring Quarry (mg/l)

Location **	Chloride (0.25)*	Fluoride (0.25)*	Nitrate (0.1)*	Sulfate (1.0)*	Uranium + (1.0 pCi/l)*
SW-1001	14	ND	4	ND	2
SW-1002	6	ND	1	38	2
SW-1003	10	ND	ND	125	86
SW-1004	12	ND	ND	141	161
SW-1005	12	ND	ND	91	44
SW-1007	7	ND	ND	90	19
SW-1008	14	0.7	0.4	141	1827
SW-1009	7	ND	ND	96	18
SW-1010	4	ND	ND	101	44
SW-1011	23	ND	3.2	130	4

SW-1013	23	0.3	2.5	111	3

\+ Units for uranium are in pCi/l.
* Detection Limit
** SW-1006 was removed from the surface water sampling program.

NITRATE

The nitrate levels measurable above the detection limit of 0.1 mg/l ranged to as high as 4.2 mg/l at SW-1011 in the Missouri River. All of the levels were insignificantly low as compared to the EPA's primary drinking water standard of 45 mg/l.

SULFATE

The sulfate measurements ranged from below the detection limit of 40 mg/l to as high as 171 mg/l at all locations in the Missouri River during the third quarter of 1989. No unusual patterns are visible in the data other than the relatively high sulfate as background in the Missouri River. The average sulfate level for all quarters from all three locations along the Missouri River was 149 mg/l. All measured levels remained well below the EPA's secondary drinking water standard for sulfate of 250 mg/l.

NITROAROMATICS

Samples were collected at three locations along the slough once annually (SW-1003 to SW-1005) to assess whether detectable levels of nitroaromatics were present in slough water. No levels above the detection limits were discovered.

The quarry pond was sampled quarterly for nitroaromatic compounds. The total quantified concentrations of all six compounds ranged from 2.4 µg/l in the first quarter to 68 µg/l in the fourth quarter. Samples will continue to be collected from the quarry pond to maintain accurate information on the levels in the water. The ponded water will ultimately be treated for nitroaromatic compounds and other organics upon completion of the quarry water treatment plant.

2.3 Radon Gas Monitoring

Radon is a naturally occurring radioactive gas in the uranium and thorium decay series. Radon-222 (Rn-222) is formed by the natural radioactive decay of radium-226 (Ra-226) which is a decay product of uranium-238 (U-238) found in soil and rock. Radon-220 (Rn-220) (also referred to historically as thoron--Tn) is formed by the natural radioactive decay of radium-224 (Ra-224) which is a decay product of thorium-232 (Th-232) found in soil and rock. A fraction of the radon diffuses into the atmosphere and accounts for natural background radon concentrations. Radon is also produced at the WSS as the Ra-226 and Ra-224 contained in the waste materials undergo decay.

Radon concentrations fluctuate with both soil conditions and meteorological dispersion conditions. This is because the amount of radon that actually enters the atmosphere varies depending on the following parameters: radium concentrations, moisture content, soil porosity, soil density, emanating fraction, and atmospheric pressure.

The emanating fraction is the portion of radon that escapes from soil particles into the pore spaces, which are the voids found in all soils regardless of density. Only the radon entering these pore spaces is available for release to the atmosphere.

Porosity is a measure of the amount of pore space or fraction of total volume occupied by the pore spaces. The higher the porosity the more pore spaces for the radon to move through.

Some fraction of the total pore space volume is typically filled with water, and soil moisture content provides a measure

of this fraction. Radon diffuses easier through air-filled pore spaces than water-filled ones, so the higher the soil moisture content, the lower the radon emanation from the exposed surface. The moisture content of the soil is the most variable of these parameters and is primarily responsible for quarterly and annual changes in radon concentrations.

Radon exposure is a potential environmental impact from the WSS. Therefore, radon has been monitored since 1981. This section discusses the monitoring program and presents a summary of the monitoring results.

2.3.1 Radon Gas Monitoring Program

The radon gas monitoring program uses one pair of radon detectors at 22 permanent locations that are exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, six locations at the Weldon Spring Quarry, four locations at the Weldon Spring Raffinate Pits, and six off-site locations. Radon monitoring locations are shown in Figures 2-22, 2-23 and 2-24. On-site detectors were spaced around the perimeter fences to ensure adequate detection of radon dissipating from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005 and RD-4006 were used to monitor background levels near the WSS.

The radon detectors used in this program were Terradex Track Etch Type F. Type F detectors are sensitive to all isotopes of radon. These detectors were housed in protective plastic cups and mounted inverted on posts. The detectors were placed and collected at the beginning and end of each calendar quarter. The detectors were deployed in pairs to evaluate and reduce the natural uncertainties associated with this type of measurement.

In addition to the Type F detectors, Terradex Track Etch Type M detectors were placed at the permanent quarry monitoring stations in the second quarter of 1989. Type M detectors have a barrier which effectively screens out Rn-220 while allowing Rn-222 to pass through. These detectors were deployed in pairs, adjacent to the Type F detectors. These measurements were taken in order to determine the percentage of Rn-220 which is contributing to the total radon concentration at the quarry perimeter.

2.3.2 Radon Gas Monitoring Results

Table 2-11 summarizes the quarterly and annual average concentration of radon detected at all WSS perimeter and off-site monitoring locations. Also contained in Table 2-11 is a comparison of the measured annual average concentration to the federally permitted concentration for unrestricted areas of 3 pCi/l (110 $Bq/^3$) as authorized by DOE Order 5400.5.

For each monitoring station, annual averages in Table 2-11 were calculated by finding the arithmetic average of the four quarterly replicate values. The standard deviation was calculated by computing the square root of the sum of the squared errors divided by four for each quarterly replicate data point. Due to vandalism, monitoring stations RD-1001 and RD-4005 were missing one of the replicate detectors in the first and third quarter, respectively. In these cases the values of the single remaining detector were reported.

Ambient background concentrations were determined by calculating the arithmetic average of concentrations for the four background locations. These four locations are: RD-4001, RD-4004, RD-4005, and RD-4006. These data yielded an annual

* DENOTES BACKGROUND STATION

background value for radon (Rn-222 plus Rn-220) in 1989 of 0.6 pCi/l (20.5 Bq/m^3).

The quarterly radon concentrations at each monitoring location were compared statistically, at the 95 percent confidence level, to the quarterly concentrations of the four background locations. Only those monitoring locations that were statistically different from background were compared to the DOE guideline.

Radon concentrations at the WSS perimeter and at off-site locations were lower in 1989 than in 1988. Abnormally high values were recorded in 1988 because of the regional drought. The 1988 drought reduced the moisture content of soils; radium-containing wastes thus allowed a greater fraction of radon in the soil and waste voids to diffuse into the atmosphere. The lower radon concentrations measured in 1989 are comparable to concentrations reported in past annual environmental monitoring reports (prior to 1988) and are typical of values expected during years of normal precipitation levels.

Radon concentrations found in the quarry are higher than concentrations measured at other WSS properties because the radium concentrations in quarry wastes are typically higher than other areas and because the quarry is a large depression in the terrain with side walls ranging from 3 to 15 meters high (10 to 50 feet). In conjunction with stable meteorological conditions, this tends to trap emanating radon within the quarry and raises the concentrations along the quarry perimeter.

Radon concentrations measured at the quarry perimeter with Type M detectors, which effectively screen out Rn-220 (thoron), are listed in Table 2-12. Table 2-12 lists the average

(a) Two samples for each Type F and Type M

concentration of the Type F and Type M detectors at the WSQ monitoring station for the second quarter of 1989. Also contained in the table is the percentage of thoron contribution to the total concentration of radon (Rn-222 plus Rn-220) recorded by the Type F detector at each station.

The concentration at each location was determined by taking the arithmetic average of the replicate values. The estimate of error was calculated by finding the square root of the sum of the squared errors divided by the number of data points.

In Table 2-12 the results of the Type M detectors were subtracted from the results of the Type F detectors to show if Rn-220 (thoron) was contributing to the total radon concentration. Only one location (RD-1002) showed a positive difference between the Type F and Type M detectors. The remaining comparisons of results were equal or showed a negative difference. Because the Type F detectors measure both Rn-222 and Rn-220, a negative difference between the Type F detection result and Type M detector results should not occur. The overall differences are attributable to the uncertainty in the measurement methods. The one positive result, which was measured in the second quarter, is not sufficient evidence to conclude that thoron is contributing to the radon concentration at that location or at the WSQ perimeter. The WSSRAP will evaluate this further by taking measurements during 1990 using continuous monitors.

2.4 Gamma Radiation Exposure Rate Monitoring

Gamma rays are electromagnetic radiation that are emitted from the nucleus of atoms following alpha or beta emissions. The environment naturally contains radioactive substances which emit

gamma radiation. Terrestrial radiation sources are natural radioactive elements in the environment (soil, water). Cosmic radiation is high-energy radiation that originates in outer space and filters through the atmosphere reaching the earth surface. Together, these two sources account for natural background gamma radiation. Terrestrial and cosmic radiation fluctuates depending on the soil composition and elevation above sea level.

Gamma radiation is emitted by many radionuclides of the U-238 and Th-232 decay series. These radionuclides are found in above-background concentrations on the WSS properties. Therefore, gamma radiation is monitored at the WSS. This section discusses the monitoring program and presents the summary of the results.

2.4.1 Gamma Radiation Exposure Rate Monitoring Program

To monitor exposure from gamma radiation at the WSS, 22 monitoring stations using spherical environmental thermoluminescent dosimeters (TLDs) were deployed. The monitoring station locations are the same as the ambient radon monitoring locations.

Ten monitoring stations are located at the WSCP/WSRP along the perimeter fence (Figure 2-22), six monitoring stations are located along the WSQ perimeter fence (Figure 2-24) and six monitoring stations are located off-site (Figures 2-22 and 2-23). Monitoring stations TD-4001, TD-4004, TD-4005, and TD-4006 measure natural background at locations unaffected by the site.

The TLDs are composed of five lithium fluoride chips in a durable spherical polyethylene holder which is designed with internal filters to measure penetrating radiation. The TLDs are

exchanged quarterly and returned to TMA/Eberline Laboratory for processing.

In addition to monitoring gamma radiation with TLDs, natural background gamma radiation exposure rates were measured one meter from the ground surface with a pressurized ionization chamber (PIC) from October through December 1988. Total gamma exposure was integrated with the PIC over time intervals ranging from one to three hours at each measurement location.

Five measurements were made in each of three distinct geographical regions in the vicinity of the WSS. These regions have differing soil characteristics and potentially have differing terrestrial gamma exposure rates. The three distinct regions are the dissected glacial till deposits, the alluvial deposition of the Missouri River Valley, and the Salem Plateau.

The WSCP/WSRP is located in a transitional region between the glacial till deposits and the Salem Plateau. The WSQ is located on the Salem Plateau just north of the alluvial deposition region of the Missouri River Valley.

2.4.2 Gamma Radiation Exposure Rate Monitoring Results

Natural background exposure rates measured with the PIC averaged 8.3 $\pm$ 1.8 microroentgen (μR)/hr, 9.3 $\pm$ 1.1 μR/hr, and 9.1 $\pm$ 1.7 μR/hr at two standard deviations for the dissected glacial till, Salem Plateau, and the alluvial deposition of the Missouri River, respectively. At the 95 percent confidence level there is no reason to suspect a difference in gamma exposure rates for the three geological regions. Averaging the results among the regions yields an estimate of the natural background surrounding the WSS of 8.9 $\pm$ 0.9 μR/hr at two standard

deviations. This translates to a yearly average gamma exposure of 78 ± 7.9 mR at two standard deviations (8.9 µR/hr times 8,760 hours per year).

To determine background levels of gamma radiation as measured with the TLDs, the gamma exposure at the four background monitoring stations were averaged. This yielded 68 ± 8.0 mR/year at two standard deviations.

The average exposure as measured by the TLDs is significantly lower than the average exposure as measured by the PIC at the 95 percent confidence level. This is probably due to the fact that the PIC measurements were short-term measurements (i.e., hourly) while the TLDs integrate gamma exposure for 13 weeks. Thus the TLD results provide a better estimate of natural background exposure.

Yearly background gamma exposures have been measured previously by the PMC and other contractors for the DOE around the WSS. Results have ranged from 60 to 104 mR/year (BNI, 1985a; BNI, 1985b; BNI, 1984; and MKF and JEG, 1989a). There continues to be agreement between previous monitoring results and current results. This is expected because nothing has significantly changed the configuration or location of the wastes at the WSS.

Table 2-13 summarizes the quarterly and annual total gamma radiation monitoring results at the 16 WSS perimeter monitoring stations, Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the four background monitoring stations. The results reported in the table include two standard deviations.

* DENOTES BACKGROUND STATION
TE TRANSPORTATION EXPOSURE - NOT REPORTED

A control TLD accompanies each quarterly shipment of TLDs to assess exposure during mailing. All second quarter TLDs (including the control and the background TLDs) had results four times higher than typical quarterly results. This may have been caused by the shipment being x-rayed during transit. For this reason the results for the second quarter were disregarded and the average of the remaining quarterly data was used for the missing second quarter data in order to calculate the annual total.

The first quarter TLD was missing for monitoring station TD-4004 and the third quarter TLD was missing for monitoring station TD-4004 and TD-4005. In order to calculate an annual total gamma exposure rate the missing data was replaced with the average of the remaining quarterly TLD results for those monitoring stations.

At the WSCP/WSRP site perimeters the annual exposures ranged from 56 to 79 mR. At the WSQ site perimeter, the annual exposures ranged from 72 to 98 mR. Annual exposure at the Francis Howell High School was 59 mR. At the Weldon Spring Army Reserve Training Area the annual exposure was 52 mR.

Except for monitoring stations TD-1001, TD-1002, TD-1003, and TD-1005, all of which are located at the WSQ perimeter, there was no reason to suspect at the 95 percent confidence level that gamma exposures exceeded natural background. This conclusion was based on a comparison of the gamma exposure measured at each station to the gamma exposure measured at the four background TLD monitoring stations. Thus at the WSCP/WSRP perimeter, Francis Howell High School, and the Army Reserve Training Area there were no external gamma exposures above natural background levels.

At four of the six quarry monitoring stations gamma exposures exceeded natural background by amounts ranging from 12 to 30 mR/year. Although gamma exposures exceeded background at four quarry stations, the DOE standard authorized in DOE Order 5400.5 of 100 mR/yr above background in unrestricted areas was not exceeded. This information is summarized in Table 2-14. In Table 2-14 the percent of DOE standard was calculated by subtracting the annual average (68 mR/year) from the annual exposure at each station and then dividing by the 100 mR/year DOE standard.

2.5 Radioactive Air Particulate Monitoring

Radioactive air particulates are dust particles that carry radioactive contaminants. The main contributors to long-lived natural background radioactivity on dust particles are Po-210 and Pb-210, naturally occurring radon-222 decay products. Surface soils also naturally contain radioactivity that becomes airborne and accounts, to a much lesser extent, for natural background concentrations of radioactive air particulates. Background concentrations of radioactive air particulates vary depending on soil moisture, wind, and geological conditions.

Many areas of the WSS properties contain elevated concentrations of radionuclides in the soil which could result in increased radioactive air particulate concentrations. Increased concentrations and possible emission from the WSS could result from work activities such as movement of equipment or vehicles in contaminated areas or from wind erosion. This section discusses the air particulate monitoring program and presents a summary of the results.

TABLE 2-14 Summary of TLD Monitoring Results of Stations That Exceeded Natural Background*

Station Number	Location	Annual Exposure (mR/year)	Percent of DOE Standard

* 95 Percent Confidence Level

2.5.1 Radioactive Air Particulate Monitoring Program

Eleven air particulate samplers are used to monitor the WSS properties. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the WSCP perimeter as shown on Figure 2-22. Two monitoring stations (AP-4006 and AP-4008) are located off-site at sensitive receptor locations, which are Francis Howell High School and the Army Reserve property. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown on Figure 2-22.

In the second quarter of 1989, monitoring of the WSQ was initiated. Two monitors (AP-1009 and AP-1010) were installed at the quarry and one (AP-4011) placed off-site to monitor background levels in the vicinity of the quarry. The quarry monitoring stations are shown on Figures 2-25 and 2-26.

Due to the different geological conditions at the quarry and the WSCP, two background stations are utilized. The quarry background monitoring station is located approximately 0.8 km (0.5 mi) to the west of the quarry. This station is suitable because at that location the predominant wind direction is toward the quarry, and the station is not influenced by radioactive air particulate releases from the quarry, yet it is close enough to the quarry to have the same regional environmental and meteorological characteristics.

The sampling station near the August A. Busch Wildlife Area (ABWA) headquarters is used as a WSCP/WSRP background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and

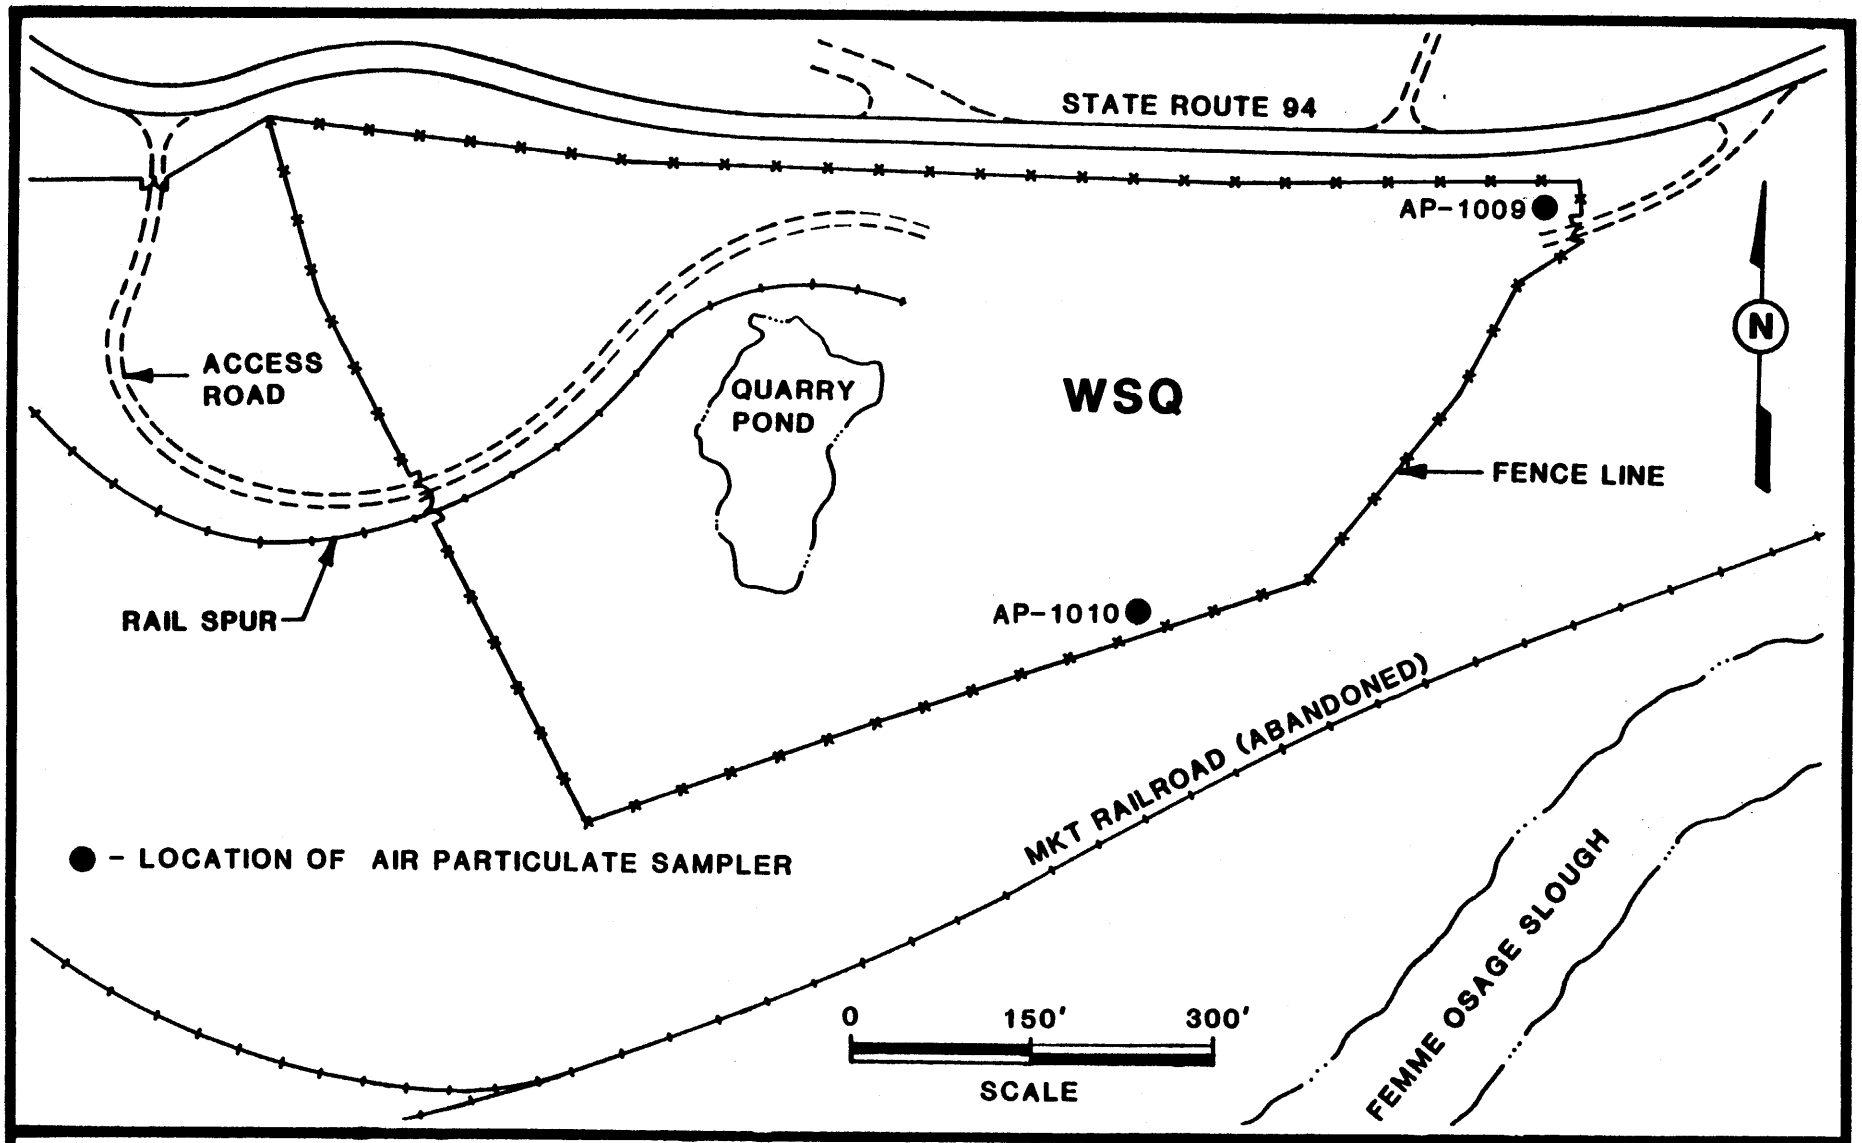

FIGURE 2-25

AIR SAMPLER LOCATIONS AT THE WSQ PERIMETER

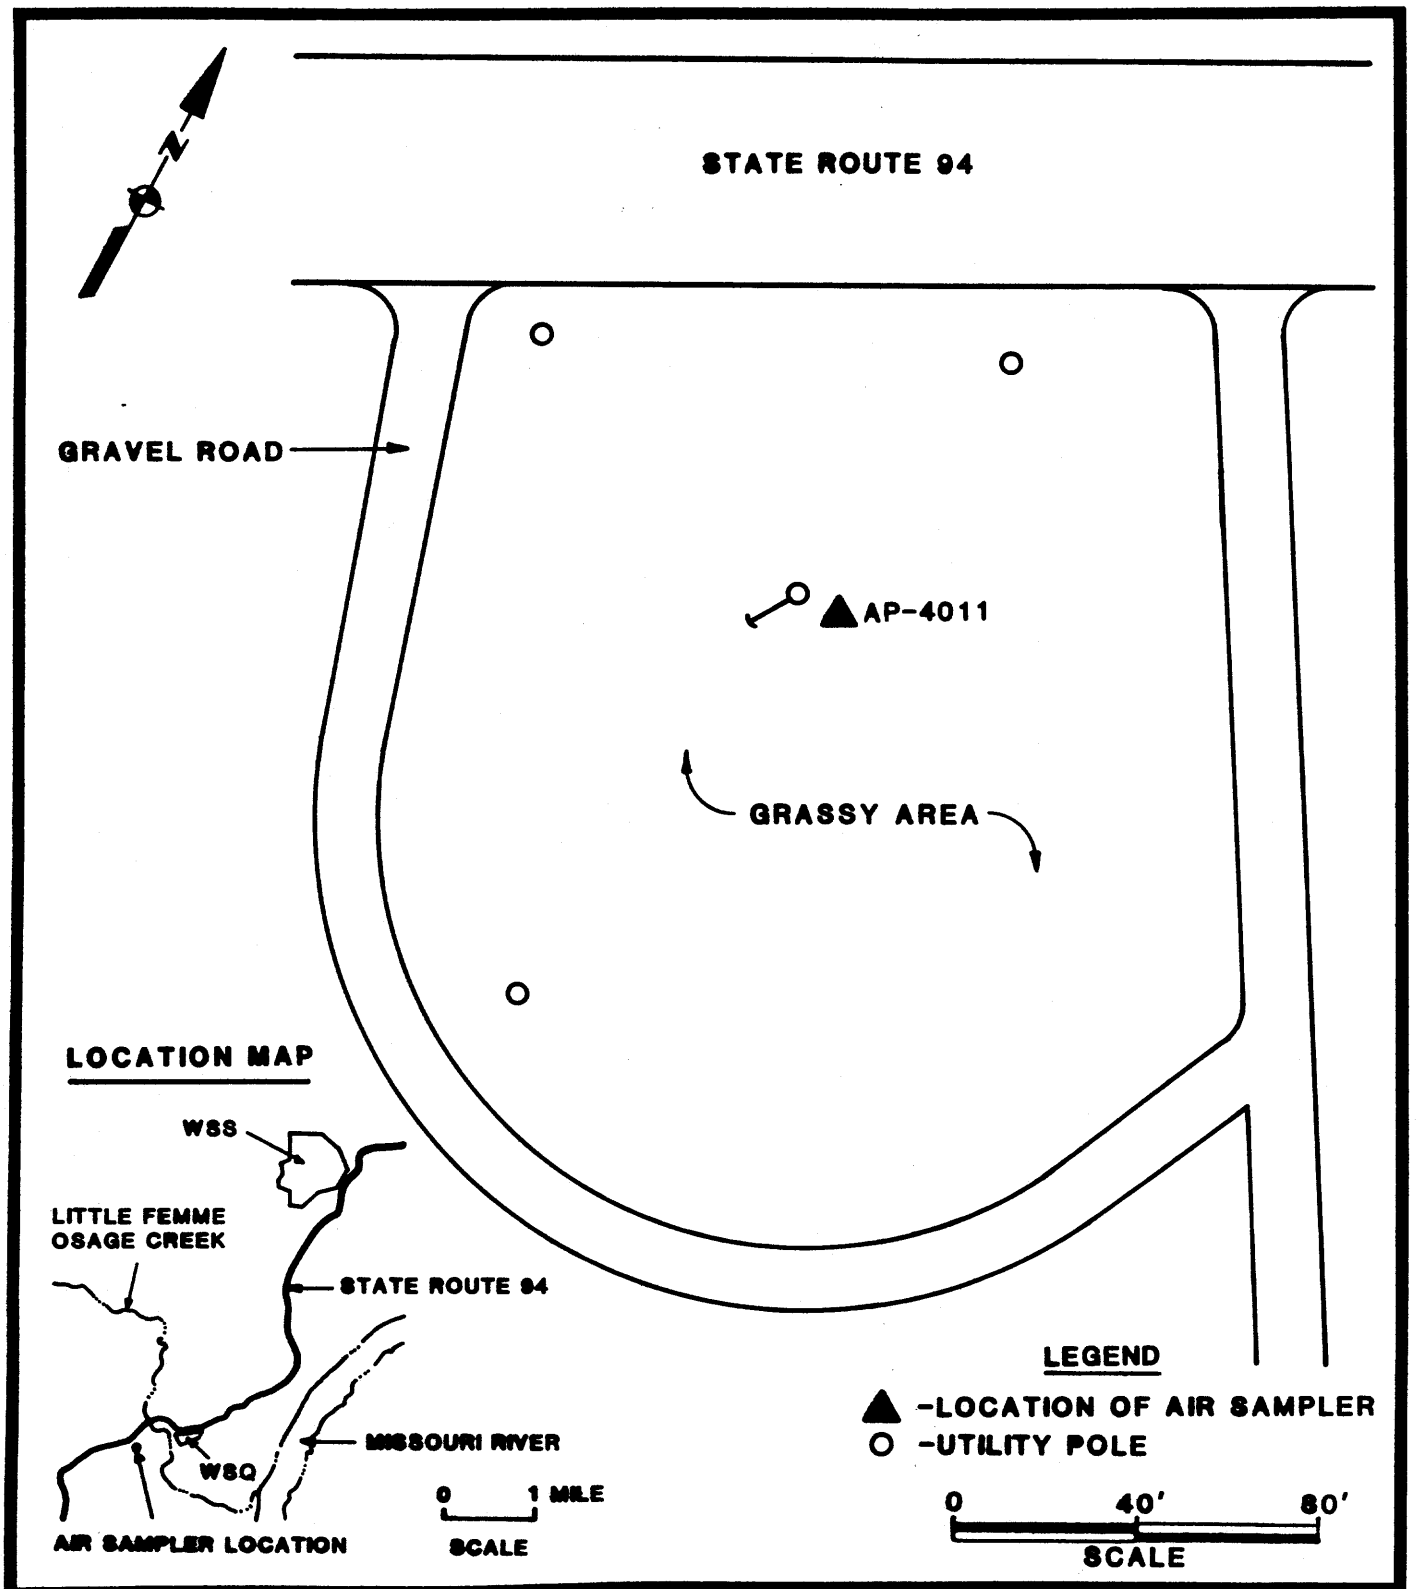

FIGURE 2-26

QUARRY BACKGROUND AIR SAMPLER LOCATION

forested, providing a significant physical barrier to airborne particulates originating from the WSCP/WSRP. In addition, winds from the southeast are relatively rare at the WSCP.

The five air particulate samplers used at the WSCP, the two nearby off-site locations, and the background station at ABWA headquarters were continuous flow dichotomous virtual impactor units operating at a constant total flow of one cubic meter per hour (35 ft^3/hour). These samplers divide suspended particles into two sizes: 2.5 to 10 micrometers in diameter (coarse respirable particles) and less than 2.5 micrometers in diameter (fine respirable particles). Particles larger than 10 micrometers (non-respirable) were not collected because they do not pose a significant risk to human health through inhalation.

Samples were collected on 37-millimeter diameter membrane filters with an effective pore size of 0.8 micrometers. All filters were collected once per week.

The three air particulate samplers used in the quarry monitoring program are constant flow dual diaphragm units operating at a continuous total flow of 2.4 cubic meters per hour (85 ft^3/hour). These monitors use open-face sampling heads and do not segregate the air flow according to particle size. This results in the collection of respirable and non-respirable particles. Therefore subsequent analysis is conservative when determining radioactivity concentrations of air because some of the collected particles would pose no human health impact. Samples, consisting of 47-millimeter diameter membrane filters with an effective pore size of 0.45 micrometers, were exchanged weekly.

The majority of the radionuclides present at the WSS and in the quarry waste are from the natural U-238 and Th-232 decay chains. Many of these radionuclides emit alpha particles during decay which pose the greatest hazard when deposited internally in the respiratory tract and lung. Therefore air particulate samples were analyzed for long-lived gross alpha activity. The long-lived gross alpha method of analysis sums the alpha activity from all of the long-lived alpha-emitting radionuclides.

2.5.2 Radioactive Air Particulate Monitoring Results7

The gross alpha measurements were made with a standard zinc-sulfide detector. The alpha counts per filter were converted to radioactivity per volume of air for that filter and reported in μCi/ml (Bq/m^3).

Table 2-15 summarizes the annual average concentration and the standard deviations for the 11 air monitoring locations. The annual average concentration for each monitoring location was calculated by averaging the weekly air particulate analysis results, or the counting instrument's lower limit of detection (LLD), whichever was greater. All of the monitoring stations exhibited some weekly sample concentrations less than the LLD. The < sign in Table 2-15 indicates that the actual average is less than the calculated average. The cause for this was the use of LLD values in calculation of the annual average concentration. When a value was reported as less than the LLD, the LLD value was used in the calculation. The standard deviation for each of the monitoring locations was calculated using only analysis results that were above the LLD because the weekly LLD values were nearly the same and to have used them would have resulted in a low bias in the annual standard deviation. If only one or less weekly

result was greater than the LLD, no standard deviation was calculated. This is indicated by NA in the table.

The typical LLD for the dichotomous virtual impactor units used at the WSCP/WSRP was approximately 1.6 x 10^{-15} µCi/ml (.06 mBq/m^3). The dual diaphragm units at the WSQ typically achieved an LLD of approximately 6.4 x 10^{-16} µCi/ml (.02 mBq/m^3). These LLDs are low enough for the detection of Th-232, the radionuclide with the lowest derived concentration guideline (DCG) found at the WSS. The DCG for Th-232 is 7 x 10^{-15} µCi/ml (.26 mBq/m^3). The DOE provides DCGs for airborne contaminants which, inhaled by a member of the public continuously for one year, would result in a committed effective dose equivalent of 100 mrem (1 mSv).

The annual average net alpha activity for each monitoring station was not statistically different at the 95% confidence level from the corresponding background station activity. This is significant because it indicates that there is no release of radioactivity from the site that can be distinguished from background levels.

2.6 Unrestricted-Area Radiological Contamination Monitoirng

The WSS contains many areas of radiological contamination due to waste deposition and spillage during former uranium and thorium refining operations. Also, due to atmospheric releases of radioactivity during operations at the WSS, all structures and roads potentially have surficial contamination. The majority of the processing involved refining uranium and thus it is the primary contaminant at the site.

Since 1986 the WSSRAP has employed an unrestricted-area monitoring program to ensure that radioactive materials are not

migrating from the site (as a result of the remedial construction) to areas used by the general public.

2.6.1 Unrestricted-Area Radiological Monitoring Program

This program includes radiological surveys of the WSSRAP Administration Building, laboratory, access control point for the site controlled area, WSSRAP trailers and subcontractor trailers, vehicles, site roadways and a portion of the Katy Trail. Radiological surveys are performed at least quarterly and usually monthly. The surveys consist of performing in situ measurements and collecting swipe samples.

In situ measurements are taken with a beta-gamma detector. Measurements are collected over a one-minute counting interval and then converted to disintegrations per minute per 100 cm^2 (dpm/cm^2). These measurements determine the total radioactivity, fixed plus removable.

Measurements of removable surficial radiation levels are made at each beta-gamma measurement location using a dry cloth or paper swipe. The swipes are wiped (smeared) over a surface area of approximately 100 cm^2. Swipes are analyzed for one minute on a standard alpha scintillation detector. The count rate results are corrected for detector efficiency to yield measurement results in dpm/cm^2.

2.6.2 Unrestricted-Area Radiological Monitoring Results

For the purpose of this report, only the monitoring results for the WSSRAP roadways outside the controlled area and the Katy Trail are presented. These areas are discussed because they represent areas accessible by the public. All other monitoring

results are on file at the WSSRAP. Performance of these surveys to date confirms that contaminated materials are not being carried into unrestricted areas.

Figure 2-27 shows the monitoring locations for the roadways outside the controlled area. Table 2-16 lists the annual average beta-gamma and alpha monitoring results at each location. Also included in the table are the associated errors of the beta-gamma and alpha results. The reported errors of the beta-gamma results are given as a percentage of the average result.

The results of the monitoring show that only fixed contamination is present at a few locations, but at levels well below the DOE uranium surface contamination guidelines for unrestricted use of 5,000 dpm/100 cm^2. The probable cause of the contamination is deposition of atmospheric releases of uranium dust during the operational period of the Weldon Spring Uranium Feed Materials Plant (WSUFMP). Since monitoring began, no increase in levels has been shown on the uncontrolled area of the roadways at the WSS. Also no removable activity has been found during the monitoring of the roadways.

The Katy Trail is shown on Figure 2-28. An approximate 1,130-m (3,700-ft) stretch of the trail is monitored due to its proximity to the WSQ and Femme Osage Slough. Beta-gamma measurements are taken at 10 locations along a section of the trail that are positioned so as to appropriately represent the entire length of the section monitored.

Table 2-17 lists the average beta-gamma monitoring results for each location. The majority of the monthly survey measurements at each location are below the lower limit of

detection (LLD) and therefore no standard deviations are reported.

The results of all monitoring locations show that the average beta-gamma results are below the LLD. However, a small isolated area represented by location number one consistently shows higher beta-gamma activity than the other monitoring locations and during one of the surveys had detectable beta-gamma radioactivity. This area is located in the far eastern section of the monitoring area. A soil sample was collected at location number one and analyzed for uranium-238, radium-226, radium-228, thorium-230 and potassium-40. The analysis did not indicate any radionuclide concentrations above background levels. This area will be investigated further to determine the reason for elevated beta-gamma radioactivity. There is no evidence of radioactive material migrating from the WSQ or Femme Osage Slough area onto the Katy Trail and thus there is no identifiable risk from radiological contamination to users of the Katy Trail.

2.6.3 Asbestos Monitoring

Environmental monitoring for asbestos was performed at five site perimeter monitoring locations and at the Francis Howell High School (FHHS) monitoring location. At these locations, worker exposure monitoring and work area sampling were conducted during asbestos abatement operations and at other times when asbestos-containing materials were being handled on the site.

During 1989, three interim response actions were completed which involved asbestos abatement activities, i.e., Administration Building (Building 409) Demolition, Steam Plant (Building 401) Demolition, and Overhead Piping and Support Removal. The asbestos abatement operations associated with these

projects were initiated in November 1988 and were completed in September 1989.

During the period from January through September 1989, site perimeter samples were collected on a weekly basis. Two concurrent samples were collected each week. Sample locations at the site perimeter were selected on the basis of the observed wind direction at the beginning of the sampling period; one sample was designated as an upwind sample and the other sample was designated as a downwind sample.

Also during this period, daily samples were collected at AP-4006, the Francis Howell High School monitoring station. Following completion of asbestos abatement activities, sampling at FHHS station was reduced to a frequency of one sample per week.

Samplers were generally operated for 7-8 hours per day, corresponding to the period during which operations were being conducted at the site.

Two different methods of sample analysis were utilized in the asbestos air monitoring program. All samples were analyzed by Phase Contrast Microscopy (PCM). This method provides a total airborne fiber concentration for fibers having a size and shape which are characteristic of asbestos fibers. This method does not distinguish between asbestos fibers and other airborne fibers having similar characteristics. The results of the PCM samples are reported in fibers per cubic centimeter of air (f/cc). Selected samples were also analyzed using Transmission Electron Microscopy (TEM). This method is capable of positively identifying asbestos fibers, whereas the PCM method is not. The

results of the TEM samples are reported in structures per cubic centimeter of air (s/cc).

The results of the environmental samples collected at the FHHS and site perimeter monitoring stations are provided in Tables 2-18 and 2-19, respectively. The results of the PCM and TEM analyses are reported separately therein.

The average fiber concentration (as determined by PCM analysis) at the upwind monitoring stations (0.001 f/cc), the downwind monitoring stations (0.001 f/cc) and the FHHS monitoring station (0.001 f/cc) are all considered to be within the range of normal background fiber concentrations, indicating that asbestos fibers were effectively contained during the asbestos abatement operations.

This conclusion is also supported by the results of the on-site asbestos monitoring activities. The results of personnel exposure monitoring conducted by site personnel indicate an average worker exposure concentration of 0.065 f/cc. Further, all major asbestos operations which involved stripping of friable asbestos-containing materials from the piping and other building components were performed within specially constructed enclosures having high efficiency particulate air (HEPA) ventilation systems. The purpose of the enclosure is to contain any airborne fibers within the work area and to filter the air as it is discharged to the atmosphere. Asbestos monitoring was performed at each HEPA filter outlet on a daily basis. A total of 174 such samples were collected, with a range from <0.001 f/cc to 0.027 f/cc and an average concentration of 0.006 f/cc.

Thirteen samples collected at the FHHS and site perimeter monitoring stations were analyzed using TEM. (See Tables 2-18

and 2-19.) These samples ranged from <0.001 s/cc to 0.060 s/cc. One of the TEM samples collected at the FHHS monitoring station xhibited a relatively high concentration of asbestos, i.e., 0.060 s/cc for the sample collected on July 7, 1989. This sample could not be analyzed by PCM because of the amount of dust loading on the filter. The sample was subsequently analyzed by TEM; however the sample had to be ashed and resuspended prior to TEM analysis. The laboratory indicated that the sample pretreatment procedure could have biased the subsequent analysis on the high side by a factor of up to 10 times the actual concentration, due to the fact that the pretreatment procedure has been shown to fracture the fibers and thereby result in a higher fiber count.

Although the specific cause of the elevated asbestos concentration is not known, an evaluation of the prevailing wind conditions and the TEM results from the site perimeter samples during the same time period suggests that the apparently anomalous asbestos result was unrelated to WSSRAP activities. Another positive asbestos measurement of 0.004 s/cc was obtained at the FHHS monitoring station sample collected on November 1, 1989. This result can be explained on the basis of normal background variability.

As a quality assurance measure, blank samples are periodically submitted to the laboratory for analysis. These samples are subjected to the same analysis as the regular air samples. During calendar year 1989 a total of 61 blank samples were submitted for analysis. Fiber loadings on all of the blank filters were less than 7 fibers per 100 fields which conforms to the requirements of the analytical method.

3 RELATED ACTIVITIES AND SPECIAL STUDIES

Numerous activities were conducted during 1989 to further characterize and improve the environmental conditions at the Weldon Spring Site (WSS). These activities were performed to provide better detail on contaminant distribution and migration mechanisms from the site and enable the U.S. Department of Energy (DOE) to more precisely and completely conduct its remedial actions. Also, several interim response actions were conducted during this monitoring year to reduce or eliminate immediately hazardous conditions at the site. Each of those activities is described below. Table 3-1 presents a list of the related and special study activities accomplished during this monitoring year.

3.1 Characterization Studies

During 1989 four characterization studies were performed to support the Remedial Investigation/Feasibility Study (RI/FS). These characterization studies included the radiological characterization of the Weldon Spring Chemical Plant (WSCP) buildings, the characterization of minor storm water discharge points, studies of the results from the new groundwater monitoring wells, and additional radon monitoring. Principal points of each characterization study are discussed in subsections 3.1.1 through 3.1.5.

3.1.1 Radiological Characterization of WSCP Buildings

To supplement radiological characterization data previously obtained in WSCP buildings, radiation measurements were collected from October 1988 through April 1989 in 25 non-process buildings. No measurements were required in buildings which processed

uranium and thorium because sufficient information had been collected by other investigations. The characterization efforts allowed estimation of which building structural components and equipment were radiologically contaminated and an assessment of the radiation hazards within each building.

Six types of samples or measurements were collected. These were: (1) total beta-gamma radioactivity, (2) removable alpha radioactivity, (3) core samples, (4) bulk samples, (5) 100% scans, and (6) air monitoring.

Results of this characterization effort were combined with previous survey results to provide a comprehensive radiological assessment of all WSCP buildings. This information is detailed in the "Weldon Spring Chemical Plant Buildings Radiological Characterization Report" (MKF and JEG, 1989d).

These surveys have revealed that all structural components and equipment within process buildings (Buildings 101, 103, 105, 108, 201, 301, 403, and 404, see Figure 3-1) are contaminated and cannot be released from the site without decontamination. The contamination level varies in the non-process buildings. Much of the equipment stored in the non-process buildings is contaminated. Some structural components of non-process buildings are not contaminated. In general, horizontal surfaces in non-process buildings have a higher probability of being contaminated than do vertical surfaces. No structural component or equipment in non-process buildings can be released from the site until further radiation measurements are performed on areas which were inaccessible to characterization measurements and to verification of the results of characterization measurements.

FIGURE 3-1

WELDON SPRING CHEMICAL PLANT-MAJOR BUILDINGS, FEATURES AND LOCATION OF OVERHEAD PIPING/ SUPPORTS

3.1.2 Characterization of Minor Storm Water Discharge Points

Surface water discharge from the site has been routinely monitored at five major discharge points in the past and analyzed for a broad range of contaminants including metals, inorganic anions, nitroaromatics and radiochemical species. Surface water from the areas of known contamination leaves the site at these major discharge points. However, little data existed regarding the character of the runoff crossing the site boundary at the smaller discharge points.

As a result of land surface contours and the configuration of the storm sewer system across the site, approximately 210 acres of land surface drain their surface runoff across the site boundary, either onto or off of the site property. Roughly 30% of that flux is not routinely monitored for contaminants. Where surface water enters the site, it is ultimately discharged via one of the three routinely monitored discharge routes. However it was unknown whether the run-on was contaminated before entering the site.

Sampling was initiated in 1989 to assess the unmonitored surface water exiting the site via minor drainageways.

Measurement data are presented on Figure 3-2. The data indicate that small quantities of surface water contaminated with low levels of uranium are leaving the site at various locations. The results also indicate that at three drainage crossings on the eastern boundary, surface water with slightly elevated uranium levels is flowing onto the site. These results are possibly due to atmospheric deposition off-site during Weldon Spring Uranium Feed Materials Plant (WSUFMP) operations since no other known sources exist within these off-site drainages. Since the levels

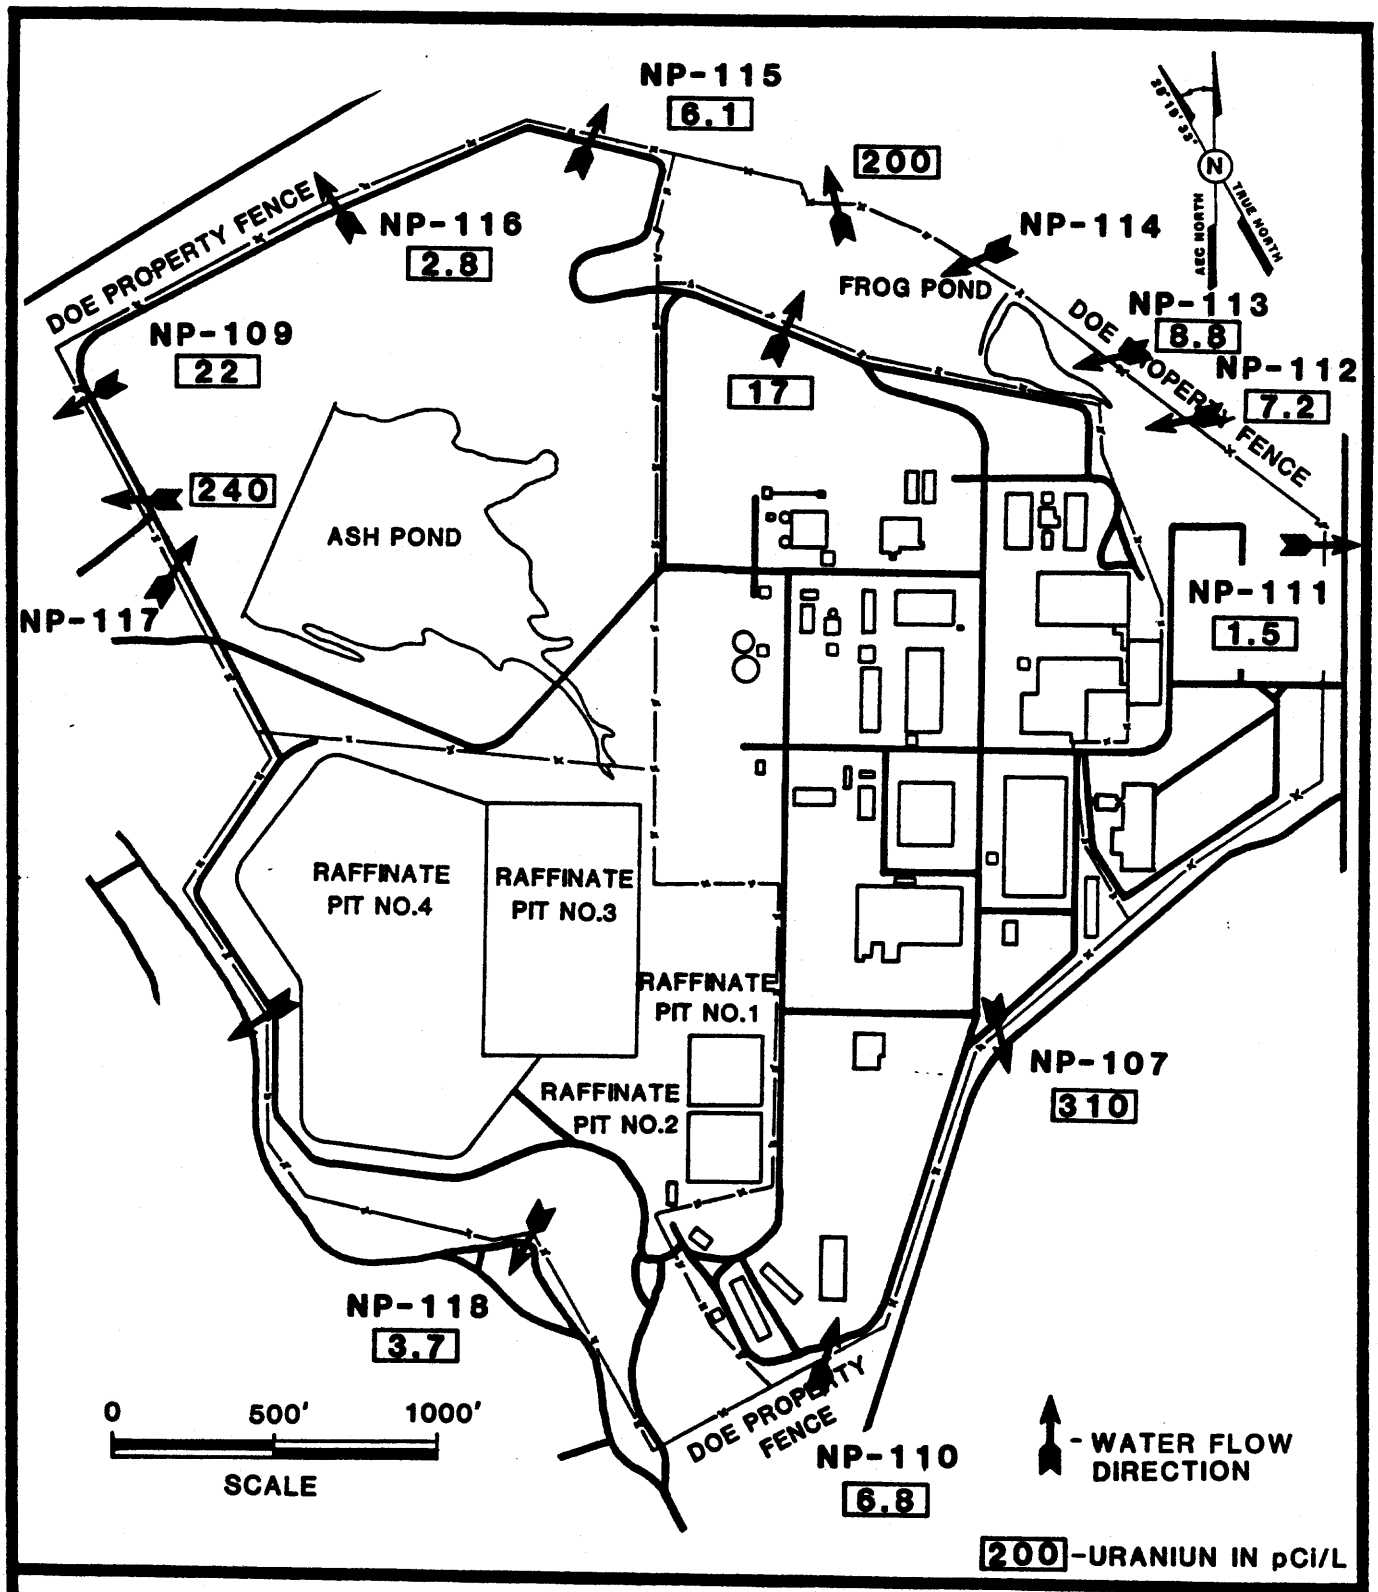

FIGURE 3-2

URANIUM LEVELS MEASURED AT MINOR DISCHARGE POINTS AROUND WSS

are very near to background concentrations and no duplicate data are available to verify or refute the preliminary results, further sampling is needed to determine the source of the uranium.

The highest release from a non-routinely monitored drainage was found to be along a small tributary to the Ash Pond drainage which drains part of the North Dump Area. At a concentration of 22 pCi/l (0.81 Bq/l) in the discharged water, the quantity of uranium contributed to the environment at this release point is relatively insignificant compared with the three major discharge points.

Based on the average annual precipitation rate of 85 cm (Section 1.3), and 65% surface runoff of that precipitation, an average of 22 pCi/l (0.81 Bq/l) would result in 0.66 kg (1.5 lb) of uranium released annually through that discharge point. This represents less than 1% of the total uranium released from the site through the major discharge routes.

3.1.3 Shallow Groundwater Monitoring Well Results

Seven additional groundwater monitoring wells were installed at the WSCP/WSRP area during the summer of 1989 as part of a geotechnical drilling program in support of the WSS RI/FS process being conducted under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA). The wells were designed and installed to monitor the uppermost saturated zone of the water table aquifer in order to gain additional information regarding the vertical distribution of contaminants present in groundwater. The monitoring wells are identified as GT-58P, GT-60P, GT-63P, GT-64P, GT-65P, GT-66P, and GT-67P. They are

represented by the symbol designated for piezometers in Figure 2-1.

Complete results of the 1989 fourth quarter sampling of the GT-series monitoring wells will be reported in detail in the Groundwater Quality and Hydrogeologic Assessment of the GT-series Monitoring Wells (MKF and JEG, in preparation).

In general, analyses of groundwater samples from these wells did not significantly change the present understanding of groundwater contamination beneath the site. Nitroaromatic compounds were detected in four wells up to a level of 52 µg/l (2,6-dinitrotoluene) in GT-58P. Concentrations up to 8.5 µg/l of other semi-volatile or volatile compounds were detected in six wells. Nitrate was the inorganic ion detected in highest concentration (1,132 mg/l in GT-64P). Analyses for total metals in unfiltered samples revealed concentrations of chromium, copper, cobalt, nickel, and lead in the suspended solids. Metals analysis of filtered samples detected sodium in concentrations above the upper bound of background (MKF and JEG, 1989a).

3.1.4 Radon Decay Product Monitoring

Radon (Rn-222) and thoron (Rn-220) decay products were monitored in the quarry during the first half of 1989. Because elevated radon levels were observed in the WSQ (Section 2.3), monitoring was performed in areas not accessible to the public to evaluate the level of hazard to which workers in the quarry may be exposed. Thus results should be compared to the Derived Air Concentrations (DAC) guidelines for occupational workers. The DAC is used primarily for radiation protection planning purposes. The DAC for Rn-222 decay products is 0.33 Working Level (WL)

(7 micro Joules/cubic meter) ($\mu J/m^3$). The DAC for Rn-220 decay products is 1.0 WL (21 $\mu J/m^3$).

The radon decay product monitoring program involved collecting grab (5-minute) samples with a low-volume air sampler. Samples were collected on the upper gate plateau on the east end of the WSQ and near the quarry sump at RD-1010 and RD-1007 respectively, as shown on Figure 3-3. At each location samples were collected at heights of 15 cm (6 in.) and 1 m (39 in.). Sampling at the two heights was intended to identify possible radon and/or thoron daughter concentration gradients in the atmosphere directly above the waste.

A decay product (daughter) is the resulting element formed by the decay of a radionuclide. As the Rn-222 and Rn-220 decay chain progresses, radon decay products are produced. All the decay products of both Rn-222 and Rn-220 are particles and both decay chains terminate with stable isotopes of lead (Pb).

Concentrations of radon decay products are dependent on the amount of radon gas entering the atmosphere and the state of equilibrium between the activity of the radon and its daughters. The concentration of radon gas changes depending on many variables, as discussed in Section 2.3. Therefore, the daughter concentrations will fluctuate.

At 100-percent equilibrium, the activity of the radon decay products and the parent would be equal. As radon decays, the particles formed attach to airborne particles (dust). Some of these radioactive particles settle out on surfaces, reducing the activity of the airborne daughters. Also, radon disperses before the daughters can grow into equilibrium, so the equilibrium of environmental air is usually less than 50 percent.

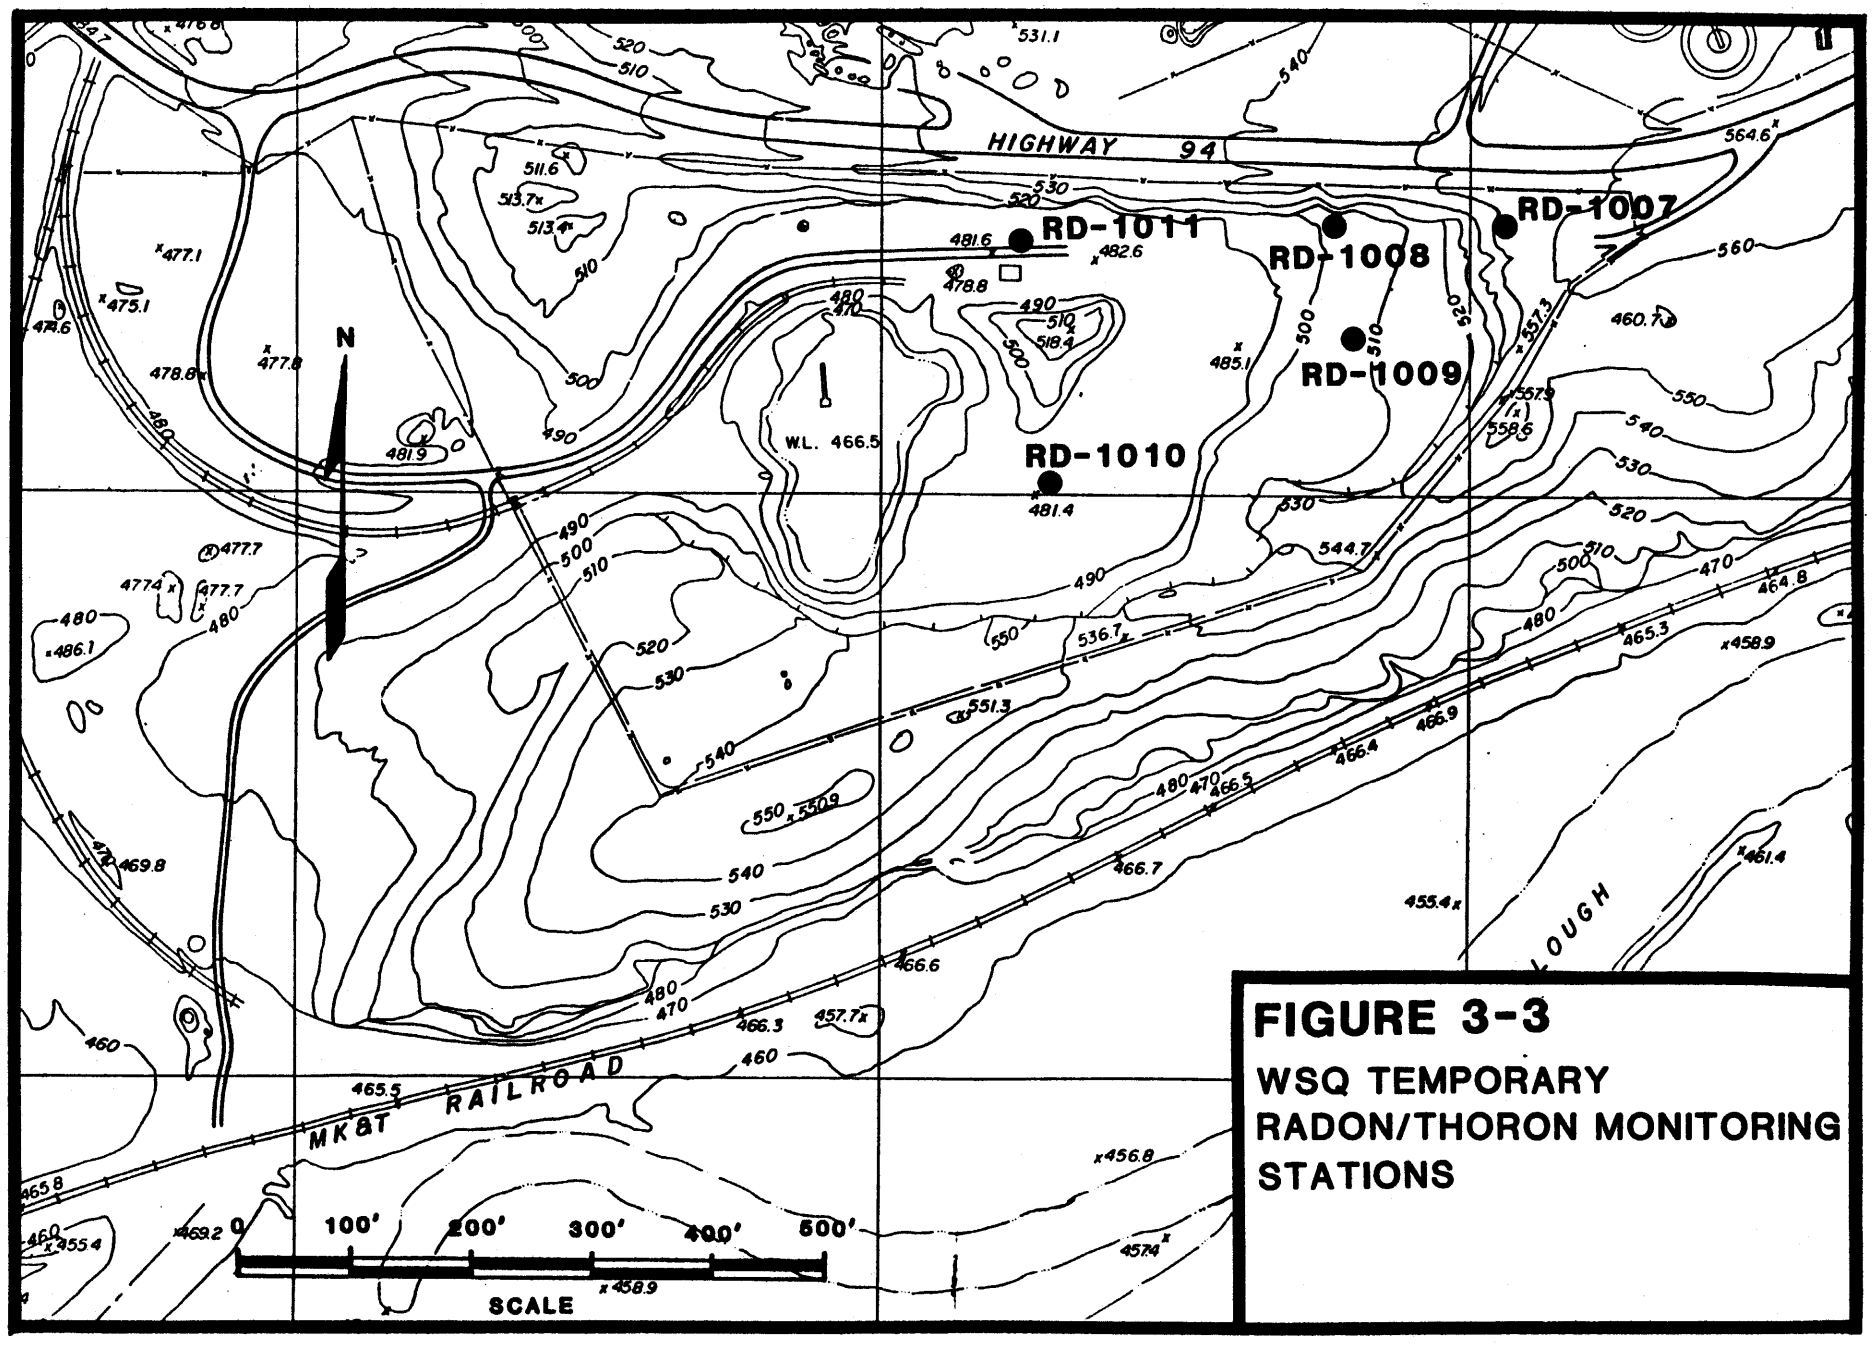

FIGURE 3-3

WSQ TEMPORARY RADON/THORON MONITORING STATIONS

Table 3-2 lists the results of the radon daughter concentration (RDC) and thoron daughter concentration (TDC) measurements at each location and the average concentration is given for the 15 cm and 1 m samples at each location. Results ranged from below the minimum detectable activity (MDA) of 0.0001 WL (0.002 $\mu J/m^3$) to 0.009 WL (0.19 $\mu J/m^3$) for Rn-222 daughters and ranged from less than the MDA of 0.001 WL (0.002 $\mu J/m^3$) to 0.003 WL (0.27 $\mu J/m^3$) for Rn-220 daughters. These concentrations are well below the DAC guidelines. In fact they are below the 0.02 WL (0.4 $\mu J/m^3$) concentration which EPA recommends as a level at which steps should be considered to reduce levels in homes.

Overall data regarding the possible existence of a concentration gradient is inconclusive. No significant concentration gradient was observed, although a few of the measurements at Location No. 2 showed a possible thoron concentration gradient between the two heights.

3.1.5 Radon Gas Monitoring Above Quarry Waste

In March 1989 the WSSRAP installed Type F and Type M track etch detectors within the quarry in order to monitor Rn-222 and Rn-220 concentrations directly above the quarry waste. Type M detectors have a membrane which screens out most Rn-220 (thoron) but allows Rn-222 to pass through, while the Type F allows both gases to pass through. Thus results of Type F monitors would be expected to be greater than or equal to results of Type M monitors. Section 2.3 provides a more detailed description of these detectors.

Ten Type F and ten Type M detectors were placed in duplicate at five temporary monitoring stations within the quarry at a height

of one meter. In addition, duplicate Type F and Type M detectors were placed at two of the stations (RD-1007 and RD-1008) at a height of 5 cm (2 in.) above the ground to determine if a Rn-222 or Rn-220 gradient exists in the atmosphere directly above the bulk waste. The locations of these temporary monitoring stations are shown on Figure 3-3.

The detectors were deployed for two different intervals: the last month of the first calendar quarter and the entire second calendar quarter of 1989. Table 3-3 contains the results of the monitoring for each period of exposure. The reported concentrations are averages of the two duplicate detectors. Also, two standard deviations of the average reported results are given to define the 95% confidence level (the average plus or minus two standard deviations). The second exposure period was for the entire second quarter of 1989 and is a better representation of long-term concentrations than the first exposure period which was only one month.

The overall results indicate an elevated concentration of radon within the quarry walls compared to the perimeter fence monitors. This is due to the location of the temporary monitors directly above the quarry waste materials. The increase in radon concentrations with respect to the location of the waste is seen through comparison of temporary monitoring station RD-1007 to the perimeter station RD-1002 (see Figure 2-24). These monitoring stations are approximately 15 m (50 ft) apart and at nearly the same elevation. However, station RD-1007, located directly above the waste, has a radon concentration two to three times higher than station RD-1002. The fact that radon concentrations are strongly influenced by proximity to quarry waste materials is further demonstrated by comparison of measurements taken at 5 cm

(2 in.) versus measurements taken at 1 m (39 in.) above the waste.

The detectors located 5 cm (2 in.) above the quarry waste at station RD-1007 and RD-1008 both show that Rn-220 (thoron) is contributing to the total radon concentration. The data from the one-meter detectors at all the locations are inconclusive overall to determine the amount of thoron present. In fact, at locations RD-1007 and RD-1009, the Type M detector results are significantly higher than Type F detector results. The inconsistencies are probably due to the different calibration factors employed for the two detector types. The WSSRAP will investigate these apparent inconsistencies further by taking radon decay product measurements during 1990 using continuous monitors.

3.2 Interim Response Actions (IRAs) Performed at the WSS During 1989

During 1989 three Interim Response Actions (IRAs) were conducted that involved release of building structural materials and equipment from the site for unrestricted use or disposal. These IRAs were: (1) dismantling of a network of overhead piping and structural steel supports; (2) dismantling of Building 409, the administration building; and (3) dismantling of Building 401, the steam plant. Salient points of each IRA are discussed in Sections 3.2.1, 3.2.2 and 3.2.3.

Another IRA performed in 1989 was the Ash Pond Isolation project. This project was performed in order to reduce uranium releases from the Ash Pond Outfall. The construction of a diversion dike and channel system around Ash Pond has limited flow of surface water over adjacent contaminated areas, thus

reducing releases of uranium off site. This IRA is discussed in Section 3.2.4.

The containerized chemical consolidation IRA involved consolidation and recontainerization of chemicals remaining from WSUFMP operations. Disposal has been delayed. This IRA is discussed in Section 3.2.5.

IRAs are designed to ensure the health and safety of on-site personnel and to minimize or preclude off-site releases of contamination. They are limited to work that can be performed under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and also remain within the constraints of the Council on Environmental Quality Regulations for the National Environmental Policy Act (i.e., they are limited to those actions that do not have an adverse environmental impact and do not limit the choice of remedial alternatives for the site as a whole).

All items that potentially came in contact with radioactive materials were surveyed according to radiological survey and release plans reviewed and approved by the DOE, EPA, and Missouri Department of Health. Structural materials and equipment were not released from the site unless they satisfied the criteria contained in the survey and release plans. These criteria were applied only to rigid surfaces. Liquids, soils, sediments, asbestos or other porous materials that could have been volumetrically (as opposed to surficially) contaminated were not released from the site if they contained any detectable radioactivity in excess of natural background levels.

To provide assurance that results of radiation surveys were accurate an independent verification contractor, Oak Ridge Associated Universities (ORAU), performed spot checks on

materials previously surveyed by the Project Management Contractor (PMC). ORAU personnel found no discrepancies with PMC survey results.

3.2.1 Overhead Piping Removal

During the operation of the chemical plant, overhead piping was used to transfer process chemicals, steam, air, brine, fuel gas, and process waste (raffinates). The pipe network was supported by steel-pipe poles, structural steel, and pipe bents, along with several structural-steel bridges. The piping structures were supported by reinforced concrete foundations. The overhead pipe network lay among several of the chemical plant buildings depicted in Figure 3-1. The overhead pipe distribution system consisted of 15,482 m (50,794 ft) of carbon and stainless steel pipe, 330 bents and 20 bridges. Approximately 33% of the piping was sheathed in asbestos- containing pipe insulation, much of which was in a deteriorated condition. The degradation of the pipe insulation caused sections of the insulation to separate from the pipe. Since the insulation contained asbestos, it posed a potential occupational hazard and as such was designated as an IRA. Dismantlement of the overhead piping and support structures started in January 1989.

Between January 20, 1989 and June 9, 1989, 23 loads of pipe, structural supports, and wire were released for unrestricted use. The released materials weighed approximately 300 metric tons (330 tons).

All pipes that transferred source or by-product (radioactive) materials were assumed to be contaminated and not released from the site. Approximately 200 metric tons (220 tons) of pipe and structural material were not released and are

currently stockpiled adjacent to Building 109. All asbestos-containing insulation was retained on site in Building 434. A detailed discussion of the processes by which the overhead piping was characterized and dismantled is presented in the Radiological and Chemical Completion Report for Overhead Piping Removal, (MKF and JEG, 1990c).

3.2.2 Building 409 Demolition

Building 409, the former Administration Building for the Weldon Spring Chemical Plant (WSCP), was a two-story rectangular structure located in the eastern portion of the WSCP approximately 180 m (600 ft) east of the process building as shown on Figure 3-1. The deteriorating condition of the building (e.g., loose floor tiles, weakened roof, and friable asbestos insulation) posed an occupational hazard to workers. Therefore, the dismantling of the building was proposed as an IRA. Dismantling of the building began in November 1988 and was completed in April 1989.

On the basis of radiation measurements taken by the PMC, it was determined that the majority of the building structure and equipment could be released from the site. This was as expected since the building housed administrative workers and no radioactive materials were processed or stored in the building.

Radiologically contaminated materials retained on the site included tar and gravel roofing, some interior furnishings, and air-handling equipment such as exhaust vents, furnace blowers, and cooling units. Air-handling equipment, especially filters, tended to concentrate any airborne uranium dust during the WSUFMP operations. It is speculated that any interior furnishings found

to be contaminated were moved from other process buildings into Building 409.

The radiologically contaminated roofing material and air handling equipment was placed on pad 303 (see Figure 3-1). The friable roofing material was covered with a protective tarp to prevent spread of contamination by wind or runoff. A detailed discussion of the processes by which Building 409 was characterized and dismantled is presented in the Building 409 Completion Report (MKF and JEG, 1990d).

3.2.3 Building 401 Demolition

Building 401, which was the steam plant for the WSUFMP was a multi-story rectangular structure located in the northwestern section of the WSCP as shown on Figure 3-1.

The deteriorating condition of the building (e.g., weakened roof and friable asbestos insulation) posed a hazard to workers and potential trespassers on the property. Therefore, it was determined that dismantling the building as an IRA would be beneficial to the project. Dismantling of the building began in December 1988 and was completed in December 1989.

Based on the results of radiation measurements performed on Building 401 the following materials were released from the WSSRAP: 459 m^3 (600 yd^3) of rubble, 620 metric tons (683 tons) of scrap metal; 61 m^3 (80 yd^3) of asbestos, and 1.5 m^3 (2 yd^3) of wood.

Radiologically contaminated materials associated with the dismantlement of Building 401 that were retained on the site included 336 m^3 (440 yd^3) of rubble and scrap metal, and 63

metric tons (70 tons) of equipment. The majority of those materials are stored on site in Buildings 109 and 110. The tar and gravel roofing material was drummed and stored on site in Building 434. In addition to the radiologically contaminated materials stored on the site, the asbestos and PCB light ballasts were retained and await radiological assessment. A detailed discussion of the processes by which Building 401 was characterized and dismantled is presented in the Building 401 Completion Report to be issued by the WSSRAP in 1990.

3.2.4 Ash Pond Diversion Project

The surface-water impoundment referred to as Ash Pond was designed and built as a fly ash sedimentation pond for the coal-fired steam plant at the WSUFMP. The main source of radioactive contamination in the Ash Pond area is the South Dump (Figure 3-4). Contaminated materials were burned and disposed of in this area during the operation and decontamination efforts at the WSUFMP. As a result of these activities, contaminants (mainly uranium) in the form of loose sediments and dissolved or suspended materials were freely transported by runoff and associated sediments, thereby contaminating the ash in Ash Pond.

Runoff flowing through the 25 ha (65-acre) Ash Pond watershed intermittently accumulated in Ash Pond and discharged off site when the pond was sufficiently full. This discharge flowed to an unnamed tributary of Schote Creek and eventually affected Lakes 34 and 35 in the August A. Busch Memorial Wildlife Area. Therefore it was determined that performing an Interim Response Action (IRA) by constructing a diversion dike that would redirect the surface water runoff around Ash Pond and the South Dump would be beneficial. This would eliminate leaching and

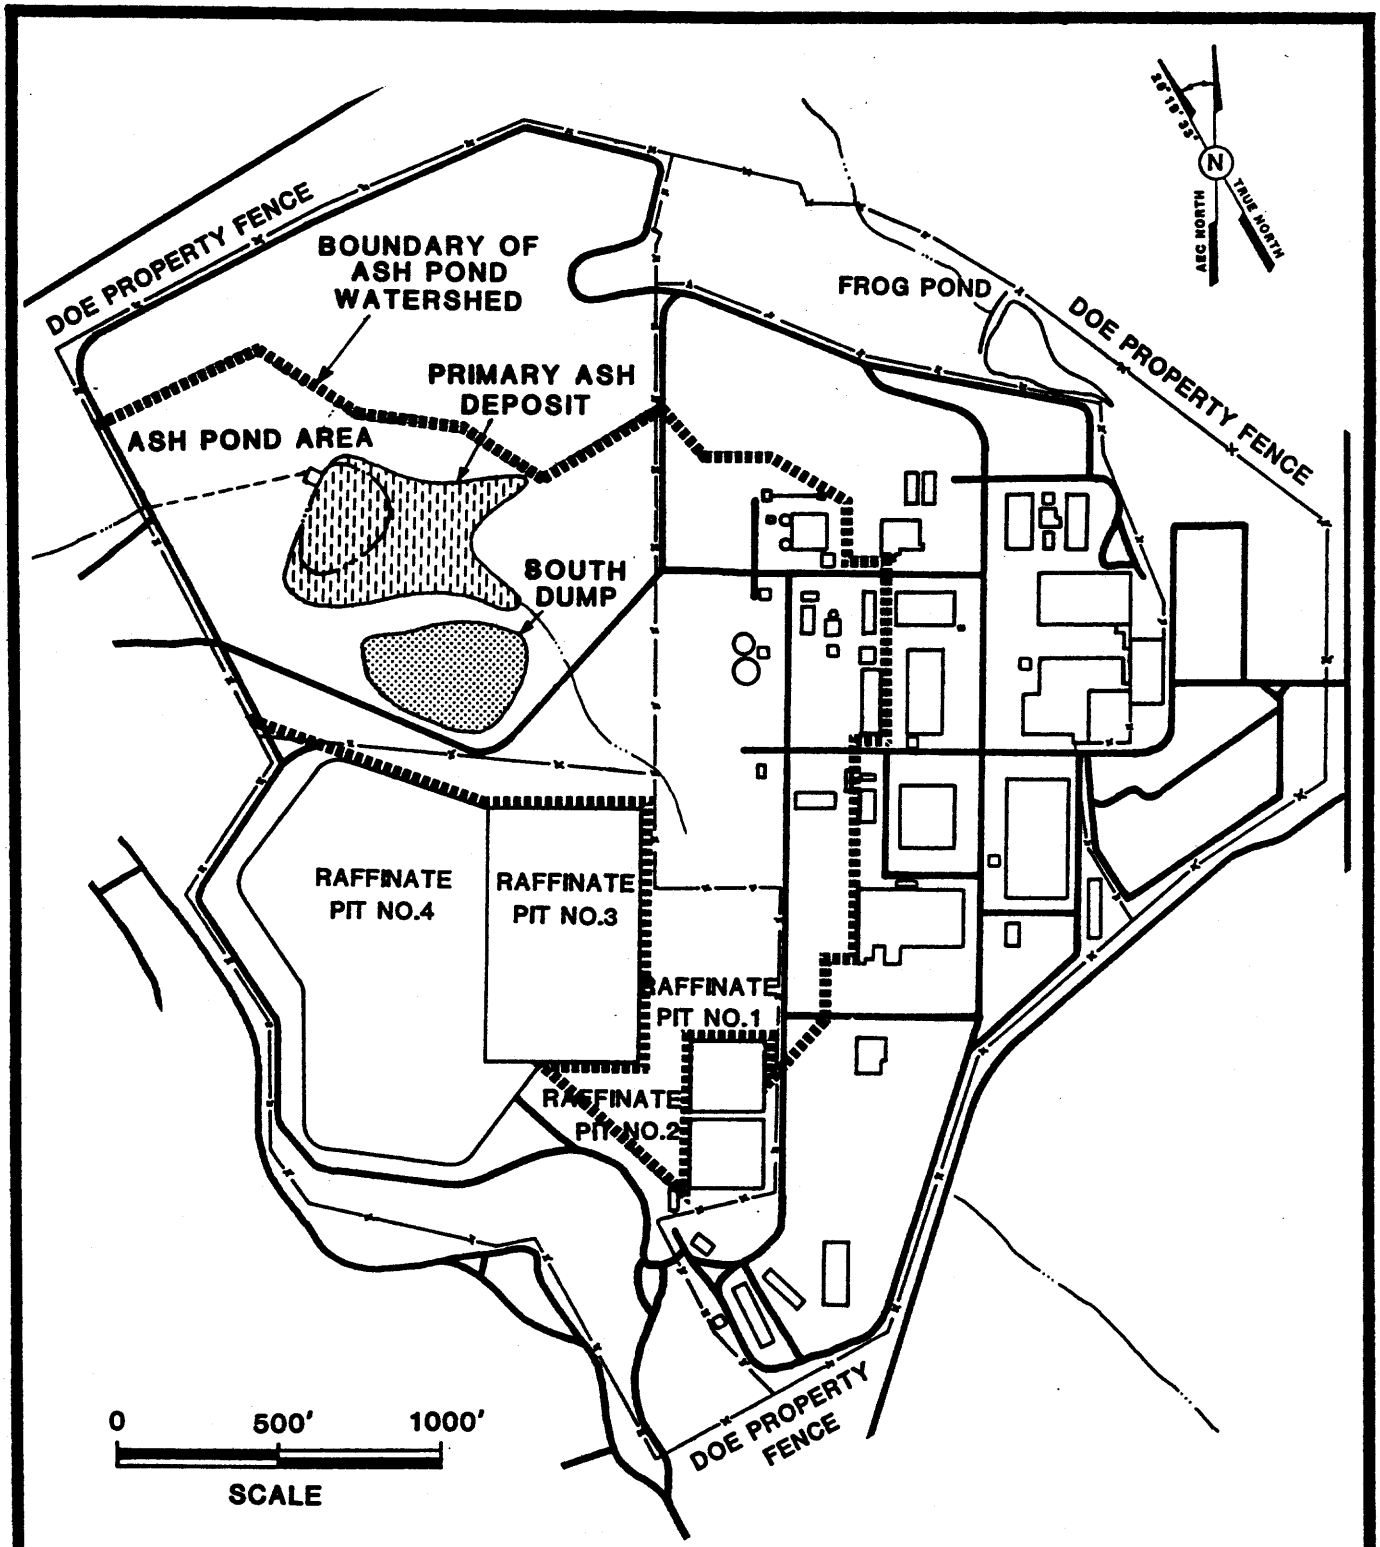

FIGURE 3-4

ASH POND AREA BEFORE CONSTRUCTION OF THE DIVERSION SYSTEM

transport of contaminated materials in these areas, thereby reducing off-site releases of uranium from the Ash Pond discharge.

Construction was initiated in November 1988 and was completed in April 1989. Figure 2-18 shows the final configuration of the Ash Pond diversion dike and how the diversion dike diverts flow through the ditches around the South Dump and Ash Pond areas.

Water samples were collected monthly from the Ash Pond outfall which discharges at the site perimeter as required in the WSCP National Pollutant Discharge Elimination System (NPDES) Permit (see Section 2.2). These samples were collected following a rainfall that produced surface runoff. Prior to the completion of the Ash Pond Diversion Project the uranium concentrations for these samples averaged 1,498 pCi/l (55 Bq/l). Since completion of the project the average uranium concentration in samples collected from May through October 1989 is 145 pCi/l (5.37 Bq/l). The data indicate a tenfold reduction in uranium released at this outfall. Discharges of uranium are now below the DOE DCG level of 550 pCi/l (20.4 Bq/l). A complete description of the isolation project is presented in the WSSRAP document entitled Assessment of Ash Pond Isolation Project Effectiveness issued in February 1990 (MKF and JEG, 1990b).

3.2.5 Containerized Chemical Consolidation

In the fall of 1988, a program was initiated to handle various chemical wastes left behind following closure of the WSCP. The WSSRAP identified, characterized, consolidated, repackaged, and temporarily stored chemical wastes throughout the chemical plant. Due to the complexity of this undertaking, and

in the absence of viable alternatives for the treatment or disposal of radioactive chemical wastes, the chemical-consolidation project has been expanded in scope. What began as a short-term Interim Response Action evolved into an ongoing program.

Work completed to date has addressed radiochemical characterization and repackaging of small containers of chemicals throughout the WSCP. Certain areas of the plant, such as the Building 407 Laboratory, were either omitted or excluded from the initial phase of this project, but are currently being addressed. To date, over 450 drums and storage bags containing various materials have been placed in a secure storage facility.

The original goal to dispose of the containerized chemicals at off-site facilities was not attained in 1989. Disposal methods were not available for chemical wastes mixed with low levels of radioactivity. Continued on-site storage is necessary until appropriate technologies become available. A state-of-the-art storage facility was created on-site during 1989 to ensure that strict administrative control of the waste inventory is maintained. This facility was designed to comply with all applicable statutes, regulations, DOE orders, and best-management practices pertaining to the storage of hazardous waste.

Current activities include handling of containerized chemicals that have not yet been consolidated as well as consolidation of residual chemical substances remaining in tanks, sumps, and process vessels. In-depth chemical and radiological characterization of the hazardous wastes will be performed during 1990.

4 RADIOLOGICAL EXPOSURE

In assessing the health effects of the radioactive materials stored at the chemical plant/raffinate pits, (WSCP/WSRP), quarry (WSQ), and vicinity properties (WSVP) as required by U.S. Department of Energy (DOE) Order 5484.1, radiological exposure was evaluated of persons at Francis Howell High School, the Busch Wildlife Area lakes and the Femme Osage Slough; of the general population within 50 miles of the Weldon Spring Site (WSS); and of a maximally exposed individual.

Individuals could be exposed to radioactivity from the WSS via five principal pathways: (1) direct external gamma radiation, (2) inhalation of radon and radon daughters, (3) inhalation of airborne radioactive dust particles, (4) ingestion of fish from nearby lakes that receive runoff from the WSS, and (5) ingestion of drinking water from sources contaminated with radionuclides from the WSS. All five pathways were included for the hypothetical maximally exposed individual. Pathway 4 was not considered in the population dose assessments because it is not reasonable or realistic to expect all members of a population to eat fish from bodies of water that receive runoff from the WSS. An evaluation of radiological exposures from these lakes when they are used for recreational purposes was included to ensure that the assessment would be thorough.

Although radiation doses can be calculated or measured for individuals, it is not practical to predict the health risk to a single individual. Estimates of health risk are based on statistical data on large groups of people exposed to radiation under various circumstances. Statistical models are not applicable to single individuals. Therefore, dose equivalents to single individuals are estimated by hypothesizing a maximally

exposed individual and placing this individual in a reasonable, but very conservative scenario.

Exposures of maximally exposed individuals and individuals near the off-site water bodies are given in terms of an effective dose equivalent. Exposures of people in neighboring facilities and populations within 80 km (50 mi) of the WSS are expressed in terms of collective effective dose equivalents or person-rems (person-sievert). All calculations were performed using the methodology described in International Commission on Radiation Protection (ICRP) reports 26 and 30 for a 50-year committed effective dose equivalent (ICRP, 1977, and ICRP 1979).

4.1 Radiation Dose From the WSCP/WSRP to a Maximally Exposed Individual

This section identifies an estimated committed effective dose equivalent to a hypothetical individual assumed to frequent the perimeter of the WSCP/WSRP and to receive a radiation dose by the five pathways identified above. No private residences are adjacent to the WSCP/WSRP sites; therefore, all calculations of direct gamma exposure, airborne dust particle inhalation exposure, and radon daughter inhalation exposure assume a realistic, less than 100% residence time. The amount of fish obtained and ingested from lakes receiving effluents from the WSCP/WSRP site assumes the average consumption rate per year according to U.S. Environmental Protection Agency statistics (EPA, 1988). None of these bodies of water are used as sources of drinking water. However, an evaluation of this pathway is included on the assumption that people could conceivably drink from them.

Gamma exposure rates were determined by means of thermoluminescent detector (TLD) monitoring stations at the Weldon Spring Training Area, the Missouri State Highway Department facility, and the Busch Wildlife Area. Airborne radiological particulates were sampled using continuous air samplers, and radon exposures were measured with track-etch radon monitoring stations at the above three locations. As shown in Section 2 there is no reason to suspect, with 95 percent confidence, that gamma exposure rates, airborne particle concentrations, and radon gas concentrations exceed natural background; therefore, the effective dose equivalent to a hypothetical individual receiving the maximum reasonable exposure from these three pathways is not measurable above normal background exposure.

Three off-site bodies of water (Busch Lakes 34, 35, and 36) receive runoff from drainage originating at the WSCP/WSRP site. All three lakes are used for fishing and boating. In 1988 a bio-uptake study (MKF and JEG, 1989d) was performed to investigate the possible exposure of humans to chemical and radiological contamination from ingestion of fish and game affected by previous operations at the WSS. This study included fish samples from the three Busch lakes. No measurable radionuclide concentrations above the detection limits were detected.

If it is assumed that the uranium concentration in the fish is equal to the detection limits of the analyses performed on the fish tissue, the concentration in fish from the three lakes would be 0.01, 0.02, and 0.01 pCi/g (0.37, 0.74, and 0.37 mBq/g), respectively. Radium and thorium concentrations in lake sediments and water were not above normal background levels and thus were not considered as a source of possible exposure. Using an average consumption rate of 6.5 grams/day for fresh-water fish

(EPA, 1988), the highest calculated annual dose from ingestion of fish living in these lakes would be less than 1 mrem (0.01 mSv).

None of the lakes are presently used for drinking or irrigation, but ingestion of lake water by an individual could possibly occur during recreational activities. In this scenario it is assumed that an individual could ingest lake water while swimming. Swimming can result in the ingestion of 0.05 liters per hour on average (EPA, 1988). Assuming that the individual swims in Lake 34, which has the highest average surface water concentration (25 pCi/l, or 925 Bq/m^3) for 12 hours per year, the calculated dose would be less than 1 mrem (0.01 mSv).

It is also possible for an individual to ingest lake sediments during visits to the lakes. The hypothetical individual is assumed to spend an average of approximately two days per year at the lakes consuming 200 mg per day. Using the average uranium concentration of surface sediments for Lake 34 which has the highest value of 46.8 pCi/g (1.7 Bq/g), the calculated dose would be below 1 mrem (0.01 mSv).

A maximally exposed individual would receive a total dose less than 1 mrem (0.01 mSv) from direct gamma exposure, inhalation of airborne dust particles, inhalation of radon daughters, ingestion of water and sediment, and ingestion of fish from contaminated waters.

4.2 Radiation Dose From the WSQ to a Maximally Exposed Individual

This section discusses the committed estimated effective dose equivalent to a hypothetical individual assumed to frequent the perimeter of the WSQ and receive a radiation dose by three of

the five pathways identified above. No private residences are adjacent to the WSQ site; therefore, all calculations of direct gamma exposure, airborne particle concentrations, and radon daughter inhalation assume a realistic, less than 100% residence time. Access to the quarry is controlled by a barbed wire fence; thus fishing, swimming, and drinking water from the quarry pond need not be evaluated.

The exposure scenario consists of a hypothetical individual who routinely walks along the northern boundary of the quarry on State Route 94. The individual is assumed to make this trip twice per day, 250 days per year. Average residence time per day is estimated to be 12 minutes (ANL, 1989). An actual exposure would occur of an individual who drives by the site twice per day, but it would be so insignificant relative to the walking scenario that it was not used in the calculation.

Data from three environmental TLD monitoring stations were used to evaluate the dose by direct gamma exposure to the hypothetical individual. The dose from external gamma radiation was calculated by multiplying the length of time the individual is exposed by the radiation field strength. Using these conservative assumptions and the highest measured gamma exposure rate (30 μR/hr at TD-1001), the calculated dose equivalent would be 1.5 mrem (0.015 mSv).

Airborne particulate monitoring at the WSQ was initiated in May and resulted in an average alpha concentration of 4.3×10^{-15} μCi/ml (.16 mBq/m^3). At the 95% confidence level there is no reason to suspect that airborne particle concentrations measured from May to December exceeded natural background. Thus it is assumed that no measurable exposure from this pathway occurred.

The risk associated with radon-222 is due primarily to inhalation of its short-lived decay products. Data from the three track-etch radon monitoring stations closest to State Route 94 were used to evaluate the dose by inhalation of radon daughters for the hypothetical individual. The highest average measured radon gas concentration at these monitoring stations was 1.0 pCi/l (37 Bq/m^3) above normal background. Assuming 50% equilibrium between radon gas and its daughters and 1.7 rem/ working level month (WLM) (17 mSv/WLM) (NCRP, 1985; ICRP, 1977), the annual calculated effective dose equivalent from inhalation of radon daughters is 2 mrem (.02 mSv).

The dose to the maximally exposed individual from the three pathways discussed above consists of a total of 3.5 mrem (0.055 mSv) from direct gamma exposure, inhalation of radon daughters and inhalation of radioactive air particulates.

4.3 Radiation Dose From WSVPs to a Maximally Exposed Individual

This section discusses the estimated effective dose equivalent to a hypothetical individual assumed to frequent the largest vicinity property (VP), the Femme Osage Slough, located south of the WSQ. This scenario provides a very conservative but plausible exposure assessment. No private residences are adjacent to the slough (it is on land that is currently managed by the Missouri Department of Conservation as part of the Weldon Spring Wildlife Refuge); therefore, all direct gamma exposure calculations assume a realistic, less than 100% time of residence. The slough is not suspected of having radioactive airborne particle concentrations and radon daughter concentrations above normal background because it is in a floodplain with saturated soil. The water in the soil minimizes

airborne migration. In addition, the slough is contaminated only with uranium, implying that above-background concentrations of radon are not possible.

The amount of fish obtained and ingested from the Femme Osage Slough assumes the average consumption rate of 6.5 g per day according to EPA estimates (EPA, 1988). Because of the stagnant water conditions, the slough is not a source of drinking water, nor is it a place for recreational swimming. Therefore, these pathways were not included in the dose calculations, and airborne particles and radon daughter concentrations were not measured.

Gamma exposure rate measurements were used to derive the effective dose equivalent by direct gamma exposure for the maximally exposed individual who is assumed to sit on the bank of the slough and fish four hours per week, 50 weeks per year. The measurements were taken with a pressurized ion chamber (PIC) on the bank of the slough in an area of known radiological soil contamination. Using the measured gamma exposure rate of 10.3 μR/hr, which is 2.5 μR/hr in excess of natural background, the calculated dose equivalent would be 2 mrem (.02 mSv).

As part of the bio-uptake study, fish samples were collected and analyzed for total uranium, Th-230, Th-232, and Ra-226. All results were below detection limits. Uranium is the only radionuclide in the slough sediments and water that is elevated above background concentrations; therefore, uranium and its decay products are the only radionuclides that were considered for possible uptake. Assuming that the uranium concentration in fish is equal to the detection limit achieved during tissue analysis, the fish tissue concentration is 0.01 pCi/g (0.37 mBq/g). Using the average annual consumption rate of 6.5 grams/year (EPA,

1988), the calculated effective dose equivalent to the maximally exposed individual from ingestion of fish living in contaminated waters would be less than 1 mrem (0.01 mSv).

The dose to the maximally exposed individual from the two pathways discussed above consists of a total of less than 1 mrem (.055 mSv) from direct gamma exposure and consumption of fish tissue.

4.4 Population Doses

The risk from radiation exposure to the general population is a function of the number of persons exposed, duration of exposure, and concentration or exposure rate to which the population is exposed. Below an absorbed dose of 10 rad (0.1 Gy) the projection of risk is uncertain. This is more than 30 times the typical yearly natural background exposure in the United States. In fact, no statistically significant adverse effects of radiation exposure have ever been proven at low doses of radiation. This is substantiated by studies of human populations exposed in regions of the world where natural background exposures are several times higher than those typically incurred in the United States. In these regions of higher background radiation exposures, the rate of adverse health effects has not been shown to increase above those which occur due to other factors.

This section summarizes the radiation exposure potential for populations surrounding the WSS. The exposures are shown to be indistinguishable from natural background. Therefore, no risks are projected.

4.4.1 Dose to Francis Howell High School Population

To determine dose equivalents accurately, the radiation exposure should be measured at the point where the collective dose equivalent is to be estimated. Collective dose equivalent is determined by multiplying calculated doses by the number of persons exposed. The Francis Howell High School (FHHS) is located 0.8 kilometers (0.5 miles) northeast of the WSCP.

Samples of radioactive airborne particles were collected weekly at the FHHS station, and radon concentrations and external gamma exposure rates were monitored quarterly. Water supplied to the school from the St. Charles County well field was also sampled and analyzed quarterly.

No radiation level or radionuclide concentration in air or water has ever exceeded natural or normal background radioactivity at the 95 percent confidence level at the FHHS station. This being the case, no risk is determined and no measurable adverse health effects are predicted to occur.

4.4.2 Population Doses Within 80 Kilometers (50 Miles)

The collective effective dose equivalent to the general public within an 80-km (50-mi) radius of the WSS must be calculated or estimated, since it is unreasonable to attempt pathway-specific measurements relative to every individual. The exposure pathways considered were: external exposure to gamma radiation, inhalation of radon and radon daughters, inhalation of radioactive airborne particles, and ingestion of water, fish, or game containing radioactivity.

At the three off-site gamma radiation monitoring stations, all measurements were at normal background levels (see Section 2.4). Likewise, measurements at the four off-site radon monitoring stations and air particulate monitoring stations were indistinguishable from background levels (see Sections 2.3 and 2.5, respectively). Therefore, the WSS does not contribute any measurable radiation dose to the general public via these three pathways.

None of the surface water or groundwater bodies that receive runoff or recharge from the WSS are used as drinking water sources; therefore, this pathway was not included in the dose evaluation. It is not realistic to expect that a significant fraction of persons living within 80 km (50 mi) of the site consumes fish or game affected by the WSS; hence this is not a significant exposure pathway (see Section 4.3). Therefore, cumulative radiation dose to the population within an 80-km (50-mi) radius resulting from radioactive materials present at the WSS is indistinguishable from the dose that the same population receives from naturally occurring radiation sources.

4.5 Radiation Dose To Individuals From Contaminated Lakes

This section calculates the realistic effective dose equivalent of an individual who uses Lakes 34, 35, 36, and the Femme Osage Slough solely for recreational purposes. The lakes are located in the Busch Wildlife Area and the Femme Osage Slough in the Weldon Spring Wildlife Area. They are used for recreational activities such as fishing and boating. None of the water bodies are presently used for drinking water or irrigation. In contrast to the previous sections, the analyses presented here attempt to realistically estimate the dosage to an individual in very plausible settings.

The potential radiation dose to individuals resulting from recreational activities at these lakes was estimated for the following potential pathways:

External: Swimming, boating, and direct exposure from the water body; and
Internal: Accidental ingestion of contaminated water.

The assumed individual spent 12 hours per year swimming and boating at the location of the contaminated water bodies. Also, this individual was assumed to ingest one liter of water from a canteen filled from one of the water bodies.

For purposes of calculation, thorium-234, protactinium-234, and uranium-234 were assumed to be in a state of secular equilibrium. In this analysis, the dose represents the 50-year effective committed dose equivalent expressed in millisievert per year (mSv/yr) and millirem per year (mrem/yr).

The total dose commitments estimated for a hypothetical individual from these exposure assumptions is much less than 1 mrem (0.01 mSv). These radiation pathways contribute an insignificant health risk to individuals or the general population.

5 FUTURE ENVIRONMENTAL MONITORING AT THE WELDON SPRING SITE

The environmental monitoring approach employed at the Weldon Spring Site (WSS) in 1990 has been modified from previous programs by several factors including issuance of DOE Order 5400.1 and the completion of numerous characterization activities. The effects of these factors are detailed in the Environmental Monitoring Plan (MKF and JEG, 1990a) for the WSS.

The groundwater monitoring program for 1990 will generally consist of semi-annual sampling of all Weldon Spring Chemical Plant/Weldon Spring Raffinate Pits (WSCP/WSRP) wells and all Weldon Spring Quarry (WSQ) wells north of the Femme Osage Slough. These samples will be analyzed for nitroaromatic compounds, inorganic anions and natural uranium. This program is designed to detect changes in contaminant concentrations and distribution. Quarterly monitoring is performed on monitoring and production wells south of the Femme Osage Slough. This portion of the groundwater monitoring program has been developed with the Missouri Department of Natural Resources and St. Charles County and is designed to document the safety of the well field, as well as detect contamination south of the slough. Analytical parameters include an annual scan for compounds known or suspected to be present in the WSQ and quarterly analyses for uranium, inorganic anions and nitroaromatic compounds.

The surface water monitoring program remains essentially unchanged from 1989. Surface water samples will generally be analyzed for uranium, with select locations analyzed for inorganic anions and/or nitroaromatic compounds. Preoperational monitoring (as required by DOE Order 5400.1) will continue in 1990. Effluent monitoring will continue as detailed in the National Pollutant Discharge Elimination System (NPDES) Permit.

Radon, gamma exposure and air particulate monitoring will be performed at the same locations and frequencies as in 1989.

Meteorological monitoring will be expanded during 1990 to include on-site measurements of hourly windspeed, wind direction, air temperature and precipitation.

The entire scope of routine effluent monitoring and environmental surveillance is detailed in the 1990 Environmental Monitoring Plan (EMP) for the WSS. The EMP discusses rationale, monitoring locations, and analytical methods to be used.

* Value is suspect since analytical holding time was exceeded.

a Documented laboratory error responsible for erroneously high result. Not entered into Annual Average.

** Value inconsitent with all previous historical data; holding time exceeded. Laboratory error suspected. Value not entered into annual average.

APPENDIX B
Glossary of Technical Terms

APPENDIX B

GLOSSARY OF TECHNICAL TERMS

ABSORBED DOSE: The amount of energy absorbed in any material from incident radiation. Measured in rads, where 1 rad equals 100 ergs of energy absorbed in 1 gram of matter.

ACTIVITY: A measure of the rate at which radioactive material is undergoing radioactive decay; usually given in terms of the number of nuclear disintegrations occurring in a given quantity of material over a unit of time. The unit of activity is the Curie (Ci) (see also Bequerel and Curie).

ALARA: An acronym for "As Low as Reasonably Achievable." This refers to the U.S. Department of Energy goal of keeping releases of radioactive substances to the environment and exposures of humans to radiation as far below regulatory limits as "reasonably achievable."

ALLUVIAL AQUIFER: A subsurface zone, formed by the deposition of sediments by running water, capable of yielding usable quantities of groundwater to wells.

ALPHA PARTICLE: A positively charged particle emitted from the nucleus during the radioactive decay of certain radionuclides. It consists of two protons and two neutrons bound together; it is identical to the nucleus of a helium-4 atom.

BACKGROUND RADIATION: Radiation due to cosmic rays and radiation from the naturally radioactive elements in the surface of earth.

BEDROCK: A rock formation usually underlying one or more unconsolidated formations.

BEQUEREL: SI unit for activity. 1 bequerel (Bq) = 1 disintegration/second = 2.703×10^{-11} Ci (curie).

BETA PARTICLE: Charged particle emitted from the nucleus of an atom, with a mass and charge equal in magnitude to that of the electron.

CHAIN OF CUSTODY: Standardized form tracing the possession and handling of individual samples from the time of field collection through laboratory analysis.

COMMITTED DOSE EQUIVALENT: The total dose equivalent averaged throughout a tissue in the 50 years after intake of a radionuclide into the body.

CONTAMINATION: A foreign substance in or on the surfaces of soils, structures, areas, objects, or personnel.

COUNTING STATISTICS: Statistical analysis required to process the results of nuclear counting experiments and to make predictions about the expected precision of quantities derived from these measurements.

CURIE: A measure of the rate of radioactive decay. One Curie (Ci) is equal to 37 billion disintegrations per second (3.7×10^{10} dps), which is equal to the decay rate of one gram of radium-226.

DAUGHTER: An element that results immediately from the disintegration of a radioactive element.

DECAY PRODUCTS: Isotopes that are formed by the radioactive decay of some other isotope. In the case of radium-226, for example, there are 10 successive decay products, ending in the stable isotope Lead-206.

DERIVED CONCENTRATION GUIDE (DCG): Concentrations of radionuclides in water and air that could be continuously consumed or inhaled and not exceed an effective dose equivalent of 100 mrem/year.

DISCHARGE: In groundwater hydrology, the rate of flow (usually from a well or spring) at a given instant in terms of volume per unit of time.

DOSE: Total radiation delivered to a specific part of the body, or to the body as a whole; also called dose equivalent.

DOSE RATE: Dose or dose equivalent per unit of time (i.e., millirem per year) as it is being delivered to the body.

DOSIMETER: A device used in measuring radiation dose, such as a lithium fluoride (LiF) thermoluminescent detector (TLD).

EFFECTIVE DOSE EQUIVALENT: The proportion of the stochastic risk resulting from irradiation of a tissue to the total risk when the whole body is irradiated uniformly. A term used to express the amount of effective radiation when modifying factors have been considered, it is the product of absorbed dose (rads) multiplied by a quality factor and any other modifying factors. It is measured in rem (Roentgen Equivalent Man).

ERG: 1 ERG = 2.8×10^{-14} KWH

EXPOSURE PATHWAY: The route by which a contaminant/health hazard may enter and move through the environment or individual.

EXPOSURE RADIATION: The amount of ionization produced in air by X-rays or gamma rays, measured in Roentgens (R).

GAMMA RADIATION: Penetrating high energy, short wave-length, electromagnetic radiation (similar to x-rays) emitted during radioactive decay. Gamma rays are very penetrating and can be attenuated only by dense materials such as lead.

GROSS ALPHA: Measurement of all alpha-emitting radionuclides in a sample.

GROSS BETA: Measurement of all beta-emitting radionuclides in a sample. Gross alpha and beta are useful analyses for screening to determine whether further analyses for specific radionuclides are merited.

HALF LIFE: The time it takes for half the atoms of a quantity of a particular radioactive element to decay into another form. Half-lives of different isotopes vary from millionths of a second or less to billions of years.

HECTARE: A unit of area in the metric system equal to approximately 2.5 acres. It is 10,000 square meters.

HYDROLOGIC: Pertaining to study of the properties, distribution, and circulation of water on the surface of the land, in the soil and underlying rocks, and in the atmosphere.

ISOTOPE: Nuclides having the same atomic number but different mass numbers.

NATURAL URANIUM: A naturally occurring radioactive element that consists of 99.2830% by weight uranium-238, 0.7110% uranium-235 and 0.0054% uranium-234.

NUCLIDE: A general term referring to isotopes, both stable (279) and unstable (about 500), of the chemical elements.

PERCHED LENSES: A small, localized water-saturated zone of subsurface material surrounded by unsaturated material.

RAD: Unit of absorbed dose; acronym for radiation absorbed dose.

RADIATION: A very general term that covers many forms of particles and energy, from sunlight and radiowaves to the energy that is released from inside an atom. Radiation can be in the form of electromagnetic waves (gamma rays, x-rays) or particles (alpha particles, beta particles, protons, neutrons).

RADIONUCLIDE: An unstable nuclide that undergoes radioactive decay.

RAFFINATE: A waste product from a refining process, i.e., that portion of a treated liquid mixture that is not dissolved and not removed by a selective solvent.

REM (Roentgen Equivalent Man): A quantity used in radiation protection to express the effective dose equivalent for all forms of ionizing radiation. A rem is the product of the absorbed dose in rads and factors related to relative biological effectiveness.

SI: International System of Units.

SIEVERT: SI unit used to express the effective dose equivalent for all forms of ionizing radiation. 1 Sv = 100 rem

STOCHASTIC: "Stochastic" effects are those for which the probability of an effect occurring, rather then its severity, is regarded as a function of dose, without a threshold.

WORKING LEVEL: Any combination of radon-222 decay products in 1 liter of air that will result in the ultimate emission of 0.21 erg of alpha energy is defined as 1 WL. It is based on the 0.21 erg of alpha energy that would be emitted by the decay products of 100 pCi of radon-222 in 1 liter of air, where the decay products are in radioactive equilibrium with the parent.

WORKING LEVEL MONTH: The product of WL and duration of exposure, normalized to a 1-month exposure period.

X-RAYS: Penetrating electromagnetic radiation having a wave length that is much shorter than that of visible light. It is customary to refer to rays originating in the nucleus as gamma rays and to those originating in the electron field of the atom as x-rays.

APPENDIX D
Quality Assurance

APPENDIX D
QUALITY ASSURANCE

The quality assurance (QA) program implemented in 1989 was greatly expanded from the previous year's program. In addition to increasing the number of field quality control blanks and duplicates collected, a data verification program was initiated to ensure that samples were preserved, shipped, maintained and analyzed in accordance with established procedures. The scope of this QA program includes all routine environmental and radiological characterization activities. The QA program is composed of two components: field and analytical QA evaluations.

The QA program for field activities included the following:

- Preparation of site-specific sampling plans and sampling procedures for collection of all environmental samples.

- Proper documentation of sample collection including sample collection forms, field logbooks, chain-of-custody records and quarterly summary sheets.

- Review of all sample tracking documentation and analytical results in accordance with the Environmental Monitoring Data Verification SOP 4.9.1.

- Collection of quality control (QC) blanks, trip blanks, and equipment blanks for characterization sampling.

- Annual audit of all field procedures with follow-up corrective programs, if required.

The analytical QA program for laboratory analyses used a number of different types of quality control samples to document the validity of the data generated. These samples included:

- Method Blanks (one per batch, each batch not to exceed 20 samples). Method blanks contain all the reagents used in the preparation and analysis of samples to assess contamination arising from reagents, glassware and other materials used in the analysis.

- Laboratory Control Samples/Spiked Blanks (LCS - one per batch, each batch not to exceed 20 samples). These samples were prepared by adding known quantities of compounds of interest to deionized water. They were used to establish that instruments and procedures were in control.

- Calibration Check Samples (as needed, or per method). Calibration standards were periodically used to verify that the original calibrations were still valid.

- Duplicate and Spiked Samples (5% duplicate; 5% spike). Duplicate samples were analyzed to enable an estimate of the precision of the analytical procedures. Spiked samples were measured to determine the accuracy of the analytical procedure and assess matrix effects. For analyses conducted according to the Contract Laboratory Program (CLP) methodology, these controls are termed matrix spike and matrix spike duplicate samples.

- Blind QC Samples (one per 20 samples). Blind QC samples were inserted into the sample load in a fashion unrecognizable to the laboratory. These samples were

used in addition to the standard duplicate sample analysis discussed above, to assess analytical precision.

- Interlaboratory Evaluation (annually). In order to assess comparability of data, sample splits were shipped to different laboratories to provide a measure of analytical or method bias.

The laboratories performing analyses maintained internal quality assurance programs that involved routine calibration of counting instruments, source and background counts, routine yield determinations for radiochemical procedures, and replicate analyses to check precision.

The specific monitoring activities included in the environmental monitoring program were measurements of radon concentration, air particulate analysis for radioactivity, and surface water and groundwater analyses for various organic, inorganic, and radioactive species. The quality assurance results for each monitoring activity, except radon, are discussed in the following text. Due to its unique measurement method, the radon quality assurance results are already included in Section 2.3 of this report.

Groundwater Quality Assurance

Field Evaluation

Field audits of all procedures associated with the collection of environmental samples were conducted during 1989. These audits were conducted by individuals from the Quality Assurance staff, who function independently from the field sampling team. All field personnel are trained and knowledgeable of the procedures used for sample collection. Standard Operating Procedures associated with the collection of environmental samples included:

- Groundwater sampling
- pH measurement in water
- Specific conductance measurement in water
- Water sample filtering
- Sampling equipment decontamination
- Sampling packaging for shipment
- Chain-of-custody

QA/QC audit reports of field procedures cited no findings of nonconformance, and no corrective action resulted.

Quality Assurance Field Blanks

Evaluation of equipment and water blanks were audited quarterly to assess field performance. Table D-1 shows the results from all equipment and water blanks taken during 1989. The equipment blanks were taken at locations which do not have dedicated well samplers in order to ensure that equipment decontamination procedures are effective in preventing contaminant carryover. The equipment blanks were designated as

either pump or bailer blanks based upon the method of sample collection utilized at that particular well. The equipment blanks were prepared by adding deionized water into the sampling pump and bailer after normal field decontamination. The deionized water was then transferred into the sample containers and analyzed. Since 1,3,5-trinitrobenzene (TNB) was present in method blanks as well as equipment and water blanks, it was dismissed as a laboratory contamination problem. The results from the pump blank taken at GW-4017 indicate possible carryover of low levels of 2,4-dinitrotoluene (DNT); however since the sample taken at GW-4017 does not contain 2,4-DNT this result is questionable. None of the equipment blanks indicated inorganic anion contamination. The equipment blanks in general indicate that decontamination methods are every effective in preventing contaminant carryover.

Water blanks and field blanks were the two types of deionized water blanks taken in 1989. The samples designated as water blanks were deionized water taken from the on-site laboratory supply. The water blanks were generally clean for all parameters except 1,3,5-TNB which, as previously explained, was also in the method blank. One water blank taken in the third quarter contained trace levels of nitrobenzene; however since the result is lower than the USATHAMA detection limit it is suspect. Field blanks were deionized water blanks taken while out in the field to evaluate the possible introduction of contaminants during field activities. One field blank contained 1,3-dinitrobenzene (DNB), once again at levels lower than the USATHAMA detection limit making this result questionable. All other field blanks were generally clean. A total of 17 equipment and water blanks were analyzed during 1989 and contamination as a result of field activities was not indicated.

Analytical Quality Assurance

Expanded data verification and validation programs were initiated in 1989 to ensure that all analytical results were precise, accurate, representative, complete, and comparable to the historical database. Data verification is a preliminary review of sampling documentation and analytical results performed on 100% of the samples in accordance with Environmental Monitoring Data Verification SOP 4.9.1. Data validation is a much more comprehensive review and analysis of laboratory results and documentation.

The number of duplicate samples taken in 1989 was double that taken from the previous year. The results of duplicate analyses are presented in Table D-2. Generally good agreement exists between duplicate samples. Relative percent difference (RPD) between duplicates was calculated and appeared to be within acceptable analytical intervals for precision. As expected, variance between laboratories was observed for 1,3,5-TNB due to laboratory contamination of the primary lab. There are also slight variances in nitrate values between labs. These variances appear to be related to differing methodologies employed for nitrate analysis.

Radiological Air Particulate Quality Assurance

After an initial gross alpha analysis was performed on the samples (filters), quality control (QC) measurements were obtained through subsequent gross alpha analysis without changing any of the analytical parameters. There were 51 QC measurements obtained; approximately 6% of the total samples were analyzed twice. The precision of the gross alpha measurements were determined by comparing the original gross alpha analysis to the

QC analysis. The standard deviation of the initial results and the QC result was calculated and then divided by the average of the two measurements to obtain the precision of each measurement. The average precision of this sample group was calculated to be 16.6% ± 2.5% at a 90% confidence level.

External Gamma Monitoring Quality Assurance

During each calendar quarter the radiation levels at two gamma monitoring stations were measured with duplicate thermoluminescent dosimeters, allowing an assessment of the precision of the external gamma measurements.

The field duplicate results for 1989 are summarized per station and per quarter in Table D-3. All second quarter measurement results, including the control and background TLDs, had results four times higher than typical quarterly results. This was probably caused by the shipment being x-rayed during transit. For this reason the second quarter results were disregarded. Overall, the duplicate dosimeters are consistent with the primary detectors, indicating good precision.

TABLE D-3 External Gamma Monitoring Quality Assurance - Duplicate and Control Results

Location Number	Results mrem/Quarter
1ST QUARTER	
Control	12.22
TD-1005	22.62
TD-1005 - Duplicate	19.89
2ND QUARTER	
Control *	77.61
3RD QUARTER	
Control	6.89
TD-1004	14.95
TD-1004 - Duplicate	15.60
4TH QUARTER	
Control	10.01
TD-1005	20.67
TD-1005 - Duplicate	20.15
TD-3001	20.02
TD-3001 - Duplicate	17.81

* All 2nd Quarter badges exposed during transportation

APPENDIX E
Standards for Protection of the Public in the Vicinity of DOE Facilities

APPENDIX E
STANDARDS FOR PROTECTION OF THE PUBLIC IN THE VICINITY OF DOE FACILITIES

RADIATION STANDARDS

A. DOSE LIMITS

1. All Pathways

The effective dose equivalent for any member of the public from all routine DOE operations[1] (natural 2background and medical exposures excluded) shall not exceed the values given below:

	Effective dose equivalents[2] mrem/year	(mSv/year)
Occasional annual exposures	500	(5)
Prolonged period of exposures[3]	100	(1)

No individual organ shall receive an annual dose equivalent in excess of 5 rem/year (50 mSv/year).

2. Air Pathway Only (Limits of 40 CFR 61, Subpart H)

	Dose Equivalent mrem/year	(mSv/year)
Whole body dose	25	(.25)
Any organ	75	(.75)

1. Routine DOE operations means normal planned operations and does not include actual or potential accidental or unplanned releases.

2. Effective dose equivalent will be expressed in rem (or millirem) with the corresponding value in sievert (or millisievert) in parenthesis. As used in this standard, effective dose equivalent includes both the effective dose equivalent from external radiation and the committed effective dose equivalent to individual tissues from ingestion and inhalation during the calendar year.

3. For the purposes of these standards, a prolonged exposure will be one that lasts, or is predicted to last, longer than 5 years.

B. DERIVED CONCENTRATION GUIDES (DCG)

The following table contains a listing of the DCG values for the ingestion of drinking water and inhalation of air for members of the public. The values are based on an annual dose equivalent rate of 100 mrem/yr. Five columns of information are shown in the table: 1) radionuclide; 2) drinking water ingestion DCG in units of μCi/ml; 3) drinking water DCG in units of Bq/ml; 4) inhalation DCG in units of μCi/ml; 5) inhalation DCG in units of Bq/mL.

Only a single mode of exposure was considered--either ingestion or inhalation.

The DCG values are given for individual radionuclides. For known mixtures of radionuclides, the sum of the ratio of the observed concentration of a particular radionuclide and its corresponding DCG for all radionuclides in the mixture must not exceed 1.0.

It should be noted that the values given in the table only account for drinking water and inhaling air, and do not include other potentially significant environmental pathways. A more complete pathway analysis is required for calculating public radiation dose equivalent resulting from the operation of DOE facilities when more complex environmental pathways are involved.

	Drinking Water		Inhaled Air	
Radionuclide	µCi/mL	Bq/mL	µCi/mL	Bq/mL
Uranium-238	6.0E-07	2.2E-02	1.0E-13	3.07-09
Uranium-235	6.0E-07	2.2E-02	1.0E-13	3.7E-09
Uranium-234	5.0E-07	1.9E-02	9.0E-14	3.3E-09
Thorium-232	5.0E-08	1.9E-03	7.0E-15	2.6E-10
Thorium-230	3.0E-07	1.1E-02	4.0E-14	1.5E-09
Radium-228	1.0E-07	3.7E-03	3.0E-12	1.1E-07
Radium-226	1.0E-07	3.7E-03	1.0E-12	3.7E-08

C. RADON

Above-background radon-222 concentrations in the atmosphere at or above any location outside the facility site shall not exceed an annual average concentration of 3 pCi/L (DOE Order 5480.1A, Attachment XI-1).

CHEMICAL STANDARDS

U.S. EPA Drinking Water Standards (mg/l) as noted in 40 CFR Parts 141 and 143

Drinking water standards are presented only for comparison purposes. These should not necessarily be construed as relevant cleanup standards.

A. HSL-Metals

Aluminum	NS	Lithium	NS
Antimony	NS	Magnesium	NS
Arsenic	0.05*	Manganese	0.05**

ABSTRACT AND WELDON SPRING SITE QUARTERLY SELF ASSESSMENT THIRD QUARTER 1990

This is the second Quarterly Environmental Data Summary for the Weldon Spring Site Remedial Action Project (WSSRAP). The purpose of this document is to provide preliminary data acquired as part of the WSSRAP environmental monitoring program. The document summarizes the environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1990 Annual Site Environmental Report.

This report includes data from environmental monitoring at the Weldon Spring Site during the third quarter of 1990. Groundwater, surface water, and air were sampled in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to calculate exposure doses (where applicable) and assess the impact of the contaminants at the site on potentially exposed populations.

No significant differences were observed in off-site exposures during the third quarter of 1990 relative to exposures calculated in previous quarters. Contaminated groundwater did not affect private water supplies or the St. Charles County well field. Surface water containing elevated uranium activity continued to impact the Femme Osage Slough and several lakes in the August A. Busch Memorial Wildlife Area. Off-site gamma, radon and air particulate exposures remained indistinguishable from background. Off-site monitoring demonstrated that exposure levels at the Francis Howell High School, the Busch Wildlife Area Headquarters, and the Weldon Spring Training Area remain indistinguishable from background levels. No EPA reportable spills or releases of hazardous or radioactive materials occurred at the Weldon Spring Site during the third quarter of 1990.

1 INTRODUCTION

This document is the second in a series of documents designed to provide a summary of the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These documents supplement the Annual Site Environmental Reports (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP Environmental Monitoring Plan and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting those which differ significantly from observations made in previous reports. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1990 ASER. It is recommended that interested readers refer to previous Environmental Monitoring Plans (EMPs), ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be used during the upcoming year is identified in the EMP and the analytical parameters are tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting Mr. James McKee (the WSSRAP Community Relations Manager at 314-441-8086).

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System, radon, gamma radiation, and air

particulates (including asbestos and radioactive particulates). However, because of delays in data delivery from the analytical laboratories, much of the data which was expected to be included in this report are not yet available for reporting. The unavailability of data is due to a nationwide shortage in analytical services. WSSRAP is taking corrective action to ensure more timely availability of data in the future. These data will be reported in the fourth quarter data summary or in the 1990 Annual Site Environmental Report (ASER). Sludges, soils, and biological specimens are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/Raffinate Pits/Vicinity Properties (WSCP/RP/VP) and the Weldon Spring quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

The groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a semi-annual basis. Monitoring well locations are shown in Figure 2-1. Data from the semiannual groundwater monitoring for the second half of 1990 will be presented in its entirety in the fourth quarter data summary which will allow the reader to see the whole picture of groundwater quality conditions.

Nitroaromatic and radiological data from first semester semiannual sampling which was not available in the previous data summary is presented in Tables 2-1 and 2-2. These results are discussed in Sections 2.1.1 and 2.1.2.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples of 25 monitoring wells for which data was unavailable in the previous quarterly environmental data summary. Nitroaromatic compounds were detected in nine of these samples. However, the data continues to reflect historical trends found in previous environmental reports.

2.1.2 Radiological Results

The radiological results for samples from wells at the WSCP/RP/VP are presented in Table 2-2. The upper bound for natural uranium background concentrations in groundwater at the WSCP/WSRP/WSVP has been determined to be 3.4 pCi/l. The EPA has not yet established drinking water standards for uranium. However, studies leading to proposed rulemaking are using uranium in the 10 to 40 pCi/l range. The U.S. Department of Energy (DOE) has a derived concentration guidelines (DCG) of 550 pCi/l.

The highest uranium level detected was 231.2 pCi/l from a sample obtained from Monitoring Well 3008. This level indicates a higher value than has previously been detected from MW-3008. The second semester sample results to be reported in the fourth quarter environmental data summary will provide more insight to this elevated level. The other concentrations reported in Table 2-2 are consistent with data from previous environmental reports.

2.2 Weldon Spring Quarry

Chemical and radiological wastes at the quarry are of particular concern because of their proximity to the St. Charles County well field. The well field is located approximately one-half mile to the south. Monitoring of contaminants in groundwater and the protection of the the well field is a top WSSRAP priority.

Groundwater is monitored in 30 wells in and around the quarry. Twenty-six monitoring wells installed by the U.S. Department of Energy (DOE) currently exist in or near the quarry. Four additional monitoring wells were installed by St. Charles County in 1986. All monitoring well locations are shown in

Figures 2-2 and 2-3. The wells currently draw water from both bedrock and alluvial aquifers.

Two separate groundwater monitoring programs have been developed for the quarry. The first program is a semiannual sampling of all wells north of the Femme Osage Slough.

The second program monitors the area south of the Femme Osage Slough, including the St. Charles County well field. Active production wells and monitoring wells are sampled quarterly. The raw and treated waters from the St. Charles County water treatment plant are also sampled. This portion of the quarry groundwater monitoring program has been jointly developed by representatives of the DOE, the Missouri Department of Natural Resources (MDNR), the U.S. Environmental Protection Agency (EPA) and St. Charles County.

Data from the second semiannual semester groundwater sampling in the quarry area will be presented in their entirety in the fourth quarter data summary. Second quarter data that were not available for the previous quarterly summary are presented in this report with third quarter data.

2.2.1 Radiological Results

Radiological data from groundwater samples taken from quarry wells south of the Femme Osage Slough are exhibited on Table 2-3. Some uranium data for third quarter have not yet been received from the analytical laboratory and will be reported in the 1990 ASER. The available results of third quarter 1990 groundwater monitoring are consistent with historical results in that they continue to indicate background uranium levels in the

alluvium on the south side of the Femme Osage Slough. Analytical results from St. Charles County Monitoring Well RMW-2 indicate a level of 7.1 pCi/l which is the highest uranium level detected in the wellfield for third quarter, but agrees with historical data from the well field.

The results of third quarter gross alpha monitoring south of the Femme Osage Slough indicated only one detected level of 13.1 pCi/l. This result was found in RMW-2 which corresponds to the highest uranium level detected from third quarter monitoring.

These findings indicate that the groundwater quality south of the Femme Osage Slough remains uncompromised.

2.2.2 Nitroaromatic Compounds Results

Analytical results for nitroaromatic compounds are presented in Table 2-4. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the third quarter 1990. The scenario for nitroaromatic contamination near the quarry remains unchanged.

2.2.3 Inorganic Anions Results

Four inorganic anions--nitrate, sulfate, chloride, and fluoride--were measured in quarry wells. Table 2-3 displays the analytical results for the third quarter of 1990, which are consistent with data reported in the 1989 Annual Site Environmental Report, as well as previous environmental monitoring reports.

2.2.3.1 Nitrate

The groundwater samples continue to indicate no significant groundwater contamination by nitrate.

2.2.3.2 Sulfate

The groundwater samples continue to indicate background concentrations of sulfate in wells south of the Femme Osage Slough.

2.2.3.3 Chloride and Fluoride

Results of chloride analyses of groundwater south of the Femme Osage Slough continue to indicate background concentrations. Results of fluoride analyses indicate no detectable levels for third quarter 1990.

2.2.4 Metals Results

A selected group of quarry wells located south of the Femme Osage Slough were sampled for arsenic and barium. Analytical results for these metals are presented in Table 2-5. Results from third quarter analyses of arsenic and barium continue to indicate elevated concentrations in selected wells. The highest levels reported for the third quarter are 51.2 µg/l for arsenic and 630 µg/l for barium as detected in Monitoring Well RMW-3.

3 SURFACE WATER MONITORING

Routine samples were collected during the third quarter of 1990 from both on-site and off-site surface water locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired.

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the third quarter, surface water samples were collected from the nine locations shown in Figure 3-1; however, radiological and chemical analyses are not yet available from the contract laboratory. Sampling results for uranium, chloride, flouride, nitrate, and sulfate for the nine locations will be presented in the 1990 Annual Site Environmental Report.

3.2 Weldon Spring Quarry

Samples from the nine surface water locations in Figure 3-2, and three surface water locations in Figure 3-3, were analyzed for uranium. Certain locations were also analyzed for radium-226, thorium-230, thorium-232, nitrate, sulfate, chloride, flouride, 1,3,5-TNB, 1,3-DNB, 2,4,6-TNT, 2,4-DNT, 2,6-DNT, and Nitrobenzene. Only the results of analyses for nitroaromatic compounds are presently available from the laboratory. Results of all other analyses will be presented in the 1990 Annual Site Environmental Report.

3.2.1 Nitroaromatics

A sample was collected at one location, the quarry sump (SW-1008), to quantify nitroaromatic concentrations. Results of

this sampling are presented in Table 3-1. The quantified concentrations of the six nitroaromatic compounds ranged from below the detection limit to 35.0 µg/l for 2,4,6-TNT. The ponded water will be treated for nitroaromatic compounds and other organics upon completion of the quarry water treatment plant. Nitroaromatic results for the third quarter of 1990 were near the values reported in the 1989 ASER, but were higher than the values during the first and second quarters of 1990.

3.3 Springs

Eleven springs around the WSS are sampled on a quarterly basis. (See Figure 3-4 for spring locations). Previous spring monitoring has indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs include SP-6301, SP-6302, SP-6306, and SP-5301 through SP-5304. All spring samples are analyzed for uranium, and select spring samples are analyzed for inorganic ions, metals, and nitroaromatics. Results for nitroaromatics only are available from the laboratory at this time. All other results will be presented in the 1990 Annual Site Environmental Report.

3.3.1 Nitroaromatics

Of the five routinely monitored springs, four were analyzed for nitroaromatic compounds because of the historical presence of nitroaromatic compounds at those locations. Spring SP-6302 was dry; therefore, a sample could not be collected. The results of these analyses are in Table 3-2 and are consistent with previous results.

3.4 National Pollutant Discharge Elimination System Data Review

Surface water and effluent samples were collected and analyzed in compliance with the Weldon Spring Site National Pollutant Discharge Elimination System (NPDES) permit. This permit (Number MO-0107701) was issued in November 1988, and addresses storm water and wastewater discharges. Six discharge points or outfalls are included in this permit, and are shown on Figure 3-5. Outfalls NP-0001 through NP-0005 represent surface water discharge and NP-0006 represents the treated effluent discharge associated with the Administration Building sanitary wastewater treatment plant. Currently NP-0006 is the only outfall with effluent limitations. The five surface water outfalls have monitoring requirements only. Analytical data for the third quarter of 1990 is presented for each outfall in Table 3-3.

Radiological analyses of samples collected on September 27 are not yet available. This is indicated on the data tables for outfalls NP-0001, NP-0002, and NP-0005. No discharge due to precipitation occurred in September. Samples obtained on September 27 were associated with artificial flow events. Water hydrants supplied by the St. Charles County distribution system were utilized in performing flow studies during this time. Flow studies were conducted in the southeast drainage by the PMC and in the Frog Pond drainage by MDNR/DGLS. For this reason, these values may not be representative of normal flows associated with precipitation events.

Radiological Analysis

Gross Alpha and Total Uranium analyses correspond well with 1989 data. The highest uranium levels were present at NP-0001

(discharge from the process sewer) followed by NP-0005 (surface flow from the southeast portion of the site combined with discharge from NP-0001). These relatively higher levels are consistent with 1989 data. Maximum values for uranium were 197.2 pCi/l at NP-0001 and 135 pCi/l at NP-0005, which are lower than maximum values for 1989.

Other outfalls exhibited the following range of uranium concentrations. NP-0002, the drainage from the Frog Pond area, ranged from 20.4 pCi/l to 88 pCi/l, which is slightly lower than 1989 values. NP-0003, drainage from the Ash Pond Diversion, ranged from 6.24 pCi/l to 96 pCi/l, which is lower than the 1989 values indicating the continued positive effect of the Ash Pond Diversion project. A uranium concentration of 6.45 was present in the third third quarter sample collected from NP-0004, raffinate pit #4 area.

Other Analysis

Other analyses include physical analysis (settleable solids and suspended solids) and chemical analysis (nitrate, pH, and lithium). Third quarter 1990 values generally correspond to 1989 values for the majority of parameters.

Settleable solids were less than 0.1 ml/l with the following two exceptions which were measured at 0.1 ml/l: NP-0003 on Jul. 11 and NP-0002 on Aug. 3. Suspended solids ranged from <1.0 mg/l (NP-0005 on Jul. 11) to 488 mg/l (NP-0002 on Aug. 3). The high suspended solids measurement for NP-0002 was caused in part by an accumulation of silt in the small basin above the weir. This accumulation of silt has been removed and subsequent suspended solids measurements have decreased significantly.

Nitrate values are slightly lower than 1989 values for all surface water outfalls and ranged from 0.1 mg/l (NP-0003 on August 3) to 1.90 mg/l (NP-0005 on August 3). Lithium was detected in outfalls NP-0001, NP-0002, and NP-0005 during the third quarter of 1990 and ranged from 0.0070 mg/l (NP-0002 on July 11) to 0.0256 mg/l (NP-0005 on September 27). These levels are relatively low and no Maximum Contaminant Level (MCL) exists for lithium in drinking water. Lithium levels were detected at all three outfalls in samples obtained on September 27. The sources of flow on this date were water hydrants supplied by the St. Charles County distribution network. As a control measurement during future flow study, additional samples will be collected directly from the hydrant source and analyzed for NPDES parameters. Lithium was detected in all three samples for third quarter 1990 at NP-0002. The PMC will continue to monitor these levels and attempt to determine the source of lithium in this drainage.

The discharge from the Administration Building treatment plant, NP-0006, has effluent limitations for quarterly samples. In addition to this quarterly monitoring, the subcontractor monitors the same parameters monthly, to assess plant performance. All data reported for third quarter 1990 was in compliance with permit effluent limitations.

Sampling was conducted in the Little Femme Osage Creek, near the Weldon Spring Quarry in order to assess erosion control measures associated with construction of the Quarry Staging Area and Water Treatment Plant Facilities. Although the treatment plant has not yet been constructed, the NPDES permit for this discharge (MO-0108987) requires that all runoff from construction and material storage areas remain within the following limits:

Total Suspended Solids: Less than 50.0 mg/l
pH greater than 6.0 and less than 9.0 (standard units)

Samples were collected from SW-1001 and SW-1002 on August 29 (See Figure 3-2). SW-1001 is located upstream of the Quarry Staging Area, and represents normally occurring concentrations in this drainage. SW-1002 is located immediately downstream of the Quarry Staging Area. Water quality impacts from QSA construction erosion are assessed by comparing values from these two locations. Results from these samples were as follows:

SW-1001	pH = 6.90	TSS=1.6 mg/l
SW-1002	pH = 7.17	TSS=<1.0 mg/l

These results indicate compliance with permit requirements.

4 AIR MONITORING

4.1 Radon Gas

The radon gas monitoring program utilizes a pair of radon detectors at each of 22 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring chemical plant, six locations at the Weldon Spring quarry, four locations at the Weldon Spring raffinate pits, and six off-site locations. Radon monitoring locations are shown in Figures 4-1, 4-2, and 4-3. On-site detectors are spaced around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, and RD-4006 were used to monitor background levels near the site.

Table 4-1 summarizes the quarterly and year-to-date average radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in Table 4-1 is a comparison of the measured year-to-date average concentration with the Federally permitted radon concentration for unrestricted areas of 3 pCi/l (110 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the four background locations. This data yielded a year-to-date average ambient background radon concentration of 0.33 pCi/l for the first three quarter of 1990. This concentration was then subtracted from the year-to-date average concentration for each monitoring station, and then compared to the DOE guideline of 3 pCi/l above background.

(b) Percent of guideline calculated by taking the year-to-date average minus the average of the background stations divided by the DOE concentration guideline for RN-222 is 3 pCi/l (100 Bq/m^3) (Annual average above background) for uncontrolled areas.
* Denotes background station

Radon concentrations at the site perimeter and at off-site locations were lower for the third quarter of 1990 than for the third quarter of 1989. However, they are within the typical range expected during years of normal precipitation. The quarterly radon concentrations (background included) ranged from 0.3 pCi/l at two locations to 3.1 pCi/l at monitoring location RD-1002.

Radon concentrations found in the quarry are higher than concentrations measured at other locations because the radium concentrations in quarry wastes are typically much higher than other areas, and because the quarry is a large depression in the terrain with side walls ranging from 3 to 15 meters (10 to 50 feet) high. In conjunction with stable meteorological conditions, this configuration tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

4.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, 22 monitoring stations using spherical environmental thermoluminescent dosimeters (TLDs) were deployed. The monitoring station locations are the same as the ambient radon monitoring locations (see Section 4.1).

Table 4-2 summarizes the quarterly and year-to-date results of total gamma radiation monitoring at the 16 WSS perimeter monitoring stations, Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the four background monitoring stations.

(a) Results include natural background.
- Denotes loss of TLD
* Denotes background station.

(b) Year-to-date totals for locations where some quarterly data is unavailable was calculated using the average of the existing quarterly data in place of the unavailable data. Due to rounding of values, the sum of the quarterly data may not equal the year-to-date total.

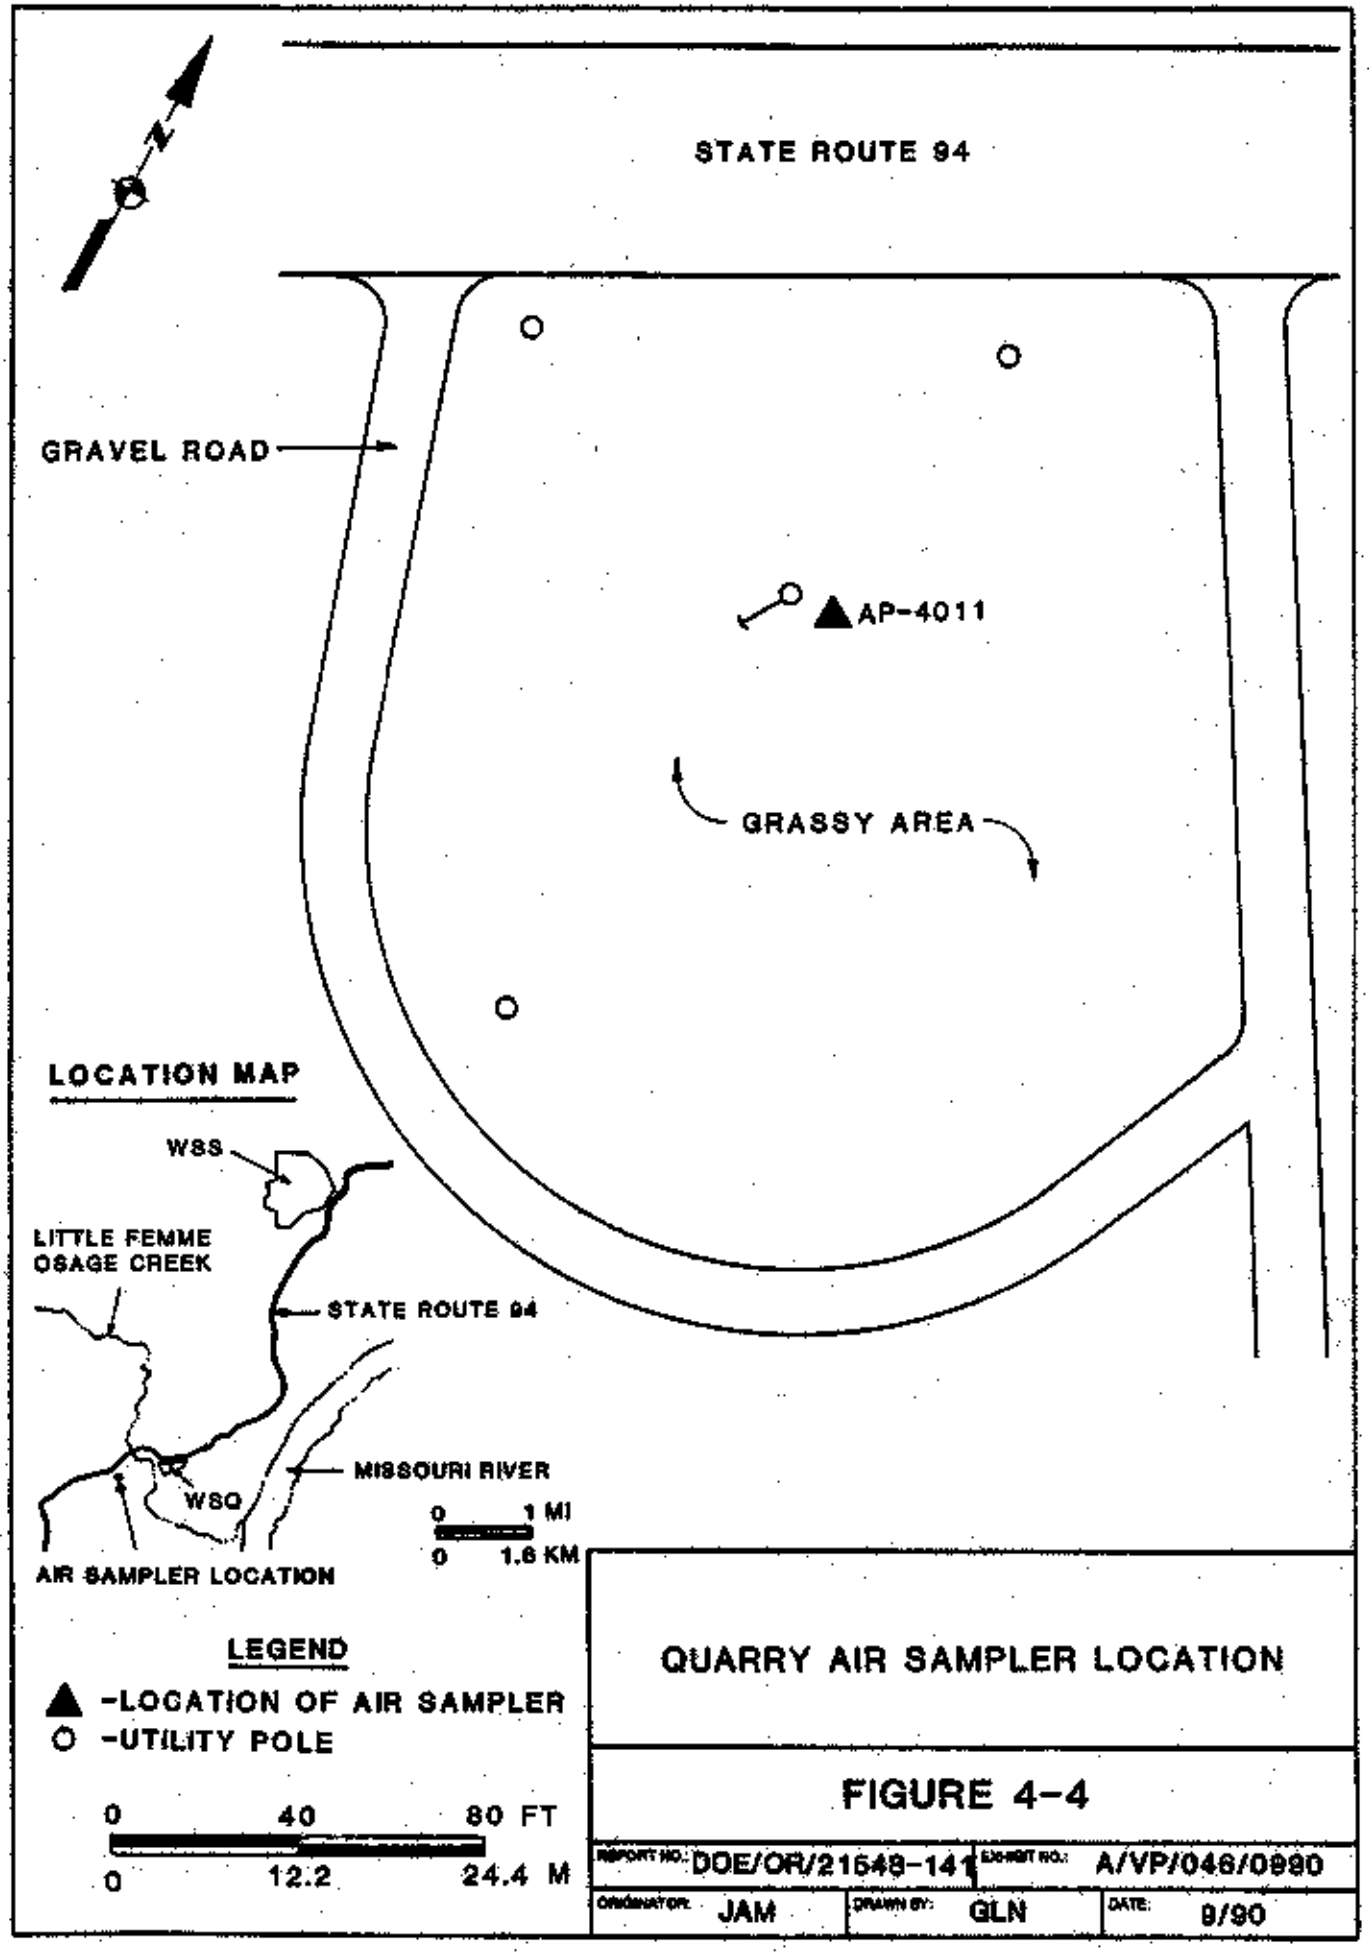
The yearly average background gamma exposure as measured with TLDs in 1989 was 68 mR/year. This would be equivalent to 51 mR/9 months which is comparable to the monitoring results of 45 mR/9 months obtained in the third quarter of 1990. This agreement with 1989 monitoring results was expected because no significant changes in the configuration or location of the wastes has occurred.

Due to external vandalism, the third quarter TLDs were missing for monitoring stations TD-1005, TD-3002, TD-4001, and TD-4005. In order to calculate a year-to-date total gamma exposure rate, the missing quarterly data were replaced with the average of the remaining quarterly TLD results for those monitoring stations.

4.3 Radioactive Air Particulates

Eleven air particulate samplers monitor the Weldon Spring site. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the chemical plant (WSCP) perimeter and two are located around the quarry perimeter as shown in Figure 4-3. Three monitoring stations (AP-4006, AP-4008, and AP-4011) are located off site at sensitive receptor locations, including Francis Howell High School, the Army Reserve property, and a residential site west of the quarry. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown in Figure 4-4.

The sampling station near the August A. Busch Wildlife Area (ABWA) headquarters is used as a background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain



QUARRY AIR SAMPLER LOCATION

FIGURE 4-4

REPORT NO.: DOE/OR/21548-141	EXHIBIT NO.: A/VP/046/0990	
ORIGINATOR: JAM	DRAWN BY: GLN	DATE: 9/90

between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/WSRP. In addition, winds from the southeast are relatively rare at the WSCP.

Table 4-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging either the weekly air particulate analysis results or the counting instrument's lower limit of detection (LLD), whichever was greater. The "<" sign in Table 4-3 appears when the actual average is less than the calculated average due to the use of LLD values in the calculation. Locations AP-1009 and AP-1010 were not in operation for five weeks due to vandalism. All of the other measurements at the two locations were above the LLD values. The standard deviation for each of the monitoring locations was calculated using only results that were above the LLD.

The third quarter net alpha concentrations ranged from $<1.34 \times 10^{-15}$ µCi/ml to 2.12×10^{-15} µCi/ml with $<1.69 \times 10^{-15}$ µCi/ml detected at the background station.

4.4 Asbestos

Air sampling for asbestos has been performed on a routine basis for two years. The monitoring data indicate no elevated levels of airborne asbestos during both asbestos abatement operations and during periods when no asbestos activities were in progress at the site. Since asbestos removal and handling operations were not in progress during the third quarter, perimeter asbestos sampling was not performed. Upon commencement

ABSTRACT AND WELDON SPRING SITE QUARTERLY SELF ASSESSMENT FOURTH QUARTER 1990

The purpose of this Quarterly Environmental Data Summary is to provide preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1990 Annual Site Environmental Report.

This report includes data from environmental monitoring at the Weldon Spring site (WSS) during the fourth quarter of 1990. Groundwater, surface water, and air were sampled in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to calculate exposure doses (where applicable) and assess the impact of the contaminants at the site on potentially exposed populations.

No significant differences were observed in off-site exposures during the fourth quarter of 1990 relative to exposures calculated in previous quarters. The WSS experienced a National Pollution Discharge Elimination System (NPDES) noncompliance on fecal coliform in December of 1990. The necessary steps have been taken to return the discharge to a compliance level. Contaminated groundwater did not affect private water supplies or the St. Charles County well field. Surface water containing elevated uranium activity continued to impact the Femme Osage Slough and several lakes in the August A. Busch Memorial Wildlife Area. Off-site gamma, radon and air particulate exposures remained indistinguishable from background. Off-site monitoring demonstrated that exposure levels at the Francis Howell High School, the Busch Wildlife Area Headquarters, and the Weldon Spring Training Area remain indistinguishable from background levels.

1 INTRODUCTION

This document is the third in a series of documents designed to provide a summary of the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These documents supplement the Annual Site Environmental Reports (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP Environmental Monitoring Plan and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from observations made in previous reports. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1990 ASER. It is recommended that interested readers refer to previous Environmental Monitoring Plans (EMPs), ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the analytical parameters are tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at 314-441-8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System, radon, gamma radiation, and air particulates (including asbestos and radioactive particulates). However, because of delays in data delivery from the analytical laboratories, some of the data that was expected to be included in this report are not yet available for reporting. The unavailability of data is due to a nationwide shortage in analytical services. WSSRAP is taking corrective action to ensure more timely availability of data in the future. These data will be reported in the 1990 Annual Site Environmental Report (ASER). Sludges, soils, and biological specimens are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater and air pathways. These analyses will be presented in the 1990 ASER.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

The groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a semi-annual basis. Monitoring well locations are shown in Figure 2-1. Data from the semiannual groundwater monitoring for the second half of 1990 are presented in this fourth quarter data summary.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples from the monitoring wells at the CP/RP/VP area. Nitroaromatic compounds were detected in twenty samples. However, the data continue to reflect levels historically found and documented in previous environmental reports.

2.1.2 Radiological Results

The radiological results for samples from wells at the WSCP/RP/VP are presented in Table 2-2. The upper bound for natural uranium background concentrations in groundwater at the WSCP/WSRP/WSVP has been determined to be 3.4 pCi/l. The EPA has not yet established drinking water standards for uranium; however, studies leading to proposed rulemaking are using uranium in the 10 to 40 pCi/l range. The U.S. Department of Energy (DOE) has a derived concentration guideline (DCG) of 550 pCi/l.

The highest uranium level detected was 74.8 pCi/l from a sample obtained from Monitoring Well 3009; however, the data is not yet available from MW-3008 which previously has indicated higher levels. The other concentrations reported in Table 2-2 continue to indicate levels below the proposed drinking water standard for uranium;

ND – Not Detected

however, several wells do indicate higher levels than historically present at those locations. The ASER will evaluate these levels and trends.

2.2 Weldon Spring Quarry

Chemical and radiological wastes at the quarry are of particular concern because of their proximity to the St. Charles County well field. The well field is located approximately one-half mile to the south. Monitoring of contaminants in groundwater and the protection of the well field is a top WSSRAP priority.

Groundwater is monitored in 30 wells in and around the quarry. Twenty-six monitoring wells installed by the U.S. Department of Energy (DOE) currently exist in or near the quarry. Four additional monitoring wells were installed by St. Charles County in 1986. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells currently draw water from both bedrock and alluvial aquifers.

Two separate groundwater monitoring programs have been developed for the quarry. The first program is a semiannual sampling of all wells north of the Femme Osage Slough. The second program monitors the area south of the Femme Osage Slough, including the St. Charles County well field. Active production wells and monitoring wells are sampled quarterly. The raw and treated waters from the St. Charles County water treatment plant are also sampled. This portion of the quarry groundwater monitoring program has been jointly developed by representatives of the DOE, the Missouri Department of Natural Resources (MDNR), the U.S. Environmental Protection Agency (EPA), and St. Charles County.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-3A and 2-3B for samples collected on semi-annual and quarterly bases, respectively. Some radiological data are not yet received from the analytical laboratory but will be included in the 1990 ASER. The results show fluctuations around the average levels in the WSQ area with no dramatic increases evident. Trend analyses will be presented in the 1990 ASER. The data in Table 2-3B also indicate no uranium levels of concern south of the slough.

2.2.2 Nitroaromatic Compounds Results

Analytical results for nitroaromatic compounds are presented in Tables 2-4A and 2-4B. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the third quarter 1990. The distribution of nitroaromatic contamination near the quarry remains unchanged.

2.2.3 Inorganic Anions Results

Four inorganic anions--nitrate, sulfate, chloride, and fluoride--were measured in quarry wells. Tables 2-3A and 2-3B display the analytical results for the fourth quarter of 1990, which are consistent with data reported in the previous environmental monitoring reports. The WSQ groundwater samples continue to indicate no significant groundwater contamination by nitrate. The groundwater samples continue to indicate background concentrations of sulfate in wells south of the Femme Osage Slough. Results of chloride analyses of groundwater south of the Femme Osage Slough continue to indicate background concentrations. Results of fluoride analyses indicate no detectable levels for fourth quarter 1990.

2.2.4 Metals Results

A selected group of quarry wells located south of the Femme Osage Slough were sampled for arsenic and barium. Analytical results for these metals are presented in Table 2-5. Results from fourth quarter analyses of arsenic and barium continue to indicate elevated concentrations in selected wells. The highest levels reported for the fourth quarter are 37.9 µg/l for arsenic in RMW-3 and 458 µg/l for barium as detected in Monitoring Well RMW-1.

3 SURFACE WATER MONITORING

Routine samples were collected during the fourth quarter of 1990 from both on-site and off-site surface water locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired.

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the fourth quarter, surface water samples were collected from the nine locations shown in Figure 3-1 and analyzed for uranium. The results, presented in Table 3-1, indicate that conditions remain similar with values within the range measured historically with the highest level (102 pCi/l) again detected at inflow to Lake 36 on the Busch Wildlife Area. Dilution and/or other factors within that lake decreased the concentration to 16.32 pCi/l at its outflow. All other values at off-site locations remain relatively low and consistent with historical values.

3.2 Weldon Spring Quarry

Surface water samples were collected from the nine locations shown in Figure 3-2 and three locations in Figure 3-3. Samples were analyzed for uranium and the results are presented in Table 3-1A. The results of all samples except the Missouri River samples indicate no apparent changes in environmental conditions, although the uranium level of the pond within the access-controlled area of the quarry was higher than in previous quarters of 1990. This level is not cause for concern. The uranium levels in the water of the quarry pond have historically fluctuated due to precipitation and dilution within that pond. The concentrations of the six nitroaromatic compounds ranged from below the detection limit to 12.0 µg/l for 2,4,6-TNT. The ponded water will be treated for nitroaromatic compounds and other organics upon completion of the quarry water treatment plant.

The fourth quarter uranium values measured in the Missouri River attract attention due to their apparent upward trend in the downstream direction. Although cause for focused attention, these values are not believed to represent a real influence from site-related uranium sources. The levels of uranium at these locations have historically fluctuated at each of the sampling locations (due to either natural fluctuations or analytical

variability) such that uranium concentrations have been higher at upstream locations than below the southeast drainage/Missouri River confluence. The U.S. Department of Energy (DOE) has increased monitoring of the Missouri River prior to the operation of the Weldon Spring Site Remedial Action Project (WSSRAP) quarry water treatment plant to ascertain the preoperational (background) levels. In addition, the National Pollution Discharge Elimination System (NPDES) permit for the quarry water treatment plant requires additional monitoring of the river. Permit monitoring will begin in 1991. This monitoring will increase the DOEs capability to ensure the safety of the public and the environment.

3.3 Springs

Eleven springs around the Weldon Spring site (WSS) are sampled quarterly (see Figure 3-4 for spring locations). Previous spring monitoring indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs are SP-6301, SP-6302, SP-6306, and SP-5301 through SP-5304. All spring samples are analyzed for uranium.

3.3.1 Uranium

The levels of uranium measured in the springs are consistent with values measured at those locations and drainages in the past. Table 3-1 presents the results of fourth quarter uranium analyses.

3.4 National Pollutant Discharge Elimination System Data Review

Surface water and effluent samples were collected and analyzed in compliance with the Weldon Spring Site National Pollutant Discharge Elimination System (NPDES) permit. This permit (Number MO-0107701) was issued in November 1988 and addresses storm water and wastewater discharges. Six discharge points or outfalls included in this permit are shown in Figure 3-5. Outfalls NP-0001 through NP-0005 represent surface water discharge and NP-0006 represents the treated effluent discharge associated with the administration building sanitary wastewater treatment plant. Currently NP-0006 is the only outfall with effluent limitations. The five surface water outfalls have monitoring requirements only. Fourth quarter 1990 analytical data for each outfall is presented in Table 3-3.

Radiological Analysis

Gross Alpha and Total Uranium analyses correspond well with 1989 data. The highest uranium levels were present at NP-0005 (surface flow from the southeast portion of the site combined with discharge from NP-0001) followed by NP-0001 (discharge from the process sewer). These relatively higher levels are consistent with 1989 data. Maximum values for uranium were 381 pCi/l at NP-0001 and 551 pCi/l at NP-0005.

Other outfalls exhibited the following range of uranium concentrations. NP-0002, the drainage from the Frog Pond area, ranged from 10.2 pCi/l to 190 pCi/l. NP-0003, drainage from the Ash Pond diversion, ranged from 8.16 pCi/l to 88.4 pCi/l. A uranium concentration of 4.2 was present in the fourth quarter sample collected from NP-0004, raffinate pit No. 4 area.

Other Analysis

Other analyses include physical analysis (settleable solids and suspended solids) and chemical analysis (nitrate, pH, and lithium). Fourth quarter 1990 values generally correspond to 1989 values for the majority of parameters.

The discharge from the administration building treatment plant, NP-0006, has effluent limitations for quarterly samples. In addition to this quarterly monitoring, the subcontractor monitors the same parameters monthly, to assess plant performance. Outfall NP-0006 is the discharge for the site administration building wastewater treatment facility. The NPDES permit contains effluent limitations on biochemical oxygen demand (BOD), total suspended solids (TSS), and fecal coliform at this outfall. These limits are 15 mg/l (BOD), 10 mg/l (TSS), and 400 colonies/100 ml (fecal coliform). NPDES permit limits were exceeded in fourth quarter 1990 at this outfall. The fecal coliform value for December 5 was 7000 colonies/100 ml. This was due to removal of additional chlorine in the chlorine contact chamber by the Subcontractor. This was done at the direction of Missouri Department of Natural Resources (MDNR) due to a concern that excess residual chlorine might be present in the effluent. The Subcontractor has since replaced this additional chlorine in a more acceptable manner resulting in a return to compliance for fecal coliform levels, while maintaining a minimal level of residual chlorine.

4 AIR MONITORING

4.1 Radon Gas

The radon gas monitoring program utilizes a pair of radon detectors at each of 22 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, six locations at the Weldon Spring quarry, four locations at the Weldon Spring raffinate pits, and six off-site locations. Radon monitoring locations are shown in Figures 4-1, 4-2, and 4-3. On-site detectors are spaced around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, and RD-4006 were used to monitor background levels near the site.

Table 4-1 summarizes the quarterly and year-to-date average radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in Table 4-1 is a comparison of the measured year-to-date average concentration with the Federally permitted radon concentration for unrestricted areas of 3 pCi/l (110 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the four background locations. This data yielded a year-to-date average ambient background radon concentration of 0.17 pCi/l for the first three quarters of 1990. This concentration was then subtracted from the year-to-date average concentration for each monitoring station, and compared to the DOE guideline of 3 pCi/l above background.

Radon concentrations at the site perimeter and at off-site locations for the fourth quarter of 1990 were within the typical range expected during years of normal precipitation. The quarterly radon concentrations (background included) ranged from 0.1 pCi/l at two locations to 1.7 pCi/l at monitoring location RD-1002.

Radon concentrations found in the quarry are higher than concentrations measured at other locations because the radium concentrations in quarry wastes are typically much higher than other areas, and because the quarry is a large depression in the terrain with side walls ranging from 3 to 15 meters (10 to 50 feet) high. In conjunction with stable

(a) Results include natural background.
(b) Percent of guideline calculated by taking the year-to-date average minus the average of the background stations divided by the DOE concentration guideline for RN-222 is 3 pCi/l (100 Bq/m^3)(Annual average above background) for uncontrolled areas.
* DENOTES BACKGROUND STATION

meteorological conditions, this configuration tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

4.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, 22 monitoring stations using spherical environmental thermoluminescent dosimeters (TLDs) were deployed. The monitoring station locations are the same as the ambient radon monitoring locations (see Section 4.1).

Table 4-2 summarizes the quarterly and year-to-date results of total gamma radiation monitoring at the 16 Weldon Spring site (WSS) perimeter monitoring stations, Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the four background monitoring stations.

The yearly average background gamma exposure as measured with TLDs in 1989 was 68 mR/year. The yearly average background gamma exposure as measured with TLDs in 1990 was 62 mR/year. This corresponds to 1989 monitoring results and was expected because no significant changes in the configuration or location of the wastes have occurred.

Due to external vandalism, the fourth quarter TLDs were missing for monitoring stations TD-3004, and TD-4005. In order to calculate a year-to-date total gamma exposure rate, the missing quarterly data were replaced with the average of the remaining quarterly TLD results for those monitoring stations.

4.3 Radioactive Air Particulates

Eleven air particulate samplers monitor the Weldon Spring site. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter as shown in Figure 4-3. Three monitoring stations (AP-4006, AP-4008, and AP-4011) are located off site at sensitive receptor locations, including Francis Howell High School, the Army Reserve property, and a residential site west of the quarry. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown in Figure 4-4.

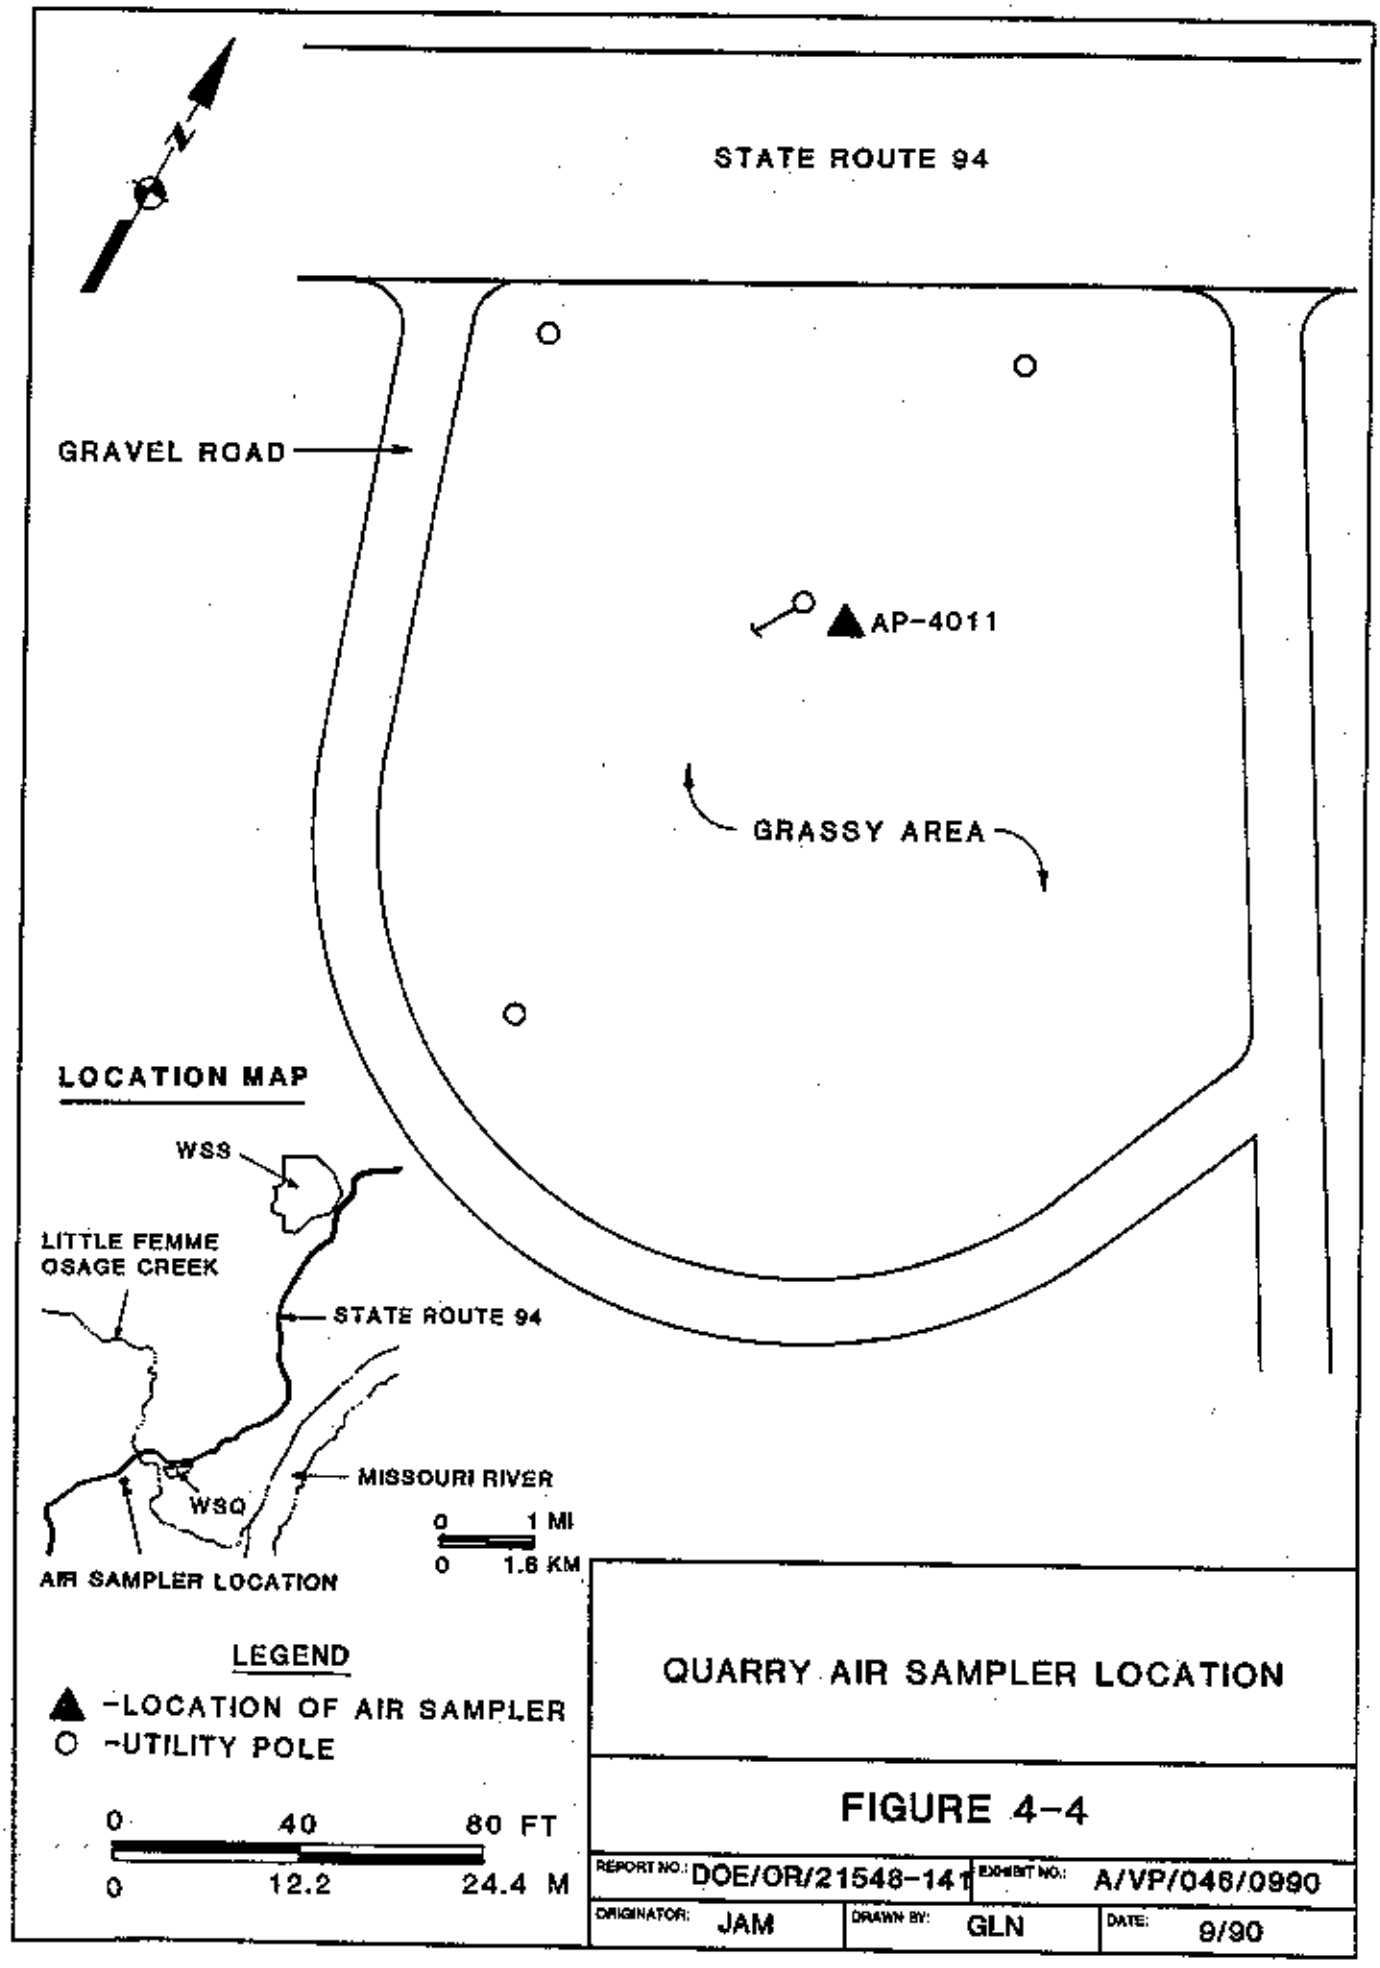
* Denotes background station.

(b) Year-to-date totals for locations where some quarterly data is unavailable were calculated using the average of the existing quarterly data in place of the unavailable data. Due to rounding of values, the sum of the quarterly data may not equal the year-to-date total.



QUARRY AIR SAMPLER LOCATION

FIGURE 4-4

REPORT NO.: DOE/OR/21548-141		EXHIBIT NO.: A/VP/046/0990	
ORIGINATOR: JAM	DRAWN BY: GLN	DATE: 9/90	

The sampling station near the August A. Busch Wildlife Area (ABWA) headquarters is used as a background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/ Weldon Spring raffinate pits (WSRP). In addition, winds from the southeast are relatively rare at the WSCP.

Table 4-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging either the weekly air particulate analysis results or the counting instrument's lower limit of detection (LLD), whichever was greater. The "<" sign in Table 4-3 appears when the actual average is less than the calculated average due to the use of LLD values in the calculation. Locations AP-1009 and AP-1010 were not in operation for five weeks due to vandalism. All of the other measurements at the two locations were above the LLD values. The standard deviation for each of the monitoring locations was calculated using only results that were above the LLD.

The third quarter net alpha concentrations ranged from $<1.34 \times 10^{-15}$ µCi/ml to 2.12×10^{-15} µCi/ml with $<1.69 \times 10^{-15}$ µCi/ml detected at the background station.

4.4 Asbestos

Air sampling for asbestos has been performed on a routine basis for two years. The monitoring data indicate no elevated levels of airborne asbestos during both asbestos abatement operations and during periods when no asbestos activities were in progress at the site. Since asbestos removal and handling operations were not in progress during the third quarter, perimeter asbestos sampling was not performed. Upon commencement of any additional asbestos abatement activities, asbestos air particulate monitoring will resume.

TABLE 4-3 Radiological Air Particulate 1990

MONITOR IDENTIFICATION NUMBER	ANNUAL AVG. CONCENTRATION (1E-15 µCi/ml)	STANDARD DEVIATION	NUMBER OF VALUES ABOVE LLD

ADDRESSEES:

QUARTERLY ENVIRONMENTAL DATA SUMMARY FOR THE FIRST QUARTER, 1991 FOR THE WELDON SPRING SITE REMEDIAL ACTION PROJECT

Enclosed for your information and use is a copy of the Quarterly Environmental Data Summary Report. The document summarizes the environmental monitoring data for the first quarter, highlights any potentially significant findings, and offers preliminary interpretations. Final interpretations will appear in the 1991 Annual Site Environmental Report.

The report concludes that no significant differences or changes in off-site exposures resulting from Weldon Spring Site contaminates have occurred during this reporting period.

If you have any questions please call Ken Lawver at (314)441-8978.

Sincerely,

Stephen H. McCracken
Project Manager

ABSTRACT AND WELDON SPRING SITE QUARTERLY SELF ASSESSMENT FIRST QUARTER 1991

The purpose of this Quarterly Environmental Data Summary is to provide preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1991 Annual Site Environmental Report.

This report includes data from environmental monitoring activities at the Weldon Spring site (WSS) during the first quarter of 1991. Groundwater, surface water, and air were sampled in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to calculate exposure doses (where applicable) and assess the impact of the contaminants at the site on potentially exposed populations.

In summary, significant differences were observed in off-site exposures during the first quarter of 1991 relative to exposures calculated in previous quarters. Contaminated groundwater did not affect private water supplies or the St. Charles County well field. Surface water containing elevated uranium activity continued to impact the Femme Osage Slough and several lakes in the August A. Busch Memorial Wildlife Area. Off-site gamma, radon and air particulate exposures remained indistinguishable from background. Off-site monitoring demonstrated that exposure levels at the Francis Howell High School, the Busch Wildlife Area Headquarters, and the Weldon Spring Training Area remain indistinguishable from background levels.

1 INTRODUCTION

This document is the fourth in a series of documents designed to provide a summary of the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These documents supplement the *Annual Site Environmental Report* (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP Environmental Monitoring Plan and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from observations made in previous reports. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1991 ASER. It is recommended that interested readers refer to previous Environmental Monitoring Plans (EMPs), ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters are tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at 314-441-8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). However, because of delays in data delivery from the analytical laboratories, some of the data that was expected to be included in this report are not yet available for reporting. The unavailability of data is due to a nationwide shortage in analytical services. The WSSRAP is taking corrective action to ensure more timely availability of data in the future. These data will be reported in the 1991 ASER. Sludges, soils, and biological specimens are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater and air pathways. These analyses will be presented in the 1991 ASER.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

The groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a semi-annual basis with the exception of MW-2001, MW-2002, MW-2003, MW-3003, MW-3006, MW-3008, MW-3009, MW-3023, MW-4012 and MW-4013 which are monitored quarterly. Monitoring well locations are shown in Figure 2-1. Data from the semiannual groundwater monitoring for the first half of 1991 will be presented in the second quarter data summary, however, data from the quarterly monitored wells are presented in each QEDS.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the quarterly monitored groundwater wells at the CP/RP/VP area. Nitroaromatic compounds were detected in seven samples. However, the data continue to reflect levels historically found and documented in previous environmental reports.

2.1.2 Radiological Results

The radiological results for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-2. The upper bound for natural uranium background concentrations in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l. The EPA has not yet established drinking water standards for uranium; however, studies leading to proposed rulemaking are using uranium in the 10 pCi/l to 40 pCi/l range. The U.S. Department of Energy (DOE) has a health based derived concentration guideline (DCG) of 600 pCi/l in surface water effluent.

ND – Not Detected

The highest uranium level detected was 49.6 pCi/l from a sample obtained from Monitoring Well 3009 adjacent to raffinate pit No. 4. The other concentrations reported in Table 2-2 continue to indicate levels below the proposed drinking water standard for uranium.

2.1.3 Geochemical Results

Geochemical results for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-3. Geochemical parameters were added to the *Environmental Monitoring Plan* for the 1991 monitoring year.

2.1.4 Inorganic Anion Results

Inorganic anion results for the quarterly monitored WSCP/RP/VP wells are shown in Table 2-2. The results reflect levels historically found in these wells.

2.2 Weldon Spring Quarry

Chemical and radiological wastes at the quarry are of particular concern because of their proximity to the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mile) to the south of the Weldon Spring quarry. Monitoring of contaminants in groundwater and the protection of the well field is a top WSSRAP priority.

Groundwater is currently being monitored in 35 wells in and around the quarry. Thirty-one monitoring wells installed by the U.S. Department of Energy (DOE) currently exist in or near the quarry, with the addition of wells MW-1035 through MW-1039 to be included in the monitoring program beginning in the second quarter, 1991. Four monitoring wells were installed by St. Charles County in 1986 and are currently included in the DOE's monitoring program. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells draw water from both bedrock and alluvial aquifers.

Two separate groundwater monitoring programs have been developed for the quarry. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough. The second program is a quarterly sampling of all wells south of the Femme Osage Slough,

including the St. Charles County well field. Both the raw and treated waters from the St. Charles County water treatment plant are also sampled. This second portion of the quarry groundwater monitoring program has been jointly developed by representatives of the DOE, the Missouri Department of Natural Resources (MDNR), and St. Charles County.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-4, 2-5, and 2-5A for samples collected on a bimonthly and quarterly bases. The results show fluctuations around the average levels in the WSQ area with no dramatic increases evident except in MW-1028 and MW-1011. MW-1028 had a level of 88.4 pCi/l during the January and February bimonthly sampling event. Previous results from this monitoring location have indicated levels less than 10 pCi/l of uranium, therefore the result of 88.4 pCi/l appears unusual. All pertinent analytical QC data has been requested from the analytical laboratory performing the analysis so that the analytical results can be validated. MW-1011 (located immediately south of the slough) indicated an unusually elevated concentration of uranium (20.4 pCi/l) during the first quarter, 1991. Through a meeting with representatives of St. Charles County and MDNR, it was decided that the DOE would pursue weekly sampling of MW-1011 and adjacent well MW-1010 and expedited analysis of the samples from that well for one month. The results of that sampling are provided in Table 2-4. The results of the weekly sampling indicate that there is no continuing, upward trend to the concentrations of uranium in the groundwater monitored by MW-1011. In fact, the last three data points represent successively lower concentrations. Throughout this incident, the uranium level in the adjacent, deeper-nested well (MW-1010) remained less than 1 pCi/l. The St. Charles County Wellfield remains safe and is not under any imminent threat from WSQ-related contamination.

The WSSRAP has increased the sampling schedule for these wells from semiannually to monthly for three months. Upon receipt of the monthly sampling results, the DOE/PMC may then assess the appropriateness of resuming the sampling schedule prescribed in the WSSRAP 1991 *Environmental Monitoring Plan*. Trend analyses for radiological results will be presented in the 1991 ASER.

2.2.2 Nitroaromatic Compounds Results

Analytical results for nitroaromatic compounds are presented in Tables 2-6 and 2-7. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the first quarter 1991. The distribution and magnitude of nitroaromatic contamination near the quarry remains unchanged.

2.2.3 Inorganic Anions Results

Two inorganic anions--nitrate and sulfate--were measured in quarry wells. Tables 2-4, 2-5, and 2-5A display the analytical results for the first quarter of 1991, which are consistent with data reported in the previous environmental monitoring reports. The WSQ groundwater samples continue to indicate no significant groundwater contamination by nitrate. The groundwater samples continue to indicate background concentrations of sulfate in wells south of the Femme Osage Slough.

2.2.4 Metals Results

A selected group of quarry wells located south of the Femme Osage Slough were sampled for cadmium, lead, and mercury in addition to arsenic and barium. Analytical results for these metals are presented in Tables 2-8 and 2-9. Results from the first bimonthly and first quarter analyses of arsenic and barium continue to indicate elevated concentrations in selected wells. The highest levels reported are 153 μg/l for arsenic in MW–1017 and 950 μg/l for barium also detected in MW-1017.

3 SURFACE WATER MONITORING

Routine samples were collected during the first quarter of 1991 from both on-site and off-site surface water and spring locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1991 ASER.

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the first quarter, surface water samples were collected from the 13 surface water sampling locations shown in Figure 3-1 and analyzed for uranium. The available results, presented in Table 3-1, indicate that conditions remain similar with values within the range measured historically with the highest level (197.2 pCi/l) detected at Frog Pond. All other values at off-site locations remain relatively low and consistent with historical values.

3.2 Weldon Spring Quarry

Surface water samples were collected from the 10 locations shown in Figure 3-2 and three locations in Figure 3-3. Samples were analyzed for uranium, arsenic, and barium and the results are presented in Tables 3-2 and 3-3. The results of all samples indicate no apparent changes in environmental conditions, although as seen in previous first quarters, the uranium levels within the slough were higher than in previous quarters. The highest measured level was 326.4 pCi/l detected at sampling location SW-1004. However, elevated levels of uranium in the slough have been observed in previous years during March, April, and May. This phenomenon is thought to be the result of the annual spring thaw. As the ground thaws, usually during February and March, an increase in groundwater movement transports uranium to the slough. The effect may be enhanced by the fact that more uranium is dissolved from the soil during the freeze/thaw process due to longer soil/water contact times. The elevated levels in the slough are not detected until March, April, or May because of the time required for uranium to reach the slough via groundwater transport. To better understand uranium concentrations in the slough, the frequency of sampling and analysis is being increased from quarterly to monthly.

The first quarter uranium values measured in the Missouri River were lower than the values detected during the previous quarter. Historically, the levels of uranium at these locations have fluctuated (due to either natural fluctuations or analytical variability) such that uranium concentrations have been higher at upstream locations than downstream, and vice versa. The U.S. Department of Energy (DOE) has increased monitoring of the Missouri River prior to the operation of the Weldon Spring Site Remedial Action Project (WSSRAP) quarry water treatment plant to ascertain the preoperational (background) levels in the river. In addition, the National Pollution Discharge Elimination System (NPDES) permit for the quarry water treatment plant requires additional monitoring of the river. This monitoring increases the DOEs capability to ensure the safety of the public and the environment.

Arsenic and barium results indicate that arsenic within the Missouri River is at levels well below the National Primary Drinking Water Standards (slightly above the detection limit) and barium found in all samples is within the background range and well below the National Primary Drinking Water Standard.

The analytical results for the six nitroaromatic compounds within the quarry slump were not available at the time of this report. The ponded water is to be treated for nitroaromatic compounds and other organics upon completion of the quarry water treatment plant.

3.3 Springs

Eleven springs around the Weldon Spring site (WSS) are sampled quarterly (see Figure 3-4 for spring locations). Previous spring monitoring indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs are SP-6301, SP-6302, SP-6306, and SP-5301 through SP-5304. All spring samples are analyzed for uranium with a select few analyzed for nitroaromatics, inorganics and metals. Analytical results for these parameters are listed in Tables 3-4, 3-5, 3-6, and 3-7. Values for these parameters remain consistent with their historical values.

3.4 National Pollutant Discharge Elimination System Data Review

Surface water and effluent samples were collected and analyzed in compliance with the Weldon Spring Site National Pollutant Discharge Elimination System (NPDES) permit.

This permit (Number MO-0107701) was issued in November 1988 and addresses storm water and wastewater discharges. The six discharge points or outfalls included in this permit are shown in Figure 3-5. Outfalls NP-0001 through NP-0005 represent storm water discharge and NP-0006 represents the treated effluent discharge associated with the administration building sanitary wastewater treatment plant. Currently NP-0006 is the only outfall with effluent limitations. The five surface water outfalls have monitoring requirements only. First quarter 1991 analytical data for each outfall is presented in Table 3-8.

Radiological Analysis

Gross Alpha and Total Uranium analyses correspond reasonably well with past data. The highest uranium levels were present in surface flow from the southeast portion of the site (NP-0005) and surface flow for the northwest area of the site (NP-0003). The peaks for these points were 2244 pCi/l and 3400 pCi/l, respectively.

Other outfalls exhibited the following range of uranium concentrations. NP-0002, the drainage from the Frog Pond area, ranged from 97 pCi/l to 197 pCi/l. NP-0001, (process sewer) was measured at 816 pCi/l. A uranium concentration of 9.5 pCi/l was present in the sample collected from NP-0004, behind raffinate pit No. 4.

Other Analysis

Other analyses include physical analysis (settleable solids and suspended solids) and chemical analysis (nitrate, pH, and lithium). First quarter 1991 values generally correspond to past values for the majority of parameters.

The discharge from the administration building treatment plant, NP-0006, has effluent limitations for quarterly samples. In addition to this quarterly monitoring, the subcontractor monitors the same parameters monthly, to assess plant performance. The NPDES permit contains effluent limitations on biochemical oxygen demand (BOD), total suspended solids (TSS), and fecal coliform at this outfall. These limits are 15 mg/l (BOD), and 20 mg/l (TSS), for weekly averages with maximum daily fecal coliform of 1000 colonies 1100 ml. NPDES permit limits were exceeded in the first quarter 1991 at this outfall. The BOD standard was exceeded in February. The cold months showed higher values due to upsets intensified by weather.

4 AIR MONITORING

4.1 Radon Gas

The radon gas monitoring program utilizes a pair of radon detectors at each of 22 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, six locations at the Weldon Spring quarry, four locations at the Weldon Spring raffinate pits, and six off-site locations. Radon monitoring locations are shown in Figures 4-1, 4-2, and 4-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, and RD-4006 were used to monitor background levels near the site.

Table 4-1 summarizes the first quarter 1991 radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in Table 4-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (110 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the four background locations. This data yielded an average ambient background radon concentration of less than 0.1 pCi/l for the first quarter of 1991. This concentration was then subtracted from the concentration for each monitoring station, and compared to the DOE guideline of 3 pCi/l above background.

Radon concentrations at the site and quarry perimeters and at off-site locations for the first quarter of 1991 were within the typical range expected during years of normal precipitation. The quarterly radon concentrations (background included) ranged from less than 0.1 pCi/l at 10 locations to 0.9 pCi/l at monitoring location RD-1002.

Radon concentrations found in the quarry are higher than concentrations measured at other locations because the radium concentrations in quarry wastes are typically much higher than other areas, and because the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high. In conjunction with stable meteorological

* Denotes Background Station

conditions, this configuration tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

4.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, spherical environmental thermoluminescent dosimeters (TLDs) were deployed at 22 locations. The gamma monitoring station locations are the same as the ambient radon monitoring locations (see Section 4.1).

Table 4-2 summarizes the quarterly and year-to-date results of total gamma radiation monitoring at the 16 Weldon Spring site (WSS) perimeter monitoring stations, Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the four background monitoring stations.

The annual average background gamma exposures measured with TLDs in 1989 and 1990 were 68 mR/year and 62 mR/year, respectively. The gamma exposures measured with TLDs in the first quarter of 1991 were consistent with 1989 and 1990 data. This was expected because no significant changes in the configuration or location of the wastes have occurred.

4.3 Radioactive Air Particulates

Eleven air particulate samplers monitor the Weldon Spring site. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter as shown in Figure 4-3. Three monitoring stations (AP-4006, AP-4008, and AP-4011) are located off site at sensitive receptor locations; including Francis Howell High School, the Army Reserve property, and near a residential site west of the quarry. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown in Figure 4-2.

(a) Results include natural background.
- Denotes loss of TLD.
* Denotes background station.

The sampling station near the August A. Busch Wildlife Area (ABWA) headquarters is used as a background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/ Weldon Spring raffinate pits (WSRP). In addition, winds from the southeast are relatively rare at the WSCP.

Table 4-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging either the weekly air particulate analysis results or the counting instrument's lower limit of detection (LLD), whichever was greater. The "<" sign in Table 4-3 appears when the actual average is less than the calculated average due to the use of LLD values in the calculation. The standard deviation for each of the monitoring locations was calculated using only results that were above the LLD. Locations AP-2005 and AP-4011 were not in operation for one and two weeks respectively, due to maintenance.

The first quarter net alpha concentrations ranged from 1.24×10^{-15} μCi/ml to 1.98×10^{-15} μCi/ml with $< 1.50 \times 10^{-15}$ μCi/ml detected at the background station.

4.4 Asbestos

Air sampling for asbestos has been performed on a routine basis for three years. The monitoring data indicate no elevated levels of airborne asbestos during both asbestos abatement operations and during periods when no asbestos activities were in progress at the site. Since asbestos removal and handling operations were in progress during the first quarter 1991, perimeter asbestos sampling was performed. The results of asbestos analyses during the first quarter of 1991 were below the standard of 0.01 f/cc. Asbestos Analyses results are shown in Table 4-4.

EXECUTIVE SUMMARY

The Weldon Spring Site Remedial Action Project (WSSRAP) Annual Site Environmental Report for 1990 is the fifth in a series of annual reports produced by the WSSRAP since 1986. It reports the results of a comprehensive, year-round program to monitor the impact of the Weldon Spring site (WSS) on the surrounding region's groundwater, surface waters, and air quality through multiple pathways as well as monitoring for potential exposure to receptor human populations. Information is also presented on the environmental monitoring quality assurance program, waste management activities, audits and reviews, and special environmental studies.

Data are included for both the Weldon Spring Chemical Plant and raffinate pits areas and the Weldon Spring quarry area. Based upon the WSSRAP's consistent exercise of quality assurance measures, in the form of both standard operating procedures and quality control sample collection, the WSSRAP asserts that the data presented in the WSSRAP Annual Site Environmental Report for 1990 (ASER) accurately reflect the environmental conditions monitored at the WSS. This ASER presents narratives, summaries, and conclusions on environmental monitoring at the subject areas and surrounding vicinity properties for the entire 1990 monitoring year. The WSSRAP also initiated a quarterly data reporting mechanism in 1990. All routine monitoring data are tabulated and presented in quarterly reports, which allows for timely public review and avoids the delays associated with final issuance of the annual report.

SCOPE AND PURPOSE

While the annual report documents environmental conditions, effluents, emissions, and monitoring results; its ultimate concern is with potential impacts to human health and the environment. To this end, contaminant levels are reported both in absolute terms and in relation to discharge limits established by State and Federal regulatory bodies according to existing national and international guidelines and standards designed to protect human health and the environment.

The WSSRAP monitoring program provides a thorough and systematic ongoing assessment to ensure compliance with State and Federal regulations. The environmental

data also provide a yardstick for measuring improvement in environmental conditions resulting from remedial actions.

The environmental management programs at the WSSRAP ensure that environmental releases from the site are at levels demonstrably and consistently "as low as reasonably achievable". This is being done concurrently with site remediation and contaminant clean-up through the course of the U.S. Environmental Protection Agency's (EPA) environmental documentation process under the Comprehensive Environmental Response Compensation, and Liability Act (CERCLA).

Therefore, the effluent and environmental monitoring program must (1) serve as an effective early indicator that detects and provides the data required to assess potentially adverse discharges and impacts, and (2) provide for continuing, regular verification of compliance with applicable State and Federal permits and regulations.

Routine monitoring for radiation, radioactive materials, and chemical substances on and off the WSS is an important tool to document compliance with appropriate standards, and to identify undesirable trends. Additionally, the monitoring programs provide information to the public in the St. Charles and St. Louis, Missouri areas, and contribute to the general scientific database of knowledge on the environmental effects of radiological and chemical substances.

MONITORING NETWORKS

The data reported in the ASER have been collected from a growing complex of monitoring stations and a routine sampling program supplemented by the following:

- An air monitoring network of 22 stations located within and on the perimeters of the two operable remedial units of the site, and at critical receptor locations around the WSS.

- Six National Pollutant Discharge Elimination System (NPDES) locations and over 25 surface water sampling locations.

- Twenty-two locations for measuring external gamma radiation.

- Groundwater monitoring networks consisting of nearly 100 groundwater monitoring wells and piezometers.

- Dozens of soil and ground surface scanning locations for potential direct contact exposure.

- An on-site meteorological monitoring station.

STATE AND FEDERAL REGULATIONS

The WSSRAP regulatory environment is multifaceted and complex. Therefore, the U.S. Department of Energy (DOE) and its Project Management Contractor (PMC), MK-Ferguson Company, have established complementary monitoring and reporting systems for responding to all applicable regulatory requirements. Modifications to improve these systems continue. The systems ensure compliance with legislation, regulations, and standards associated with the Clean Air Act; the Clean Water Act; the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA); the Resource Conservation and Recovery Act (RCRA); Superfund Amendments Reauthorization Act (SARA); and the Atomic Energy Act. These regulations and standards are enforced by the Environmental Protection Agency (EPA), the Missouri Department of Natural Resources (MDNR), and other Federal, State and local agencies.

SUMMARY AND CONCLUSIONS:

In 1990, the WSSRAP continued to adhere to its mission of environmental protection and site remediation. The DOE is pursuing the Weldon Spring Site Remedial Action Project as a coordinated effort among the DOE, the EPA, the MDNR, and others.

Comprehensive environmental monitoring data for 1990 show that emissions of radiological contamination from the WSS continue to decrease, and contaminant migration pathways and environmental variability are better understood.

The calculated total radiation dose to a hypothetical maximally exposed individual from the WSCP/WSRP was less than 1 mrem (0.01 mSv). The calculated total radiation dose from the WSQ to a maximally exposed individual was 3.9 mrem (0.055 Msv). The

calculated total radiation dose to a hypothetical maximally exposed individual for the vicinity properties was less than 1 mrem.

The collective dose equivalent estimate for 1990 is less than 0.018 person-rem for an estimated exposed population of 72,000 persons. Section 4.1.8 of the report describes the assessment of collective population dose.

Additional investigations are underway to further characterize environmental conditions and contaminant distributions; these investigations will support planning for the next stage of remedial action. Waste consolidation and water treatment plant construction are examples of the efforts undertaken.

Total costs associated with the environmental and remedial activities at the WSS for 1990 were approximately $16.1 million. Remedial action at the WSS is presently slated to continue through the year 2000.

The 1990 environmental report pays particular attention to the following areas of health and environmental concern: Airborne discharges of radionuclides and air particulates; waterborne discharges and surface water monitoring; external gamma exposure levels; meteorological measurements and potential chemical and radiation exposures to the surrounding public and public-use areas. Key results by sampling program are highlighted below.

GROUNDWATER

Groundwater at the WSSRAP is monitored at least semiannually for total natural uranium, nitroaromatic compounds, and inorganic anions in all monitoring wells at the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and at the Weldon Spring quarry (WSQ). The groundwater monitoring network for the WSCP/RP/VP area consists of 59 monitoring wells. The monitoring network at the WSQ consists of 26 DOE monitoring wells, four St. Charles County monitoring wells, eight St. Charles County production wells, and the St. Charles County Water Treatment Plant.

Overall, the 1990 groundwater analytical results for samples at the WSCP/RP/VP and the WSQ are consistent with previous monitoring. The analytical results for 1990 did

indicate uranium concentrations slightly above background levels over a larger area than indicated in previous years. Although these slightly higher levels are believed to be due in part to laboratory contamination, as evidenced by contamination of water blanks collected during the monitoring year, the WSSRAP will focus attention on the situation during the 1991 monitoring year.

SURFACE WATER

During 1990, surface water and spring monitoring involved the collection of samples for radiological and chemical parameters from a total of 35 locations. Radiological parameters included uranium, thorium, and radium. Chemical parameters included chloride, fluoride nitrate, sulfate and nitroaromatic compounds. All results were near or within their historical range of values. However, results also indicate that uranium continues to migrate from the site at relatively low levels in surface water and springs along known discharge pathways. Concentrations for both chemical and radiological parameters at the monitoring locations fluctuated due to seasonal and climatic effects.

An analysis for trends of uranium concentrations in surface water was performed for the site and the quarry area to compare with previous years' monitoring results. No trends were evident at the site other than fluctuations due to seasonal effects. The quarry area (Femme Osage Slough) indicated a possible trend; as uranium increased from 1987 to 1989, but then decreased during 1990 at most of the surface water locations. This is believed due to the effects of drought conditions on the concentrations in the slough during the 1988-89 period, followed by normal precipitation levels during 1990 which affected dilution.

EFFLUENT MONITORING (NPDES)

Surface water effluents from the WSS during 1990 were primarily due to precipitation runoff. The WSSRAP maintains discharge permits under the National Pollutant Discharge Elimination System (NPDES). During 1990, the permit at the WSCP applied to one sanitary discharge point and five stormwater discharge points or outfalls. The five monitored outfalls that discharge precipitation runoff are subject to monitoring requirements only under the permit. The sixth outfall (administration building's treated sanitary effluent) is subject to specific discharge limits.

During 1990, the five storm water outfalls maintained levels that corresponded with prior year values. Sampling was performed on three occasions when flows were not representative of normal storm water flows. These three sampling events were performed during water release which was not associated with precipitation. Some abnormal levels of monitored constituents were detected in the discharge associated with these events. Section 4.2.4 further explains the 1990 discharge history.

The sanitary wastewater outfall was monitored for comparison to effluent limitations for biochemical oxygen demand (BOD), total suspended solids (TSS), and fecal coliform. NPDES permit levels were exceeded twice in 1990 at this outfall. Operational adjustments and repairs to the treatment plant were performed by the operating subcontractor and levels returned to within the range of the compliance limits.

GAMMA RADIATION MONITORING

To monitor exposure from gamma radiation, 22 permanent monitoring stations using spherical environmental thermoluminescent dosimeters (TLDs) were utilized. Monitoring stations are located at the WSCP, WSRP, WSQ and at off-site locations. None of the monitoring stations around the WSCP, the WSRP, or at the off-site locations detected gamma radiation levels above background, at a 95% confidence level. Two of the six stations around the quarry were statistically greater than background levels, although the measured exposure rate was less than the DOE guideline of 100 mrem/yr above background levels.

RADON GAS MONITORING

The radon gas monitoring program at the WSSRAP utilizes two radon gas detectors (track etch cups) at each of 22 permanent locations. These detectors are situated at the same locations as the above referenced gamma TLDs. The WSSRAP has concluded that none of the stations at the WSCP, the WSRP, or at off-site areas measured levels above background.

The results for the WSQ did indicate measurable levels above background. These measurable levels are due to the higher radium concentrations within the quarry; the contours of the terrain within and around the quarry; and the effects of those contours on

wind direction within the quarry. The concentrations released were below the DOE guidelines of 3 pCi/l annual average above background.

RADIOACTIVE AIR PARTICULATES

Eleven samplers are utilized to monitor the gross alpha concentrations of radioactive air particulates at the WSCP, the WSRP, the WSQ, and at off site locations. The WSSRAP has concluded that no measurable levels of radioactive air particulates were detected above background levels at any stations around the WSCP, the WSRP, or at off-site stations.

The results from one station at the WSQ were statistically greater than background levels. During 1990, remediation activities at the quarry were in progress and engineering controls were in place to control dust. The calculated effective dose equivalent as a result of the above background results to a hypothetical maximally exposed individual was <1 mrem.

ABSTRACT

The Weldon Spring Site Remedial Action Project (WSSRAP) Annual Site Environmental Report for 1990 is the fifth in a series of annual reports produced by the WSSRAP since 1986. It reports the results of a comprehensive, year-round program to monitor the impact of the Weldon Spring site (WSS) on the surrounding region's groundwater, surface waters, and air quality through multiple pathways as well as monitoring for potential exposure to receptor human populations. Information is also presented on the environmental monitoring quality assurance program, waste management activities, audits and reviews, and special environmental studies.

While the annual report documents environmental conditions, effluents, emissions, and monitoring results; its ultimate concern is with potential impacts to human health and the environment.

The WSSRAP monitoring program provides a thorough and systematic ongoing assessment to ensure compliance with State and Federal regulations. The environmental data also provide a yardstick for measuring improvement in environmental conditions resulting from remedial actions.

The data reported in the ASER have been collected from a growing complex of monitoring stations and a routine sampling program supplemented by the following:

- An air monitoring network of 22 stations located within and on the perimeters of the two operable remedial units of the site, and at critical receptor locations around the WSS.
- Six National Pollutant Discharge Elimination System (NPDES) locations and over 25 surface water sampling locations.
- Twenty-two locations for measuring external gamma radiation.
- Over 100 groundwater monitoring wells and piezometers.
- Dozens of soil and ground surface scanning locations for potential direct contact exposure.
- An on-site meteorological monitoring station.

Comprehensive environmental monitoring data for 1990 show that emissions of radiological contamination from the WSS continue to decrease, and contaminant migration pathways and environmental variability are better understood.

1 INTRODUCTION

This report presents the findings of the environmental monitoring program conducted at the Weldon Spring site (WSS) in 1990. The report presents summary environmental data, discusses compliance with environmental standards, and highlights significant programs and efforts undertaken at the WSS. Annual environmental monitoring reports have been prepared for this site (or portions thereof) since 1981. The WSS is part of the U.S. Department of Energy (DOE) Surplus Facilities Management Program (SFMP), one of the remedial action programs under the direction of the Office of Environmental Restoration and Waste Management. The WSS is comprised of the Weldon Spring raffinate pits (WSRP), the Weldon Spring Chemical Plant (WSCP), and the Weldon Spring quarry (WSQ). These areas encompass 20.7, 67.2 and 3.6 ha (51, 166, and 9 acres), respectively. The WSRP and WSCP areas are contiguous. The WSQ is approximately 6.4 km (4 mi) to the south-southwest of the site.

When custody of the WSCP was transferred in 1985 from the U.S. Department of the Army (DA) to the DOE, the WSCP became part of the WSS. In conjunction with this transfer, the Weldon Spring Site Remedial Action Project (WSSRAP) was created as DOE Major Project Number 182 (DOE Order 4240.1E - 05/14/85). Consistent with the DOE environmental restoration mission, the WSSRAP will eliminate potential hazards to the public and the environment and make surplus real property available for other uses.

DOE Order 5400.1, *General Environmental Protection Program* requires that an environmental radioactivity monitoring program be maintained at existing sites and, as determined on a case-by-case basis, at certain former sites to determine:

- Background levels and site contribution of radioactivity and other pollutants from DOE operations to the site environs.

- Compliance with applicable and appropriate environmental standards for radioactivity and other pollutants specified by the DOE and the U.S. Environmental Protection Agency (EPA).

- Compliance with environmental commitments in official documents such as environmental impact statements and Federal Facility Agreements (FFA).

This DOE Order also requires a listing of environmental permits. Existing permits and compliance with those permits is discussed in Section 2 of this report.

This *Annual Site Environmental Report* is the DOE's vehicle for documenting the results of its extensive monitoring program at the WSSRAP. The report provides the public and concerned regulatory agencies with summary level discussions regarding the routine environmental monitoring program. It explains how the WSSRAP effluent monitoring program meets the requirements of the National Pollution Discharge Elimination System (NPDES) program and compares the measured contaminant levels to applicable standards. Further, the report indicates whether changes are occurring in contaminant distribution or contaminant source conditions on and around the site--changes which might equate to variations in potential exposure scenarios to the public or environmental receptors.

Environmental monitoring is the WSSRAP's most effective means by which to assess the impacts from the site. The data and evaluations contained in the report provide the summary of that monitoring for 1990. Section 4 reports results of the contaminant level measurements and compares the environmental levels of radioactivity and chemical contaminants released from the site with applicable standards. Quarterly data are presented in Appendix A.

In addition to the routine environmental monitoring conducted in 1990, a number of related activities and special studies were performed. These activities and studies are directly applicable to the assessment of the overall impact of site operations on the environment. Therefore, these activities are described and the results are discussed in Section 7.

Section 4 presents the results of calculations, based on the 1990 sampling results, of the maximum radiation dose to a hypothetical maximally exposed individual at the WSCP/WSRP and WSQ areas. Calculations of the doses to the general population in the vicinity of the WSS are also reported.

Appendix B contains trend analyses figures for groundwater wells. For definitions of selected terms used in this report, the reader may consult Appendix C. Although each acronym used in this report is defined when it is first used in each main section, a list of all abbreviations used is provided in Appendix D. Appendix E presents a discussion of the

environmental guidelines that apply to the monitoring program. Appendix F provides a useful conversion table, Appendix G is Dose Assessment Calculations and Appendix H is the distribution list for this report.

1.1 Location and Description

The WSS is located in St. Charles County, Missouri, about 48 km (30 mi) west of St. Louis. The WSRP and WSCP areas are reached from Missouri State Route 94, 3.2 km (2 mi) southwest of the junction of Route 94 and U.S. Route 40/61. The WSQ is also reached from Route 94, 6.4 km (4 mi) south-southwest of the WSRP and WSCP areas. The Missouri River is located approximately 2.4 km (1.5 mi) southeast of the WSRP and WSCP areas and 1.6 km (1 mi) east of the WSQ. The Mississippi River lies approximately 22 km (14 mi) northeast of the WSRP and WSCP areas and roughly 29 km (18 mi) northeast of the WSQ. The general locations of these properties are illustrated in Figure 1-1.

Uranium and thorium residues, waste materials, and contaminated rubble are stored at the WSS. In addition to environmental monitoring, engineering activities are being conducted to minimize the migration of contaminants from these facilities into surface water and groundwater.

Additional characterization activities have been conducted at the WSCP and WSRP during 1990. These activities provide information on the types and magnitudes of the contamination. The complete picture of characterization information has been presented in the Draft WSSRAP Remedial Investigation (RI) report issued to EPA in 1990 and scheduled for completion in 1991. This information will be used to evaluate the course of remedial actions.

Brief descriptions of each major area of the site are given below.

Weldon Spring Raffinate Pits

Figure 1-2 is map of the WSCP/WSRP area. The 20.7-ha (51-acre) area includes four pits that cover approximately 10.5 ha (26 acres). The raffinate pits were constructed by excavating into the existing clay soils and using the removed clay for construction of dikes. These pits contain radioactive residues (raffinates) from uranium and thorium processing

operations at the former Weldon Spring Uranium Feed Materials Plant (WSUFMP) which is now the WSCP.

Access to the area is controlled by a 2.1-m (7-ft) high fence that encloses the DOE property. In addition, each pit is enclosed by a fence at least 1.3 m (4 ft) high. All drains and transfer lines from the pits to the WSCP process sewer have been sealed (Ficker 1981). During the 1990 monitoring year, surface water covered the vast majority of the residues in the pits.

Weldon Spring Chemical Plant

The 67.2-ha (166-acres) WSCP is located to the north and east of the WSRP area (Figure 1-2). The WSCP, which operated as the WSUFMP until 1966, comprises 13 major buildings and 27 smaller buildings. Of the former, five were used as process buildings, and eight were major support buildings. The entire site is fenced. Access is controlled at a manned gate-house and site security continues to be maintained by guards periodically patrolling the site 24 hr/day.

The interiors of the eight major support buildings are heavily contaminated with uranium that is mostly "fixed" on surfaces. The rest of the buildings contain only small quantities of uranium contamination.

Surface water runoff from the WSCP drains primarily along three corridors. These include the natural drainageways leading to Ash Pond and Frog Pond, and the complex of tributaries which exits the site to the southeast. Surface water drains into these ponds and drainageways where it transports uranium off-site.

Chemically hazardous substances are also present both in the buildings and as contamination in the soil in several areas of the site. These substances include asbestos, polychlorinated biphenyls (PCBs), nitroaromatic compounds, ammonia, hydrofluoric acid, sulfuric acid, and nitric acid. The data on these substances and their impacts to the environment will be detailed in the previously mentioned Remedial Investigation (RI) report.

Weldon Spring Quarry

The WSQ, an abandoned 3.6-ha (9-acres) limestone quarry, is located approximately 6.4 km (4 mi) south-southwest of the WSRP/WSCP area. As shown in Figure 1-3, the WSQ is accessible at both the upper and lower levels from Missouri State Route 94. The WSQ is essentially a closed basin; surface water within the rim flows to the quarry floor and into a pond which covers approximately 0.2 ha (0.5 acres). The pond contains approximately 12 million liters (3 million gal) of water and is 6.1 m (20 ft) deep at its deepest point. The amount of water in the pond varies according to seasonal variations in precipitation and evaporation.

The only structures at the WSQ site are a small storage shed and a sampling platform in the pond area. Access to the site is restricted by a locked, 2.1-m (7-ft) high chain link fence. The amounts and types of wastes in the WSQ are summarized in the *Remedial Investigation Report for Quarry Bulk Wastes* (MKF and JEG 1989a).

1.2 Site History

The WSS has a complex history of production processes within its boundaries. Between 1941 and 1944, the U.S. Department of Army (DA) occupied the property (Weldon Spring Ordnance Works--WSOW) and located four of its 20 explosives production lines across the WSS area (the remaining 16 production lines were distributed across an adjacent property which is now referred to as the U.S. Army's Reserve Training Area, Weldon Spring, Missouri). The WSOW produced dinitrotoluene and trinitrotoluene (DNT and TNT) for the Allied Forces during World War II.

In 1955, 83 ha (205 acres) of the former ordnance works property was transferred to the U.S. Atomic Energy Commission (AEC) for construction of the WSUFMP. Until 1966, the AEC operated an integrated facility for the conversion of processed uranium ore concentrates to pure uranium trioxide, intermediate compounds, and uranium metal. A small amount of thorium was also processed. The wastes generated from these operations were stored in four raffinate pits on the site property.

In 1958, the AEC acquired title to the WSQ from the DA. The WSQ had been used earlier by the DA for disposal of TNT-contaminated rubble during the operation of the

WSOW. The AEC used the WSQ as a disposal area for a small amount of thorium residue, but most of the material disposed of there consisted of uranium- and radium-contaminated building rubble and soils from the demolition of a uranium ore processing facility in St. Louis.

In February 1985, the DOE proposed designating the control and decontamination of the WSRP, WSCP, and WSQ as a major project. Designation was effected by DOE Order 4240.1E dated May 14, 1985. A Project Management Contractor (PMC) for the WSSRAP was selected in February 1986. In July 1986, a DOE project office was established on site. The PMC, MK-Ferguson Company, assumed control of the WSS on October 1, 1986. The WSQ was placed on the Environmental Protection Agency's National Priorities List (NPL) in July 1987. The WSCP/WSRP was added to the NPL in March 1989.

Remedial investigations were conducted at the WSCP/WSRP area in 1988 and 1989. The investigations included characterization of the groundwater, on-site soil contamination, contaminated sediments in off-site surface drainages and lakes, surface water, and springs; the chemical and radiological characteristics of the raffinate wastes; and other smaller scale efforts. The results of each of these investigations are presented in stand-alone documents on the respective efforts and are brought together and summarized in the RI report for the WSCP/WSRP, which is in the final stage of production following agency review.

Several small-scale actions have been conducted to mitigate or eliminate conditions that pose immediate or potential threats to worker safety, public health or the environment. These have included removal of exposed friable asbestos and overhead piping, PCB electrical equipment removal, power pole and wire removal, nonprocess-building demolition, Ash Pond isolation, and containerized chemical consolidation. Section 7.2 of this report details the interim response actions (IRAs) in process or completed during 1990.

The WSSRAP evolved from a National Environmental Policy Act (NEPA) authority decommissioning and cleanup project in 1986 into a remedial action project under combined NEPA-Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) authority requiring a Remedial Investigation/Feasibility Study (RI/FS) and complete environmental documentation in July of 1987. The environmental documentation process necessary to begin the excavation of the bulk waste from the WSQ is completed.

The residual contamination within the quarry confines can be characterized when the excavation is completed.

A more detailed presentation of the production, ownership and waste history of the WSS is available in the RI reports for the WSQ and the draft WSCP/WSRP reports prepared by the DOE Project Office.

1.3 Environmental Setting

The environmental setting of the WSCP/WSRP and the WSQ are described briefly below. A more detailed description is provided in the *Work Plan for the Remedial Investigation/Feasibility Study-Environmental Impact Statement for the Weldon Spring Site, Weldon Spring, Missouri* (Peterson et al. 1988). The WSRP/WSCP area is located on the Missouri-Mississippi River surface-drainage divide. The topography is gently undulating and generally slopes northward toward the Mississippi River. To the southeast are bluffs that overlook the Missouri River floodplain. Though the bedrock under the site is fractured, it is overlain by low permeability clays ranging from 1 m to 9 m (3 ft to 30 ft) thick.

Most surface water runoff from the WSCP/WSRP area discharges either through an intermittent stream in the Army Reserve Training Area or through the Ash Pond diversion structure on the WSCP property to Schote Creek. An additional surface drainage system reaching Schote Creek exits the WSCP area along the Frog Pond drainage. That drainageway carries storm water from most of the plant area where concrete surfaces drain into a storm water sewer system. The Frog Pond drainageway also carries runoff from the northeastern portion of the WSCP. Drainage from the southern portion of the WSCP property travels southeast to the Missouri River. Schote Creek joins with Dardenne Creek and flows northeast to the Mississippi River. Schote Creek and several of its tributaries are impounded on the August A. Busch Memorial Wildlife Area (ABWA). Dardenne Creek, portions of Schote Creek, and lakes on the ABWA support aquatic life and are accessible to the public for recreational activities, such as fishing. The WSQ is located on the northern bluff of the Missouri River valley. The unconsolidated upland material overlying bedrock consists of up to 10 m (30 ft) of silty clay soil developed from loess deposits. A residual soil is present in some areas between the silty clay and bedrock. Figure 1-4 shows the environmental setting of the Weldon Spring site.

2 COMPLIANCE SUMMARY

2.1 Compliance Status for 1990

The Department of Energy's Weldon Spring Site Remedial Action Project (WSSRAP) is subject to meeting or exceeding the regulatory requirements of Federal, State, and local laws and statutes. The WSSRAP maintains a permanent staff of compliance experts who monitor the progress and status of the project relative to the environmental laws. The following is a summary of applicable regulations and the WSSRAPs current compliance status.

2.1.1 Compliance Status

National Environmental Policy Act

The WSSRAP has successfully integrated the procedural and documentation requirements of the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) and the National Environmental Policy Act (NEPA), as required by the policy stated in DOE Order 5400.4. Site documents are published as integrated documents, such as the sites' Remedial Investigation/Feasibility Study-Environmental Impact Statement (RI/FS-EIS). For example, Engineering Evaluation/Cost Analysis (EE/CA) and Remedial Investigation/ Feasibility Study (RI/FS) documents are adopted by the U.S. Department of Energy (DOE) as Environmental Assessments (EAs) and Environmental Impact Statements (EISs) and contain the required NEPA information. Proposed plans and actions are evaluated in terms of both NEPA and CERCLA. Actions falling under the categorical exclusion (CX) classification are submitted as such for approval. The WSSRAP submitted six categorical exclusions in 1990; four have been approved. The CX actions approved are: (1) the off-site removal of tributyl phosphate (TBP) to the Oak Ridge incinerator for destruction, (2) removal and disposal of transformers and equipment contaminated with polychlorinated biphenyls (PCBs) from an out-of-service electrical substation, (3) site characterization and environmental monitoring activities, and (4) a variety of general plant projects, e.g., repaving the administration building parking lot. A memorandum-to-file was approved in September for a material staging area which will serve as a temporary storage area for debris resulting from building dismantlement at the chemical plant.

Comprehensive Environmental Response, Compensation, and Liability Act

The WSSRAP removal and remedial actions are performed under CERCLA (as amended by Superfund Amendments and Reauthorization Act [SARA]). The requirements of the following acts, laws, regulations, etc. may have Applicable or Relevant and Appropriate Requirements (ARARs) for the site.

Resource Conservation and Recovery Act

Hazardous waste at the Weldon Spring site (WSS) is managed as required by Resource Conservation Recovery Act (RCRA) (and substantive ARARs) and includes the characterization, consolidation, inventory, storage, transportation, and disposal of hazardous and other wastes that remained on-site after closure of the Weldon Spring Uranium Feed Materials Plant (WSUFMP) and for wastes generated during remedial activities. Phase II of the chemical consolidation is discussed in more detail in the Issues and Action Section. RCRA permits are not required at the WSS since the remediation is being performed in accordance with decisions reached under CERCLA. Section 121(e) of CERCLA states that no Federal, State, or local permit shall be required for the portion of any removal or remedial action conducted entirely on site.

Toxic Substances Control Act

PCBs are managed at the WSS under the requirements of the Toxic Substances Control Act (TSCA). Non-radiologically contaminated PCBs are scheduled for off-site disposal in 1991. More information is offered in the Issues and Actions Section.

Clean Air Act

The portion of the Clean Air Act (CAA) that pertains to the WSSRAP is the National Emission Standards for Hazardous Air Pollutants (NESHAPs). The standards contain maximum levels for radionuclides and asbestos. The WSSRAP plan for monitoring radionuclide emissions was approved by the Environmental Protection Agency (EPA), and is explained in more detail in the Issues and Actions Section.

Clean Water Act

Compliance under the Clean Water Act (CWA) consists of the two National Pollution Discharge Elimination System (NPDES) permits. Both effluent and erosion control monitoring is performed. NPDES permit limits were exceeded twice in 1990 at the administration building sanitary wastewater plant. Operational adjustments to the plant were made by the subcontractor, bringing levels to below permit limits.

Archaeological and Historical Preservation Act

In 1986, the Missouri Department of Natural Resources determined that any archaeological resources present in the chemical plant area would have been so severely damaged or destroyed during plant construction that further investigation would not be warranted. A competent archaeologist was consulted for the quarry and the quarry haul road. The archaeologist found six sites in the quarry vicinity, that unless disturbed by newly planned activity, will need no mitigation. A preliminary investigation and surveillance was performed by the archaeologist on the haul road in 1990. The investigation will continue in 1991 before construction begins.

Endangered Species Act

The U.S. Fish and Wildlife Service (USFWS) has been consulted under Section 7(a) of the Endangered Species Act. An ecological assessment is being performed in conjunction with the Baseline Assessment. The Baseline Assessment will evaluate risks to human health and the environment in support of overall site waste management decisions. The ecological evaluation includes a review of threatened and endangered species present, or potentially present, in the area of the Weldon Spring site.

Consultation with USFWS regarding endangered species continued in 1990. The USFWS will be contacted in 1991 concerning the biological assessment requirement for the quarry haul road and the chemical plant. The Missouri Department of Conservation lists numerous threatened or endangered species for the county in which the WSS is located and will be consulted concerning the state's requirement for a biological assessment.

Executive Order 11988 Floodplain Management

The Engineering Evaluation/Cost Analysis Environmental Assessment (EE/CA-EA) for the proposed management of contaminated water at the Weldon Spring quarry contains a floodplain assessment that describes the impact of the floodplain as a result of construction activities at the quarry. The structure to be located in the floodplain is the effluent pond associated with the quarry water treatment plant. The floodplain assessment was written in accordance with 10 CFR 1022.12 of the DOE Floodplains/Wetlands Environmental Review Requirements which establishes policy and procedures for discharging the DOEs compliance responsibilities for EO 11988.

2.1.2 Issues and Actions

2.1.2.1 Ongoing Issues. An amended Federal Facilities Agreement (FFA) is being negotiated between the DOE and the EPA. The EPA transmitted the final draft of the FFA to DOE-Headquarters for approval. Any final issues will be negotiated during DOE review and the signature process.

In June 1988, electrical equipment was discovered on a concrete pad (Substation 411) outside of the WSS property boundaries. The equipment consisted of three transformers, a circuit breaker, three pole-mounted units and other electrical equipment that had remained in place since the closure of the chemical plant. One of the transformers contained 1,637 liters (360 gal) of oil contaminated with approximately 150 parts per million (ppm) of PCBs. One of the pole-mounted units contained 55 liters (12 gal) of oil contaminated with 1,100 ppm of PCBs. More discussion on Substation 411 is included in Section 7 of this report.

In August 1990, eight drums of PCB contaminated oil were generated by draining the transformers containing greater than 50 ppm of PCB. Two pole-mounted transformer units were placed in overpack containers. The containers have been stored in the RCRA/TSCA regulated building (Building 434) awaiting disposal. The containers will be disposed off site before August 1991.

Three compliance issues that were identified in 1990 still remain unresolved. They are described below.

Issue No. 1: Storage of PCB wastes beyond allowable time limits (40 CFR 761.65(a)).

Approximately 28,120 liters (7,400 gal) of tributyl phosphate (TBP) contaminated with radionuclides and with PCBs in excess of 50 ppm are on the Weldon Spring site. In addition, preliminary analyses indicate the TBP is also contaminated with mercury exceeding the regulatory level for Toxicity Characteristic, thereby making it a RCRA hazardous waste. On the site, there are also small amounts of radiologically contaminated PCB waste within electrical capacitors, and eight drums of PCB-contaminated soil suspected of radiological contamination.

All PCB wastes identified to date by investigative and remedial activities have been present since the plant was operational in the 1950s and 1960s. The WSSRAP continues to locate and identify all PCB-containing material and to place it in proper storage.

Corrective Action for Issue No. 1: In December 1989, the WSSRAP-DOE sent a letter to the EPA (Region VII) notifying them that the one-year storage limitations had been exceeded.

Efforts to send the TBP to the Oak Ridge Gaseous Diffusion Plant Incinerator for destruction continued during 1990. The incinerator was not operational during 1990.

An attempt by the WSSRAP to decontaminate the radiologically contaminated PCB capacitors failed. Therefore, the capacitors will remain on site and eventually be disposed with other radiologically contaminated material when a viable disposal option is identified.

Issue No. 2: Unknown abandoned wastes at the processing plant have not been chemically analyzed or placed in proper storage (40 CFR 264).

When the uranium processing plant was shut down in 1966, large quantities of organic and inorganic chemicals were abandoned in both process and non-process buildings. Phase I characterization activities included an initial effort to identify and containerize these chemicals. As Phase I progressed, more chemicals were discovered; these are being addressed by Phase II. Chemicals were found during both phases in tanks, sumps, process vessels, and in abandoned buildings. Phase I was completed in January 1989.

Corrective Action for Issue No. 2: After the containers which were accumulated and consolidated during Phase I were moved to the new RCRA storage area in Building 434, emphasis was directed to identifying, characterizing, and containerizing the remaining chemicals in accordance with the appropriate regulations. Activities included moving unknown chemicals to the site staging areas; and sampling, testing, and repackaging as necessary to meet the requirements of 40 CFR 264. As chemicals are properly packaged, they are placed in the RCRA storage facility in Building 434 pending final disposition.

Issue No. 3: Surpassing the Missouri State maximum permissible exposure limit for radon at the quarry (19 CSR 20 - 10.040)

Missouri Code of State Regulations limits quarterly-averaged radon concentrations outside controlled areas to 1 pCi/l. This concentration is regularly exceeded at one quarry perimeter monitoring station and occasionally exceeded at other quarry perimeter monitoring stations.

Corrective Action for Issue No. 3: The long term solution is the excavation and final disposal of the bulk waste (which is the primary radon source). This is addressed in the quarry Record of Decision (ROD).

2.1.2.2 Significant Accomplishments. In March 1990, Building 434 remodeling was completed for the storage of TSCA and RCRA wastes. The building meets storage requirements for RCRA and TSCA wastes and is inspected on a weekly basis.

The WSSRAP NEPA Compliance Officer (NCO) position was created in 1990 to review and ensure compliance with the requirements of NEPA. A procedure for ensuring early review of proposed activities was developed and has been implemented. Categorical exclusion determinations are being made for relevant subcontracts and projects to ensure compliance. NEPA EA and EIS documents are integrated with CERCLA EE/CA and RI/FS documents.

2.1.2.3 NESHAPs Compliance. The WSSRAP has developed an alternate method for NESHAP compliance as provided in 40 CFR 61.93 paragraph (b)(5) whereby air concentrations are monitored at five designated critical receptor locations on and around the Weldon Spring site. The WSSRAP plan is contained in the report *Plan for Monitoring*

Radionuclide Emissions Other Than Radon at Weldon Spring Site Critical Receptors, (MKF and JEG 1990a) which has been approved by the EPA. The EPA has also approved the WSSRAP plan to report annual monitoring results and effective dose equivalents at critical receptor locations via the *Annual Site Environmental Report*.

The air at each critical receptor location is continuously sampled for radionuclides. The air sampling filters from each critical receptor location are separately composited and analyzed annually for the radionuclides that are major contributors to the effective dose equivalent, i.e., U-234, U-238, Th-228, Th-230, Th-232, Ra-226 and Ra-228. Air sampling filter collection, handling, and analysis methods are regimented such that radionuclide concentrations that would cause an effective dose equivalent of 10% of the standard (i.e., 1 mrem) are readily detectable and distinguishable from background. Radionuclide detection levels and sampled air volumes are sufficient to meet the sensitivity requirements of Table 2, Appendix E of 40 CFR 61 which determine compliance with the standard. The quality assurance program described in Section 5 of the WSSRAP NESHAPs compliance plan (MKF and JEG 1990a) meets the requirements of 40 CFR 61 Appendix B. Detailed information, including calculations on radiation monitoring and dose calculations are found in Sections 4.1.6 and Appendix G. During calendar year 1990, no significant asbestos abatement activities were performed at the site.

2.1.2.4 Satisfaction of Reporting Requirements

2.1.2.4.1 Continuous Release Reporting. There have been no reportable quantity releases from the WSS not exempted as a Federally permitted release. Consequently, no continuous release reports have been submitted.

2.1.2.4.2 SARA Title III Report. For the 1990 calendar year, WSSRAP reported the following hazardous chemicals in the SARA Title III Annual Chemical Inventory Report: 15 drums of polychlorinated biphenyls (PCBs); two process tanks containing a solution of tributyl phosphate (TBP)/uranyl nitrate; four raffinate pits containing sludge and water contaminated with uranium, thorium, radium, lead, arsenic, and other inorganic contaminants; approximately 1,011 cu m (1,330 cu yd) of bagged asbestos; and 16 drums of elemental magnesium and magnesium oxide. WSSRAP is not a facility in the standard industrial classification and is therefore not required to submit the annual Toxic Release Inventory under Section 313 of SARA.

2.1.2.5 Audit Summary. The DOE from Oak Ridge National Laboratory (ORNL) conducted an environmental compliance audit at the Weldon Spring site in October 1990. Draft findings were subsequently submitted to the WSSRAP. In December 1990, a Corrective Action plan responding to the findings was submitted to ORNL.

Oak Ridge Operations (ORO) also conducted an appraisal of the environmental safety and health and quality assurance procedures at the site in October 1990. Findings were transmitted to the WSSRAP in December 1990. A response to the findings was submitted to ORO in January 1991.

The audits identified Major (Priority II) and Minor (Priority III) findings. The attached matrix gives the status of the Major findings. The Minor findings are addressed in the corrective action plan for each audit. No Significant (Priority I) findings are known and none were determined by audit.

2.1.3 Summary of Permits for 1990

The WSSRAP maintains the following permits:

2 NPDES permits (quarry and chemical plant).

1 Construction permit from the Missouri Department of Natural Resources (MDNR) for the quarry water treatment plant.

1 Driveway permit from the Missouri Highway and Transportation Department for the entrance at the quarry.

1 Floodplain Development permit from St. Charles County Planning and Zoning Commission.

TABLE 2-1 ORNL Audit October 1, 2, 3, 1990

REGULATION	ISSUE	CORRECTIVE ACTION	DATE IN COMPLIANCE
40 CFR 264.194	TBP tanks spill/overflow controls are inadequate.	No material has been added or taken from the tanks in 20 years. Openings and valves are closed and the tanks are less than 75% full to allow expansion. Tanks are inspected daily. Letter transmitted to MDNR 10/16/90 seeking concurrence.	OPEN
40 CFR 761.65(b)(i)ii	TBP tanks require roof and walls to prevent rain contact with PCB materials.	On 10/11/90 the TSCA branch of EPA Region VII was consulted. It was determined that roof and walls were not needed.	OPEN

TABLE 2-2 ORO Audit October 15-19, 1990

REGULATION	ISSUE	CORRECTIVE ACTION (From Corrective Action Plan dated 1/91)	DATE IN COMPLIANCE
40 CFR 268.50	Land ban wastes stored beyond time limits.	WSSRAP does not concur because WSSRAP waste was stored prior to land ban (51 FR 40577).	OPEN
40 CFR 265.194	TBP tanks spill/overflow controls are inadequate.	See ORNL corrective action above.	OPEN
40 CFR 61, Subpart M	Areas of uncontained, possibly friable, asbestos materials were observed.	The major portion of uncontained asbestos from outdoor locations has been abated. The current schedule for remediation of uncontained ACM is appropriate for site remedial action priorities.	OPEN

Archaeological and Historic Preservation Act

In March 1991, the WSSRAP consulting archaeologist further investigated the potential sites along the quarry haul road to determine whether mitigation will be necessary before construction of the road begins.

2.2 Compliance Status for the Period January 1 - April 15, 1991

Status remains unchanged under CERCLA, RCRA, TSCA, CWA, the Endangered Species Act, and Executive Order 11988.

NEPA

Approval of two categorical exclusions is anticipated in April 1991. The approval will allow construction of an annex to the administration building and construction of a composite building to house the new access control, warehouse, and lab space.

Clean Air Act (CAA)

Removal of asbestos from buildings and tanks at the chemical plant was initiated in February 1991. Under this activity, asbestos, and asbestos-containing material will be removed according to the NESHAP and OSHA regulations.

Archaeological and Historic Preservation Act

In March 1991, the WSSRAP consulting archaeologist further investigated the potential sites along the quarry haul road to determine whether mitigation will be necessary before construction of the road begins.

2.2.1 Current Issues and Actions

Beginning in February 1991, an asbestos abatement action was initiated. This project involved removal of friable and nonfriable asbestos materials from six non-process buildings, three outside insulated storage tanks, and several asbestos items stored in outside debris storage areas. The revised asbestos NESHAPs regulations, including the amended

notification requirements, were incorporated into the abatement project specifications. Friable asbestos wastes were containerized and transferred to Building 103 for interim on-site storage.

No other new issues or actions were initiated from January 1 to April 15, 1991.

2.2.2 Summary of Permits for 1991

The WSSRAP currently maintains the following permits:

2 NPDES permits (quarry and chemical plant).

1 Construction permit from Missouri Department of Natural Resources for the quarry water treatment plant (QWTP).

1 Application of renewal of construction permit for the QWTP.

1 Driveway permit from the Missouri Highway and Transportation Department for the entrance at the quarry.

1 Floodplain Development permit from St. Charles County Planning and Zoning Commission for construction of a portion of the equalization basins at the quarry.

3 ENVIRONMENTAL PROTECTION PROGRAM

3.1 Environmental Program Overview

The U.S. Department of Energy (DOE) has implemented a multifaceted environmental management approach at the Weldon Spring site (WSS) to meet the requirements of the National Environmental Policy Act (NEPA) and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), as amended by the Superfund Amendments and Reauthorization Act (SARA). The project is designed to reduce the health or safety threats to on-site workers and the public, mitigate actual or potential uncontrolled contaminant releases, provide for public participation through an active community relations program, and lead to timely initiation of remedial actions. The DOE approach for implementing remedial action at the Weldon Spring site consists of the following major elements:

- Site characterization.
- Risk evaluation.
- Preparation of Remedial Investigation/Feasibility Study (RI/FS) Environmental Impact Statement (EIS) consistent with both NEPA and CERCLA.
- Initiation and completion of interim response actions.
- Removal of quarry bulk wastes as a separate operable unit.
- Preparation of a separate RI/FS and baseline assessment for the quarry as a separate operable unit.
- Site remediation.

The difficulty in characterizing the wastes and environmental media at the quarry has led to the identification of the quarry as a separate operable unit. Quarry bulk waste will be removed and transported to the chemical plant site for temporary storage. This remedial action is addressed under a separate RI for quarry bulk wastes (MKF and JEG 1989a). The

quarry bulk waste will ultimately be disposed of with wastes from the chemical plant and the raffinate pits. Subsequent to the removal of the bulk wastes from the quarry, an RI/FS and baseline assessment for the quarry environs will be conducted. The results will be presented in separate documents which are consistent with the overall Weldon Spring Site Remedial Action Project (WSSRAP) objectives and CERCLA and NEPA requirements.

While the environmental documentation process and remedial action is ongoing, environmental monitoring has been and will continued to be performed to assess the impacts of remedial action on all affected media. Over the long term, this monitoring will document the effectiveness of remedial action. Environmental monitoring will also demonstrate, in the near term, the effectiveness of engineering controls on minimizing releases and exposures during remedial action. Currently, routine monitoring at the WSS provides baseline data prior to remedial action and documents releases and exposures to the public and the environment.

3.2 Site Programs to Ensure Quality

The WSSRAP maintains numerous on-site programs to ensure the quality of the work performed. These programs continually stress the project priorities of quality and environmental safety and health. Two programs include self-assessment and training maintenance and tracking. The following is a summary description of those programs exercised in 1990.

3.2.1 Self-Assessment Program

During 1990, development of a formal self-assessment program was initiated. Although a formal self-assessment program did not exist during 1990, project quality assurance personnel performed audits and surveillances covering essentially all quality-affecting aspects of the environmental monitoring program. Specifically, environmental protection, radiation protection, industrial hygiene, and environmental compliance activities were reviewed to assess procedural compliance. Environmental protection activities associated with sample collection and integrity were reviewed. Radiation protection procedures regarding worker protection and environmental monitoring activities and shipping of radioactive materials were evaluated. Asbestos and worker protection monitoring procedures were reviewed within the Industrial Hygiene group. Environmental Compliance

activities regarding the storage of hazardous waste, the shipping of regulated materials, and the NPDES program were reviewed.

Corrective action plans have been formulated for discrepancies identified in audits and are currently being implemented. Progress in the implementation of corrective actions is verified and tracked through the site-wide audit tracking system.

3.2.2 Training

Training is a key element of the environmental protection program. Through training, each employee is instructed in the policies and procedures related to environmental protection. On-going training sessions also continually reinforce the objectives of the program.

The training program can essentially be broken into four main areas; (1) documents, (2) procedures, (3) special courses taught on-site to convey specific policies or issues and, (4) off-site courses designed to provide instruction for specific areas. Each new employee at WSSRAP is evaluated and assigned training requirements based on job assignment. The department manager establishes a unique training matrix for each employee that includes documents, procedures, and on and off site training courses.

Course selection for each employee is specifically designed to ensure a comprehensive understanding of position requirements and overall policies and program requirements. The need for off-site training to augment site training is evaluated annually and included in the FY budget. Courses specific to waste management are reviewed and planned throughout the year for general employee training. Other off-site courses are mandated for key individuals as a part of on-going training or certification requirements.

The status of employee training is reported to the various departmental managers and the individual employees on a monthly basis. Monthly reports include status of documents and procedures reviewed, as well as training programs and off site courses taken during the current year.

3.3 Waste Minimization/Pollution Prevention Program

The waste minimization/pollution prevention activities at the WSS have been combined and are described in the *Waste Minimization/Pollution Awareness Plan* (MKF and JEG 1990b). The waste minimization program's key elements include:

- Chemical Control - To minimize the generation of hazardous waste, a review and approval mechanism has been developed for chemical control. New purchase orders initiated by site personnel for chemically related materials are reviewed, evaluated, and approved by qualified personnel prior to purchase.

- Training and Awareness - Personnel at the WSSRAP maintain awareness of waste minimization concepts and on-site policy through periodic presentations, seminars, and other training.

- Work Activity Review - The site has developed and implemented a subcontractor work package review system that allows each affected site organization to review and comment on all proposed subcontracted work. Each package is reviewed to ensure that proper measures have been incorporated into the subcontractors requirements in support of waste minimization and pollution prevention.

- Recycling Program - A small, but successful, office recycling program was initiated by the WSSRAP in 1990. Conceived by the employees and endorsed by project management, the site presently reuses office materials and recycles office paper to the extent practical. It is also standard practice to purchase recycled paper products in an effort to increase the markets for recyclable materials. The program exemplifies the effectiveness of the sites employee participation program.

3.4 Waste Management

Consolidation of containerized wastes at the WSS was completed in a two-phase effort in January 1991. Over 1000 containers (varying in size from 209 liters [55 gal] drums to small vials) were collected, field analyzed, consolidated and placed in interim storage pending final disposition. The field analysis provided qualitative data to support the consolidation effort. Treatment and disposal options are being supported by a

comprehensive off-site analysis program. This detailed characterization program is guided by the *Weldon Spring Site Waste Analysis Plan* (MKF and JEG 1991a). The wastes will be stored in the on-site Resource Conservation Recovery Act (RCRA) storage facility, Building 434, until a final treatment or disposal option is available.

The on-site RCRA storage facility, Building 434, provides approximately 1,767 sq m (19,000 sq ft) of storage area. The building, originally a warehouse, was renovated to meet the RCRA standards for containerized storage areas. The majority of wastes are contained in U.S. Department of Transportation (DOT) approved 209 liters (55 gal) drums and overpacks. The current containerized inventory includes 486 drums of hazardous material, 187 drums of asbestos containing material, 138 drums of RCRA regulated material, 43 drums of the Missouri Department of Natural Resources (MDNR) regulated material, 31 drums of Toxic Substance Control Act (TSCA) regulated material, 87 drums of other DOT hazardous material, and 550 drums of non-hazardous material. These drums are stored according to RCRA standards.

All wastes at the WSS are tracked using the Waste Inventory/Tracking System (WITS), a computer oriented inventory database which facilitates tracking of bulk and containerized waste data. The WITS has four functions: inventory, tracking, disposal, and report generation. The inventory function consists of original material inventory. The tracking function is capable of tracking material from its original location, a temporary location, or tracking a specific container. The disposal function is capable of providing information on the disposal of material from its original location, disposal from a temporary location, or disposal of a specific container. The report generation function is capable of producing reports based on the original inventory, remaining inventory, transferred inventory, disposed inventory, reportable quantities, and the tracking of a specific container, or type of waste.

3.5 Unusual Occurrence Reporting for Environmental Incidents

On September 20, 1990 an incident occurred within the chemical plant area in Building 406. During containerized chemical consolidation activities, incompatible substances, i.e., sodium metal bars and an aqueous caustic solution, were combined. The ensuing reaction resulted in the release of approximately 95 liters (25 gal) of caustic liquid

which was confined to the interior bermed portion of the building. Therefore, the release was not reportable under CERCLA and RCRA.

The released material was subsequently neutralized and recontainerized. No radioactive material was involved in the incident and only minor chemical burns were sustained by three employees working in the area. Corrective actions involved the implementation of a new safety oversight/management procedure that is designed to ensure communication of safety and health hazards and preventative measures at the working level. The incident was reported as an unusual occurrence under DOE Order 5000.3A.

3.6 Dam Safety Inspections

In early 1990, the PMC evaluated the dam safety requirements applicable to the WSSRAP. The PMC evaluated the raffinate pits, the Ash Pond dam, and the Ash Pond diversion structure against State and Federal regulations. It was determined that State requirements do not apply to Federally-owned structures or properties regulated by a dam safety program. Under Federal regulations, a dam or berm is regulated if it has a height of 7.6 m (25 ft) or greater as measured from the downstream toe to the maximum water storage elevation, and also if failure of the dam creates a significant downstream hazard.

It was determined that all four raffinate pits fall under Federal regulations. The berms of pits 3 and 4 meet the slope length regulations and the contamination in the pits poses a significant potential downstream hazard. Pits 1 and 2 also pose a significant potential downstream hazard. The PMC determined that the Ash Pond structures do not qualify as regulated dams.

Federal regulations require that all regulated structures be subjected to a standard inspection program. This program consists of surveillance on a regular basis, intermediate inspections on a yearly basis, and a formal inspection once every five years. An emergency inspection may also be performed if some significant damage occurs to the structure. An informal surveillance of the raffinate pit berms was performed on a monthly basis beginning in June of 1990. This schedule will continue through mid-1991 so that the baseline condition of the berms can be established. After this time, the informal surveillances will be performed on a quarterly basis.

4 ENVIRONMENTAL MONITORING PROGRAM INFORMATION

4.1 Radiological Monitoring Program Information

The Weldon Spring Site Remedial Action Project (WSSRAP) operates its environmental monitoring and surveillance program in accordance with the DOE Order 5400 series. The substances present as wastes on the site require monitoring for both radiological and non-radiological species. Although the programs are described separately in this report for information utility, the sampling and analysis programs for each are conducted simultaneously. The environmental monitoring programs and the analytical results, which represent the status of environmental impacts from site related contaminants, are described below.

4.1.1 Surface Water And Spring Monitoring

Surface water samples were collected and analyzed for radiological parameters from a total of 25 locations; 13 within or near the Weldon Spring Chemical Plant/Weldon Spring raffinate pits (WSCP/WSRP) and 12 near the quarry. A total of 10 springs were monitored both north and south of the WSCP/WSRP for radiological parameters. All samples were analyzed for uranium and selected sites were analyzed for Ra-226, Th-230, and Th-232. Radium and thorium isotopes have been analyzed in water samples from surface water runoff from the WSS in past years. The analyses of those samples indicate that radium and thorium do not constitute a radiological contaminant in surface water leaving the site perimeter. Because the water solubility of those radionuclides in the environment is low, and because there was not significant disturbance in radium or thorium contaminated soil materials during 1990, it is not expected that the discharge of those nuclides in surface water would differ significantly from previous years. Many of these locations have been sampled by the WSSRAP for four consecutive monitoring years and are considered to be the most representative for monitoring contaminants that may pose a risk to the public health or the environment.

In an effort to maintain a current understanding of site-related contaminant concentrations in potentially affected surface water features, surface water samples were collected from five on-site and seven off-site locations. Locations SW-2007 and SW-2001 are upstream and downstream, respectively, of the surface water migration pathway from the

site. Locations SW-2002, SW-2003, SW-2004, SW-2005 and SW-2006 are located within or near August A. Busch Wildlife Area (ABWA) lakes while SW-2010 (Ash Pond), SW-2011 (Frog Pond), and SW-3001 through SW-3004 (raffinate pits) are located onsite. These locations are shown on Figure 4-1.

Springs SP-5201, SP-5203 and SP-5301 through SP-5304 (southeast drainage) are located south of the site while springs SP-6301 (Burgermeister Spring), SP-6302, SP-6303, and SP-6306 are located north of the site as shown on Figure 4-2.

The 12 surface water locations in Figures 4-3 and 4-4 were selected for routine monitoring to evaluate and document the possibility that surface waters near the Weldon Spring quarry (WSQ) might pose a risk to human health or the environment. Locations SW-1001 and SW-1002 monitor the Little Femme Osage Creek at points upstream and downstream of the WSQ, respectively. Six sampling locations, SW-1003 through SW-1005, SW-1007, SW-1009, and SW-1010 are distributed along the Femme Osage Slough. Location SW-1006 was renamed during the 1990 monitoring year as a groundwater monitoring location - GW-RAWW. Location SW-1008 monitors the ponded water within the WSQ. The samples from this location permit a rough determination of the concentrations of the various contaminants in the ponded surface water (in contact with the quarry wastes) that may migrate to groundwater. Locations SW-1011, SW-1012, and SW-1013 were added to the monitoring program in 1989 to provide baseline water quality data from the Missouri River. SW-1011 is the upstream Missouri River location above potential influences from Weldon Spring site (WSS) contamination, while SW-1013 is furthest downstream below the outfall point of the southeast drainage easement.

4.1.1.1 Weldon Spring Chemical Plant/Raffinate Pits. The average total uranium activities at off-site locations SW-2001, SW-2006, SW-2007, SP-5203, and SP-6303 were at background levels of less than 5 pCi/l (0.185 Bq/l) (see Tables 4-1 and 4-2 for annual averages). Off-site locations SW-2002, SW-2003, SW-2004, and SW-2005 ranged from a low of 7.34 pCi/l (0.27 Bq/l), or 1% of the derived concentration guideline (DCG) to a high of 190 pCi/l (7.03 Bq/l), or 32% of the DCG. These values were within their historical ranges as were all other off-site locations SP-5301, SP-5302, SP-5303, SP-5304, SP-5503, SP-6301, SP-6302, and SP-6306 which ranged from a low of 6.80 pCi/l (0.25 Bq/l), or 1% of the DCG, to a high of 592 pCi/l (21.9 Bq/l), or 99% of the DCG. The six on-site surface water

* Detection limit

impoundments, the four raffinate pits, Ash Pond, and Frog Pond indicated a low of 170 pCi/l (6.29 Bq/l), or 28% of the DCG, to a high of 2,584 pCi/l (95.6 Bq/l), or 430% of the DCG. These levels are within their historical ranges.

No significant changes were observed between the average values measured in 1990 and 1989 at any of the 13 surface water or the 10 spring locations within or near the site. At the furthest downstream location, SW-2001 (the confluence of Schote and Dardenne creeks), the average of the quarterly measurements remained at background levels as in 1989, while the maximum value increased only slightly. No seasonal pattern was observed in the values.

The sampling results indicate that uranium continues to migrate from the site at relatively low levels in surface water and springs along known discharge pathways. The concentrations (activity) of the total uranium is reduced by dilution and natural processes to the point that the level falls to within the range of natural background at the farthest downstream measurement location, SW-2001.

Other radiological species (radium and thorium) were monitored in 1990 at the raffinate pits only (see Table 4-3). Historically, no other monitoring locations have detected elevated levels of those species. The raffinate pits were sampled once in 1990 to maintain a baseline on the radioisotope levels. The radium and thorium values within the pits for 1990 were very similar to those of 1989.

4.1.1.2 Weldon Spring Quarry. The primary radionuclide of concern at the WSQ and surrounding area is total uranium, which was detected at levels ranging from 2.7 pCi/l (0.10 Bq/l) or less than 1% of the DCG within the Missouri River to a quarterly high of 3130 pCi/l (115.8 Bq/l) or 522% of the DCG in the quarry pond water within the access-controlled area. Refer to Table 4-4 for annual averages of uranium for sample locations near the quarry.

The quarry pond water was once again sampled quarterly for uranium. The average measured value was 2400.7 pCi/l (88.8 Bq/l) which is similar to but slightly higher than the average measured value of 1827 pCi/l (76.6 Bq/l) during 1989. The quarry pond poses little direct threat to the public health.

TABLE 4-3 1990 Radiological Results For Raffinate Pits (pCi/l)

WSSRAP ID	RADIUM-226	@	THORIUM-230	@	THORIUM-232	@
SW-3001	130.0	(1/1)	100.0	(1/1)	0.2	(1/1)
SW-3002	95.0	(1/1)	90.0	(1/1)	0.3	(1/1)
SW-3003	7.0	(1/1)	3.8	(1/1)	1.2	(1/1)
SW-3004	98.0	(1/1)	92.0	(1/1)	2.8	(1/1)

@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4) indicates that four samples were taken in 1990, two of which average 2.00 and the other two samples were ND.

Locations SW-1011 to SW-1013 are distributed along the north bank of the Missouri River to provide samples of river water for water quality testing in preparation for effluent discharge from the WSQ water treatment plant (WTP). The results of the measurements yielded annual average uranium activities for 1990 of 5.9 pCi/l (0.22 Bq/l) at SW-1013 (downstream), 5.7 pCi/l (0.21 Bq/l) at SW-1012, and 4.3 pCi/l 4.3 Bq/l) at SW-1011 (upstream). The error is $\pm$1.0 pCi/l (0.037 Bq/l). The highest quarterly measured uranium activity in the Missouri River was detected during the fourth quarter of 1990 at 9.52 pCi/l (0.35 Bq/l) or 2% of the DCG at SW-1013. These values fluctuate due to natural variations in the river water.

Uranium activities slightly above background were detected in the waters of the Little Femme Osage Creek both up and downstream of the quarry during the first quarter of 1990. Upstream (SW-1001) indicated 8.16 pCi/l and downstream (SW-1002) indicated 11.5 pCi/l. However, the later quarters for both locations were at background or non-detect. The higher uranium values for the first quarter were probably due to laboratory error as sampling blanks also contained uranium. The two locations will continue to be monitored.

The Femme Osage Slough, which is the former channel of the Femme Osage Creek prior to rerouting that stream course, is a nearly stagnant water body. The slough has been known to receive uranium contamination from the contaminated groundwater in the bedrock

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

ND - Not Detected

NSF - Not Scheduled For Sampling

@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4)Indicates that four samples were collected in 1990, two of which average 2.00 and the other two samples were ND.

* Detection limit

and alluvium to the north. In 1990, the uranium activities within the Slough ranged from a low of 8.84 pCi/l (0.33 Bq/l) or 1% of the DCG at SW-1009 to a high of 57.1 pCi/l (2.11 Bq/l) or 10% of the DCG at SW-1004. This is attributed to uranium contaminated groundwater discharging to the slough from the north side. The water level in the slough is managed by the Missouri Department of Conservation, whereby water is allowed to fill the slough during high river stage. The valve is closed at high stage and the water is retained in the slough. These fluctuating water levels are a mechanism for migration. All average uranium levels for the slough remained within their historical ranges.

According to the 1990 measurements, the quarry pond water did not contained Ra-226 or Ra-228 above the detection limit of 2 pCi/l (0.074 Bq/l), and Th-230 activities were measurable near the detection limit of 0.5 pCi/l (0.018 Bq/l) while Th-232 remained undetected. See Table 4-5. These values remain within their historical ranges.

4.1.2 Four Year Trend Analysis for Uranium in Surface Water

4.1.2.1 Weldon Spring Chemical Plant/Raffinate Pits. A four year trend analysis for uranium in surface water near the site was performed using surface water sampling locations SW-2001 through SW-2005 and SW-2007. Annual averages were used for the years 1987 through 1990. Refer to Figure 4-4A for a representation of this data.

The trend analysis does not portray an increase or decrease in uranium over a four-year period, but indicates fluctuations in concentrations that can be accounted for by natural dilution effects.

4.1.2.2 Weldon Spring Quarry. A four-year trend analysis for uranium in surface water near the quarry was performed using surface water sampling locations SW-1001 through SW-1005. Annual averages were once again used for the years 1987 through 1990 due to availability. Refer to Figure 4-4B for a representation of this data.

The trend analysis indicates fluctuations in uranium concentrations over a four-year period that can also be accounted for by natural dilution effects. However, it should be noted that surface water locations SW-1003 and SW-1004 do indicate a consistent trend of increasing from 1987 to 1989 and then decreasing during 1990. This pattern could be a

result of the drought conditions that existed during 1988-1989 followed by an above normal amount of precipitation during 1990.

4.1.3 Groundwater Monitoring Radiological Results

All Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and WSQ monitoring wells were sampled during 1990 for radiological parameters. An understanding of groundwater quality and hydrogeology has been established over the past four years through routine monitoring and investigations at the site. Therefore, the groundwater monitoring program has been modified each year to include areas where more information is needed, and to be more efficient by avoiding unnecessary or redundant sampling and analysis. Through these modifications, a high quality program to effectively assess the groundwater quality has been maintained.

All wells sampled at the WSCP/RP/VPs and the WSQ were monitored at least semi-annually for total natural uranium. The St. Charles County pumping wells, the treated and untreated water from the St. Charles County Water Treatment Plant, and a select group of monitoring wells in the county wellfield were monitored for total natural uranium and gross alpha on a quarterly basis. These same locations were also monitored on an annual basis for Th-230, Th-232, Ra-226, Ra-228 and gross beta. This quarterly and annual sampling was performed to ensure the safety of the St. Charles County water supply from contaminant

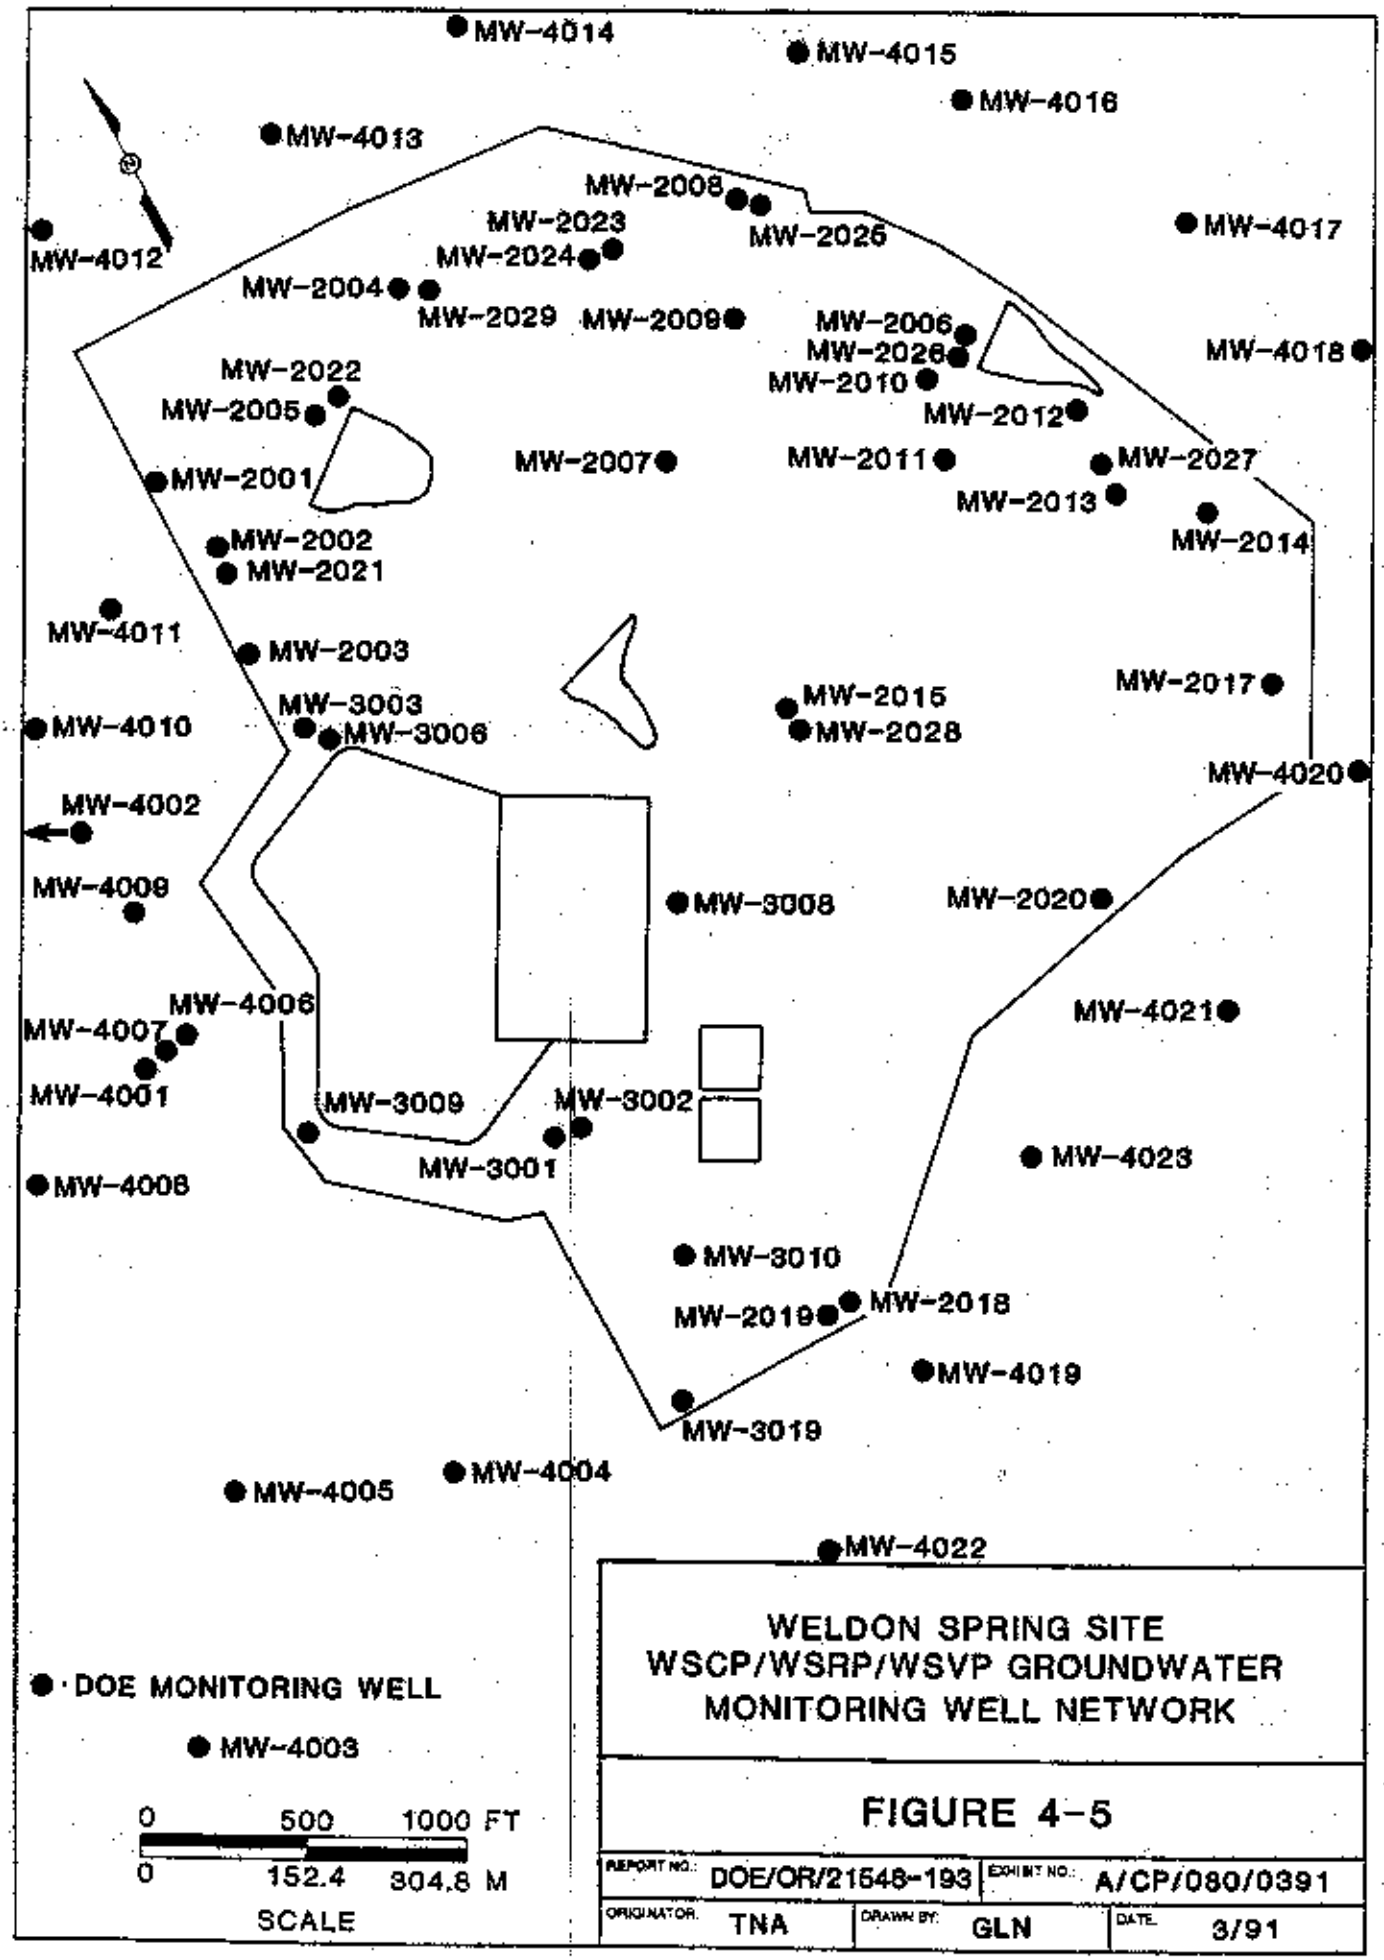
migration originating from the WSQ. The protection of the wellfield is an issue of great sensitivity to the public, the U.S. Department of Energy (DOE), and other regulatory agencies.

Data tables for all laboratory analytical results of uranium analysis presented in this section contain annual average concentrations calculated from data generated during 1990 where more than one analysis was conducted. The values from the tables are compared to background concentrations and/or to Environmental Protection Agency (EPA) guidelines. The annual average concentration is stated in each column with a fraction in parentheses adjacent to that value. The numerator represents the number of samples used to calculate the annual concentration. The denominator represents the number of times that particular well was sampled during 1990. An "ND" indicates "Not Detected" and appears only if a particular parameter was not measurable above the detection limit in any analyses performed on samples obtained from that well during 1990. If the analytical laboratory reported an "ND" for a particular parameter for a particular sampling event, the ND was not used to calculate the annual concentration. Quarterly results are presented in data tables in Appendix A. Where quarterly data points were not received from the analytical laboratory in time for inclusion in this report, the annual average was calculated based on available data. Where semi-annual data points might have been absent for calculation of annual average, sufficient historical data exists to verify the 1990 measured values.

4.1.3.1 Chemical Plant/Raffinate Pits. Groundwater at the WSCP/RP area became radiologically contaminated as a result of operations at the Weldon Spring Uranium Feed Materials Plant (WSUFMP) during the 1950s and 1960s. The *Water Quality Phase I Assessment Report* (MKF and JEG 1987) reported that: "groundwater near the raffinate pits contains elevated amounts of uranium and is a result of leaking raffinate pits and other sources." The Phase II Groundwater Quality Assessment Report (MKF and JEG 1989b), an expanded, comprehensive evaluation of groundwater quality at the WSCP/RP/VP area during the third quarter of 1988, is essentially in agreement with the Phase I report for radiological parameters.

The groundwater monitoring network consists of 59 wells; 28 at the WSCP, eight at the WSRP, and 23 at the WSVP. Figure 4-5 shows the locations of individual wells in the WSCP/RP/VP monitoring well network. All of these wells are screened in the uppermost unconfined aquifer. The wells are completed at a range of depths so that the entire



WELDON SPRING SITE
WSCP/WSRP/WSVP GROUNDWATER MONITORING WELL NETWORK

FIGURE 4-5

REPORT NO.: DOE/OR/21548-193	EXHIBIT NO.: A/CP/080/0391	
ORIGINATOR: TNA	DRAWN BY: GLN	DATE: 3/91

uppermost aquifer is monitored. Detailed well construction information for individual wells is available in the 1990 *Environmental Monitoring Plan* (MKF and JEG 1990c). The upper bound for total natural uranium background concentrations in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l (0.125 Bq/l) (MKF and JEG 1989b). the EPA has not yet established drinking water standards for uranium; however studies leading to proposed rulemaking are using uranium concentration in the 10 pCi/l to 40 pCi/l (0.37 Bq/l to 1.48 Bq/l) range (MKF and JEG 1989b).

Each groundwater monitoring well was sampled and analyzed for total natural uranium during 1990. Table 4-6 provides the annual concentrations.

Twenty-seven of the 59 groundwater monitoring wells have average total natural uranium concentrations below the upper bound for natural background. As Table 4-6 shows, 27 monitoring wells have annual average concentrations above background but below 10 pCi/l. Three wells, MW-3003, MW-4005 and MW-4020 have annual average concentrations in the 10 pCi/l to 40 pCi/l range. Monitoring wells MW-3008 and MW-3009 have the highest annual average concentrations, 231.2 pCi/l and 52.36 pCi/l (8.55 Bq/l and 1.94 Bq/l) respectively. Figure 4-6 highlights those wells with annual average total natural uranium concentrations above 10 pCi/l (the lowest proposed drinking water standard). These results show a larger area of groundwater uranium contamination than previous studies have indicated. This is believed to be due in part to the laboratory contamination discussed in Section 6.3.2.

4.1.3.2 Quarry. Groundwater near the WSQ has become radiologically contaminated as a result of contact with or migration from the radioactive substances present in the WSQ. Twenty-six DOE groundwater monitoring wells located at or near the WSQ were sampled and analyzed during 1990 to monitor for the presence of WSQ related contaminants. The St. Charles County production wells and the treated and untreated water from the St. Charles County Water Treatment Plant were also monitored for the presence of these contaminants. Figures 4-7 and 4-8 show the locations of the monitoring wells, pumping wells, and the St. Charles County Water Treatment Plant. The groundwater monitoring wells are screened in a range of geologic formations from the Ordovician-aged Plattin Limestone, upsection to and including the unconsolidated Quaternary-aged Missouri River alluvium. Samples from four monitoring wells (RMW series) screened in the Missouri River alluvium and owned by St. Charles County were also analyzed during 1990. During

Average is calculated using non-ND results. An ND is reported in this table only if all all samples from that location had ND reported.
ND - Not Detected
* - Detection limit
@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4) indicates that four samples were collected in 1990, two of which average 2.00 and the other two samples were ND.

1988 and 1989, samples of groundwater were taken from a private water well which produces from the Missouri River alluvium and is located several miles upstream of the WSQ and St. Charles County wellfield. These samples were analyzed for a suite of parameters including total natural uranium. Four separate total natural uranium analyses were run on samples from this background well and the results ranged from 4.8 pCi/l to 9.0 pCi/l (0.18 Bq/l to 0.33 Bq/l) with an average value of 6.8 pCi/l (0.25 Bq/l). Although not a comprehensive study, results of the monitoring suggest that the lower range for background in the Missouri River alluvium is approximately 4.2 pCi/l (0.19 Bq/l).

All groundwater sampling locations at the WSQ were sampled for total natural uranium during 1990. Table 4-7 presents the results of analyses performed on these samples. The average 1990 uranium results continue to show elevated levels in the bedrock adjacent to the quarry and the alluvium on the north side of the Femme Osage Slough. Figure 4-9 highlights the wells with concentrations above the lowest proposed drinking water standard of 10 pCi/l. One of the four samples collected from MW-1022 indicated a detectable level of uranium of 10.2 pCi/l. This measured value is attributed in part to be the result of the laboratory error discussed in Section 6.3.2 of this report. Two wells, RMW-2 and MW-1011, south of the slough exhibited annual uranium averages above background. However, the average concentrations from these wells, were still below the most restrictive proposed drinking water standard of 10 pCi/l.

Fifteen locations from the St. Charles county wellfield were sampled for gross alpha in 1990. Table 4-8 presents the results of analyses performed on these samples. These results are within a range that corresponds to the uranium values discussed earlier. These locations were also sampled once in 1990 for Th-230/Th-232, Ra-226/Ra-228 and gross beta. The results of these sample analyses are shown in Appendix A. The gross beta results are within the expected range to correspond with uranium and gross alpha values. No elevated values of thorium or radium were detected.

4.1.4 Radon Gas Monitoring

Radon is a naturally occurring radioactive gas in the uranium and thorium decay series. Rn-222 is formed by the natural radioactive decay of Ra-226 which is a decay product of U-238 found in soil and rock. Rn-220 (also referred to historically as thoron) is formed by the natural radioactive decay of Ra-224 which is a decay product of Th-232.

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

ND - Not Detected

* - Detection limit

@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4) indicates that four samples were collected in 1990, two of which average 2.00 and the other two samples were ND.

found in soil and rock. A fraction of the radon diffuses into the atmosphere and accounts for natural background radon concentrations. Radon is also produced at the WSS as the Ra-226 and Ra-224 contained in the waste materials undergo decay.

Radon concentrations fluctuate with both soil conditions and meteorological dispersion conditions. This is because the amount of radon that actually enters the atmosphere varies depending on the following parameters: radium concentrations, moisture content, soil porosity, soil density, emanating fraction, and atmospheric pressure.

The emanating fraction is the portion of radon that escapes from soil particles into the pore spaces, which are the voids found in all soils regardless of density. Only the radon entering these pore spaces is available for release to the atmosphere.

Porosity is a measure of the amount of pore space or fraction of total volume occupied by the pore spaces. The higher the porosity the more pore spaces for the radon to move through.

Some fraction of the total pore space volume is typically filled with water, and soil moisture content provides a measure of this fraction. Radon diffuses easier through air-filled pore spaces than water-filled ones, so the higher the soil moisture content, the lower the radon emanation from the exposed surface. The moisture content of the soil is the most variable of these parameters and is primarily responsible for quarterly and annual changes in radon concentrations.

The radon gas monitoring program uses a pair of radon detectors at each of 22 permanent monitoring locations; six locations are at the WSCP, six locations are at the WSQ, four locations are at the WSRP, and there are six off-site locations. Radon monitoring locations are identified with an "RD" prefix and are shown in Figures 4-10, 4-11, and 4-11A. On-site monitoring locations are spaced around the perimeter fences to ensure adequate detection of radon dissipating from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005 and RD-4006 were used to monitor background radon concentrations near the Weldon Spring site (WSS).

The radon detectors used in this program are Terradex Track Etch Type F. Type F detectors are sensitive to all isotopes of radon. These detectors are housed in protective

plastic cups and are mounted in an inverted fashion on posts. The detectors are exchanged at the beginning of each calendar quarter and are sent to a subcontract laboratory for analysis. The detectors were deployed in pairs to evaluate and reduce the natural uncertainties associated with this type of measurement.

Table 4-9 summarizes the quarterly and annual average radon concentrations detected at all WSS perimeter and off-site monitoring locations. Also contained in Table 4-9 is a comparison of the measured annual average concentration to the Derived Concentration Guideline for unrestricted areas of 3 pCi/l (111 Bq/m^3) as authorized by DOE Order 5400.5.

For each monitoring station, annual averages in Table 4-9 were calculated by finding the arithmetic average of the four quarterly values. The annual standard deviation was calculated by taking the square root of the sum of the squared quarterly standard deviations.

Ambient background concentrations were determined by calculating the arithmetic average of concentrations for the four background monitoring locations. These four locations are: RD-4001, RD-4004, RD-4005, and RD-4006. These data yielded an annual average background radon concentration (Rn-222 plus Rn-220) in 1990 of 0.3 pCi/l (11.1 Bq/m^3).

The quarterly radon concentrations at each monitoring location were compared statistically at the 95% confidence level, to the quarterly concentrations of the four background locations. Only those monitoring locations that were statistically greater than background were compared to the Derived Concentration Guideline.

4.1.4.1 Chemical Plant/Raffinate Pits. Radon concentrations at the WSS perimeter and at the raffinate pit locations were lower in 1990 than in 1989. Abnormally high values were recorded in 1988 because of a regional drought. The 1988 drought reduced the moisture content of soils and radium-containing wastes, thus allowing a greater fraction of radon in the soil and waste voids to diffuse into the atmosphere. Lower radon concentrations were measured in 1989 and continued to decrease in 1990. The concentrations measured in 1990 are typical of values expected during years with normal precipitation levels.

(c) Percent of guideline calculated only for stations that are statistically different from background.
* Denotes background station.
\- Denotes missing detector (vandalism).

4.1.4.2 Quarry. Only at the quarry were measured radon concentrations found to be statistically greater, at the 95% confidence level, than background radon concentrations. Radon concentrations found at the quarry are much greater than in concentrations measured at other WSS properties because the radium concentrations in quarry wastes are typically much greater than in other contaminated areas, and because the quarry is a large depression in the terrain with side walls ranging from 3 m to 15 m high (10 ft to 50 ft). In conjunction with stable meteorological conditions, this tends to trap emanating radon within the quarry and raises the concentrations along the quarry perimeter. However, none of the locations at the quarry showed annual average radon concentrations above the DOE DCG annual average radon concentration of 3 pCi/l (111 Bq/m^3). Third quarter results for station RD-1002 were above 3 pCi/l (111 Bq/m^3), but when averaged with the other three quarters the annual average concentration was less than 3 pCi/l. The concentrations at the quarry in 1990 were typical of years with normal precipitation.

4.1.4.3 Off-Site. Radon concentrations found at the off-site locations were lower in 1990 than in 1989. The concentration levels measured in 1990 were typical of years with normal precipitation.

4.1.5 Gamma Radiation Exposure Rate Monitoring Program and Results

Gamma rays are electromagnetic radiation emitted from the nucleus of atoms. The environment naturally contains radioactive substances which emit gamma radiation. Terrestrial radiation sources are natural radioactive elements in the environment found in soil and water. Cosmic radiation is high-energy radiation that originates in outer space and filters through the atmosphere reaching the earth's surface. Together, these two sources account for natural background gamma radiation. Terrestrial and cosmic radiation fluctuates depending on the soil composition and elevation above sea level.

Gamma radiation is emitted by many radionuclides in the U-238 and Th-232 decay series. These radionuclides are found in above-background concentrations at the WSS properties. Therefore, gamma radiation is monitored at the WSS.

Spherical environmental thermoluminescent dosimeters (TLDs) were deployed at 22 monitoring stations to monitor exposure from gamma radiation at the WSS. The monitoring station locations are the same as the ambient radon monitoring locations.

Ten monitoring stations are located at the WSCP/WSRP along the perimeter fence (Figure 4-10), six monitoring stations are located along the WSQ perimeter fence (Figure 4-11) and six monitoring stations are located off-site (Figures 4-10 and 4-11). Monitoring stations TD-4001, TD-4004, TD-4005, and TD-4006 measure natural background at locations unaffected by the site.

The TLDs are composed of five lithium fluoride chips in a durable spherical polyethylene holder. The TLDs are exchanged quarterly.

To determine background levels of gamma radiation as measured with the TLDs, the gamma exposures at the four background monitoring stations were averaged. This yielded an average of 62 mrem/year (0.62 mSv/yr) with two standard deviations of 16.3 mrem/yr (0.163 mSv/yr).

Table 4-10 summarizes the quarterly and annual total gamma radiation monitoring results at the 16 WSS perimeter monitoring stations, Francis Howell High School, the Weldon Spring Army Reserve Training Area (WSTA), and at the four background monitoring stations. The results reported in the table include two standard deviations. The United Nations (UNSCEAR 1982) estimates the external annual effective dose equivalent from all naturally occurring radiation in "normal" parts of the world to be 30 mrem/yr (0.3 mSv/yr) from cosmic sources and 35 mrem/yr (0.35 mSv/yr) from terrestrial radiation for a total of 65 mrem/yr (0.65 mSv/yr). This correlates well with the results from the WSS background monitoring stations.

TLDs were missing at various monitoring stations during all four quarters. In order to calculate an annual total gamma exposure rate, the missing data were replaced with the average of the remaining quarterly TLD results for those monitoring stations. Missing TLDs are indicated in Table 4-10 by a dash (-).

(a) Results include natural background.
(b) Year-to-date totals for locations where some quarterly data are unavailable were calculated using the average of the existing Quarterly data in place of the unavailable data.
* Denotes background station.
– Denotes a missing TLD.
To convert to mSv/yr, Divide by 100.

4.1.5.1 **Chemical Plant/Raffinate Pits.** At the WSCP/WSRP site perimeters, the annual exposures ranged from 53 mrem to 73 mrem (0.53 mSv to 0.73 mSv). There was no reason to suspect at the 95% confidence level, that any of the stations were greater than the background level.

4.1.5.2 **Quarry.** Two of the six monitoring stations at the quarry, TD-1001 and TD-1002 located on the north and east perimeter respectively, were statistically greater than background at the 95% confidence level. Station TD-1003 had the same annual total as TD-1002, but because it had a larger standard deviation it did not meet the statistically significant at 95% confidence level criteria. Permissible exposure level of 100 mrem (1.0 mSv) above background in unrestricted areas was not exceeded. Table 4-11 presents a comparison of the annual effective dose equivalent from external gamma radiation measured at TD-1001 and TD-1002, to the DOE 100 mrem/yr standard for all exposure modes as cited in DOE 5400.5. The percent of the DOE standard was calculated by subtracting the annual average background dose equivalent rate (62 mrem/year ± 16.3 mrem/year [0.62 ± 0.163 mSv/yr]) from the annual dose equivalent rate measured at stations TD-1001 and TD-1002 and then dividing by the 100 mrem/year (1.0 mSv/yr) DOE standard.

TABLE 4-11 Summary of TLD Monitoring Results of Stations That Exceeded Natural Background

STATION NUMBER	LOCATION	ANNUAL EXPOSURE (mrem/yr)	PERCENT OF DOE GUIDELINE[a]
TD-1001	WSQ North Perimeter	92	30
TD-1002	WSQ East Perimeter	76	8

(a) Percent of the DOE guideline is calculated by taking the annual exposure results minus the average background results divided by the DOE guideline of 100 mrem.

4.1.5.3 Off-Site. At the off-site locations the annual exposures ranged from 48 mrem to 69 mrem. Annual exposure at the Francis Howell High School was 51 mrem (0.51 mSv). At the U.S. Army Weldon Spring Training Area (WSTA) area the annual exposure was 57 mrem (0.57 mSv). At these two locations, the only off-site locations that are not background stations; there was no reason to suspect at the 95% confidence level, that the measured exposure levels were greater than background.

4.1.6 Radioactive Air Particulate Monitoring and Results

Radioactive air particulates are dust particles that carry radioactive contaminants. The main contributors to long-lived natural background radioactivity on dust particles are Po-210 and Pb-210 which are naturally occurring Rn-222 decay products. Surface soils also naturally contain radioactivity that becomes airborne and accounts, to a much lesser extent, for natural background concentrations of radioactive air particulates. Background concentrations of radioactive air particulates vary depending on soil moisture, wind, and geological conditions.

Many areas of the WSS properties contain elevated concentrations of radionuclides in the soil which could result in increased radioactive air particulate concentrations. Increased airborne radioactive particulate emissions from the WSS could result from work activities such as movement of equipment or vehicles in contaminated areas or from wind erosion.

Eleven air particulate samplers are used to monitor the WSS properties. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the WSCP

perimeter as shown on Figure 4-10. Two monitoring stations (AP-4006 and AP-4008) are located off-site at sensitive receptor locations, which are Francis Howell High School and the WSTA. The monitoring station (AP-4007), at the August A. Busch Wildlife Area (ABWA), is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown on Figure 4-11A. Two monitors (AP-1009 and AP-1010) located at the quarry, and one monitor (AP-4011) located approximately 0.7 km (0.4 mi) west of the quarry are used to monitor levels in the vicinity of the quarry. The quarry monitoring stations are shown on Figure 4-11.

The sampling station near the ABWA headquarters is used as a WSCP/WSRP and WSQ background air monitoring station. This station is approximately 0.8 km (0.5 mi) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/WSRP. In addition, winds from the southeast are relatively rare in this region.

The five air particulate samplers used at the WSCP, the two nearby off-site samplers, the background samplers at ABWA headquarters, and the three air particulate samplers used in and near the quarry are constant flow dual diaphragm units operating at a continuous total flow of 2.4 cu m/hr (85 ft^3/hour). These monitors use open-face sampling heads and do not segregate the air flow according to particle size. This results in the collection of respirable and non-respirable particles. Since respirable particles pose the most significant detrimental human health impacts, the analysis of both respirable and non-respirable radioactive air particulates will overestimate the respirable radioactive air particulate concentrations as well as the associated potential health hazard. Radioactive air particulate samples are collected on 47-mm (1.88 in.) diameter membrane filters with an effective pore size of 0.45 μm and filters are exchanged weekly.

The majority of the radionuclides present at the WSS and in the quarry waste are from the natural U-238 and Th-232 decay chains. Many of these radionuclides emit alpha particles during decay which pose the greatest hazard when deposited internally in the respiratory tract and lung. Therefore air particulate samples were analyzed for long-lived gross alpha activity. The long-lived gross alpha method of analysis sums the alpha activity from all of the long-lived alpha-emitting radionuclides.

The long-lived gross alpha measurements were made with a standard zinc-sulfide alpha scintillation detector. The alpha counts per filter were converted to radioactivity per volume of air for that filter and reported in μCi/ml (Bq/m^3).

The annual average long-lived concentrations and the calculated standard deviations for the 11 air monitoring locations are summarized in Table 4-12. The annual average long-lived alpha concentration for each monitoring location was calculated by averaging the weekly air particulate analysis results, or the counting instrument's lower limit of detection (LLD), whichever was greater.

All of the monitoring stations exhibited some long-lived alpha weekly concentrations less than the LLD. The "<" sign in Table 4-12 indicates that the actual average is less than the calculated average. The cause for this was the use of LLD values in calculation of the annual average concentration. When a value was reported as less than the LLD, the LLD value was used in the calculation. The standard deviation for each of the monitoring locations was calculated using only analysis results that were above the LLD, because the weekly LLD values were nearly the same, and to have used them would have resulted in a low bias in the annual standard deviation.

The typical LLD at the WSCP/WSRP monitoring locations was approximately 7.5×10^{-16} μCi/ml (.03 mBq/m^3). The WSQ monitoring locations typically achieved an LLD of approximately 7.7×10^{-16} μCi/ml (.03 mBq/m^3). These LLDs are low enough to allow detection of Th-232, the radionuclide with the lowest derived concentration guideline (DCG) found at the WSS. The DCG for Th-232 is 7×10^{-15} μCi/ml (.26 mBq/m^3). The DOE provides DCGs for airborne contaminants which, if inhaled by a member of the public continuously for one year, would result in a committed effective dose equivalent of 100 mrem (1 mSv).

4.1.6.1 Chemical Plant/Raffinate Pits. There was no reason to suspect at the 95% confidence level, that the annual average long-lived gross alpha concentrations measured at WSCP/WSRP monitoring stations were greater than background station (AP-4007). This means that there were no statistically significant above background radioactive air particulates concentrations measured at the WSCP/WSRP perimeter during 1990.

TABLE 4-12: 1990 Radioactive Air Particulate Results for the WSCP/RP and WSQ Areas

MONITOR IDENTIFICATION NUMBER	ANNUAL AVG. LONG-LIVED GROSS ALPHA CONCENTRATION ($X\ 10^{-15}$ µCi/ml)[b]	STANDARD DEVIATION	NUMBER OF VALUES ABOVE LLD[c]
AP-2001	<2.1	2.0	42
AP-2002	<2.5	8.6	45

4.1.6.2 Quarry. There are two airborne radioactive particulate monitoring stations along the WSQ perimeter. The long lived gross alpha activity measured at station AP-1009, located on the northeastern perimeter, was not statistically different at the 95% confidence level than the long lived gross alpha activity measured at the background station. The long lived gross alpha activity measured at Station AP-1010, located on the southern perimeter, was statistically different at the 95% confidence level than the long lived alpha activity measured at the background station. This is the first time that an annual average gross alpha concentration measured at any of the WSS air particulate monitoring stations has ever been statistically different at the 95% confidence level than the measured background concentration. During 1990, remediation activities at the quarry were in progress. Although engineering controls were in place to control dust, these activities could have resulted in the statistically significant above-background gross alpha activity measured at Station AP-1010. Although this was a statistically significant event, it would result in an effective dose

equivalent of less than 1 mrem to a hypothetical maximally exposed individual as is discussed in Section 4.1.8.2.

4.1.6.3 Off-Site. The annual average long-lived gross alpha concentrations at all off-site monitoring stations were not significantly different at the 95% confidence level than the long-lived background alpha activity measured at the background station during 1990. This is significant because it indicates that there are no releases from the WSQ or chemical plant that can be distinguished from background levels at these locations.

4.1.6.4 NESHAPs Annual Report. In 1990, the WSS initiated an environmental airborne particulate monitoring and quality assurance program sensitive enough to detect airborne radionuclide concentrations (other than radon) at the levels specified in the National Emissions Standards for Hazardous Air Pollutants (NESHAPs) (40 CFR 61 Subpart H). Subpart H of 40 CFR 61 requires that radionuclide emissions other than radon be determined and effective dose equivalents to members of the public be calculated using EPA approved procedures and computer models, or other procedures for which EPA has granted prior approval. The WSS has chosen to meet the NESHAPs emission monitoring and dose assessment requirements by measuring airborne radionuclide concentrations at designated critical receptor locations rather than through the use of computer modeling using the CAP-88, AIRDOS-PC, or EPA COMPLY computer models for determining dose. The WSS monitoring plan is contained in the report *Plan For Monitoring Radionuclide Emissions Other Than Radon at Weldon Spring Site Critical Receptors* (MKF and JEG 1990a) which has been approved by the EPA Region VII.

Airborne emissions at the WSS result from wind dispersal of surface soils, dust and dirt within the deteriorating buildings, and fugitive dust generated during remedial actions. Accurate monitoring of these emission sources is not practical because of uncertainties associated with the emissions inventory, dust particle entrainment, and micro-meteorology associated with these emission sources. The most accurate method of dose estimation at receptor locations near the WSS is via measurement of airborne concentrations at these locations, which are designated as critical receptor locations. Critical receptors are locations where members of the public abide or reside, and where the highest potential off-site concentrations of radionuclide other than radon are likely to occur during remediation of the WSS.

Tables 4-13 through 4-17 present the estimated effective dose equivalents (EDE) at each of the five designated critical receptor locations. The estimated EDEs at all critical receptor locations are less than 1 mrem (0.01 mSv). In order to determine EDEs, both the net airborne radionuclide concentrations (i.e., the airborne concentration at the critical receptor location less the background concentration) and the amount of time members of the public reside or abide at the critical receptor location must be known.

As outlined in the *Plan For Monitoring Radionuclides Other Than Radon at Weldon Spring Site Critical Receptor Locations* (MKF and JEG 1990a), air at critical receptor locations is sampled continuously and the air sample filters are collected weekly. All filters collected weekly in 1990 were composited separately for each critical receptor location, and the composited samples were sent to a subcontract laboratory for radiochemical analysis. The subcontract laboratory separated each composite sample into three aliquots to allow for a determination of analytical precision. Each aliquot was analyzed for isotopic uranium, isotopic thorium, Ra-226, and Ra-228. The gross radionuclide concentrations reported in Tables 4-13 through 4-17 are the averages of the results for the three aliquots. The net radionuclide concentrations equal the gross results minus the results reported for the WSS background monitoring station at the ABWA, which is designated as station AP–4007. The estimated EDE is then calculated by multiplying the net radionuclide concentrations in μCi/ml by an assumed breathing rate of 1.25 m^3/hr (44.14 ft^3/hr), the dose conversion factor in mrem/μCi as reported in *EPA Federal Guidance Report No. 11* (Eckerman et al. 1988) and the assumed exposure time at the specific critical receptor location. If the net concentration (gross minus background) was zero, or less than zero, then the net airborne concentration and the effective dose equivalent in Tables 4-13 through 4-17 was recorded as zero.

An EDE was calculated for each designated critical receptor monitoring location as is required by the EPA-approved NESHAPs compliance monitoring program for the WSS (MKF and JEG 1990a). Effective dose equivalents were calculated using net measured airborne radionuclide concentrations, the exposure time stated in the NESHAPs compliance monitoring program, a breathing rate of 1.25 m^3/hr, and the radionuclide-specific dose conversions factors provided in EPA Federal Guidance Report No. 11 (Eckerman, et al. 1988). The EDEs calculated for all critical receptor locations are all less than 0.3 mrem as is shown in Tables 4-13 through 4-17. It is likely, however, that the airborne radionuclide concentrations measured at all critical receptor locations are all measurements

of background concentrations. This is because, based on a T-test statistical comparison of airborne radionculide concentrations measured at the critical receptor locations versus concentrations measured at the background station, there is no reason to suspect, at the 95% confidence level, that there is a difference between the average of the concentration results measured at the background monitoring station and the average of the concentration results measured at any of the critical receptor locations other than at location AP-2005. The comparison of Th-228 analyses from stations AP-2005 and AP-4007 (background station) did not pass the statistical test at the 95% confidence level. The analysis results from station AP-2005 for Th-228 are probably an anomily because they are not supported by characterization data collected at the WSSRAP.

When Th-228 is detected uranium should also be detected. All site characterization data have indicated that whenever Ra-228 activity is present there are at least the same or greater U-238 activity concentrations. Th-228, a radioactive daughter product of Ra-228, has

a half-life of 1.9 years. At least 20 years have passed since the shutdown of the chemical plant, which is more than ample time for Th-228 to attain secular equilibrium with Ra-228. Therefore, whenever Ra-228 is present at the site, Th-228 should also be present at approximately the same activity level; and the U-238 activity should be equal to or greater than both Ra-228 and Th-228. However, analyses from station AP-2005 show that average gross Th-228 activity was almost five times higher than average gross U-238 activity. In addition, all uranium analyses from station AP-2005 passed the statistical test at the 95% confidence level. There is also no reason to suspect, at the 95% confidence level, that there is a difference between the long-lived gross alpha concentrations measured at the background monitoring station and the concentrations measured at any of the critical receptor locations.

There are five critical receptor locations surrounding the WSS. These locations are designated with the following identification numbers: AP-2001, AP-2005, AP-4006, AP-4008, and AP-4011. Critical receptor AP-2001 is the common boundary of the WSCP and the Missouri Highway Maintenance Facility. There are nine workers at the highway maintenance facility. The exposure time at this critical receptor location is 40 hr/wk for 50 wk/yr, or 2,000 hr/yr. Critical receptor AP-2005 is located near the WSSRAP administration building. There are approximately 150 workers at the administration building. The exposure time at this critical receptor location is 50 hr/wk, for 50 wk/yr, or 2,500 hr/yr. Critical receptor AP-4006 is located at the Francis Howell High School. There are approximately 1,800 students, faculty, and staff members at the high school. Faculty and staff generally spend more time at the school than do students. The exposure time for students, faculty and staff members at the high school is 45 hr/wk for 50 wk/yr at the school or 2,250 hr/yr. In addition, there is one employee who lives on the high school grounds; therefore, his exposure time is assumed to be continuous. This employee's exposure time is 24 hr/day, 365 day/yr or 8,760 hr/yr. Critical receptor AP-4008 is located on the WSTA. A remedial investigation is being conducted at the WSTA where Subcontract workers intermittently perform site characterization tasks. One employee of the Department of the Army works 40 hr/wk, 50 wk/yr which yields an exposure time of 2,000 hr/yr. Critical receptor AP-4011 is located approximately 0.7 km (0.4 mi) west of the quarry. There is a residence within 150 m (165 yd) of the critical receptor and directly in line with the quarry and critical receptor. The exposure time at the residence is continuous i.e., 8,760 hr/yr. Based on this exposure time and the radionuclide concentrations shown in Table 4-17, an effective dose equivalent of less than 1 mrem would be calculated for the residence.

In order to meet the detection limits specified in 40 CFR 61 Subpart H a strict quality control program must be maintained. The quality control program for the critical receptor includes spikes, blanks, duplicates, and control charts. In addition, analytical data quality objectives have been established for precision and accuracy. Precision is determined by averaging the results of the three duplicate analyses. The results of the precision samples are considered acceptable if the standard deviation of duplicate analysis is within ±50% of the average for 85% of the duplicate data sets. Analytical precision is also calculated for U-238/U-234 for each composite sample. Precision results are acceptable if the standard deviation of U-238 and U-234 results for each composite sample falls within ±50% of the average for 85% of all samples analyzed. Accuracy objectives are that 85% of the results for spiked samples are within ±50% of the known values.

Except for spiked samples, data quality objectives were met in all cases. Two samples were spiked with different concentrations of both U-238 and Th-230. Each spiked sample contained 13 filters; these were divided into thirds and each composite third was analyzed separately. All six composite thirds from the two U-238 spikes met the established criteria previously mentioned. However, four of the six Th-230 composite thirds did not meet established criteria for accuracy, so only 67% of all the spiked samples met accuracy criteria. Although accuracy for thorium spikes was not met, five of the six results were greater than the actual concentration and four of those were almost twice the actual concentration. This would indicate a probable high bias for Th-230 results. If Th-230 results are biased high, the effective dose equivalent calculation for Th-230 would also be high.

The Ra-228 analyses for the five critical receptor locations have gross radionuclide concentrations higher than those for the other isotopes of radium, thorium, and uranium. The higher Ra-228 results were consistent for all samples including blanks and spikes. The Ra-228 results are higher because the procedure for extracting Ra-228 also extracts other beta emitters into the analyte. This high bias for the method used is noted in the EPA document *Prescribed Procedures for Measurement of Radioactivity in Drinking Water* (EPA 1980).

The procedure for measurement of Ra-228 in drinking water is applicable to the analysis of air filters because the same radiochemistry procedure is applicable for both matrixes.

4.1.7 Unrestricted-Area Radiological Contamination Monitoring and Results

The WSS contains many areas of radiological contamination due to waste deposition and spillage during former uranium and thorium refining operations. Also, due to atmospheric releases of radioactivity during operations at the WSS, all structures and roads may have surficial contamination. The majority of the processing involved refining uranium, and thus uranium is the primary contaminant at the site.

Since 1986, the WSSRAP has employed an unrestricted-area monitoring program to ensure that radioactive materials are not migrating from the site (as a result of the remedial construction) to areas used by the general public.

This program includes radiological surveys of the WSSRAP administration building, laboratory, access control point for the site controlled area, WSSRAP trailers, subcontractor trailers, vehicles, site roadways, and a portion of the Katy Trail. Radiological surveys are usually performed monthly or at least quarterly. The surveys involve performing in situ measurements and collecting swipe samples.

In situ measurements are taken with a beta-gamma detector. Measurements are collected over a one-minute counting interval and then converted to disintegrations per minute per 100 cm^2 (dpm/100 cm^2) (dpm/15.5 $in.^2$). These measurements determine the total radioactivity; fixed plus removable.

Measurements of removable surficial contamination levels are made at each beta-gamma measurement location using a dry cloth or paper swipe. The swipes are wiped (smeared) over a surface area of approximately 100 cm^2 (15.5 $in.^2$). Swipes are analyzed for one minute using an alpha scintillation detector. The count rate results are corrected for detector efficiency to yield measurement results in dpm/100 cm^2 (dpm/15.5 $in.^2$).

For the purpose of this report, only the monitoring results for the WSSRAP roadways outside the controlled area and the Katy Trail are presented. These areas are discussed because they represent areas accessible to the public. All other monitoring results are on file at the WSSRAP. Performance of these surveys to date confirms that contaminated materials are not being carried into unrestricted areas.

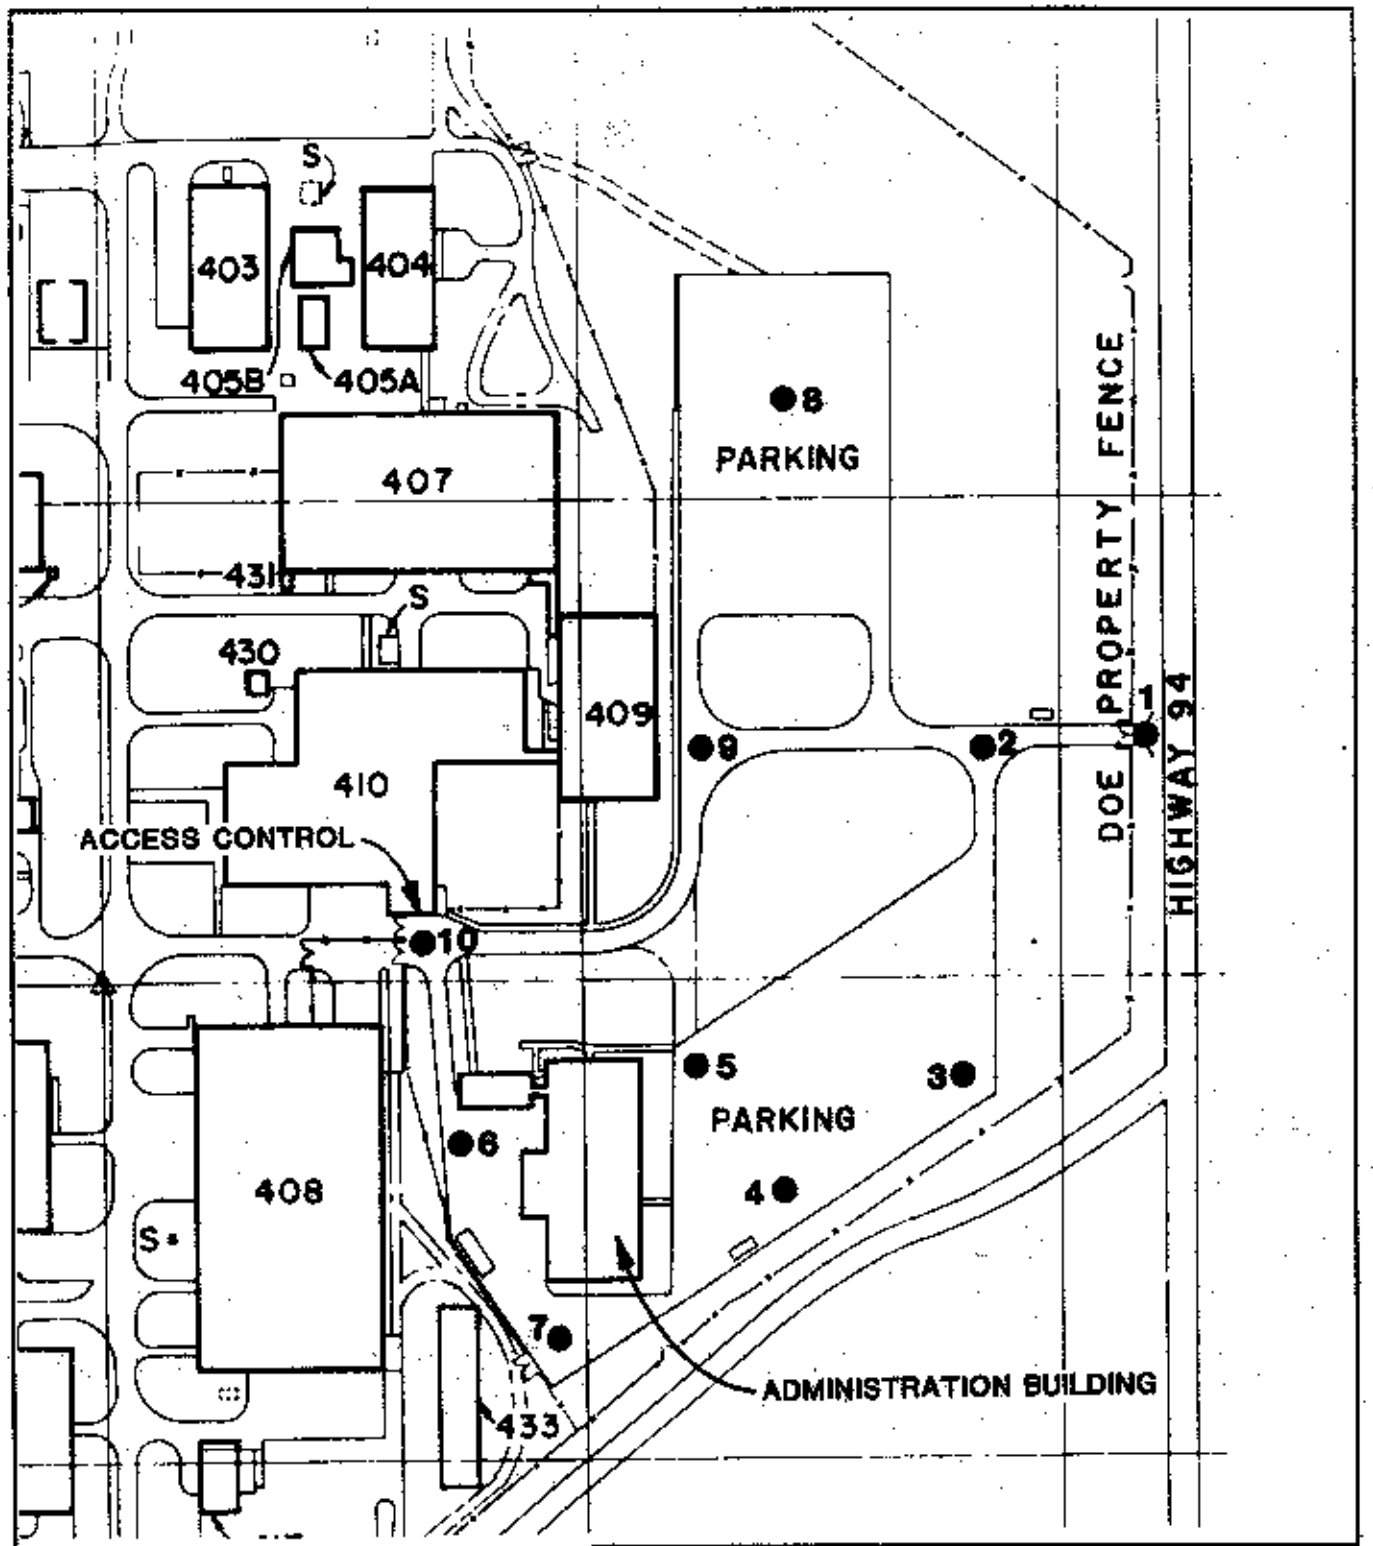
Figure 4-12 shows the monitoring locations for the roadways outside the controlled area. Table 4-18 lists the annual average beta-gamma and alpha monitoring results at each location. The "<" signs in the table indicate that some of the measurements at that location were less than the minimum detectable activity (MDA) of the instruments used. In such cases, the MDA of the instrument was used to calculate the annual average. Also included in the table are the associated standard deviations of the beta-gamma and alpha results. The standard deviation for each of the monitoring locations was calculated using only analysis results that were above the MDA, because the weekly MDS values were nearly the same, and to have used them would have resulted in a low basis in the standard deviation.

The results of the monitoring show that fixed contamination is present at a few locations, but only at levels well below the DOE uranium surface contamination guidelines for unrestricted use of 5,000 dpm/100 cm^2 (5,000 dpm/15.5 $in.^2$). The probable cause of the contamination is the deposition of atmospheric releases of uranium during the operation of the Weldon Spring Uranium Feed Materials Plant (WSUFMP). Since monitoring began, there has been no increase in the removable contamination levels on the uncontrolled area roadways at the WSS.

The Katy Trail is shown on Figure 4-13. An approximate 1,130-m (1,243 yd) stretch of the trail is monitored due to its proximity to the WSQ and Femme Osage Slough. Beta/gamma measurements are taken at 10 locations along the trail. The section that is monitored is shaded in Figure 4-13. The 10 locations are varied each time so as to check for any mobile contamination over the entire length of the monitored portion of the trail.

Table 4-19 lists the average beta-gamma and alpha monitoring results for each location. The "<" signs in the table indicate that some of the measurements at that location were less than the MDA of the instrument used. In such cases, the MDAs of the instruments were used to calculate the annual average. The table also includes associated standard deviations of the beta-gamma and alpha results.

The results from all monitoring locations along the Katy Trail indicate background radionuclide concentration levels. A soil sample was taken at location No. 1 because this location had the highest average beta-gamma monitoring results. The analysis of this soil sample showed concentrations within the typical background concentrations ranges of U-238, Ra-226, Ra-228, and K-40. There is no evidence of radioactive material migrating from the



ROAD SURVEY LOCATIONS

WSQ or the Femme Osage Slough area on to the Katy Trail, and thus, there is no identifiable probability of radiological contamination to users of the Katy Trail.

4.1.8 Radiological Exposure Assessments

In assessing the health effects of the radioactive materials present at the WSCP/WSRP, WSQ, and WSVP as required by DOE Order 5484.1; radiological exposure was evaluated for a maximally exposed individual at the WSCP/WSRP, the WSQ, the WSVP, and for the general population within 80 km (50 mi) of the WSS. The scenarios and models used to evaluate radiological exposures are conservative and simplistic, but are realistic in the attempt to estimate exposures attributable to the WSSRAP. This is appropriate since the above-background airborne radioactive particulate concentrations, radon concentrations, and external gamma radiation measured during 1990 result in an estimated effective dose

equivalent of less than 3.9 mrem to a hypothetical maximally exposed individual as shown in Table 4-20 and discussed in this section.

Many of the parameter values and assumptions used in the calculation of effective dose equivalents to hypothetical maximally exposed individuals and to the potentially exposed population are provided in subsections 4.1.8.1 through 4.1.8.4. A more detailed account of assumptions, parameters valves, and equations used to calculate effective dose equivalents is provided in Appendix G, Dose Assessment Calculations.

Individuals could be exposed to radioactivity from the WSS via five principal pathways: (1) direct external gamma radiation, (2) inhalation of radon, (3) inhalation of airborne radioactive dust particles, (4) ingestion of fish from nearby lakes that receive runoff from the WSS, and (5) ingestion of drinking water from sources contaminated with

TABLE 4-20 Estimated Effective Dose Equivalent to a Maximally Exposed Individual and Estimated Collective Population Dose for the Weldon Spring Site

	AIRBORNE PARTICULATES EDE	GAMMA EDE	RADON EDE	TOTAL EDE	PERCENT OF EPA[a] STANDARD	PERCENT OF DOE[b] GUIDELINE
Radiation dose to a maximally exposed individual	0.006 mrem	0.55 mrem	3.3 mrem	3.9 mrem	0.06	3.9
Radiation collective population dose	0.0002 person-rem	0.004 person-rem	0.055 person-rem	0.059 person-rem	N/A	N/A

(a) The EPA standard limits effective dose equivalents (EDE) from airborne emissions other than radon to 10 mrem annually. The WSSRAPs effective dose equivalent from airborne particulates was compared to the EPA standard.

(b) The DOE guideline limits effective dose equivalents from plant emissions to 100 mrem annually. The WSSRAPs total effective dose equivalent was compared to the DOE guideline.

radionuclides from the WSS. All five pathways were included for the hypothetical maximally exposed individual. Pathway 4 was not considered in the population dose assessments because it is not reasonable or realistic to expect all members of a population to eat fish from bodies of water that receive runoff from the WSS. Pathway 5 was not considered in the population dose estimate because none of the surface water or groundwater voids that receive runoff or recharge from the WSS are used as drinking water sources. An evaluation of radiological exposures from these lakes when they are used for recreational purposes was included to ensure that the assessment would be thorough.

Although radiation doses can be calculated or measured for individuals, it is not practical to predict the health risk to a single individual. Estimates of health risks related to radiation doses are based on statistical data collected from large groups of people exposed to radiation under various circumstances. Statistical models are not applicable to a single individual. Therefore, dose equivalents to a single individual are estimated by hypothesizing a maximally exposed individual and placing this individual in a reasonable, but very conservative scenario.

Exposures of maximally exposed individuals and individuals near the off-site water bodies are given in terms of an effective dose equivalent (EDE). Exposures of people in neighboring facilities and populations within 80 km (50 mi) of the WSS are expressed in

terms of collective effective dose equivalent (CEDE) in units of person-rems (person-sieverts). Table 4-20 reports the estimated effective dose equivalents to the hypothetical maximally exposed individual and the estimated collective population dose. The effective dose equivalents to the hypothetical maximally exposed individual near the WSCP/WSRP, WSQ,
and WSVP are <1 mrem, 3.8 mrem, and <1 mrem (<0.01 mSv, 0.038 mSv, and <0.01 mSv) respectively. The highest of these three results was included in Table 4-20. All calculations were performed using the methodology described in International Commission on Radiation Protection (ICRP) reports 26 and 30 for a 50-yr committed effective dose equivalent (ICRP 1977; 1979). Fifty-year committed effective dose equivalent conversion factors were obtained from the EPA Federal Guidance Report No. 11 (Eckerman 1988).

In Table 4-20, the estimated effective dose equivalent for the hypothetical maximally exposed individual due to airborne radioactive particulates is compared to the EPA standard of 10 mrem annually for airborne emissions other than radon. It is not clear whether the emission standards in 40 CFR 61 subpart H are meant to apply to fugitive emissions from a site being remediated according to CERCLA. DOE is attempting to clarify this through a draft Memorandum of Understanding (MOU) with EPA. Until this issue is resolved, exposures due to fugitive emissions from area sources will be compared to the standards in 40 CFR 61 subpart H.

4.1.8.1 Radiation Dose From the WSCP/WSRP to a Hypothetical Maximally Exposed Individual. This section provides an estimated committed effective dose equivalent to a hypothetical individual assumed to frequent the perimeter of the WSCP/WSRP and to receive a radiation dose by the five pathways identified above. No private residences are adjacent to the WSCP/WSRP sites; therefore, all calculations of dose equivalent due to direct gamma exposure, airborne radioactive particle inhalation, and radon daughter inhalation assume a realistic less than 100% residence time. The amount of fish obtained and ingested from lakes receiving effluent from the WSCP/WSRP is assumed to be the average consumption rate per year according to U.S. Environmental Protection Agency statistics (Eckerman et al. 1988). None of these bodies of water are used as sources of drinking water. However, an evaluation of this pathway is included on the assumption that people could conceivably drink from them.

Direct gamma exposure rates were determined by means of TLD monitoring stations at the WSTA, the Missouri State Highway Department facility, and the ABWA. Continuous air samplers measured airborne radioactive particulates at these three locations, and radon exposures were measured via alpha track-etch detectors. There is no reason to suspect (with 95% confidence) that gamma exposure rates, airborne radioactive particulate concentrations, and radon gas concentrations exceed natural background; therefore, the effective dose equivalent to a hypothetical individual receiving the maximum reasonable exposure from these three pathways is not measurable above normal background exposure.

Three off-site bodies of water (Busch Lakes 34, 35, and 36) receive runoff from drainage originating at the WSCP/WSRP site. All three lakes are used for fishing and boating. In 1990, a bio-uptake investigation was conducted in order to determine the possible exposure of humans to chemical and radioactive contamination from ingestion of fish and game affected by previous operations at the WSS. This investigation included collecting fish samples from the three Busch lakes.

A variety of fish were collected from the lakes which included bass, catfish, sunfish, and crappie. Fillets representing the edible portion of the fish were sent for analysis. The fish were analyzed for uranium only because radium and thorium concentrations in lake sediments and water were not above normal background levels.

The analysis results for the various fish were combined and averaged. The average U-238 concentrations in the fish collected from Lakes 34, 35, and 36 were 0.001 pCi/g, 0.005 pCi/g, and 0.018 pCi/g, respectively. Using an average consumption rate of 6.5 g/day (0.23 oz/day) for fresh-water fish (EPA 1988) and EPA dose conversion factors (Eckerman et al. 1988) the highest calculated annual dose from ingestion of fish living in these lakes would be less than 1 mrem (0.01 mSv).

None of these lakes are presently used for drinking or irrigation. Swimming is not permitted in these lakes; however, it is realistic to assume the hypothetical maximally exposed individual would swim in the lakes despite the rules. Swimming can result in the ingestion of 0.05 liters/hr (0.05 qt/hr) on average (EPA 1988). Assuming that the individual swims in Lake 36, which has the highest average surface water concentration (51 pCi/l, or 1,887 Bq/m^3) for 12 hr/yr based on swimming 1 hr/wk during the summer or approximately

three months and using EPA dose conversion factors (Eckerman et al. 1988), the calculated dose would be less than 1 mrem (0.01 mSv).

It is also possible for an individual to ingest lake sediments during visits to the lakes. It is assumed the hypothetical individual would spend an average of approximately 2 day/yr at the lakes consuming 200 mg/day. Using the average uranium concentration of surface sediments for Lake 34 which has the highest value of 46.8 pCi/g (1.7 Bq/g) and EPA dose conversion factors, the calculated effective dose equivalent would be below 1 mrem (0.01 mSv).

A maximally exposed individual would therefore receive a total effective dose equivalent of less than 1 mrem (0.01 mSv) from direct gamma exposure, inhalation of airborne dust particles, inhalation of radon daughters, ingestion of water and sediment, and ingestion of fish from contaminated waters.

4.1.8.2 Radiation Dose From the WSQ to a Hypothetical Maximally Exposed Individual. This section discusses the estimated committed effective dose equivalent of a hypothetical individual assumed to frequent the perimeter of the WSQ and receive a radiation dose by three of the five pathways identified above. No private residences are adjacent to the WSQ site; therefore, all calculations of direct gamma exposure, airborne radioactive particulate concentrations, and radon daughter inhalation assume a realistic less than 100% residence time. Access to the quarry is controlled by a barbed wire fence; thus fishing, swimming, and drinking water from the quarry pond need not be evaluated.

In order to estimate the effective dose equivalent received via the inhalation pathway, a breathing rate must be assumed. The breathing rate assumed for all inhalation pathway calculations is 1.25 m^3/hr (Cember 1983). All effective dose equivalent conversion factors were determined from the EPA Federal Guidance Report No. 11 (Eckerman et al. 1988).

The exposure scenario consists of a hypothetical individual who routinely walks along the northern boundary of the quarry on State Route 94. The individual is assumed to make this trip twice per day, 250 day/yr. Average residence time per day is estimated to be 12 min (ANL 1989), resulting in an annual exposure time of 50 hr/yr. An individual driving by the site twice per day, could receive an exposure; but it would be insignificant relative to the walking scenario and, therefore, was not considered in the calculation.

Data from three environmental TLD monitoring stations were used to evaluate the dose by direct gamma exposure of the hypothetical individual. The dose from external gamma radiation was calculated by multiplying the length of time the individual would be exposed by the radiation field strength. Using these conservative assumptions and the highest measured gamma exposure rate (30 μrem/hr at TD-1001), the calculated dose equivalent would be less than 1 mrem (0.01 mSv).

Analysis of long-lived gross alpha activity from airborne radioactive particulate data from 1990 indicated that results from monitoring station AP-1010 on the quarry southern perimeter were significantly different than background at the 95% confidence level. The net average airborne long-lived gross alpha concentration at station AP–1010 (i.e., the concentration measured at AP-1010 less the background concentration measured at the Busch Wildlife Area) was 4.6 E–16 μCi/ml. This net airborne gross alpha concentration was proportioned among uranium, radium, and thorium isotopes according to the average radionuclide concentration results measured in the surface (0 m to 0.15 m) wastes within the WSQ and reported in the Remedial Investigation for the Quarry Bulk Waste (MKF and JEG 1989a). Using this assumption, the measured concentration would result in an estimated effective dose equivalent of less than 1 mrem (0.01 mSv).

The risk associated with Rn-222 is due primarily to inhalation of its short-lived daughter products. Data from the three alpha track-etch radon monitoring stations closest to State Route 94 were used to evaluate the dose by inhalation of radon daughters for the hypothetical individual. The highest average measured radon gas concentration at these monitoring stations was 1.8 pCi/l (67 Bq/m^3) above normal background. Assuming a 50% equilibrium between radon gas and its daughters and 1.25 rem/working level month (WLM) (12 mSv/WLM) effective dose equivalent conversion factor derived from EPA guidance (Eckerman et al. 1988), the estimated effective dose equivalent from inhalation of radon daughters is 3.3 mrem (0.033 mSv).

The dose to the hypothetical maximally exposed individual from the three pathways discussed above consists of a total of 3.8 mrem (0.038 mSv) from direct gamma exposure, inhalation of radon daughters and inhalation of radioactive air particulates.

4.1.8.3 Radiation Dose From WSVPs to a Hypothetical Maximally Exposed Individual. This section discusses the estimated effective dose equivalent to a hypothetical

individual assumed to frequent the largest vicinity property, the Femme Osage Slough, located south of the WSQ. This scenario provides a very conservative but plausible exposure assessment. No private residences are adjacent to the slough (it is on land that is currently managed by the Missouri Department of Conservation as part of the Weldon Spring Wildlife Refuge); therefore, all direct gamma exposure calculations assume a realistic less than 100% time of residence. The slough is not suspected of having airborne radioactive particulate concentrations and radon daughter concentrations above normal background because it is in a floodplain with saturated soil. The water in the soil minimizes airborne migration. In addition, the slough is contaminated only with uranium, implying that above-background concentrations of radon are not possible.

The amount of fish obtained and ingested from the Femme Osage Slough assumes the average consumption rate of 6.5 g/day (0.23 oz/day) according to EPA estimates (EPA 1988). Because of the stagnant water conditions, the slough is not a source of drinking water, nor is it a place for recreational swimming. Therefore, these pathways were not included in the dose calculations, and airborne radioactive particulates and radon daughter concentrations were not measured.

External gamma dose rate measurements were used to derive the effective dose equivalent by direct gamma exposure for the maximally exposed individual who is assumed to sit on the bank of the slough and fish 4 hr/wk, 50 wk/yr. The measurements were taken with a pressurized ion chamber (PIC) on the bank of the slough in an area of known radioactive soil contamination. Using the measured external gamma dose equivalent rate of 10.3 μrem/hr, which is 2.5 μrem/hr in excess of natural background, the calculated dose equivalent would be less than 1 mrem (0.01 mSv).

As part of the bio-uptake study, fish samples were collected and analyzed for total uranium, Th-230, Th-232, and Ra-226. All results were below detection limits. Uranium is the only radionuclide in the slough sediments and water that is elevated above background concentrations; therefore, uranium and its decay products are the only radionuclides that were considered for possible uptake. Assuming that the uranium concentration in fish is equal to the detection limit achieved during tissue analysis, the fish tissue concentration is 0.01 pCi/g (0.27 mBq/g). Using the average annual consumption rate of 6.5 g/day (0.23 oz/day) (EPA 1988), the calculated effective dose equivalent to the maximally exposed

individual from ingestion of fish living in contaminated waters would be less than 1 mrem (0.01 mSv).

The dose to the maximally exposed individual from the two pathways discussed above consists of a total of less than 1 mrem (0.01 mSv) from direct gamma exposure and consumption of fish tissue.

4.1.8.4 Collective Population Dose. The risk from radiation exposure to the general population is a function of the number of persons exposed, duration of exposure, and concentration or exposure rate to which the population is exposed. Below an absorbed dose of 10 rad (0.1 Gy) the projection of risk is uncertain. This is more than 30 times the typical yearly natural background exposure in the United States. In fact, no statistically significant adverse effects of radiation exposure have ever been proven at low doses of radiation. This is substantiated by studies of human populations exposed in regions of the world where natural background exposures are several times higher than those typically incurred in the United States. In these regions of higher background radiation exposures, the rate of adverse health effects has not been shown to increase above those which occur due to other factors (BEIR IV 1988).

The collective effective dose equivalent estimate is the product of the effective dose equivalent estimate at the exposure point and the number of persons exposed. Exposure points are locations where members of the public are potentially being exposed to airborne radioactive particulate concentrations, radon gas concentrations, external gamma radiation, or radionuclide concentration in water or food at above-background levels. The effective dose equivalent is calculated by estimating radionuclide concentrations in the air, water, food, and external gamma pathways at a given exposure point and developing reasonable exposure scenarios to estimate the amount of radioactivity ingested and inhaled and external gamma radiation received by the potentially exposed population.

The collective dose equivalent estimate for 1990 is less than 0.059 person-rem. The estimated exposed population is 72,000 persons. The following paragraphs discuss the exposure points, estimated radionuclide concentrations in the various pathways, and summaries of exposure scenarios used to develop the collective effective dose equivalent estimate.

The potential exposure point locations were chosen on the basis of analytical results from critical receptor monitoring stations and WSQ perimeter monitoring stations. None of the analytical results from critical receptor monitoring stations were significantly different than background concentrations at the 95% confidence level for long-lived gross alpha concentrations of airborne radioactive particulates, radon gas, and external gamma exposure. Since the results from all critical receptor monitoring locations were not significantly different than background concentrations, no collective effective dose equivalent estimate was made for populations at or beyond the critical receptor locations.

Analytical results from the WSQ perimeter monitoring stations were used to estimate airborne radioactive particulate and radon gas concentrations and the resulting collective effective dose equivalent estimate at the Katy Trail, which is a recreational trail located on state-owned land south of the quarry. The Katy Trail lies approximately 45 m (46 yd) south of the quarry at its closest point and about 25 m (27.5 yd) below the southern quarry rim. It parallels the southern rim for approximately 260 m (286 yd). The Katy Trail was chosen as the only potential exposure point location because only at the quarry were statistically significant above background radon and air particulate concentrations measured. The estimated number of people using the Katy Trail annually is 72,000, which was derived from an estimate provided by the Missouri State Parks Department in February 1991, (Maher 1991). Results from monitoring stations at other potentially affected populations near the WSQ (e.g., monitoring stations AP-4011 and RD-4006) are not significantly different than background levels. Figure 4-11 shows the locations of all WSQ perimeter monitoring stations as well as the Katy Trail.

The Katy Trail was chosen as the only potential exposure point location; because only at the WSQ were measured concentrations found to be statistically different at the 95% confidence level than the measured background concentrations for radon, external gamma radiation, and airborne radioactive particulates. Results at all non-WSQ monitoring locations, including the designated critical receptor locations, were not statistically different than the measured background concentrations at the 95% confidence level. Since measured concentrations at all monitoring locations other than the WSQ monitoring stations were not significantly different than background, and the monitoring network includes a monitoring station at every public receptor location within 2.5 km (1.5 mi) of the site, there were no other potential public exposure points during 1990.

The collective effective dose equivalent estimate was determined by calculation of conservatively-estimated airborne particulate and radon gas concentrations at the Katy Trail and an assumed exposure time of 5 min, which corresponds to a 3.2 km/hr (2 mi/hr) walking speed along the 260 m (286 yd) length of trail which parallels the WSQ. The breathing rate used in calculation of effective dose equivalent via the inhalation pathway was 1.25 m^3/hr (Cember 1983) and the dose equivalent conversion factors were obtained from EPA Federal Guidance Report No. 11 (Eckerman et al. 1988). Airborne radioactive particulate and radon concentrations at the WSQ were estimated using a Gaussian atmospheric dispersion model modified to predict concentrations close to an area source (DOE 1986). External gamma radiation is estimated using the inverse square law modified for an area source (Cember 1983). Details on calculations and assumptions used to calculate the effective dose equivalent are provided in Appendix G.

None of the surface water or groundwater bodies that receive runoff or recharge from the WSS are used as drinking water sources; therefore, this pathway was not included in the dose evaluation. It is not realistic to expect that a significant number of persons living within 80 km (50 mi) of the site consume fish or game affective by the WSS; hence this is not a significant exposure pathway (see Section 4.1.8.1).

The above-background airborne particulate and radon gas concentration estimates at the Katy Trail were 1.7E-16 µCi/ml and 0.26 pCi/l respectively. The above-background external gamma dose equivalent rate estimate is 7.7E-4 mrem/hr.

The resultant concentration estimates at the Katy Trail exposure point are conservative, because the model used to estimate concentrations at the trail assumes that the wind direction toward the trail remains continuous. Since the wind direction is variable, the true average concentrations of airborne particulates and radon gas at the exposure point would be lower than predicted by the model. More realistic wind direction estimates were not included in the model, because increasing the model complexity was not warranted based on the extremely low collective population dose estimate obtained by the conservative model used (DOE Order 5400.5).

4.1.8.5. Five Year Trend Analysis of Radon Gas. Track etch radon detector results from the last five years are represented graphically in Figure 4-14. The graph represents the

yearly averages of results from the monitoring stations at the quarry, chemical plant, raffinate pits, and off-site locations. The results shown include natural background.

The graph shows a definite increase and decrease in radon concentrations centered around 1988. This is due to the regional drought which occurred during this time period. The drought reduced the moisture content of the soil and the low moisture content allowed a greater fraction of the radon in the voids to diffuse into the atmosphere.

The quarry annual average concentrations, which are higher than other locations, also had greater increases in radon concentrations in proportion to the other locations. This is due to the higher concentrations of uranium and thorium at the quarry. Radon is a naturally occurring radionuclide in the uranium and thorium decay series.

4.1.8.6. Five Year Trend TLD. Gamma radiation exposure monitoring results from the last five years are represented graphically in Figure 4-15. the graph represents the yearly averages of results from monitoring stations at the quarry, chemical plants, raffinate pits, and off-site locations. The results shown include natural background.

As shown in the graph, there is a difference of approximately 20 mrem between 1986 and 1987 data, and 1988-1990 data. The 20 mrem change between the two time periods can not be explained by changes in the radionuclide inventory, since the radionculide inventory at the WSSRAP has not significantly changed since 1986. The control thermoluminescent dosimeter (TLD) results reported in 1986 and 1987 were also approximately 20 mrem higher than the control TLD results reported in 1988 through 1990. Control TLDS are included in every quarterly shipment of environmental TLDs and are used as a quality control check to verify that the environmental TLDs were not exposed to a radioactive source during transportation from the WSSRAP to the subcontract laboratory. The subcontract laboratory that provides and analyzes the TLDs was contacted and indicated that a probable cause for the change between 1987 and 1988 could be due to improvements, based on additional testing and research, in the calculation of effective dose equivalents measured by the environmental TLDs. The graph shows that while there has been small variations in the effective dose equivalents measured with the environmental TLDs, during the period from 1988 to 1990, there is not an increasing trend in the effective dose equivalents resulting from gamma exposure.

4.1.9 Radiological Release Estimates

During 1990 air particulate monitoring station AP-1010, located at the rim of the quarry, was the only location which had results that were statistically above background. An average of 4.6E-16 pCi/ml above background gross alpha results were obtained at station AP-1010. Using this concentration and a box model, calculations showed that 1.08E-5 Ci of gross alpha activity was released form the quarry perimeter. Assuming that the ratios of the various nuclides on filter are the same as those for surface soils reported in the remedial investigations for quarry bulk waste report (MKF and JEG 1989), the calculated amounts of the radionuclides range from 5.8 pCi to 0.3 pCi. Based on the reported activity of uranium that was released, and a specific activity of 3.3E-5 pCi/g, a total of 8.9 grams of uranium were released from the quarry perimeter. The results of the calculated quantities of radioactive materials are shown in Table 4-20A.

Intermittent surface water runoff also transported uranium (in the natural distribution) from the site area during 1990 through five major discharge routes. These routes are monitored through monthly sampling of the runoff water, as is required under the site's NPDES permit (see Section 4.2.4). Table 4-28 shows the discharge of natural uranium from the NPDES outfalls. Based upon those estimated total activities, and since the uranium on the site maintains a natural distribution of the isotopes, the estimated activity by isotope is calculated and is shown in Table 4-20A. Other radionuclides were not measured in surface water during 1990.

4.2 Non-Radiological Monitoring Program Information

4.2.1 Surface Water and Spring Monitoring

The environmental monitoring program for chemical constituents in surface water and springs for 1990 include 10 locations, nine of which were within or near the site and the other location was located within the quarry sump. The four surface water locations within the four on-site raffinate pits (SW-3001 through SW-3004), were monitored annually for inorganic anions. The five spring locations, SP-5201, SP-6301, SP–6302, SP-6303, and

TABLE 4-20A Radionuclide Emissions to the Environment

RADIONUCLIDE	ACTIVITY OF RADIONUCLIDE RELEASED TO AIR (Ci)	ACTIVITY OF RADIONUCLIDE RELEASED TO WATER	HALF-LIFE (yrs)
U-238	2.89E-6	1.8E-2	4.47E9
U-235	1.34E-7	8.0E-4	7.04E8
U-234	2.89E-6	1.8E-2	2.45E5
Th-232	3.24E-7	—	1.40E10
Th-230	2.49E-6	—	7.54E4
Ra-228	3.24E-7	—	5.76
Ra-226	1.76E-6	—	1,600
Rn-222	16.4	—	3.82 days

SP–6306 located off-site were monitored for nitroaromatics either semiannually or quarterly, and two of the same springs, SP-6301 and SP-6306, were monitored annually for inorganic anions. The surface water monitoring location within the quarry, the quarry pond (SW–1008), was sampled quarterly for inorganic anions and nitroaromatics.

4.2.1.1 Inorganic Anion Analyses in Surface Water at the WSCP. The inorganic anions of interest included chloride, fluoride, nitrate, and sulfate. The following text details the results and implications of the anion analyses. Annual averages of these analytical results are presented in Tables 4-1 and 4-2.

The average chloride levels measured in the two off-site surface water locations ranged from 7.4 mg/l at SP-6306 to 32.0 mg/l at SP-6301. These values are within their historical range. These results indicate that the chloride levels off-site do not pose a threat to public health or safety as the secondary standard for chloride is 250 mg/l. No standards exist for protection of aquatic life or biota. The average chloride levels located onsite ranged from 7.83 mg/l to 30.3 mg/l within the raffinate pits. These values are also within their historical ranges.

The measured average fluoride concentrations at the off-site sampling locations remained below 0.2 mg/l. The highest concentration measured in the raffinate pits was 0.9 mg/l which remains well within the EPA's maximum contaminant level (MCL) of 4 mg/l

for fluoride. Fluoride does not constitute a major contamination problem at the WSCP/WSRP.

Off-site concentrations of nitrate (as N) ranged from 2.7 mg/l at SP-6306 to 42.0 mg/l at SP-6301, (Burgermeister Spring). The level at Burgermeister Spring is below its historical range. However, the nitrate levels reinforce the conclusion that contaminated groundwater is apparently contributing to the elevated nitrate levels in the Burgermeister Spring. The levels of nitrate (as N) that are present in Burgermeister Spring are above the drinking water standard of 10 mg/l; however, these nitrate levels constitute no particular threat to human health or the environment as the water is not used domestically, but they do provide valuable information on the mechanics of contaminant migration from the WSS. Nitrate levels within the raffinate pits remained within their historical ranges also. Nitrate values ranged from a low of ND in SW-3002 to a high of 1900 mg/l in SW-3003 (see Table 4-1).

The off-site sulfate measurements made as part of the surface water monitoring program yielded levels ranging between 13.5 mg/l at SP-6306 and 54.0 mg/l at SP-6301. The sulfate value of 54 mg/l at Burgermeister Spring remains within its historical range and possibly suggests a component of sulfate contaminated groundwater discharging at that point. The measured level is well below the EPA's secondary drinking water standard of 250 mg/l for sulfate.

Sulfate levels within the raffinate pits remained within their historical range with a low of 37.5 mg/l at SW-3004 and a high of 695.0 mg/l at SW-3003.

4.2.1.2 Nitroaromatic Compound Monitoring - WSCP/RP Surface Water. The monitoring program for nitroaromatic compounds in 1990 involved quarterly and semi-annual sampling at five off-site locations, SP-5201, SP-6301, SP-6302, SP-6303 and SP-6306. Table 4-21 shows the levels of nitroaromatic compounds detected in those springs. No routine monitoring for nitroaromatic compounds was performed during 1990 at the raffinate pit locations (SW-3001 through SW-3004).

The monitoring results confirm what has been detected historically at the off-site monitoring locations. Total nitroaromatics were detected at levels above the detection limits to a high of 0.8 µg/l at Burgermeister Spring. Positive results were also indicated at SP-5201,

TABLE 4-21 1990 Annual Average Nitroaromatic Concentrations (ug/l) in Springs

WSSRAP ID	1,3,5-TRINITROBENZENE	@	1,3-DINITROBENZENE	@	2,4,6-TNT	@	2,4-DNT	@	2,6-DNT	@	NITROBENZENE	@	NITROTOLUENE	@
SP-5201	1.1	(1/2)	ND	(0/2)	8.4	(2/2)	ND	(0/2)	0.4	(2/2)	ND	(0/2)	NSF

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.
ND - Not Detected
NSF - Not Scheduled For Sampling
@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4) indicates that four samples were taken in 1990, two of which average 2.00 and the other two samples were ND.

downstream of a known source of this contamination known as the Department of Army Burn Area No. 1.

4.2.2 Weldon Spring Quarry Surface Water Monitoring

4.2.2.1 Inorganic Anions Results. Inorganic anions were analyzed on a quarterly basis on samples from the quarry pond. The inorganic anions category includes chlorides, fluorides, nitrates, and sulfates. The results of the analyses are presented for each parameter below. Table 4-4 shows the annual averages for each parameter measured.

The highest measured chloride value detected in the quarry sump was 12.4 mg/l with an annual average of 12.1 mg/l. The levels measured in 1990 at SW-1008 have remained very nearly the same compared to historical values. The relatively slight variations can be accounted for by natural dilution effects.

Fluoride levels also remained within their historical range at SW-1008. The annual average for fluoride at SW-1008 was 0.9 mg/l.

The nitrate levels for SW-1008 remained below the detection limit for 1990.

The sulfate measurements ranged from 118 mg/l to 161 mg/l with an average value of 139.5 mg/l at SW-1008. This level is the same as historical values at this location. All measured levels remained well below the EPA's secondary drinking water standard for sulfate of 250 mg/l.

4.2.2.2 Results for Nitroaromatics Analyses in WSQ Surface Water. The quarry pond SW-1008 was sampled quarterly for nitroaromatic compounds. The total quantified concentrations of all six compounds ranged from 1.8 ug/l during the first quarter to 16.2 ug/l during the fourth quarter. Table 4-22 shows those measured values. Samples will continue to be collected from the quarry pond to maintain accurate information on the levels in the water. The ponded water will ultimately be treated for nitroaromatic compounds and other organics upon completion of the quarry water treatment plant.

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

ND - Not Detected

@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4) indicated that four samples were taken in 1990, two of which average 2.00 and the other two samples were ND.

4.2.3 Groundwater Monitoring Non-Radiological Results

All WSCP/RP/VP and WSQ monitoring wells were sampled during 1990 for nitroaromatics, nitrate, sulfate, chloride, and fluoride. These parameters are sampled with the same frequency and same monitoring program as uranium described in Section 4.1.3 of this report. The St. Charles County pumping wells, treated and untreated water from the St. Charles County Water Treatment Plant, and a select group of monitoring wells in the county wellfield were monitored quarterly for arsenic and barium. These same locations at the wellfield were sampled once in 1990 for volatile and semi-volatile organics, pesticides\polychlorinated biphenyls (PCBs), mercury, lead, and cadmium.

Data tables for all laboratory analytical results presented in this section contain annual concentrations calculated in the same format as the uranium table of Section 4.1.3.1 of this report.

4.2.3.1 Chemical Plant/Raffinate Pits. Groundwater at the WSCP/RP area became contaminated as a result of the Weldon Spring Ordnance Works (WSOW) operations during World War II and operations at the WSUFMP during the 1950s and 1960s. The *Phase I Water Quality Assessment Report* (MKF and JEG 1987) reported: "nitroaromatic compounds are present at low to high levels over much of the site; and relatively widespread nitrate and sulfate contamination problems are the result of leaking raffinate pits and other sources." The *Phase II Groundwater Quality Assessment Report* (MKF and JEG 1989b), an expanded comprehensive evaluation of groundwater quality at the WSCP/RP/VP area during the third quarter of 1988, is essentially in agreement with the Phase I report. Two notable exceptions are that the nitrate plume has been more clearly defined and that the original sulfate plume reported in the *Phase I Water Quality Assessment* is actually several isolated plumes, and its source is not exclusively the raffinate pits. These exceptions were detected as a result of additional monitoring well installations.

The groundwater monitoring network is described in Section 4.1.3.1 of this report. Figure 4-5 shows the location of individual wells at the WSCP/RP/VP area.

4.2.3.1.1 Analytical Results for Nitroaromatic Compounds - WSCP/RP Groundwater. No primary or secondary drinking water standards have been promulgated for any of the six nitroaromatic compounds of interest at the WSCP/RP/VP area. However, standards set by

the Clean Water Act-Federal Ambient Water Quality Criteria may be utilized as a reference for discussion. The criteria for 2,4-DNT is 0.11 µg/l based on a lifetime 10^{-6} cancer risk. For nitrobenzene, the criteria is 30 µg/l based on toxicity. Both 2,4-DNT and 2,6-DNT are suspected carcinogens. Nitroaromatic compounds are not naturally occurring; therefore any concentration detected indicates contamination of the groundwater system.

Each groundwater monitoring well was sampled and analyzed for nitroaromatic compounds during 1990. Table 4-23 summarizes the results of these analyses. Nitroaromatic compounds were not detected in 34 monitoring wells. Eighteen wells exhibited cumulative annual average concentrations of nitroaromatic compounds above detection limits, but below 10 µg/l. Seven wells exhibited annual average concentrations greater than 10 µg/l. They are MW-2006, MW-2011, MW-2012, MW-2013, MW-4001, MW-4006 and MW-4013. Figure 4-16 highlights wells with detected annual concentrations.

All 25 of the wells with detected concentrations of nitroaromatics exhibited concentrations of one or both of the suspected carcinogens 2,4-DNT and 2,6-DNT. Ten groundwater monitoring wells--MW-2009, MW-2010, MW-2011, MW-2012, MW-2013, MW-2014, MW-3001, MW-3009, MW-4001 and MW-4013--exhibited annual concentrations of 2,4-DNT above the ambient water quality criteria (0.11 µg/l). No detectable concentrations of nitrobenzene were observed in 1990. Overall the nitroaromatic results are consistent with past environmental monitoring and characterization studies.

4.2.3.1.2 Analytical Results for Inorganic Anions - WSCP/RP Groundwater. All groundwater monitoring wells at the WSCP/RP/VP were sampled for nitrate, sulfate, chloride, and fluoride in 1990. Table 4-6 shows the annual average concentrations of these inorganic anions.

The standard issued in the Safe Drinking Water Act for nitrate (as nitrogen) is 10 mg/l. Background concentrations are below 3.26 mg/l (MKF and JEG 1989a). During 1990, concentrations exceeding background occurred in 16 groundwater monitoring wells. The range of values for these wells is 3.93 mg/l in MW-4014 to 1280 mg/l in MW-3003. Figure 4-17 highlights wells with nitrate values above the EPAs drinking water standard of 10 mg/l. Although values from individual wells have fluctuated somewhat from previous

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

ND - Not Detected

* - Detection limit

@ - The numerator is number of samples with detectable concentrations upon which the average is based and the denominator is the number of times the location was sampled during 1990. For example, 2.00 2/4) indicates that four samples were collected in 1990, two of which average 2.00 and the other two samples were ND.

monitoring and characterizations, the groundwater scenario for nitrate contamination at the WSCP/RP/VP remains unchanged.

The upper bound of natural background sulfate concentrations in the aquifer at the WSCP/RP/VP was determined to be 50 mg/l (MKF and JEG 1989b). The EPA secondary drinking water standard for sulfate is 250 mg/l. Monitoring wells MW-2017 and MW-4021 exhibited average sulfate concentrations above the drinking water standard in 1990. Thirteen monitoring wells exhibited average sulfate concentrations between the upper bound of background and the drinking water standard. Figure 4-18 highlights monitoring wells with average sulfate concentrations above the upper bound of background. The *Phase II Groundwater Quality Assessment* (MKF and JEG 1989b) established that former WSOW processes were the primary source of these areas of sulfate contamination.

The upper limit of background for chloride in groundwater at the WSCP/RP/VP area is 22 mg/l (MKF and JEG 1989b). The EPA secondary drinking water standard for chloride is 250 mg/l. Five wells--MW-2006, MW-2008, MW-2010, MW-2012 and MW-2014--exhibited annual average chloride concentrations above the upper bound of background, but below the secondary drinking water standard in 1990. All five of these wells are located adjacent to a surface water drainage that drains a salt (sodium chloride) depot of the Missouri Highway Department off Highway 94. All of these wells have exhibited elevated chloride concentrations in the past.

Background concentrations for fluoride in groundwater are below 1 mg/l. The maximum contaminant level (MCL) for fluoride is 4.0 mg/l. One groundwater monitoring well, MW-2001 exhibited a fluoride concentration of 1.27 mg/l for the first sample of 1990 and was not detected in the second sample. No other monitoring wells exceeded background concentrations in 1990. This is consistent with previous monitoring results.

4.2.3.2 Non-Radiological Monitoring Results for WSQ Groundwater. Groundwater near the WSQ has become contaminated as a result of contact with or migration from the hazardous substances present in the WSQ. The monitoring well network for the WSQ is described in Section 4.1.3.2 of this report. The analytical results for non-radiological substances in groundwater at the WSQ are discussed in the following sections.

4.2.3.2.1 Analytical Results for Nitroaromatic Compounds - WSQ Groundwater. During 1990, samples from all WSQ wells were analyzed for nitroaromatic compounds. Ten monitoring wells yielded detectable concentrations of at least one of the six nitroaromatic compounds analyzed. The analytical results are presented in Table 4-24. The 10 wells yielding detectable concentrations are all north of the Femme Osage Slough. No groundwater samples taken south of the Femme Osage Slough exhibited detectable concentrations of nitroaromatic compounds. Overall the nitroaromatic results are consistent with past environmental monitoring and characterization. The one exception is MW-1002 which indicated no detectable levels of nitroaromatic compounds in 1989 (MKF and JEG 1989b), but did average 47.97 µg/l total nitroaromatics in 1990. This well has, however, indicated detectable concentrations of nitroaromatics before 1989.

4.2.3.2.2 Analytical Results for Inorganic Anions - WSQ Groundwater. All monitoring wells in the WSQ area were sampled for nitrate, sulfate, chloride and fluoride in 1990. Table 4-7 displays the annual averages for these inorganic anions.

Groundwater samples collected at the WSQ area in 1990 continued to indicate no notable groundwater contamination by nitrate. The highest annual average observed was at MW-1012, which is adjacent to the WSQ. This level was 1.44 mg/l. Nitrate does not constitute a particular threat to the groundwater system near the WSQ.

The quarry bulk waste is a source of sulfate contamination to the surface water in the WSQ pond and subsequently to the groundwater surrounding the quarry. Sulfate levels in most of the wells adjacent to the quarry and in the alluvium north of the Femme Osage Slough appear to be elevated as a result of migration from the quarry. The highest 1990 sulfate average value of 529 mg/l was measured in MW-1006. Wells to the south of the slough continue to remain at background concentration levels. Groundwater samples collected in 1988 and 1989 from the upgradient background well referenced in Section 4.1.3.2 indicate a background level of 95 mg/l for sulfate in the alluvial groundwater.

Groundwater samples collected for chloride analysis in 1990 continue to agree with previous environmental monitoring and characterizations. The upper limit for background chloride levels in the bedrock aquifer near the WSCP/RP/VP was established at 22 mg/l in the WSSRAP's *1988 Environmental Monitoring Report* (MKF and JEG 1988). Data from the Missouri River alluvial water samples indicate that the background for the alluvium is

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

ND - Not Detected

@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4) indicates that four samples were taken in 1990, two of which average 2.00 and the other two samples were ND.

* - Detection limit

similar. The quarry sump shows an annual average concentration of 12.1 mg/l chloride. Based upon the comparison with background, chloride levels appear to be slightly elevated north of the Femme Osage Slough. The elevated chloride levels remain well below the EPA secondary drinking water standard of 250 mg/l. The highest level of chloride measured south of the Femme Osage Slough was 22.05 mg/l. Chloride does not constitute a threat to the groundwater system near the WSQ.

Fluoride levels ranged from 0.17 mg/l to 1.21 mg/l in the groundwater near the WSQ. These levels do not exceed the EPA's maximum contaminant level of 4.0 mg/l.

4.2.3.2.3 Analytical Results for Metals - WSQ Groundwater. Samples were collected for arsenic, barium, cadmium, lead, and mercury in 1990 at the St. Charles County pumping wells and the treated and untreated water from the St. Charles County Water Treatment Plant. These metals have been detected in previous samples of the quarry bulk waste. Arsenic and barium samples were also retrieved from the St. Charles County RMW series monitoring wells and monitoring well MW-1024. The results of analyses for these samples are shown in Table 4-25. The WSQ does not appear to influence metals concentrations in the well field area. Uranium is the primary indicator for WSQ contaminant migration.

4.2.3.2.4 Analytical Results for Organics - WSQ Groundwater. The St. Charles County pumping wells; treated and untreated water from the St. Charles County Water Treatment Plant; the St. Charles County RMW series monitoring wells; and monitoring well MW-1024 were sampled once in 1990 for PCBs, pesticides, and volatile and semi-volatile organics. No PCBs, pesticides, or semi-volatiles were detected in sample analyses. Low levels of acetone were detected in two samples and a low level of xylene was detected in one sample. Low levels of these compounds were also detected in quality control laboratory blanks. Due to this, the levels are believed to be a result of lab contamination. Laboratory analysis also indicated low levels of three trihalomethanes (chloroform, bromodichloromethane and dibromochloromethane) in the treated water from the water treatment plant. However, the summed concentrations of the three compounds are less than 100 ug/l, which is the maximum contaminant level from the Safe Drinking Water Act for the sum of all four trihalomethanes that may occur in drinking water. The compounds are believed to be a result of the natural organics in the groundwater reacting with the chlorine in the water treatment process.

Average is calculated using non-ND results. An ND is reported in this table only if all samples from that location had ND reported.

ND - Not Detected
NOL - Well Not on Line or Sample Date
NSF - Not Scheduled For Sampling
* - Detection limit
@ - Numerator is number of samples the concentration is based on and denominator is the number of times the location was sampled during 1990. For example, 2.00 (2/4) indicates that four samples were taken in 1990, two of which average 2.00 and the other two samples were ND.

4.2.4 Effluent Monitoring Results

Surface water and effluent samples were collected and analyzed in compliance with the Weldon Spring Site National Pollutant Discharge Elimination System (NPDES) permit. This permit (Number MO-0107701) was issued in November 1988, and addresses storm water and wastewater discharges. Six discharge points or outfalls are included in this permit and are shown on Figure 4-19. Outfalls NP-0001 through NP-0005 represent surface water discharge and NP-0006 represents the treated effluent discharge associated with the administration building sanitary wastewater treatment plant. Currently, NP-0006 is the only outfall with effluent limitations. The five surface water outfalls have monitoring requirements only. A summary of permit requirements including monitoring parameters and frequencies is shown in Table 4-26.

Annual averages of analytical results for the storm water locations are presented in Table 4-27. This table presents an annual summary of the individual sampling events. Tables indicating analytical results for the individual NPDES sampling events may be found in Appendix A.

In general, all values correspond well with prior year values. On three occasions sampling was performed when flows were not representative of normal storm water flows. These three sampling events were performed during water release which was not associated with precipitation:

March 1: Samples collected at NP-0003 in conjunction with a release of water from Ash Pond retention basin.

May 8: Samples collected at NP-0003 in conjunction with a release of water from the Ash Pond retention basin.

September 27: Samples collected at NP-0001, NP-0002, and NP-0005 in conjunction with flow testing in the Frog Pond and Southeast drainages.

During the March 1 release, above average concentrations of gross alpha, uranium, settleable solids and nitrate were observed. These values are within the expected range with the exception of nitrate. An intermittent nitrate source has been observed in this drainage

in the past. Values from the May 8 discharge were within expected ranges. Values from the September 27 sampling were slightly lower than normal, with the exception of lithium at NP-0005. This was the only sampling event in 1990 when lithium was detected at NP-0005 and the lithium levels at NP-0001 and NP-0002 were highest in samples obtained on this date.

4.2.4.1 Radiological Analysis. Annual average uranium levels ranged from 7.59 pCi/l (0.281 Bq/l), about 1% of the DCG at the minimum concentration discharge point (NP-0004) to 413.4 pCi/l (15.3 Bq/l), about 75% of the DCG at the maximum concentration discharge point (NP-0001) (Table 4-27). The highest average uranium concentration was measured at the off-site discharge of the abandoned sanitary and process sewer outfall (NP-0001). Uranium concentrations measured at NP-0001 ranged from 197 to 952 pCi/l (7.29 to 35.22 Bq/l) during 1990. Flows from the process and sanitary sewer outfall (NP-0001) combine with surface runoff from the southeast drainage easement. Uranium concentrations measured at NP-0005 exhibited similar levels with an annual average of 364.45 pCi/l (13.48 Bq/l), 66% of the DCG, and a range of 17.7 to 1020 pCi/l (0.65 to 37.74 Bq/l).

Frog Pond's off-site discharge (NP-0002) exhibited an annual average uranium concentration of 139.47 pCi/l (5.16 Bq/l), 25% of the DCG. Individual monthly measurements ranged from 10.2 to 367.2 pCi/l (0.38 to 13.59 Bq/l).

Off-site runoff from the area of raffinate pit No. 4 (NP-0004) exhibited an annual average uranium concentration of 7.59 pCi/l (0.281 Bq/l), 1 % of the DCG with a range of individual measurements from 4.2 to 10.9 pCi/l (0.16 to 0.40 Bq/l).

Runoff from the Ash Pond drainage (NP-0003) exhibited an annual average uranium concentration of 89.45 pCi/l (3.31 Bq/l). This continues a downward trend in uranium concentration at this outfall. The 1988 annual average at NP-0003 was 1178 pCi/l (43.59 Bq/l). The 1989 annual average of 280 pCi/l (10.36 Bq/l) signaled the start of the downward trend in uranium concentrations, primarily due to the completion of the Ash Pond diversion project. This project provided for diversion of surface water around the south dump and the Ash Pond areas.

Annual average gross alpha levels generally followed the same pattern as the natural uranium results. This correlation between the average uranium and gross alpha values indicates that the majority of all off-site radionuclide release in surface water is in the form of soluble uranium.

Estimated quantities of total uranium released off site through surface water are presented in Table 4-28. If it is assumed that the entire annual precipitation runoff is discharged from these points and the discharge from each point is proportional to the site drainage area for each point, an upper bound estimate of the total uranium released can be calculated. These results are consistent with values from 1989 with the exception of NP-0003 which was lower in 1990.

4.2.4.2 Physical/Chemical Analysis. Physical analysis (settleable solids and suspended solids) and chemical analysis (nitrate, pH, and lithium) were also performed on NPDES samples in 1990. The 1990 values generally correspond to 1989 values for the majority of parameters.

Settleable solids analyses of all outfalls averaged <0.1 ml/l in 1990. All outfalls exhibited at least one sample equal to 0.1 ml/l, with the following exceptions: all samples from NP-0004 were <0.1 ml/l and two samples from NP-0003 were equal to 0.1 ml/l.

Suspended solids analyses were comparable to prior data. Annual average values ranged from 4.6 mg/l at NP-0001 to 91.42 mg/l at NP-0002. Higher values of suspended solids were present at NP-0002 in July and August due to an accumulation of silt immediately above the outfall structure. Following removal of this sediment, measured values dropped and remained much lower.

Nitrate values were lower in 1990 compared to 1989 in all outfalls except NP-0003. Annual average values ranged from 0.290 mg/l at NP-0004 to 95.31 at NP-0003. The higher values at NP-0003 were present due to the single high value reported for March 1 during release from the Ash Pond retention basin, as mentioned previously.

Lithium values were slightly higher in 1990 compared to 1989. Annual average values ranged from ND (not detected) at NP-0003 and NP-0004 to 0.0256 mg/l at NP-0005. A

TABLE 4-28 1990 Estimated Annual Release of Natural Uranium from NPDES Outfalls

OUTFALL LOCATION*	DRAINAGE AREA (ACRES)	PERCENT OF PRECIPITATION AS RUNOFF**	AVERAGE CONCENTRATION (pCi/l)	UPPER BOUND TOTAL VOLUME (Mgal/yr)	UPPER BOUND TOTAL URANIUM (Ci/yr)	UPPER BOUND TOTAL URANIUM (kg/yr)
NP-0001 & NP-0005	20.2	60%	388.93	12.8	0.019	27.78
NP-0002	39.1	65%	139.47	26.9	0.014	20.87
NP-0003	60.1	20%	89.45	12.7	0.004	6.32
NP-0004	5.6	50%	7.59	3.0	0.00009	0.13
TOTALS =					0.0371	55.10

* See Figure 4-19 for Outfall Locations

** Estimated

limited number of samples from NP-0001 and NP-0002 contained lithium values slightly above the detection limit. The highest lithium value (at NP-0005) was present in a sample obtained during flow testing on September 27. As discussed previously, this flow was not representative of normal storm water flows.

4.2.4.3 Sanitary Wastewater. Outfall NP-0006 is the discharge for the site administration building wastewater treatment facility. The NPDES permit contains effluent limitations on biochemical oxygen demand (BOD), total suspended solids (TSS), and fecal coliform at this outfall. These limits are 10 mg/l BOD, 15 mg/l TSS, and 400 colonies/100 ml (fecal coliform). Samples were analyzed quarterly for these parameters by the Subcontractor operating this facility. A table illustrating all of these results is presented in Appendix A. NPDES permit limits were exceeded twice in 1990 at this outfall. The BOD value of April 12 was 13.8 mg/l. Operational adjustments to the plant were performed by the Subcontractor, and BOD levels returned to below permit limits. The fecal coliform value for December 5 was 7000 colonies/100 ml. This was due to removal of additional chlorine in the chlorine contact chamber by the Subcontractor. This was done at the direction of Missouri Department of Natural Resources (MDNR), due to a concern that excess residual chlorine might be present in the effluent. The Subcontractor has since replaced this additional chlorine in a more acceptable location resulting in a return to compliance for fecal coliform levels, while maintaining a minimal level of residual chlorine.

4.2.4.4 Erosion Control Monitoring. Sampling was conducted in the Little Femme Osage Creek, near the Weldon Spring quarry to assess erosion control measures associated with construction of the quarry staging area and water treatment plant facilities. Although the treatment plant has not yet been constructed, the NPDES permit for this discharge (MO-0108987), requires that all runoff from construction and material storage areas remain within the following limits.

Total Suspended Solids: Less than 50.0 mg/l (standard units)
pH: greater than 6.0 and less than 9.0

Samples were collected from SW-1001 and SW-1002 during rainfall events (see Figure 4-3). SW-1001 is located upstream of the quarry staging area and represents normally occurring concentrations in this drainage. SW-1002 is located immediately downstream of the quarry staging area. Water quality impacts from quarry staging area

construction are assessed by comparing values from these two locations. Results from these samples were as follows:

DATE	SW-1001		SW-1002	
	TOTAL SUSPENDED SOLIDS	pH	TOTAL SUSPENDED SOLIDS	pH
08/29/90	1.6	6.90	<0.1	7.17
10/10/90	6.0	7.32	7.0	7.32
11/05/90	7.0	6.74	7.0	6.66

These results indicate compliance with permit requirements.

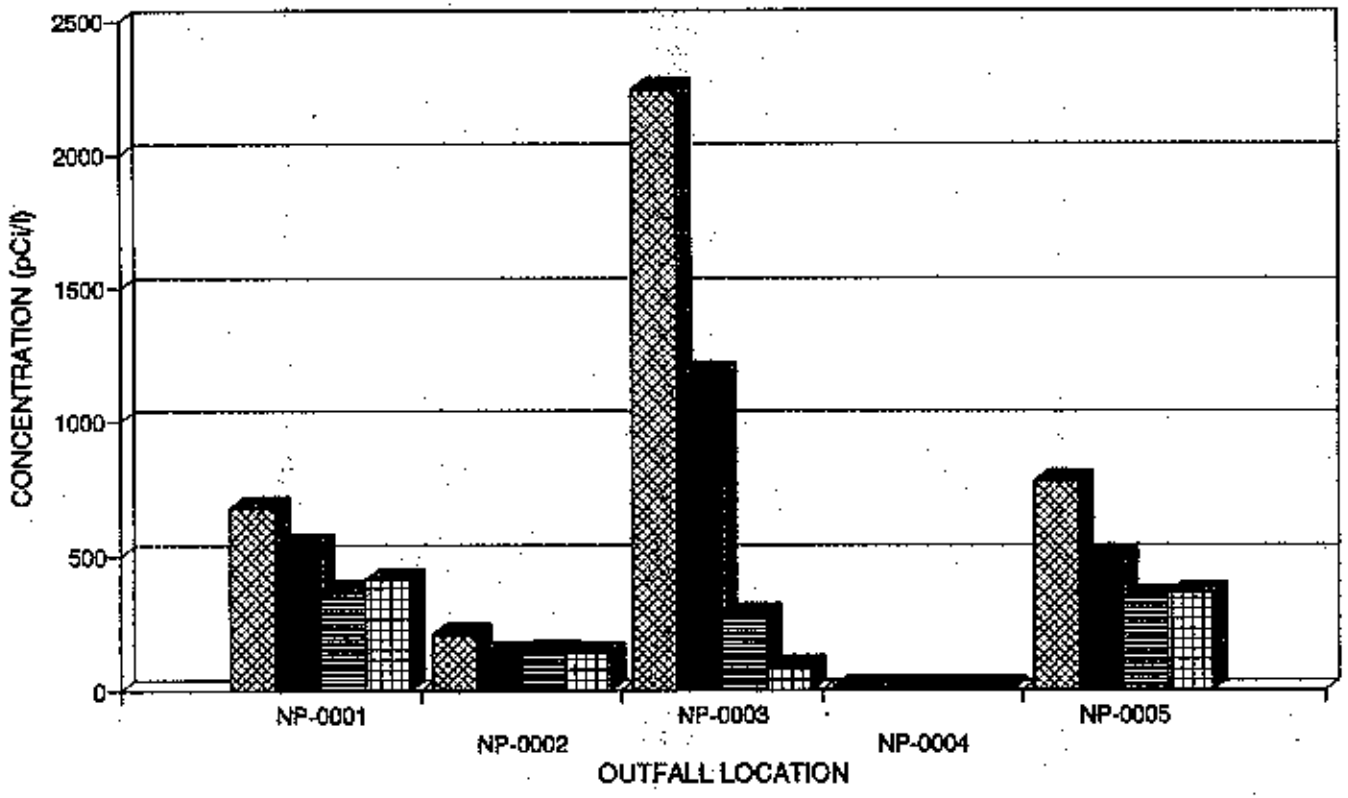
4.2.4.5 Uranium Trend Analysis. Annual average uranium concentrations in NPDES Outfalls from 1987 through 1990 are presented in Table 4-29. Uranium trends in NPDES Outfalls are shown in Figure 4-20. Uranium concentrations show an overall decline for the past four years with the exceptions of NP-0001 and NP-0005 which show a slight increase in 1990. All average values for both 1989 and 1990 are below the DCG of 600 pCi/l (22.2 Bq/l). The most dramatic decrease during this period was at NP-0003, the Ash Pond outfall. The Ash Pond diversion project is an interim response action that was completed in early 1989. This project provided surface water diversion around the south dump and Ash Pond areas and resulted in a subsequent decrease in uranium levels.

Comparison of values between Outfall locations indicates the following:

Uranium concentrations at NP-0004 remain extremely low indicating no significant contaminant migration in this area.

Uranium concentrations at NP-0002 do not indicate any significant fluctuation. This is expected since very little excavation or disruption has occurred within this watershed.

Outfall NP-0003 has shown a dramatic decrease in uranium concentrations due to effective surface water management.



TRENDS OF ANNUAL AVERAGE
URANIUM VALUES
FOR NPDES OUTFALLS

FIGURE 4-20

REPORT NO.:	DOE/OR/21548-193	EXHIBIT NO.:	A/PI/090/0591		
ORIGINATOR:	JAM	DRAWN BY:	GLN	DATE:	5/91

TABLE 4-29 Annual Average Uranium Values at NPDES Outfalls 1987-1990

URANIUM VALUES pCi/l				
OUTFALL LOCATION	1987	1988	1989	1990
NP-0001	660	539	366	413
NP-0002	210	141	145	139
NP-0003	2240	1178	280	89
NP-0004	9.5	6.2	6.5	7.6
NP-0005	780	497	347	384

Currently, the highest values of uranium release in surface water occur in the southeast drainage (from Outfalls NP-0001 and NP-0005).

4.2.5 Airborne Asbestos Monitoring

During the first and second quarters of 1990, asbestos was monitored at five site perimeter stations and at the off-site monitoring station located at Francis Howell High School (FHHS) (Figure 4-10). Samples were typically collected once per week. Each sample was collected over a 7 hr to 8 hr sampling period, during normal site working hours. During the subject period, no asbestos abatement operations were conducted at the site. On the basis of the air monitoring results obtained from the site perimeter and off-site asbestos monitoring stations for the period from April 1988 through May 1990, in which no significant trends or findings were observed, site perimeter and off-site asbestos monitoring for the third and fourth quarters was discontinued. Routine asbestos monitoring at the FHHS and site perimeter stations will resume whenever on-site asbestos abatement operations are underway.

All samples were analyzed by Phase Contrast Microscopy (PCM). This method provides a measurement of total airborne concentration for fibers having size and shape characteristics typical of asbestos fibers. PCM methodology does not distinguish between airborne asbestos fibers and non-asbestos fibers having similar morphology. One sample, collected at the FHHS on May 18, was analyzed by Transmission Electron Microscopy

(TEM) which is capable of positively identifying asbestos fibers. No asbestos fibers were detected in the TEM sample.

The results of the PCM analyses for the air samples collected at the site perimeter and off-site monitoring stations are provided in Table 4-30. The average fiber concentration for the 28 site perimeter samples was 0.002 f/cc. The average concentration for the 18 FHHS samples was < 0.001 f/cc.

Table 4-30 Asbestos Monitoring Summary Calendar Quarter 1 and 2, 1990

SAMPLING LOCATIONS[a]	CONCENTRATION RANGE MIN. (FIBERS/CC)	CONCENTRATION RANGE MAX. (FIBERS/CC)	AVERAGE (FIBERS/CC)[b]	NO. OF SAMPLES REPORTED AS BELOW DETECTION LIMIT	TOTAL NUMBER OF SAMPLES COLLECTED
AP-2001	<0.001	<0.001	<0.001	4	5
AP-2002	<0.001	0.007	0.003	3	4
AP-2005	<0.001	0.002	0.001	9	11
AP-3003	<0.001	0.009	0.002	5	6
AP-3004	<0.001	<0.001	<0.001	2	2
AP-4006	<0.001	<0.001	<0.001	18	18

(a) See Figure 2-7 for monitoring station locations.
(b) For those samples with fiber concentrations less than the limit of detection, the limit of detection was used to calculate the overall average fiber concentration for each sampling location.

Routine area and employee exposure monitoring were conducted throughout 1990. This monitoring was conducted in the vicinity or in the breathing zones of site personnel engaged in asbestos related activities or other activities for which there were potential asbestos exposures. The results of the PCM analysis for the area and employee exposure monitoring are provided in Table 4-31. The average fiber concentration for the seven area

TABLE 4-31 Area and Worker Asbestos Exposure Monitoring Summary Calendar Year 1990

SAMPLE TYPE	CONCENTRATION RANGE (fibers/cc)	AVERAGE (fibers/cc) [a]	NO. OF SAMPLES REPORTED AS BELOW DETECTION LIMIT	TOTAL NO. OF SAMPLES COLLECTED
Area	<0.002 - 0.006	.009	4	7
Worker Exposure	<0.003 - 0.069[b]	.013	4	9

(a) For those samples with fiber concentrations less than the limit of detection, the limit of detection was used to calculate the overall average fiber concentration for each sample type.

(b) Concentrations represent 8-hr time weighted average exposures.

samples was 0.009 f/cc. The air sample results for the employee exposure monitoring indicate that worker exposures were less than the Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELS). OSHA's PEL for an 8-hr time weighted average (TWA) is 0.2 f/cc and for a 30-min excursion limit is 1 f/cc.

4.2.6 Meteorological Monitoring

In 1990, the WSSRAP installed a new meteorological tower and associated equipment capable of monitoring current weather data and recording the data for later use. Located near the main entrance to the chemical plant site, the meteorological station monitors the following parameters: wind speed, wind direction, temperature, barometric pressure, and precipitation. The intended uses of the meteorological system include:

1. Correlation with background fluctuations of naturally occurring radionuclides in ambient air measured at nearby locations.

2. Real time data read out of the meteorological variables influencing the dispersion of potentially released airborne materials.

3. Post incident data review to potentially explain source and receptor results.

The WSSRAP meteorological monitoring system produces data that can be used in routine dispersion modeling to predict impacts from site operations and as input to emergency response atmospheric models used in the event of accidental releases from the site.

5 GROUNDWATER PROTECTION PROGRAM

5.1 Groundwater Protection Program Management Plan

The Weldon Spring Site Remedial Action Project (WSSRAP) Groundwater Protection Program (GWPP) began in 1981 when the U.S. Department of Energy (DOE) appointed Bechtel National, Inc. (BNI) as the custodial contractor, responsible for installing the first groundwater monitoring wells and investigating water quality beneath the Weldon Spring site (WSS). Since the establishment of the WSSRAP in 1986, the current Project Management Contractor (PMC) has had an informal organization in place devoted to the protection, investigation, and remediation of the groundwater system at the WSS. The purpose of the WSSRAP GWPP Management Plan is to formalize and structure the program both for internal consistency and ease of external review. The formal plan developed in 1990 meets the requirements for a Groundwater Protection Management Program and Groundwater Monitoring Plans as described in DOE Order 5400.1. The scope of the plan is as follows:

- To define the purpose, policies, and objectives of the WSSRAP GWPP.
- To define the interfaces between the GWPP and other programs.
- To define the methods, procedures, and schedules to be utilized in meeting the GWPP objectives.
- To provide effective quality maintenance for the GWPP. (A separate quality assurance [QA] plan that meets Nuclear Quality Assurance (NQA-1) requirements has been developed for the project.)
- To provide the most effective overall management possible for the GWPP.

5.1.1 History of Groundwater Protection Program Activities

A large number of wells, piezometers, and borings have been installed at the WSS for groundwater monitoring, aquifer testing, geologic characterization, and geotechnical studies. The current monitoring well network includes wells constructed to support the

current Remedial Investigation/Feasibility Study-Environmental Impact Statement (RI/FS-EIS) studies and wells installed for routine monitoring.

The following well designations are currently used at the WSS. Monitoring wells with 1000 series numbers are located at or near the WSQ; wells with 2000 series numbers are located within the chemical plant area; wells with 3000 series numbers are located in the raffinate pit area; and wells with 4000 series numbers are located outside the site boundaries near the WSCP/WSRP.

Monitoring wells constructed at the WSS have been drilled, installed, and developed generally in accordance with accepted procedures as discussed in the U.S. Environmental Protection Agency (EPA) Resource Conservation and Recovery Act (RCRA) *Groundwater Monitoring Technical Enforcement Guidance Document* (EPA 1986). Standard operating procedures have been developed for WSSRAP based on these EPA guidelines.

5.1.2 Application of the GWPP Management Plan

The WSSRAP GWPP Management Plan is a management tool for the formalization of the DOE groundwater protection and management policies at the WSS. The Management Plan establishes criteria for the performance of groundwater management practices at the WSSRAP. Functionally, it serves the DOE, the PMC, and the public by establishing the groundwater protection and management criteria for the project. Annual review and appropriate updates to the plan also ensure that the plan remains up to date.

5.1.3 Plugging and Abandonment Requirements

The proper plugging of a groundwater monitoring device that is being removed from service is essential to maintaining the integrity of the associated aquifer or aquifers. For this reason, the WSSRAP has established requirements for plugging wells at the WSS. The lines of authority, procedures, and plugging criteria are established by the Groundwater Protection Program Management Plan (GWPPMP).

Project Structure and Lines of Authority

Since all monitoring wells are used by, and are under the authority of, the PMC Environmental Safety and Health (ES&H) Department, this department will approve the plugging and abandonment (P&A) process. The process will proceed as follows:

- The ES&H Department will authorize removing a well from service. The ES&H Department will notify the Construction Management and Operations (CM&O) and Engineering departments to begin their respective tasks.

- The Engineering Department will prepare a specification, subject to approval by the ES&H Department, and a request for bids to subcontract for the work will be issued by the Procurement Department.

- The CM&O and ES&H departments will oversee the Subcontractor's work.

- The ES&H and QA Departments may also choose to perform quality-related supervision of the P&A activities.

Well Plugging Criteria

The WSSRAP has developed a standard operating procedure (SOP) for the ES&H Department (ES&H Procedure 4.4.4s) for the abandonment of all subsurface monitoring devices, including wells. Wells will be plugged in accordance with all applicable State and Federal regulations and requirements. Currently, the State of Missouri has some formal requirements for P&A; however, the regulations do not specify how technical specifications should be written. The Missouri Code of State Regulations (10 CSR 23-3.02) requires that wells be plugged to prevent the vertical migration of pollutants. These regulations will be reviewed prior to the preparation of each P&A specification to ensure, at a minimum, that the State regulations and reporting requirements are met.

The WSSRAP will take greater precautions than required by the State regulations when plugging wells. As a standard practice, the WSSRAP will remove the well casing, filter pack, and drilling debris from the borehole and grout the hole using a tremie method.

5.2 Groundwater Contaminant Trend Analysis

Appendix B presents graphs of annual average concentrations of total nitroaromatics, total natural uranium, nitrate (as N) and sulfate for the years 1987 through 1990. Some of the monitoring wells were installed during this time. Accordingly, not all of the locations list four years of data. The monitoring wells are grouped primarily by concentration, due to the wide range of concentrations. The annual average concentrations are calculated in the same format as described in Sections 4.1.2 and 4.2.2.

Overall, the data for nitroaromatics show consistency with the exception of 1988 when a problem with laboratory contamination and error biased some results. The largest discrepancy evident is a reduction by one order of magnitude at location MW-2013.

As the graphs illustrate, (see Figure 4-20) the uranium concentrations show an overall increase in 1990. As discussed in Section 6.3, many distilled water blanks showed detectable levels of uranium in 1990, indicating laboratory contamination.

There appears to be a gradual increase in nitrate concentrations for certain wells adjacent to the raffinate pits. The nitrate levels for monitoring wells MW-1002, MW-1004, MW-1005, and MW-1014 show consistency for the years 1988 through 1990. The 1987 concentrations for these wells are believed to be in error due to laboratory contamination or sample handling.

Due to the widespread areas of sulfate contamination at the Weldon Spring Chemical Plant/raffinate pits/vicinity property (WSCP/RP/VP) and the WSQ, the graphs illustrate some fluctuations for the four years in certain monitoring wells. There appears to be some concentration error involved for certain wells in 1987. This is believed to be related to the nitrate concentration errors from the same year.

6 QUALITY ASSURANCE PROGRAM INFORMATION

The Weldon Spring Site Remedial Action Project (WSSRAP) Quality Assurance Program Plan (QAPP) establishes the quality program for those activities performed by the Project Management Contractor (PMC) during the WSSRAP. The QAPP requires compliance with the criteria of ANSI/ASME NQA-1 1986; the U.S. Department of Energy (DOE) Order 5700.6B, as required by the PMC; the DOE contract document DE-AC05-86OR21548; and the MK-Environmental Services NQA-1 Quality Assurance Manual. The purpose of the QAPP is to assure compliance with these documents.

All criteria of NQA-1 are applicable to the WSSRAP. The MK-Environmental Services NQA-1 Quality Assurance program provides guidance for the development of requisites to implement quality at the WSSRAP. The QAPP, however, does not address all criteria. Only criteria that describe quality assurance departmental actions are described. QA Audits, QA Surveillances, and the WSSRAP Self-Assessment program ensure compliance with criteria not addressed in the QAPP.

Certain environmental compliance issues are addressed in the WSSRAP Remedial Investigation Quality Assurance Program Plan (RIQAPP). The RIQAPP addresses the specific EPA/QAMS 005-80 Quality Assurance requirements for the characterization of the WSSRAP. The RIQAPP does not supersede the project QAPP, but rather it expands on specific requirements.

This chapter includes a discussion of the data administration and validation program in Section 6.1, the external audits and audit tracking system in Section 6.2, and the quality assurance sample results in Section 6.3.

6.1 Data Administration and Data Quality

The WSSRAP quality assurance (QA) program for environmental data has numerous initiatives within each aspect of data collection, evaluation, and reporting. The *Environmental Data Administration Plan* (EDAP), (MKF and JEG 1991b) a specific program-level plan, provides the foundation for collecting, verifying, validating, and interpreting data. The EDAP provides site-specific guidance for managing data and associated documentation, and establishes general data quality goals. This plan also includes

guidance on sampling plan preparation, data verification, validation requirements, database administration, and data archival.

All WSSRAP environmental surveillance and effluent monitoring activities required by permits and DOE Orders are performed as detailed in the *Environmental Monitoring Plan* (MKF and JEG 1990c) which describes sampling methods, locations, rationale, and quality control measures.

Site specific procedures have been developed for all aspects of sample collection and handling. These procedures were developed from EPA and other relevant guidance documents. They are reviewed annually and revised as necessary. Sampling personnel are trained in appropriate procedures prior to sample collection. All procedure training is documented and tracked so that personnel are retrained as procedures are revised. Variances or field modifications to procedures are noted in field notebooks and on sampling forms.

Quality control samples are collected to assess location variability, the effects of sample matrix on analytical procedures, laboratory precision, and the effects of sampling methods and shipping on analytical results. Chain of custody documentation is maintained for all samples from sample collection through shipment to the analytical laboratory. Completed chain of custody records are maintained at the WSSRAP as QA records.

Laboratories analyzing the WSSRAP samples are required to use standard methods and to have a quality assurance program. These quality assurance programs are reviewed and approved by the project's Quality Assurance Department prior to commencement of analyses. Laboratories are also required to comply with standardized reporting requirements, thus simplifying data verification, validation, and interpretation. Laboratories are routinely audited to assure compliance with their QA programs and appropriate analytical procedures.

All data received from analytical laboratories are subjected to data verification. The data verification process is detailed in ES&H Procedure 4.9.1 and consists of a preliminary review of the quality-impacting aspects of sampling, analysis, and reporting. Data verification includes reviewing field sampling documentation, sample preservation, chain of custody, analytical holding times, and a comparison of electronic versus hard copy reporting.

Data verification assures that all data are received for every sample submitted for analyses and includes a preliminary review by the data users. The verification process also ensures that any discrepancies noted have been addressed and that the resultant changes are documented.

Data validation is performed independent of the analytical laboratory. Data validation consists of two primary functions. First, the analytical process is reviewed and the quality of the data is documented. This consists of reviewing all records related to sample integrity, sample preparation, and the analytical measurement systems. Second, the data are compared to the method-specific criteria and site-specific data quality requirements. This ensures that data quality is evaluated based on the end use of the data. At the WSSRAP, approximately 10% of all analytical data is validated according to site-specific procedures. Approximately 5% is evaluated on a random basis to provide coverage across all data sets. The other 5% is selected from critical data. The 10% validation actually reviews a large portion of the analytical lots, effectively validating a much larger percentage of the data base. This is accomplished by reviewing information affecting data quality, such as instrument calibration, which is the same for all samples in an analytical lot.

The useability of the data is established by data validation. The final step involves comparing results to the method criteria and data quality requirements. Qualifiers are attached to data records that have been validated. This allows data users to assess the quality of the data being used without requiring a detailed knowledge of the analytical processes. The data validation process is detailed in Engineering Procedure ENG-9.

The result of these programs and procedures is that analytical data quality is known and documented. The data presented in this report have been verified and a percentage have been validated. Additional information regarding data quality is available in the *Chemical Plant Site Remedial Investigation/Feasibility Study Data Validation Report* (MKF and JEG 1991c).

6.2 Quality Assurance Audits and Audit Tracking System

In 1990, WSS operations were reviewed during seven audits by outside entities. Four of these audits directly evaluated environmental aspects of the project. These audits evaluated the topics, and were performed by the organizations listed below.

Scope of Audit	Auditing Organization
Management Appraisal of ES&H and Quality Assurance	DOE - Oak Ridge Operations
Waste Management and Regulatory Compliance	Oak Ridge National Laboratories
ES&H and QA Appraisal	DOE - Oak Ridge Operations
Quality Assurance Project Plan Compliance	M-K Environmental Services Quality Assurance

Each audit resulted in an audit report which detailed findings and proficiencies. A response was prepared and corrective actions were defined and scheduled. All audit-related information is entered into a site-wide audit tracking system (SWATS) which tracks findings from initiation through corrective action and verification by both internal and external entities. The majority of findings in these audits relate to problems that only remedial action can solve (such as storage of polychlorinated biphenyls (PCBs) beyond the one-year limit), or relate to best management practices (which can be resolved through upgrading existing systems or by developing or revising procedures). The status of all audits is routinely reviewed by project management and QA personnel to ensure that progress is being made and that adequate resources are applied to correcting problems.

6.3 Quality Control Data Summary

Quality control samples were collected during all phases of the routine environmental monitoring program at the WSS. In some programs such as the external gamma and radon monitoring, the results are directly incorporated into the discussion of the data.

Groundwater, surface water, spring and National Pollution Discharge Elimination System (NPDES) monitoring, quality control sample results are discussed in this chapter. These samples include trip blanks, water and bottle blanks, field blanks, and duplicates. The results from these quality control samples are discussed in the following sections. Quality control data has been reviewed to evaluate impacts on the conclusions and interpretations presented in this report. The detection of uranium in water and bottle blanks, and field blanks has not impacted the dose calculations discussed in this report.

The WSSRAP did not participate in the DOE interlab comparison program in 1990. Participation will be implemented during 1991 for subcontract laboratory samples that were analyzed. The WSSRAP did collect quality control samples that were analyzed by numerous laboratories. The results of this program are discussed in Section 6.3.4.

6.3.1 Trip Blanks

Trip blank samples were collected to assess the impacts of sample shipping on analytical results. Trip blanks are sent with each shipment of samples to be analyzed for volatile organic compounds. During 1990, six trip blank samples were analyzed for volatile organic compounds. Analysis of these samples detected only low concentrations of acetone, methylene chloride, and toluene. These compounds were also detected in laboratory blanks, indicating that lab contamination is the source of these compounds.

6.3.2 Water and Bottle Blanks

Water and bottle blank samples are collected to evaluate the cleanliness of sampling containers and the purity of distilled water used to decontaminate nondedicated sampling equipment. These samples also serve as additional laboratory blanks. Eleven water and bottle blank samples were collected during 1990. These samples were analyzed for combinations of the following parameters: inorganic anions, uranium, gross alpha, and nitroaromatic compounds. These samples detected low concentrations (near the detection limit) for chloride (1 of 5 samples), fluoride (1 of 5 samples), sulfate (3 of 5 samples) and uranium (6 of 6 samples). The detection of uranium is particularly significant due to the concentrations detected. Uranium concentrations in these samples ranged from less than 1 pCi/l to 4.8 pCi/l (0.037 Bq/l to 0.177 Bq/l). As a result of these analyses, the uranium results (in water samples) presented in Section 4 are likely biased high, up to approximately

.5 pCi/l (0.185 Bq/l). In many areas, this slight bias may not be significant. However, in surface water and groundwater at the Weldon Spring Chemical Plant/raffinate pits (WSCP/WSRP), this bias may have artificially increased concerns regarding elevated uranium levels.

6.3.3 Field Blanks

Field blank samples are collected by filling sample containers with distilled water at an actual sampling location. These samples evaluate potential contamination resulting from actual sample collection activities. Seven field blank samples were collected during 1990. Field blank results must be used in conjunction with water and bottle blank sample results to accurately assess any impacts associated with actual sample collection. Field blank sample results correlated with water and bottle blanks sample results, indicating either bottle or laboratory contamination as the source for biased results for uranium and sulfate analyses. Uranium concentrations in field blanks ranged from less than 1 pCi/l to 5.4 pCi/l (0.037 Bq/l to 0.199 Bq/l), supporting the conclusions reached in Section 6.3.2.

6.3.4 Duplicate Sample Results

Two types of duplicate samples were collected and analyzed during 1990 for groundwater, surface water, spring, and NPDES samples. The first duplicate type is blind duplicate samples which were collected at the same time and in the same manner as regular samples, given a unique sample number, and analyzed by the laboratory analyzing the regular sample. The second duplicate type is replicate samples which are collected at the same time and in the same manner as the original sample and analyzed by a different laboratory.

Duplicate samples were analyzed for the same parameters as the original samples at the rate of approximately one per 20 samples. Therefore, duplicate samples were most frequently analyzed for uranium, nitroaromatic compounds, and inorganic anions. The number of duplicate samples analyzed by analytical parameter is presented in Table 6-1. Overall, the duplicate and replicate analyses indicated good agreement between the original and duplicate samples.

TABLE 6-1 Duplicate Sample Summary for Water Samples

PARAMETER	NUMBER OF DUPLICATE SAMPLES
1,3,5-Trinitrobenzene	25
1,3-Dinitrobenzene	25
Nitrobenzene	25

Uranium	26

7 SPECIAL STUDIES AND REMEDIAL ACTIVITIES

7.1 Characterization Special Studies

7.1.1 Haul Route Characterization

A haul road is planned for transportation of quarry bulk wastes from the Weldon Spring quarry (WSQ) to the Weldon Spring Chemical Plant (WSCP). This road will traverse an abandoned railroad grade and parallel Highway 94 when deviating from the railroad grade. The majority of this route crosses portions of the Weldon Spring Wildlife Area (owned by the Missouri Department of Conservation [MDOC]). Chemical and radiological characterization efforts were performed along this route in 1990 to assess waste management requirements for excavated materials and personnel exposure during construction of the road.

Chemical sampling included soil sampling in the marshalling yard (near the WSCP) and soil sampling near two abandoned drum locations adjacent to the railroad grade. The most intensive sampling was performed in the marshalling yard since this area presented the highest potential for contamination due to additional railcar operations and documentation of potential contaminant sources in this area. Soil samples were analyzed for volatile organics, semi-volatile organics, pesticides and polychlorinated biphenyls (PCBs), hazardous substance list metals, and nitroaromatic compounds. Samples from the marshalling yard indicated detectable levels of nitroaromatics in one grab sample and in one composite sample. PCBs were found at levels just above the detection limit near an abandoned transformer station. Metals concentrations were at or near background levels. No contaminants were found above background levels near the two abandoned drum locations. Chemical characterization did not indicate any contaminant levels which would require the use of special personnel protection equipment or present waste management concerns during construction of the haul road. The chemical results on wastes in the marshalling yard area will be given to the Department of the Army to support their remedial action decision on the Weldon Spring Training Area (WSTA).

Radiological characterization was performed along the entire railroad grade from the WSQ up to and including the marshalling yard. The characterization included: total beta-gamma radiation measurement and loose alpha contamination measurement surveys, and collection of physical samples from railroad ties, soil, and rail. Total beta-gamma

measurements and loose alpha contamination measurement surveys were performed to determine the levels of contamination present. Physical samples were collected to determine which radionuclides were present. Radiological characterization results indicated that all materials surveyed were within the release criteria established in the *Radiological Survey and Release Plan for the Quarry Haul Road* (MKF and JEG 1990e). Additional surveying of areas on the rails and ties that are inaccessible at this time (e.g., bottoms of rails), will be completed before any materials can be released for unrestricted use.

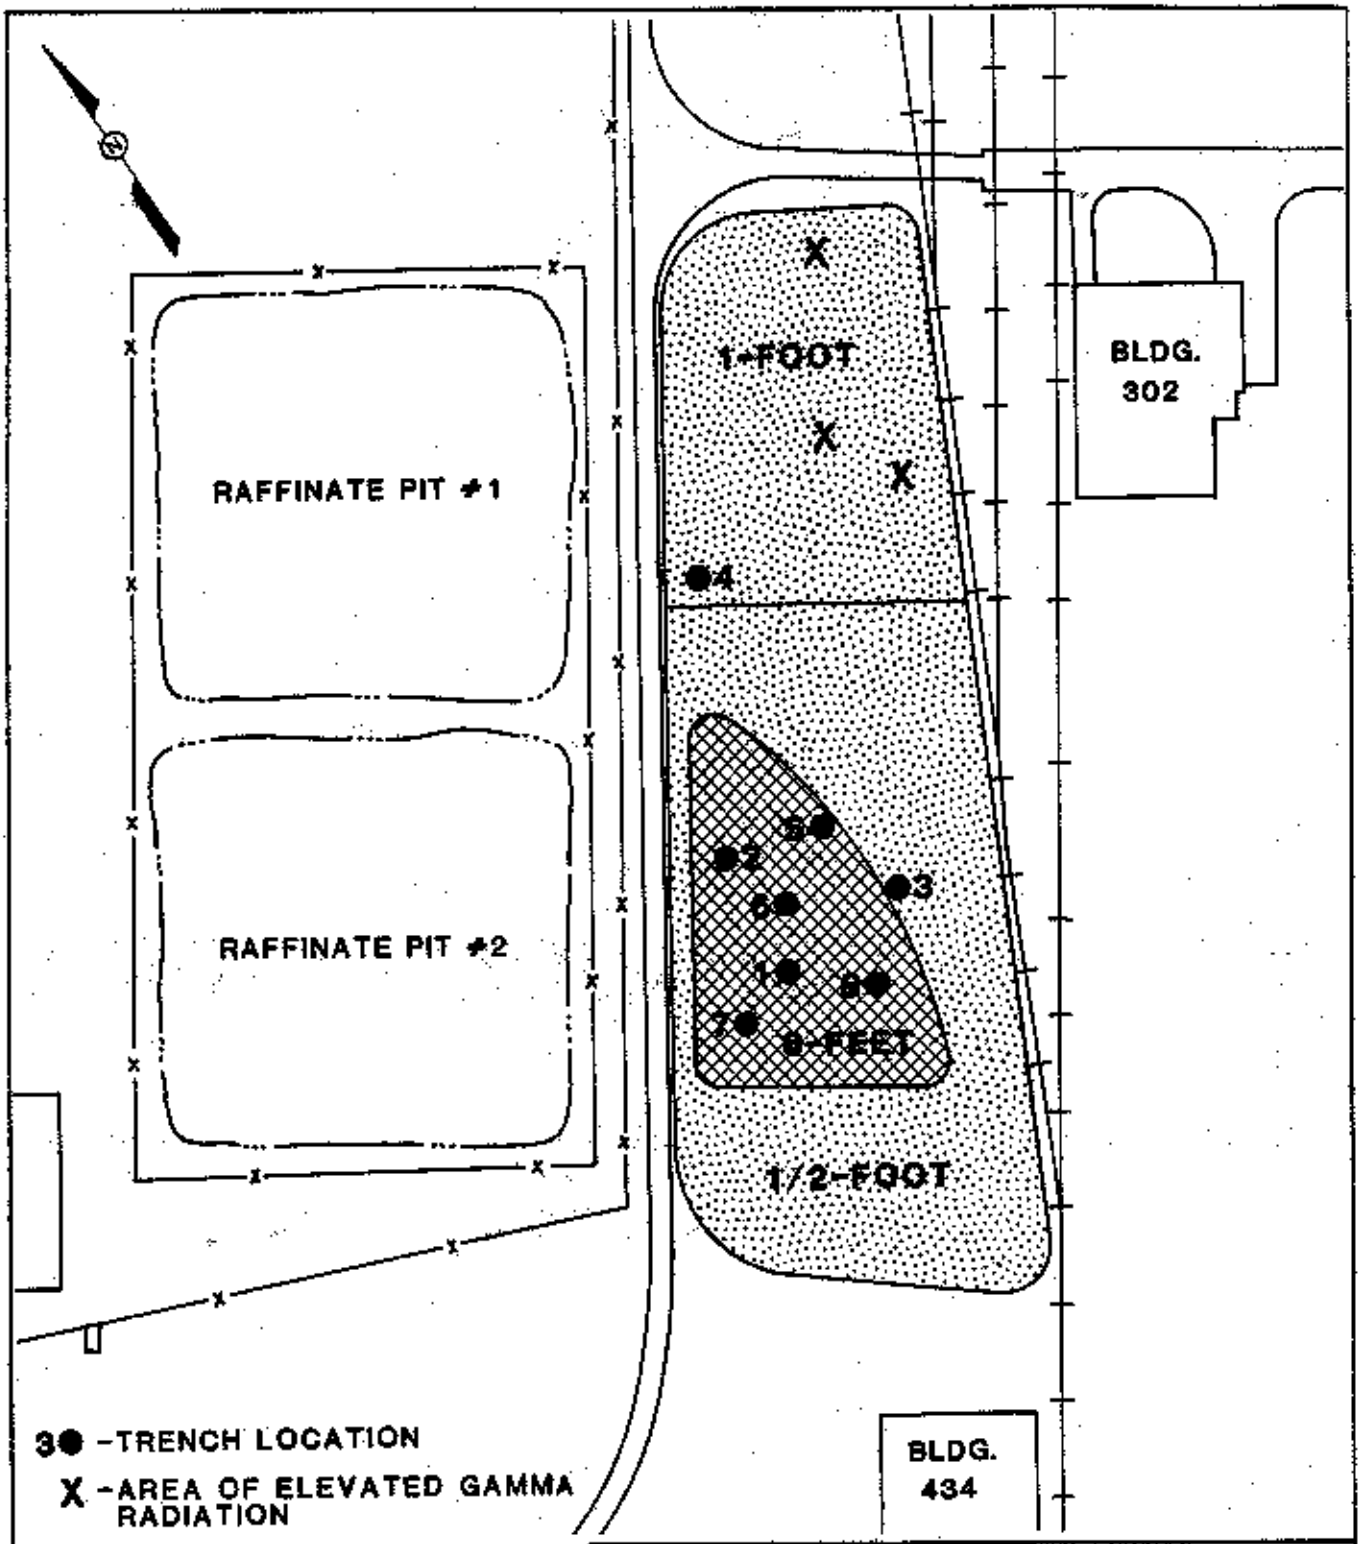
7.1.2 Aquatic Sampling

Fish and turtle specimens were collected during the 1990 calendar year to assess bio-uptake in aquatic habitats. In May 1990, a fish survey was performed in conjunction with MDOC in the Busch Wildlife area. Lakes 34 and 35 were sampled using electroshocking methods. Channel and bullhead catfish, sunfish (redear, green and bluegill) and largemouth bass were collected from Lake 34. The same three species were also collected in Lake 35, along with black crappie and white crappie. Fish samples which included (fillets, cakes, and the entire fish) were analyzed for isotopic uranium. The data results showed a range of concentrations from below the detection limit of .001 pCi/g to 0.349 pCi/g (0.000037 Bq/g to 0.0129 Bq/g). The whole fish samples from Lakes 34 and 35 showed the highest uranium concentrations.

On May 16, 1990, a snapping turtle was captured from the raffinate pit area. The turtle was analyzed to determine bioaccumulation of U-238, isotopic thorium, and isotopic radium. Four samples; skin, muscle tissue, bones, and internal organs were analyzed separately for each of the isotopes. Data results ranged from <.001 pCi/g (<0.000037 Bq/g) for Th–232 in muscle tissues and organs to 7.17 pCi/g (0.265 Bq/g) for Th-228 in the bone sample. A report is being prepared that will present the data and further discuss the findings of this study.

7.1.3 Southeast Drainage Sampling

The Southeast Drainage Flow Study was initiated during 1990 as a three-step investigation to determine the impacts of contaminated sediments on relatively uncontaminated stream flow. Steps one and two were performed in the autumn of 1990 at flow rates of 100 gal/min (gpm) (378.5 liters/min) and 200 gpm (757 liters/min). Step three



BURIED BRICK TRENCHING AREA

FIGURE 7-1

REPORT NO: DOE/OR/21548-193	EXHIBIT NO: A/CP/112/0491	
ORIGINATOR: JAM	DRAWN BY: GLN	DATE: 4/91

is consistent with site characterization results for this area. The average U-238 concentration in this area, based on site characterization performed in 1987, is approximately 20 pCi/g (0.74 Bq/g). Trench No. 4 exhibited unexpected results. This trench was out of the suspected debris area, and no debris other than gravel was encountered. However, the composite soil sample collected from this location contained 125 pCi/g (4.625 Bq/g) of U-238. This is much higher than the 20 pCi/g (0.74 Bq/g) average found during site characterization. A more thorough discussion and presentation of the data are included in the completion report being prepared by the Project Management Contractor (PMC).

7.1.6 Transformer 411 Characterization

Number 411 Electrical Substation is located on Department of Conservation property south of the Weldon Spring Chemical Plant (WSCP). The objective of the characterization effort was to supply the data necessary to prepare a subcontract package for the removal of all transformers and dielectric fluids contained at Substation 411.

Actual sampling of Substation 411 was performed on April 23 and 24, 1990. This included soil sampling throughout the area and collection of dielectric fluid (oil) samples from each transformer. A sampling plan was developed prior to sampling which contained detailed information on sampling locations, equipment, techniques, and personal protective equipment to be used during the sampling effort.

Two pole mounted transformers located within Substation 411 could not be sampled in April due to safety concerns. On June 14, 1990, a subcontractor was employed to disconnect and remove the transformers from their respective poles and place them on the substation concrete pad. The transformers were sampled on June 20, 1990, using the prescribed sampling techniques.

The results of the sampling were as follows: the oils in the transformers were determined to contain background levels of uranium; the oils contained varying levels of PCBs ranging from 6.1 ppm to 1,100 ppm of PCB (Arochlor 1260); the transformers were drained and rinsed as required by 40 CFR 761.60(b)(1)(i)B.

The soils surrounding the substation were sampled for Hazardous Substance List (HSL) metals, nitroaromatics, and PCBs. Metal levels were within the range of background.

Two soil samples showed low levels of nitrobenzene. Two samples showed detectable levels of PCBs, although both were below the 10 ppm clean-up criteria in 40 CFR 761.125(c)(4). Further detail on this investigation is available in the completion report for this effort (MKF and JEG 1990d).

7.2 Interim Response Actions

7.2.1 Quarry Water Treatment Plant Soil Remediation

The quarry construction staging area (QCSA) is an area adjacent to the WSQ to be used for placement of a quarry water treatment system to support the treatment of contaminated water from the quarry pond and subsequent removal of bulk wastes from the quarry.

The planned QCSA is to include an equalization basin, two effluent ponds, roads, parking areas, and infrastructure along with a water treatment plant. Before work could begin on the QCSA, contamination due to spills from haul trucks and railroad cars bringing wastes into quarry during past disposal operations had to be characterized.

Prior to radiological characterization, background gamma radiation levels and soil radionuclide concentrations were measured in the vicinity of the WSQ. The background locations were selected in areas unaffected by previous operations at the Weldon Spring site. Soil samples were collected in these background areas to a depth of 15.24 cm (6 in). All soil samples were analyzed for U-238, Ra-226 and Th-232 via high-purity germanium (HpGe) gamma spectroscopy.

Using background gamma radiation levels and soil radionuclide concentrations as a guide, initial characterization of the QCSA was performed. Systematic soil sampling was performed within the QCSA. Sample locations were established approximately every 68 m (200 ft) along the Little Femme Osage Creek, the quarry access road, and the abandoned railroad tracks and spurs. Seventeen sample locations were established and 20 soil samples were collected. These soil samples were taken to determine whether radioactive contamination occurs in these areas and, if necessary, to guide further sampling. Further information concerning the QCSA initial characterization may be found in the *Radiological*

and Chemical Characterization Report For The Planned Quarry Construction Staging Area and Water Treatment Plant, (MKF and JEG 1989d).

The areal extent of contamination was determined after the initial characterization was performed and contaminated areas were identified. This was done to determine explicit perimeter boundaries (depth and area) of the contaminated zones determined in the initial characterization. Previously determined background radiation and background radionuclide concentrations were used in this phase of characterization.

Thirty-four sample grids bordering the perimeters of the contaminated Zones 1, 2, and 3, previously identified in the initial characterization were established, and total of 36 composite soil samples were collected. Figure 7-2 displays these zones.

As a result of this characterization, the perimeters of the extent of contamination were unchanged from those previously determined by initial characterization. The single exception was one sample grid which had results for Th-230 of 6.9 pCi/g (0.255 Bq/g). This area was added to those which required remediation.

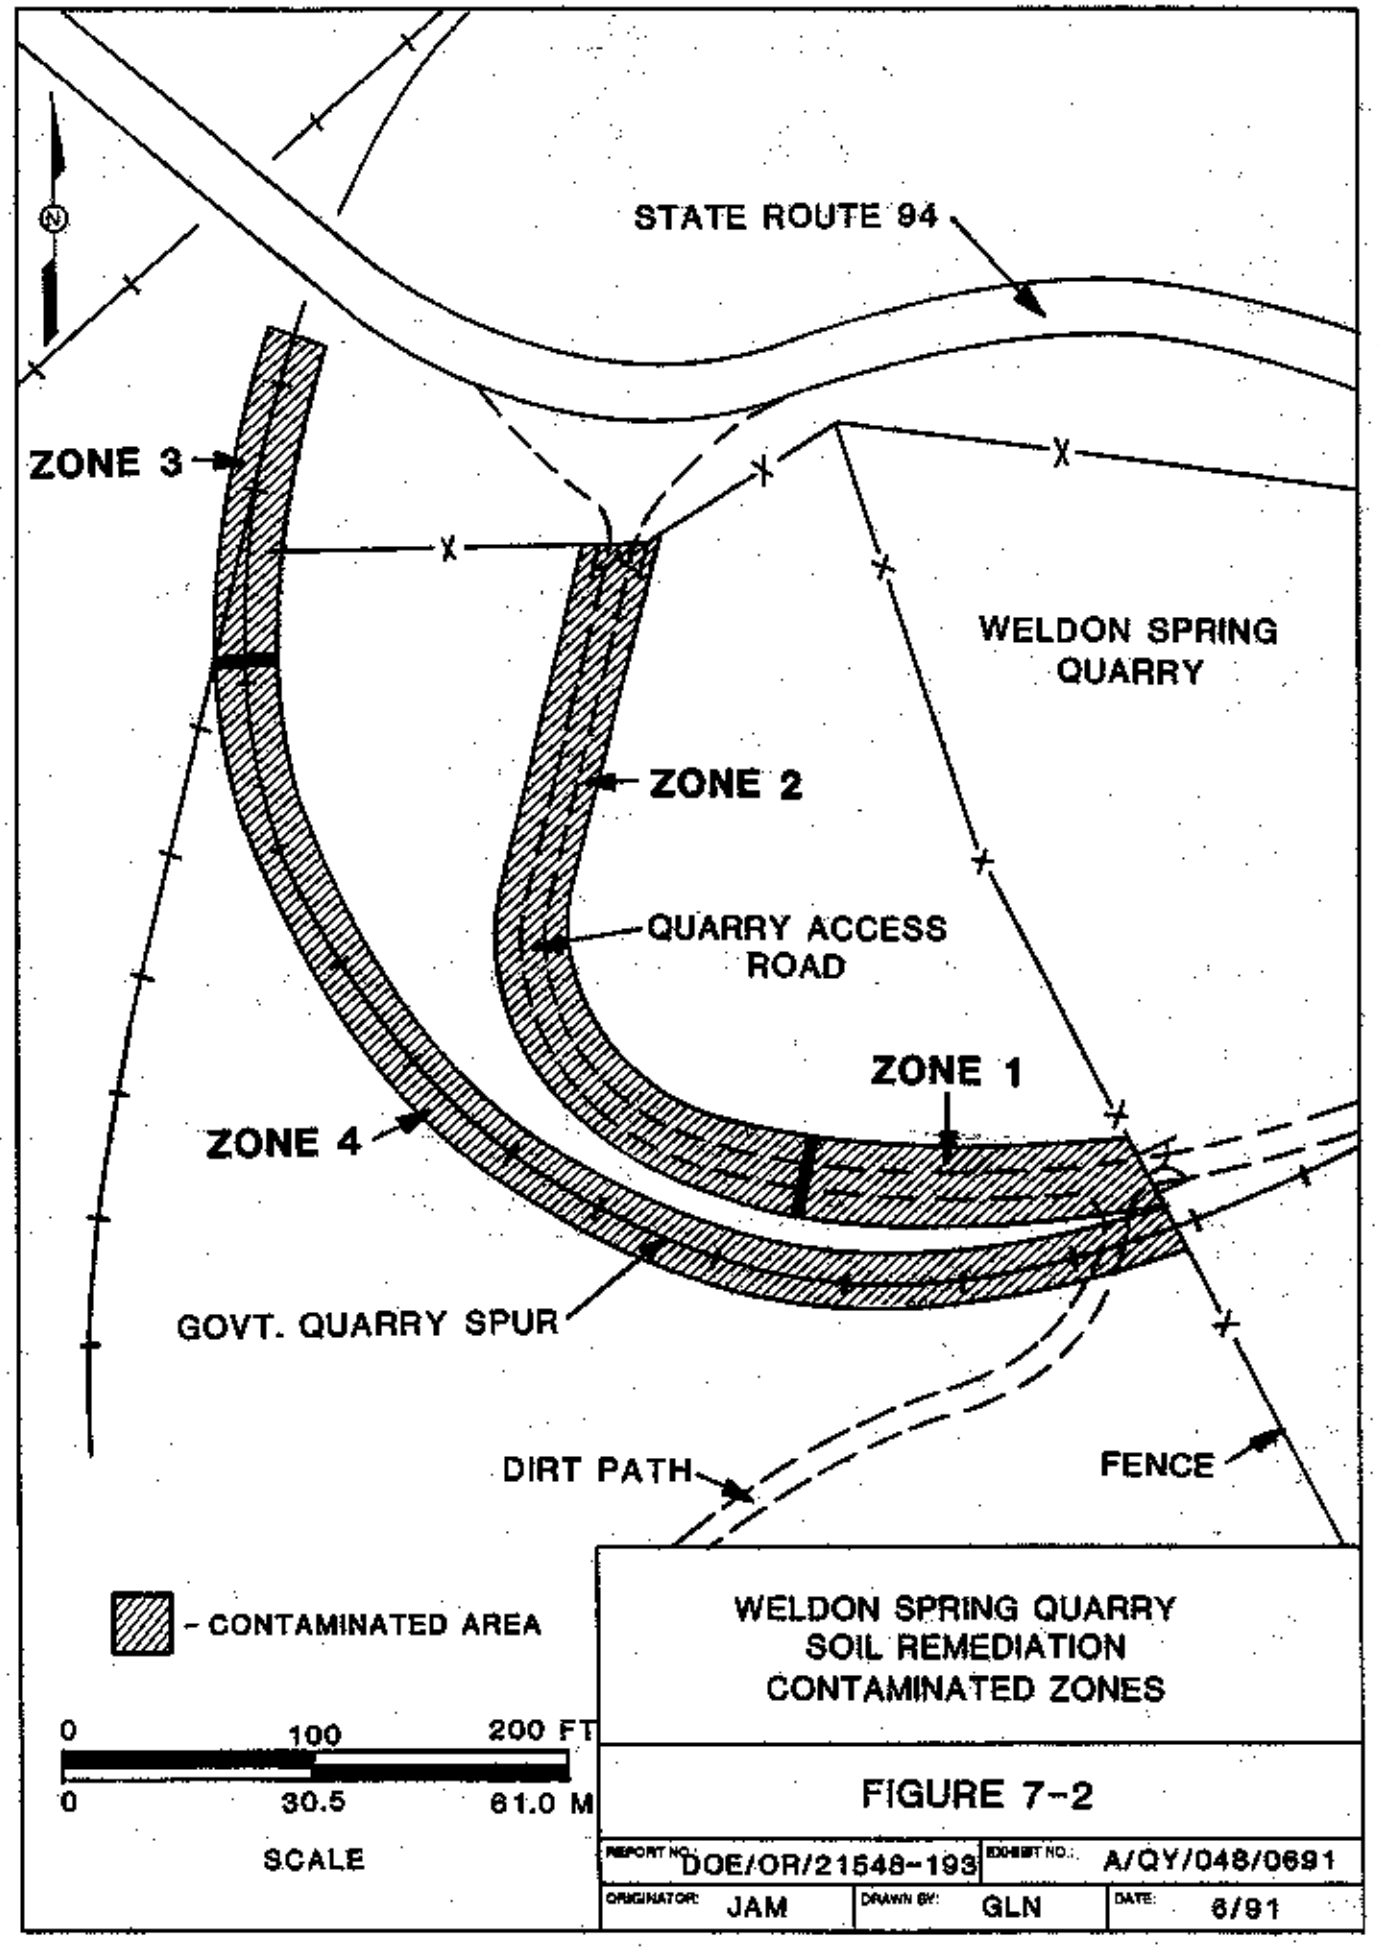
After contaminated zone perimeters were established through initial and areal extent characterization, remediation was performed by excavating with a backhoe and dumptruck. The excavated soil was placed in a soils staging area within the fenced inner quarry area.

Characterization to confirm the completion of remediation was performed immediately following excavation of each area. After each area was remediated, a walk-over scan of the exposed surface was performed. Walk-over scans after remediation revealed background levels of contamination.

Soil was sampled in each area after the walk-over scans were performed. All verification samples taken after remediation revealed concentrations of Th-230, U-238, Ra-226, and Ra-228 below criteria established for this project.

7.2.2 Containerized Chemical Consolidation

As reported in the 1989 *Annual Site Environmental Report* (MKF and JEG 1989c) the containerized chemical consolidation program continued to identify, characterize, consolidate,



WELDON SPRING QUARRY
SOIL REMEDIATION
CONTAMINATED ZONES

FIGURE 7-2

repackage and temporarily store chemical wastes which were located throughout the chemical plant. Approximately 6,000 containers (bottles, jars, barrels, etc.) have been repackaged and placed into storage. Work has begun on characterizing the process piping, sumps, tanks, and vessels which occur throughout the site. Upon completion, the results of this program will be described in a characterization report.

APPENDIX A
QUARTERLY MONITORING DATA FOR WATER MEDIA

Appendix A contains all of the measured valves that were used to calculate the annual averages reported in the preceding text. Although the quarterly and annual sampling schedules varied by media and location, all data in the appendix are tabulated by the quarter during which they were collected.

Consequently, this format represents differing numbers of data points per location based on the sampling schedule of each location.

The data are organized by media beginning with groundwater, followed by springs, and then surface water. Data within each section are arranged by analytical category as follows: nitraromatics, inorganic anions, and radiological species.

APPENDIX C
GLOSSARY OF TECHNICAL TERMS

m:\users\joanne\aser\append-o

APPENDIX C
GLOSSARY OF TECHNICAL TERMS

ABSORBED DOSE: The amount of energy absorbed in any material from incident radiation. Measured in rads, where 1 rad equals 100 ergs of energy absorbed in 1 gram of matter.

ACTIVITY: A measure of the rate at which radioactive material is undergoing radioactive decay; usually given in terms of the number of nuclear disintegrations occurring in a given quantity of material over a unit of time. The unit of activity is the Curie (Ci) (see also Bequerel and Curie).

ALARA: An acronym for "As Low as Reasonably Achievable." This refers to the U.S. Department of Energy goal of keeping releases of radioactive substances to the environment and exposures of humans to radiation as far below regulatory limits as "reasonably achievable."

ALLUVIAL AQUIFER: A subsurface zone, formed by the deposition of sediments by running water, capable of yielding usable quantities of groundwater to wells.

ALPHA PARTICLE: A positively charged particle emitted from the nucleus during the radioactive decay of certain radionuclides. It consists of two protons and two neutrons bound together; it is identical to the nucleus of a helium-4 atom.

BACKGROUND RADIATION: Radiation due to cosmic rays and radiation from the naturally radioactive elements in the surface of earth.

BEDROCK: A rock formation usually underlying one or more unconsolidated formations.

BEQUEREL: SI unit for activity. 1 bequerel (Bq) = 1 disintegration/second = 2.703×10^{-11} Ci (curie).

BETA PARTICLE: Charged particle emitted from the nucleus of an atom, with a mass and charge equal in magnitude to that of the electron.

CHAIN OF CUSTODY: Standardized form tracing the possession and handling of individual samples from the time of field collection through laboratory analysis.

COMMITTED DOSE EQUIVALENT: The total dose equivalent averaged throughout a tissue in the 50 years after intake of a radionuclide into the body.

CONTAMINATION: A foreign substance in or on the surfaces of soils, structures, areas, objects, or personnel.

COUNTING STATISTICS: Statistical analysis required to process the results of nuclear counting experiments and to make predictions about the expected precision of quantities derived from these measurements.

CURIE: A measure of the rate of radioactive decay. One Curie (Ci) is equal to 37 billion disintegrations per second (3.7×10^{10} dps), which is equal to the decay rate of one gram of radium-226.

DAUGHTER: An element that results immediately from the disintegration of a radioactive element.

DECAY PRODUCTS: Isotopes that are formed by the radioactive decay of some other isotope. In the case of radium-226, for example, there are 10 successive decay products, ending in the stable isotope Lead-206.

DERIVED CONCENTRATION GUIDE (DCG): Concentrations of radionuclides in water and air that could be continuously consumed or inhaled and not exceed an effective dose equivalent of 100 mrem/year.

DISCHARGE: In groundwater hydrology, the rate of flow (usually from a well or spring) at a given instant in terms of volume per unit of time.

DOSE: Total radiation delivered to a specific part of the body, or to the body as a whole; also called dose equivalent.

DOSE RATE: Dose or dose equivalent per unit of time (i.e., millirem per year) as it is being delivered to the body.

DOSIMETER: A device used in measuring radiation dose, such as a lithium fluoride (LiF) thermoluminescent detector (TLD).

EFFECTIVE DOSE EQUIVALENT: The proportion of the stochastic risk resulting from irradiation of a tissue to the total risk when the whole body is irradiated uniformly. A term used to express the amount of effective radiation when modifying factors have been considered, it is the product of absorbed dose (rads) multiplied by a quality factor and any other modifying factors. It is measured in rem (Roentgen Equivalent Man).

ERG: 1 ERG = 2.8×10^{-14} KWH

EXPOSURE PATHWAY: The route by which a contaminant/health hazard may enter and move through the environment or individual.

EXPOSURE RADIATION: The amount of ionization produced in air by X-rays or gamma rays, measured in Roentgens (R).

GAMMA RADIATION: Penetrating high energy, short wave-length, electromagnetic radiation (similar to x-rays) emitted during radioactive decay. Gamma rays are very penetrating and can be attenuated only by dense materials such as lead.

GROSS ALPHA: Measurement of all alpha-emitting radionuclides in a sample.

GROSS BETA: Measurement of all beta-emitting radionuclides in a sample. Gross alpha and beta are useful analyses for screening to determine whether further analyses for specific radionuclides are merited.

HALF LIFE: The time it takes for half the atoms of a quantity of a particular radioactive element to decay into another form. Half-lives of different isotopes vary from millionths of a second or less to billions of years.

HECTARE: A unit of area in the metric system equal to 10,000 square meters. It is approximately 2.5 acres.

HYDROLOGIC: Pertaining to study of the properties, distribution, and circulation of water on the surface of the land, in the soil and underlying rocks, and in the atmosphere.

ISOTOPE: Nuclides having the same atomic number but different mass numbers.

MDA/LLD: The minimum amount of a material or characteristic property being measured that can be detected with reasonable certainty by the analytical procedure being used.

NATURAL URANIUM: A naturally occurring radioactive element that consists of 99.2830% by weight uranium-238, 0.7110% uranium-235 and 0.0054% uranium-234.

NUCLIDE: A general term referring to isotopes, both stable (279) and unstable (about 500), of the chemical elements.

PERCHED LENSES: A small, localized water-saturated zone of subsurface material surrounded by unsaturated material.

RAD: Unit of absorbed dose; acronym for radiation absorbed dose.

RADIATION: A very general term that covers many forms of particles and energy, from sunlight and radiowaves to the energy that is released from inside an atom. Radiation can be in the form of electromagnetic waves (gamma rays, x-rays) or particles (alpha particles, beta particles, protons, neutrons).

RADIONUCLIDE: An unstable nuclide that undergoes radioactive decay.

RAFFINATE: A waste product from a refining process, i.e., that portion of a treated liquid mixture that is not dissolved and not removed by a selective solvent.

REM (Roentgen Equivalent Man): A quantity used in radiation protection to express the effective dose equivalent for all forms of ionizing radiation. A rem is the product of the absorbed dose in rads and factors related to relative biological effectiveness.

SI: International System of Units.

SIEVERT: SI unit used to express the effective dose equivalent for all forms of ionizing radiation. 1 Sv = 100 rem

STOCHASTIC: "Stochastic" effects are those for which the probability of an effect occurring, rather than its severity, is regarded as a function of dose, without a threshold.

WORKING LEVEL: Any combination of radon-222 decay products in 1 liter of air that will result in the ultimate emission of 0.21 erg of alpha energy is defined as 1 WL. It is based on the 0.21 erg of alpha energy that would be emitted by the decay products of 100 pCi of radon-222 in 1 liter of air, where the decay products are in radioactive equilibrium with the parent.

WORKING LEVEL MONTH: The product of WL and duration of exposure, normalized to a 1-month exposure period.

X-RAYS: Penetrating electromagnetic radiation having a wave length that is much shorter than that of visible light. It is customary to refer to rays originating in the nucleus as gamma rays and to those originating in the electron field of the atom as x-rays.

APPENDIX E
ENVIRONMENTAL GUIDELINES

m:\users\joanne\eser\append-e

APPENDIX E
ENVIRONMENTAL GUIDELINES

This Appendix contains standards and guidelines that are either applicable to the WSS or are presented to provide a frame of reference for discussion.

RADIATION STANDARDS (DOE Order 5400.5, *Radiation Protection of the Public and the Environment*)

A. DOSE LIMITS

1. All Pathways
The effective dose equivalent for any member of the public from all routine DOE operations[1] (natural background and medical exposures excluded) shall not exceed the values given below:

	Effective dose equivalents[2] mrem/year	(mSv/year)
Occasional annual exposures	100	(1)

2. Air Pathway Only (Limits of 40 CFR 61, Subpart H)

Effective Dose Equivalent 10 mrem/year or 0.1 mSv/year

1. Routine DOE operations means normal planned operations and does not include actual or potential accidental or unplanned releases.

2. Effective dose equivalent will be expressed in rem (or millirem) with the corresponding value in sievert (or millisievert) in parenthesis. As used in this standard, effective dose equivalent includes both the effective dose equivalent from external radiation and the committed effective dose equivalent to individual tissues from ingestion and inhalation during the calendar year.

B. DERIVED CONCENTRATION GUIDES (DCG)

---

1 Routine DOE operations mean normal planned operations and does not include actual or potential accidental or unplanned releases.

2 Effective dose equivalent will be expressed in rem (or millirem) with the corresponding value in sievert (or millisievert) in parenthesis. As used in this standard, effective dose equivalent includes both the effective dose equivalent from external radiation and the committed effective dose equivalent to individual tissues from ingestion and inhalation during the calendar year.

The following table contains a listing of the DCG values for the ingestion of drinking water and inhalation of air for members of the public. The values are based on a committed dose equivalent rate of 100 mrem/yr. Five columns of information are shown in the table: 1) radionuclide; 2) drinking water ingestion DCG in units of μCi/ml; 3) drinking water DCG in units of Bq/ml; 4) inhalation DCG in units of μCi/ml; 5) inhalation DCG in units of Bq/mL.

Only a single mode of exposure was considered--either ingestion or inhalation.

The DCG values are given for individual radionuclides. For known mixtures of radionuclides, the sum of the ratio of the observed concentration of a particular radionuclide and its corresponding DCG for all radionuclides in the mixture must not exceed 1.0.

It should be noted that the values given in the table only account for drinking water and inhaling air, and do not include other potentially significant environmental pathways. A more complete pathway analysis is required for calculating public radiation dose equivalent resulting from the operation of DOE facilities when more complex environmental pathways are involved.

	Drinking Water		Inhaled Air	
Radionuclide	μCi/mL	Bq/mL	μCi/mL	Bq/mL
Natural Uranium	6.0E-07	2.2E-02		
Uranium-238	6.0E-07	2.2E-02	1.0E-13	3.07-09
Uranium-235	6.0E-07	2.2E-02	1.0E-13	3.7E-09
Uranium-234	5.0E-07	1.9E-02	9.0E-14	3.3E-09
Thorium-232	5.0E-08	1.9E-03	7.0E-15	2.6E-10
Thorium-230	3.0E-07	1.1E-02	4.0E-14	1.5E-09
Radium-228	1.0E-07	3.7E-03	3.0E-12	1.1E-07
Radium-226	1.0E-07	3.7E-03	1.0E-12	3.7E-08

C. RADON

DCGs for radon (Rn-220) are being assessed by DOE. Until the review has been completed and new valves issued, the valve of 3.E-09 μCi/ml stated in DOE Order 5400.5 shall be used from radon releases from DOE facilities. In addition, interim storage facilities will not exceed an annual average concentration of 3 pCi/l at or above any location outside the facility site.

CHEMICAL STANDARDS

U.S. EPA Drinking Water Standards (mg/l) as noted in 40 CFR Parts 141 and 143

Drinking water standards are presented only for comparison purposes. These should not necessarily be construed as relevant cleanup standards.

A. HSL-Metals

Aluminum	NS	Lthium	NS

APPENDIX F
CONVERSION FACTORS

m:\users\joanne\asar\append-f

CONVERSION FACTORS

1 millisievert (mSv)	=	100 mrem
1 milliroentgen (mR)	=	1 mrem (for gamma radiation)
1 Curie (Ci)	=	3.7×10^{10} dps (disintegrations/sec)
1 Bequerel (Bq)	=	1 disintegration per second
1 M^3	=	1000 litres
1 Bq/M^3	=	3.7×10^{-2} pCi/M^3
1 Bq/l	=	3.7×10^{-2} pCi/l
1 Bq/kg	=	3.7×10^{-2} pCi/kg
1 km	=	.62 miles
1 m	=	3.28 ft
1 m^3	=	1.31 cu yd
1 mm	=	.039 inches
1 ha	=	2.47 acres
1 Gy	=	100 RAD

APPENDIX G
DOSE ASSESSMENT CALCULATIONS

A. Dose from the WSCP/WSRP to a maximally exposed individual.

1. Inhalation and external gamma pathways: not applicable since there is no reason to suspect at the 95% confidence level that airborne radioactive particulate, radon gas, and external gamma radiation data are greater than the respective background concentrations.

2. Ingestion pathway:

   a. fish - assume a 6.5 g/d fresh water fish consumption rate (EPA 1988) from Lake 36 (highest average uranium concentration in fish of all lakes receiving runoff from the WSS).

   b. water - assume a 0.05 liter/hr swimming ingestion rate (EPA 1988) for 1hr/wk for 12 wks, total of 0.6 liters. Assume water has uranium concentrations as detected in Lake 36 (highest uranium in water concentrations of all lakes receiving runoff from the WSS).

   c. sediment - assume a 200 mg/day ingestion rate for 2 days/yr for a total of 400 mg of sediment. Assume sediment has uranium concentrations as detected in Lake 34 (highest uranium concentration of all lakes receiving runoff from the WSS).

EDE (ingestion) = annual fish consumption x isotopic uranium concentration x isotopic DCF(1) + annual water consumption x uranium concentration x uranium DCF(2) + annual sediment concentration x uranium concentration x uranium DCF(2)

EDE (ingestion) = 0.0246 mrem

---

(1) Isotopic Dose Conversion Factor (DCF) was the greater of the two DCFs reported for each uranium isotope as reported in Table 2.2 of Eckerman et al. (1988).

(2) Uranium DCF was obtained from DOE (1988). DOE DCF guidance was used for water and sediment consumption to be consistent with the exposure scenario used in the 1989 Annual Site Environmental Report.

B. Dose from the WSQ to a maximally exposed individual.

1. Inhalation pathway:

a. Airborne radioactive particulate - assume that the net concentration measured at AP-1010 (4.6E-16 μCi/ml) had the same ratio of radionuclides in the radionuclide inventory of the quarry surface soils, as reported in the quarry remedial investigation report (MKF and JEG 1989b) Activity ratios are given in Section D of this appendix. Assume an annual residence time of 50 hrs (Section 4.1.8.2). Assume a breathing rate of 1.25 m^3/hr (Cember 1983).

b. Radon gas - assume the concentration at State Route 94 is equal to the measured net concentration RD-1002 1.8 pCi/l. Assume an annual residence time of 50 hrs (Section 4.1.8.2). Assume that the working level ratio for Rn-222 was 50%.

EDE (inhalation) = net radon concentration x breathing rate x exposure time x dose conversion factor + net isotopic airborne particulate concentration x breathing rate x exposure time x isotopic DCF(1).

EDE (inhalation) = 3.306 mrem

2. External gamma radiation pathway: assume that the net gamma exposure at State Route 94 was the same as measured at monitoring station TD-1001 (0.003 mrem/hr), (the highest rate measured at the quarry). Assumed that the annual residence time was 50 hrs (Section 4.1.8.2).

EDE = Exposure rate x exposure time
EDE (gamma) = 0.15 mrem

(1) Dose Conversion Factors (DCF) were obtained from the EPA (Eckerman et al. 1988).

3. Ingestion pathway: because the quarry is controlled by an 2.4 m (8 ft) high barbed wire fence; fishing, swimming, and drinking water at the quarry does not constitute a realistic scenario.

C. Dose from the WSVPs to a maximally exposed individual.

1. Inhalation pathway: the Femme Osage Slough, that the hypothetical individual is assumed to frequent, is not suspected of having airborne radioactive particulate concentrations or radon daughter concentrations above normal background levels (Section 4.1.8.3), and thus there should be no effective dose exposed individual via this pathway.

2. External gamma pathway: assumed that the hypothetical individual sat on the bank of the slough a total of 200 hr/yr (Section 4.1.8.3). In addition the measured net gama exposure rate of 2.5 μR/hr was used to calculate the effective dose equivalent.

EDE = Exposure time x exposure rate
EDE = 0.5 mrem

3. Ingestion pathway:

Fish - assume a 6.5 g/day fresh water fish consumption rate (EPA 1988) from the slough. Assumed that the uranium concentration in fish is equal to the detection limit achieved during analysis (Section 4.1.8.3).

EDE = Fish consumption x uranium concentration x DCF[(1)]
EDE = 0.006 mrem

(1) Dose Conversion Factor (DCF) is from DOE guidance to be consistent with the exposure scenario used in the 1989 Annual Site Environmental Report.

D. Collective Population Dose Estimate

Exposure Points - Exposure points are locations where members of the public are potentially being exposed to above-background concentrations of: (1) airborne radioactive particulates; (2) radon gas concentrations; (3) external gamma radiation; or (4) radionuclides in food or water. The first three pathways will be addressed for the collective population dose estimate. Exposure to above-background radionuclide concentrations in food or water will not be addressed since it is not reasonable to assume that a majority of the population eats fish from bodies of water that receive runoff from the WSS, and because no surface water or groundwater bodies that receive runoff or recharge from the WSS are used as drinking water sources.

Exposure points, by definition, must be located where there is potential for public exposure as a result of activities performed at the WSS or from materials stored at the WSS. If there is no reason to suspect that environmental monitoring results are different than the appropriate background monitoring results, then the area surrounding the environmental monitoring station cannot be considered an exposure point; therefore, the population near the station as well as the population beyond the station is not included in the collective population dose estimate.

The only area where there was reason to suspect that environmental monitoring results could be different than the appropriate background monitoring results was at the WSQ perimeter. This was true for airborne radioactive particulate concentrations, radon concentrations, and external gamma radiation. The only potential receptors near the WSQ perimeter are people using the Katy Trail, a recreational hiking and biking trail located on state-owned land south of the quarry. The Katy Trail lies approximately 45 m (49 yd) south of the quarry at its closest point and about 25 m (28 yd) below the southern quarry rim. It parallels the southern rim for approximately 260 m (286 yd). The estimated annual population using the trail is 72,000 persons, which is derived from a one-calendar-quarter estimate made by the Missouri State Parks Department (Maher 1991). The exposure time estimate is approximately 5 min, which corresponds to a 3.2 km/hr (2 mi/hr) walking speed along the 260 m (286 yd) length of trail paralleling the quarry.

The Katy Trail was chosen as the only public exposure point near the quarry because there currently are no environmental monitoring stations near the trail, and therefore, it could not be concluded with confidence that an above-background concentration

could be measured there. At all environmental monitoring locations near the WSQ (i.e., AP-4011, RD-4006, and TD-4006), there was no reason to suspect at the 95% confidence level that the monitoring results were different than the background monitoring results. Since there was no reason to suspect that environmental monitoring results at all WSCP/WSRP perimeter stations and at all off-site stations were different than the background monitoring results, no exposure points other than the Katy Trail were included in the population dose estimate.

Although the Katy Trail was chosen as an exposure point, and a collective population dose estimate was calculated for persons using the trail, this does not mean that measurable exposures did in fact occur there. Implicit in the following radioactive air particulate and radon gas concentration calculations is the conservative assumption that the wind is blowing from the WSQ towards the Katy Trail 100% of the time. This is definitely not the case; therefore, these calculations overestimate the maximum above-background average airborne radioactive particulate and radon concentrations which could have occurred at the trail.

Models

In order to estimate airborne radioactive particulate and radon concentrations at the Katy Trail, the above-background results measured at the WSQ perimeter were incorporated into a box model. A box model predicts a radon or airborne radioactive particulate release rate in pCi/s by multiplying the measured net airborne radioactive particulate or radon concentration by the assumed box model parameters for length, height, and average annual wind speed. The box model assumes that airborne contaminants are dispersed homogeneously within the modeled volume of air. The selected value for model length is 122 m (134 yd); for height it is 3 m (3.3 yd); and the value for average annual wind speed is 2 m/s (4.4 mi/hr). The model length value corresponds to the length of the major contaminated area within the quarry. A simplified box model is justified for calculating the airborne radioactive particulate and radon release rates because: (1) in the case of airborne radioactive particulates the net measured gross alpha concentration (i.e., the concentration measured at quarry monitoring station AP-1010 less the background concentration measured at station AP-4007) is an extremely small 4.6E-16 μCi/ml, and (2) in the case of both the airborne particulate and radon concentrations, the effective dose equivalent and population doses are low as indicated by the calculation results.

Once airborne radioactive particulate and radon release rates are obtained using the box model, fluxes are calculated by dividing the release rates by the surface area of the quarry. Once estimated airborne radioactive particulate and radon fluxes are calculated, estimated concentrations at the Katy Trail are calculated using the Gaussian atmospheric dispersion model modified to predict concentrations close to an area source (DOE 1986).

The modified Gaussian dispersion model can predict airborne concentrations at distances as close as 50 m (55 yd) from the edge of the area source, therfore this minimum distance was chosen as the distance between the quarry rim and the Katy Trail for the purposes of the model. This 50 m (55 yd) distance is comparable to the 45 m (50 yd) minimum distance between the quarry rim and the trail.

The net annual average radon concentration at the WSQ is 0.7 pCi/l and is calculated by averaging the results from stations RD-1001 through RD-1006 less the average background result of 0.3 pCi/l.

1. Box Model: length = 122 m (134 yd), height = 3 m (3.3 yd), average wind speed (μ) = 2 m/s (4.4 mi/hr)

   a. Release rate = length x height x μ x net annual average radon concentration

   b. Flux (Ø) = Release rate; where quarry floor area = 3.6 ha (9 acre) quarry floor area (MKF and JEG 1989b)

      = 14 pCi/m^2/s

2. Modified Gaussin Dispersion Model (DOE 1986)

   Model inputs include source diameter (D), distance from source edge to receptor (d), and atmospheric stability class. Given 3.6 ha (9-acre) quarry floor area and using $A = \pi r^2$, effective diameter of quarry is D = 215 m (237 yd). Assume d = 50 m (55 yd) (minimum distance for input into model) and atmospheric stability Class D.

Given the input parameters, the model predicts values for $(X\mu/\phi)$[1]

$(X\mu/\phi)$ for D = 215 m (237 yd) is found by interpolation to be 36.63

$$\frac{X\mu}{\phi} = 36.63$$

$$X = 36.63 \times \frac{\phi}{\mu} = 0.26 pCi/l$$

3. Estimated Effective Dose Equivalent (EDE) = radon concentration x working level ratio x exposure time x DCF[2]

   EDE (from radon) = 7.6E-7 rem

4. Population Dose Estimate from radon = 72,000 persons x 7.6E-7 mrem = 0.055 person rem

5. Population dose estimate due to airborne radioactive particulates

   The same box model and modified Gaussion dispersion model are applicable to predict the airborne radioactive particulate concentration. The difference is that the net measured annual average long-lived gross alpha concentration of 4.6E-16 μCi/ml (Section 4.1.8.2) is substituted for the net annual average radon concentration.

---

(1) X = predicted concentration at receptor location. For atmospheric stability Class D and d = 50 m (55 yd) the following $X\mu/\phi$ values are predicated:

Source Diameter(m)	$(X\mu/\phi)$
200 (220 yd)	35.39
300 (330 yd)	43.66

(2) Radon concentration = 0.26 pCi/l
Working level ratio = 0.50 (assumed)
Exposure time = 0.06 hr = 5 min
Dose conversion factor = 1.25 rem/working level month (Eckerman et al. 1988)

Using the same calculation and parameter values used to estimate the radon concentration:

Release Rate = 3.4E-7 μCi/s

Flux (ϕ) = 9.3E-12 μCi/m^2/s

$$\frac{X\mu}{\phi} = 36.63$$

$$X = 36.63 \times \frac{\phi}{\mu}$$

$$= 36.63 \times \frac{9.3E\text{-}12\ \mu Ci/m^2 \cdot s}{2\ m/s}$$

X = 1.7E-16 μCi/ml

To estimate radionuclide concentrations contributing to the long-lived gross alpha concentration, 1.7E-16 μCi/ml is proportioned among radium, thorium, and uranium isotopes according to average radionuclide concentrations in quarry surface (0 to 0.15 m) soils as reported in Table 4.6 of MKF and JEG 1989b. Additionally, U-238, U-234 and U-235 isotopes were assumed to be in their natural equilibrium state as were Ra-228 and Th-232. This results in the following percent of total activity and estimated airborne radionuclide concentrations:

RADIONUCLIDE	PERCENT OF TOTAL ACTIVITY	RADIONUCLIDE AIRBORNE CONCENTRATION µCi/ml
U-234	28.8	4.6E-17
U-235	1.2	2.0E-18
U-238	28.8	4.6E-17
Ra-226	16.1	2.7E-17
Ra-228	3.0	5.1E-18
Th-230	23.1	3.9E-17
Th-232	3.0	5.1E-18

EDE = airborne radionuclide concentration x breathing rate x exposure time x radionuclide DCF(1)

EDE (airborne radioactive particulates) = 3.3E-6 mrem

$$\textit{Population dose estimate airborne particulates} = 72{,}000\ \textit{persons} \times 3.3E\text{-}6\ \textit{mrem} \times \left(\frac{\textit{rem}}{10^3 \textit{mrem}}\right)$$

= 0.0002 person rem

6. Population dose estimate due to external gamma radiation

Model the quarry as a circular area source of diameter D = 215 m (same as for previous estimates) and use the following formula for ratio of external gamma dose equivalent rates at two points near a circular planar source.

(1) Breathing rate = 1.25 m^3/h (Gamber 1983)
Exposure time = 0.06 h
Radionuclide DCFs are as reported in Table 4-13

$$\frac{H_1}{H_2} = \frac{\ln[(R^2+h_1^2)/h_1^2]}{\ln[(R^2+h_2^2)/h_2^2]} \qquad \textit{(Cember 1983)}$$

H_1 = Average above-background dose equivalent rate at the quarry rim = 14.8 mrem/yr

H_2 = Estimated dose equivalent rate at Katy Trail

R = D/2 = 108 m

h_1 = Distance from quarry center to southern rim = 58 m (64 yd)

h_2 = h_1 + distance from quarry's southern rim to Katy Trail = 109 m (120 yd)

H_2 = 7.7E-4 mrem/hr

$$\textit{Population Dose Estimate} = 72{,}000 \textit{ persons} \times 7.74E{-}4 \frac{mrem}{h} \times 0.08h \times \left(\frac{rem}{10^3 \ mrem}\right)$$

= 0.004 person rem

ADDRESSEES:

QUARTERLY ENVIRONMENTAL DATA SUMMARY FOR THE SECOND QUARTER, 1991 FOR THE WELDON SPRING SITE REMEDIAL ACTION PROJECT

Enclosed for your information and use is a copy of the Quarterly Environmental Data Summary Report. The document summarizes the environmental monitoring data for the second quarter, highlights any potentially significant findings, and offers preliminary interpretations. Final interpretations will appear in the 1991 Annual Site Environmental Report.

The report concludes that no significant differences or changes in off-site exposures resulting from Weldon Spring Site contaminates have occurred during this reporting period.

If you have any questions please call Ken Lawver at (314)441-8978.

Sincerely,

Stephen H. McCracken
Project Manager

ABSTRACT AND WELDON SPRING SITE QUARTERLY SELF ASSESSMENT SECOND QUARTER 1991

The purpose of this Quarterly Environmental Data Summary is to provide preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1991 Annual Site Environmental Report.

This report includes data from environmental monitoring activities at the Weldon Spring site (WSS) during the second quarter of 1991. Groundwater, surface water, and air were sampled in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to calculate exposure doses (where applicable) and assess the impact of the contaminants at the site on potentially exposed populations.

In summary, no significant differences were observed in off-site exposures during the second quarter of 1991 relative to exposures calculated in previous quarters. Contaminated groundwater did not affect private water supplies or the St. Charles County well field. Surface water containing elevated uranium activity continued to impact the Femme Osage Slough. Off-site gamma, radon and air particulate exposures remained indistinguishable from background. Off-site monitoring demonstrated that exposure levels at the Francis Howell High School, the Busch Wildlife Area Headquarters, and the Weldon Spring Training Area remain indistinguishable from background levels.

1 INTRODUCTION

This document is the fifth in a series of documents designed to provide a summary of the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These documents supplement the *Annual Site Environmental Report* (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP Environmental Monitoring Plan and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from observations made in previous reports. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1991 ASER. It is recommended that interested readers refer to previous Environmental Monitoring Plans (EMPs), ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters are tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at 314–441–8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). However, because of delays in data delivery from the analytical laboratories, some of the data that was expected to be included in this report are not yet available for reporting. The unavailability of data is due to a nationwide shortage in analytical services. The WSSRAP is taking corrective action to ensure more timely availability of data in the future. These data will be reported in the 1991 ASER. Sludges, soils, and biological specimens are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater and air pathways. These analyses will be presented in the 1991 ASER. Included for the first time are QC data for the second quarter which are presented in tables throughout this document.

This information provides insight as to the performance of the laboratory and the quality of the data. This QC data is provided for information only. Final interpretation will be presented in the 1991 Annual Site Environmental Report (ASER).

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

The groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a semi-annual basis with the exception of MW-2001, MW-2002, MW-2003, MW-3003, MW-3006, MW-3008, MW-3009, MW-3023, MW-4012 and MW-4013 which are monitored quarterly. Monitoring well locations are shown in Figure 2-1. Data from the semiannual groundwater monitoring for the first half of 1991 are presented in this quarterly data summary, however, data from the quarterly monitored wells are presented in each QEDS.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the quarterly and semi-annual monitored groundwater wells at the CP/RP/VP area. Nitroaromatic compounds were detected in 22 samples. However, the data continue to reflect levels historically found and documented in previous environmental reports.

2.1.2 Radiological Results

The radiological results for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-2. The upper bound for natural uranium background concentrations in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l. The EPA has not yet established drinking water standards for uranium; however, studies leading to proposed rulemaking are using uranium in the 10 pCi/l to 40 pCi/l range. The U.S. Department of Energy (DOE) has a health based derived concentration guideline (DCG) of 600 pCi/l in surface water effluent.

The highest uranium level detected was 122.4 pCi/l from a sample obtained from Monitoring Well 4005. The other concentrations reported in Table 2-2 continue to indicate levels below the proposed drinking water standard for uranium.

2.1.3 Geochemical Results

Geochemical results for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-3. Geochemical parameters were added to the *Environmental Monitoring Plan* for the 1991 monitoring year.

2.1.4 Inorganic Anion Results

Inorganic anion results for the quarterly monitored WSCP/RP/VP wells are shown in Table 2-2. The results reflect levels historically found in these wells.

2.2 Weldon Spring Quarry

Chemical and radiological wastes at the quarry are of particular concern because of their proximity to the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mile) to the south of the Weldon Spring quarry. Monitoring of contaminants in groundwater and the protection of the well field is a top WSSRAP priority.

Groundwater is currently being monitored in 48 wells in and around the quarry. Thirty-six monitoring wells installed by the U.S. Department of Energy (DOE) currently exist in or near the quarry. Four monitoring wells were installed by St. Charles County in 1986 and are currently included in the DOE's monitoring program. Eight St. Charles County municipal wells are also included in the DOE's monitoring program. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells draw water from both bedrock and alluvial aquifers.

Two separate groundwater monitoring programs have been developed for the quarry. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough and MW-1010 and MW-1011. The second program is a quarterly sampling of all wells south of the Femme Osage Slough, excluding MW-1010 and -1011 but including the St. Charles

County well field. Both the raw and treated waters from the St. Charles County water treatment plant are also sampled.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-4, 2-5, and 2-6 for samples collected on a bimonthly and quarterly bases. The results show typical fluctuations near the average levels in the WSQ area with no dramatic increases evident except in MW-1015 and MW-1016. The increases in these two wells from the first bimonthly to the second and third bimonthly sampling events are on a magnitude of 2 to 5 times. The wells will continue to be monitored closely.

2.2.2 Nitroaromatic Compounds Results

Analytical results for nitroaromatic compounds are presented in Tables 2-7, 2-8, and 2-9. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the second quarter 1991. The distribution and magnitude of nitroaromatic contamination near the quarry remains unchanged with slight increases of 2,4,6-TNT and 1,3,5-TNB found in MW-1002, MW-1004, MW-1006, MW-1015, and MW-1016.

2.2.3 Inorganic Anions Results

Two inorganic anions--nitrate and sulfate--were measured in quarry wells. Tables 2–4, 2-5, and 2-6 display the analytical results for the second quarter of 1991, which are consistent with data reported in the previous environmental monitoring reports. The WSQ groundwater samples continue to indicate no significant groundwater contamination by nitrate. The groundwater samples continue to indicate background concentrations of sulfate in wells south of the Femme Osage Slough.

2.2.4 Metals Results

A selected group of quarry wells located south of the Femme Osage Slough were sampled for cadmium, lead, and mercury in addition to arsenic and barium. Analytical results for these metals are presented in Tables 2-10, 2-11, and 2-12. Results from the

second and third bimonthly and second quarter analyses of arsenic and barium continue to indicate elevated concentrations in selected wells. The highest levels reported are 149 µg/l for arsenic in MW-1017 and 1,030 µg/l for barium also detected in MW-1017.

3 SURFACE WATER MONITORING

Routine samples were collected during the second quarter of 1991 from both on-site and off-site surface water and spring locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1991 ASER.

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the second quarter, surface water samples were collected from the 13 surface water sampling locations shown in Figure 3-1 and analyzed for uranium. The results, presented in Table 3-1, indicate that conditions remain similar to values measured historically.

3.2 Weldon Spring Quarry

Surface water samples were collected from the 10 locations shown in Figure 3-2 and three locations in Figure 3-3. Samples were analyzed for uranium, arsenic, and barium and the results are presented in Table 3-2. However, only the uranium results are available at this time. The results of all samples indicate no apparent changes in environmental conditions, although as seen in the previous first quarter, the uranium levels within the slough remain slightly elevated. The highest measured level was 312 pCi/l detected at sampling location SW-1004.

The second quarter uranium values measured in the Missouri River were almost the same as the values detected during the previous quarter. Historically, the levels of uranium at these locations have fluctuated (due to either natural fluctuations or analytical variability) such that uranium concentrations have been higher at upstream locations than downstream, and vice versa. The U.S. Department of Energy (DOE) has increased monitoring of the Missouri River prior to the operation of the Weldon Spring Site Remedial Action Project (WSSRAP) quarry water treatment plant to ascertain the preoperational (background) levels in the river. In addition, the National Pollution Discharge Elimination System (NPDES) permit for the quarry water treatment plant requires additional monitoring of the river. This

monitoring increases the DOEs capability to ensure the safety of the public and the environment.

Arsenic and barium results in the second quarter for samples collected from the Missouri River were not available.

The analytical results for the six nitroaromatic compounds within the quarry sump were not available at the time of this report. The ponded water is to be treated for nitroaromatic compounds and other organics upon completion of the quarry water treatment plant.

3.3 Springs

Eleven springs around the Weldon Spring site (WSS) are sampled quarterly (see Figure 3-4 for spring locations). Previous spring monitoring indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs include SP-6301, SP-6302, SP-6306, and SP-5301 through SP-5304. All spring samples are analyzed for uranium with a select few analyzed for nitroaromatics, inorganics and metals. Available analytical results for these parameters are listed in Tables 3-3 and 3-4. Values for these parameters remain consistent with their historical values.

3.4 National Pollutant Discharge Elimination System Data Review

Surface water and effluent samples were collected and analyzed in compliance with the Weldon Spring Site National Pollutant Discharge Elimination System (NPDES) permit. This permit (Number MO-0107701) was issued in November 1988 and currently addresses these seven storm water and wastewater discharges shown in Figure 3-5. Outfalls NP-0001 through NP-0005 represent storm water discharge and NP-0006 represents the treated effluent discharge associated with the administration building sanitary wastewater treatment plant. Outfall NP-0007 represents the new site contaminated water treatment plant which is under contract but not yet constructed. Outfalls NP-0006 and NP-0007 have effluent limitations. The five surface water outfalls have monitoring requirements only. Second quarter 1991 analytical data for each outfall is presented in Table 3-5.

3.4.1 Radiological Analysis

Gross Alpha and Total Uranium analyses correspond reasonably well with past data. The highest uranium levels were present in surface flow from the southeast portion of the site (NP-0001 and NP-0005). The peaks for these points were 666 pCi/l and 571 pCi/l, respectively.

Other outfalls exhibited the following peaks of uranium concentrations. NP-0002, the drainage from the Frog Pond area, was measured at 150 pCi/l. NP-0003, with drainage from the Ash Pond area, was measured at 156 pCi/l. A uranium concentration of 9.5 pCi/l was present in the sample collected from NP-0004, behind raffinate pit No. 4.

3.4.2 Other Analysis

Other analyses include physical analysis (settleable solids and suspended solids) and chemical analysis (nitrate, pH, and lithium). Second quarter 1991 values generally correspond to past values for the majority of parameters. The Ash Pond weir (NP-0003) discharged an excessive amount of solids because of erosion from a new construction activity on the day the samples were taken.

The discharge from the administration building treatment plant, NP-0006, has effluent limitations for quarterly samples. In addition to this quarterly monitoring, the subcontractor monitors the same parameters monthly, to assess plant performance. The NPDES permit contains effluent limitations on biochemical oxygen demand (BOD), total suspended solids (TSS), and fecal coliform at this outfall. These limits are 15 mg/l (BOD), and 20 mg/l (TSS), for weekly averages with maximum daily fecal coliform of 1,000 colonies per 100 ml. NPDES permit limits were not exceeded in the second of quarter 1991 at this outfall.

4 AIR MONITORING

4.1 Radon Gas

The radon gas monitoring program utilizes a pair of radon detectors at each of 22 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, six locations at the Weldon Spring quarry, four locations at the Weldon Spring raffinate pits, and six off-site locations. Radon monitoring locations are shown in Figures 4-1, 4-2, and 4-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, and RD-4006 were used to monitor background levels near the site.

Table 4-1 summarizes the second quarter 1991 radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in Table 4-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (110 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the four background locations. This data yielded an average ambient background radon concentration of 0.3 pCi/l for the second quarter of 1991. This concentration was then subtracted from the concentration for each monitoring station, and compared to the DOE guideline of 3 pCi/l above background.

Radon concentrations at the site and quarry perimeters and at off-site locations for the second quarter of 1991 were within the typical range expected during years of normal precipitation. The quarterly radon concentrations (background included) ranged from 0.1 pCi/l at RD-2002 to 1.3 pCi/l at monitoring location RD-1001 and RD-1002.

Radon concentrations found in the quarry are higher than concentrations measured at other locations because the radium concentrations in quarry wastes are typically much higher than other areas, and because the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high. In conjunction with stable meteorological conditions,

(b) Percent of guideline calculated by taking the quarterly average minus the average of the background stations divided by the DOE concentration guideline for RN-222 which is 3 pCi/l (100 Bq/m^3)(Annual average above background) for uncontrolled areas.
* Denotes Background Station

this configuration tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

4.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, spherical environmental thermoluminescent dosimeters (TLDs) were deployed at 22 locations. The gamma monitoring station locations are the same as the ambient radon monitoring locations (see Section 4.1).

Table 4-2 summarizes the first and second quarter results of total gamma radiation monitoring at the 16 Weldon Spring site (WSS) perimeter monitoring stations, the Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the four background monitoring stations.

The annual average background gamma exposures measured with TLDs in 1989 and 1990 were 68 mR/year and 62 mR/year, respectively. The gamma exposures measured with TLDs in the first and second quarter of 1991 were consistent with 1989 and 1990 data. This was expected because no significant changes in the configuration or location of the wastes have occurred.

4.3 Radioactive Air Particulates

Eleven low volume air particulate samplers monitor the Weldon Spring site continuously. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter as shown in Figure 4-3. Three monitoring stations (AP-4006, AP-4008, and AP-4011) are located off site at sensitive receptor locations; including Francis Howell High School, the Army Reserve property, and near a residential site west of the quarry. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown in Figure 4-2.

* Denotes background station.

The sampling station near the August A. Busch Wildlife Area (ABWA) headquarters is used as a background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/ Weldon Spring raffinate pits (WSRP). In addition, winds from the southeast are relatively rare at the WSCP.

Table 4-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging either the weekly air particulate analysis results or the counting instrument's lower limit of detection (LLD), whichever was greater. The "<" sign in Table 4-3 appears when the actual average is less than the calculated average due to the use of LLD values in the calculation. The standard deviation for each of the monitoring locations was calculated using only results that were above the LLD. Due to maintenance, all monitors were not operating the entire 13 weeks as indicated in Table 4-3. However, the sensitive receptor monitoring stations (AP-4006, AP-4008, and AP-4011) were in operation the majority of the time and these stations are also equipped with high volume air monitoring. The high volume air monitors are part of the WSS radionuclide National Emissions Standards for Hazardous Air Pollutants (NESHAPs) requirements and were in operation the entire 13 weeks. The high volume monitoring results will be presented in the *Annual Site Environmental Report.*

The first quarter net alpha concentrations ranged from $< 9.19 \times 10^{-16}$ µCi/ml to $< 1.28 \times 10^{-15}$ µCi/ml with 1.12×10^{-15} µCi/ml detected at the background station.

4.4 Asbestos

No environmental asbestos monitoring was performed in the second quarter of 1991.

QUARTERLY ENVIRONMENTAL DATA SUMMARY FOR THE THIRD QUARTER, 1991 FOR THE WELDON SPRING SITE REMEDIAL ACTION PROJECT

Enclosed for your information and use is a copy of the Quarterly Environmental Data Summary Report. The document summarizes the environmental monitoring data for the third quarter, highlights any potentially significant findings, and offers preliminary interpretations. Final interpretations will appear in the 1991 Annual Site Environmental Report.

The report indicates the occurrence of slightly elevated levels of total suspended solids for Outfalls NP-0001 and NP-0005 resulting from construction activities and a 2.24 inch rainfall prior to sampling.

If you have any questions please call Alan D. Gibson at (314)441-8978.

ABSTRACT AND WELDON SPRING SITE QUARTERLY SELF ASSESSMENT THIRD QUARTER 1991

The purpose of this Quarterly Environmental Data Summary is to provide preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1991 Annual Site Environmental Report.

This report includes data from environmental monitoring activities at the Weldon Spring site (WSS) during the third quarter of 1991. Groundwater, surface water, and air were sampled in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to calculate exposure doses (where applicable) and assess the impact of the contaminants at the site on potentially exposed populations.

In summary, no significant differences were observed in off-site exposures during the third quarter of 1991 relative to exposures calculated in previous quarters. Contaminated groundwater did not affect private water supplies or the St. Charles County well field. Surface water containing elevated uranium activity continued to impact the Femme Osage Slough. Off-site gamma, radon, and air particulate exposures remained indistinguishable from background. Off-site monitoring demonstrated that exposure levels at the Francis Howell High School, the Busch Wildlife Area Headquarters, and the Weldon Spring Training Area remain indistinguishable from background levels.

1 INTRODUCTION

This document is the sixth in a series of documents designed to provide a summary of the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These documents supplement the *Annual Site Environmental Report* (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP Environmental Monitoring Plan and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from observations made in previous reports. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1991 ASER. It is recommended that interested readers refer to previous Environmental Monitoring Plans (EMPs), ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters are tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at 314-441-8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). However, because of delays in data delivery from the analytical laboratories, some of the data that was expected to be included in this report are not yet available for reporting. The unavailability of data is due to a nationwide shortage in analytical services. These data will be reported in the 1991 ASER. Sludges, soils, and biological specimens are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater and air pathways. These analyses will be presented in the 1991 ASER. Quality control (QC) data for the third quarter are presented in tables throughout this document. This information provides insight as to the performance of the laboratory and the quality of the data. This

QC data is provided for information only. Final interpretation will be presented in the 1991 Annual Site Environmental Report (ASER).

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring Quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

The groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a semi-annual basis with the exception of MW-2001, MW-2002, MW-2003, MW-3003, MW-3006, MW-3008, MW-3009, MW-3023, MW-4012 and MW-4013 which are monitored quarterly. Monitoring well locations are shown in Figure 2-1. Data from the semiannual groundwater monitoring for the second half of 1991 will be presented in the fourth quarterly data summary, however, data from the quarterly monitored wells are presented in each Quarterly Environmental Data Summary (QEDS).

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the quarterly monitored groundwater wells at the WSCP/RP/VP area. Nitroaromatic compounds were detected in 18 samples. However, not all the data are currently available. The data available continues to reflect levels historically found and documented in previous environmental reports.

2.1.2 Radiological Results

The radiological results for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-2. The upper bound for natural uranium background concentrations in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l. The U.S. Environmental Protection Agency (EPA) has not yet established drinking water standards for uranium; however, studies leading to proposed rulemaking are using uranium in the 10 pCi/l to 40 pCi/l range. The U.S. Department of Energy (DOE) has a health based derived concentration guideline (DCG) of 600 pCi/l in surface water effluent.

The highest uranium level detected from the available data was 20.5 pCi/l from a sample obtained from Monitoring Well MW-3003. The concentrations reported in Table 2-2 continue to indicate levels below the proposed drinking water standard for uranium.

2.1.3 Geochemical Results

Geochemical results for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-3. Geochemical parameters were added to the *Environmental Monitoring Plan* for the 1991 monitoring year.

2.1.4 Inorganic Anion Results

Inorganic anion results for the quarterly monitored WSCP/RP/VP wells are shown in Table 2-2. The results reflect levels historically found in these wells.

2.2 Weldon Spring Quarry

Chemical and radiological wastes at the quarry are of particular concern because of their proximity to the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mile) to the south of the Weldon Spring quarry. Monitoring of contaminants in groundwater and the protection of the well field is a top Weldon Spring Site Remedial Action Project (WSSRAP) priority.

Groundwater is currently being monitored in 48 wells in and around the quarry. Thirty-six monitoring wells installed by the DOE currently exist in or near the quarry. Four monitoring wells were installed by St. Charles County in 1986 and are currently included in the DOE's monitoring program. Eight St. Charles County municipal wells are also included in the DOE's monitoring program. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells draw water from both bedrock and alluvial aquifers.

Two separate groundwater monitoring programs have been developed for the quarry. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough and MW-1010 and MW-1011. The second program is a quarterly sampling of all wells south of the Femme Osage Slough, excluding MW-1010 and MW-1011 but including the St. Charles

ORIGINATOR:	CSJ	DRAWN BY:	GLN	DATE:	12/91

County well field. Both the raw and treated waters from the St. Charles County water treatment plant are also sampled.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-4 and 2-5 for samples collected on a bimonthly and quarterly bases. The results show typical fluctuations near the average levels in the WSQ area with no dramatic increases.

2.2.2 Nitroaromatic Compounds Results

Analytical results for nitroaromatic compounds are presented in Tables 2-6 and 2-7. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the third quarter 1991. The distribution and magnitude of nitroaromatic contamination near the quarry remains unchanged.

2.2.3 Inorganic Anions Results

Two inorganic anions--nitrate and sulfate--were measured in quarry wells. Tables 2-4 and 2-5 display the analytical results for the fourth bimonthly sampling event and the third quarter of 1991, which are consistent with data reported in the previous environmental monitoring reports. The WSQ groundwater samples continue to indicate no significant groundwater contamination by nitrate. The groundwater samples continue to indicate background concentrations of sulfate in wells south of the Femme Osage Slough.

2.2.4 Metals Results

A selected group of quarry wells located south of the Femme Osage Slough were sampled for arsenic and barium. Analytical results for these metals are presented in Tables 2-8 and 2-9. Results from the fourth bimonthly and third quarter analyses of arsenic and barium continue to indicate elevated concentrations in selected wells. The highest levels reported are 146 µg/l for arsenic in MW-1022 and 5,380 µg/l for barium detected in RMW-3.

3 SURFACE WATER MONITORING

Routine samples were collected during the third quarter of 1991 from both on-site and off-site surface water and spring locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1991 Annual Site Environmental Report (ASER).

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the third quarter, surface water samples were collected from the 13 surface water sampling locations shown in Figure 3-1 and analyzed for uranium. The results, presented in Table 3-1, indicate that conditions remain similar to values measured historically.

3.2 Weldon Spring Quarry

Surface water samples were collected from the 10 locations shown in Figure 3-2 and three locations in Figure 3-3. Samples were analyzed for uranium, and the results are presented in Table 3-2. The results of all samples indicate no apparent changes in environmental conditions. The highest measured level was 667 pCi/l detected at sampling location SW-1008, the quarry sump.

The third quarter uranium values measured in the Missouri River that are available are nearly the same as were detected during the previous quarter. Historically, the levels of uranium at these locations have fluctuated (due to either natural fluctuations or analytical variability) such that uranium concentrations have been higher at upstream locations than downstream, and vice versa. The U.S. Department of Energy (DOE) has increased monitoring of the Missouri River prior to the operation of the Weldon Spring Site Remedial Action Project (WSSRAP) quarry water treatment plant to ascertain the preoperational (background) levels in the river. In addition, the National Pollution Discharge Elimination System (NPDES) permit for the quarry water treatment plant requires additional monitoring of the river. This monitoring increases the DOEs capability to ensure the safety of the public and the environment.

NA - Not Available

The analytical results for the six nitroaromatic compounds within the quarry sump were not available at the time of this report. The ponded water is to be treated for nitroaromatic compounds and other organics upon completion of the quarry water treatment plant.

3.3 Springs

Eleven springs around the Weldon Spring site (WSS) are sampled quarterly (see Figure 3-4 for spring locations). Previous spring monitoring indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs include SP-6301, SP-6302, SP-6306, and SP-5301 through SP-5304. All spring samples are analyzed for uranium with a select few analyzed for nitroaromatics, inorganics and metals. Available analytical results for these parameters are listed in Tables 3-3 and 3-4. Values for these parameters remain consistent with their historical values.

3.4 National Pollutant Discharge Elimination System Data Review

Surface water and effluent samples were collected and analyzed in compliance with the Weldon Spring site NPDES permits. Permit No. MO-0107701 was issued on October 1, 1990, and currently addresses the five storm water and two wastewater discharges shown in Figure 3-5. Outfalls NP-0001 through NP-0005 represent storm water discharges; Outfall NP–0006 represents the treated effluent discharge associated with the administration building sanitary wastewater treatment plant, and Outfall NP-0007 represents the contaminated site water treatment plant which is under contract but not yet constructed. Outfalls NP-0006 and NP-0007 have effluent limitations. The five storm water outfalls have monitoring requirements only. Third quarter 1991 analytical data for each outfall is presented in Table 3-5. Permit No. MO-0108987 was issued on May 5, 1989, for Outfall NP-1001 of the Weldon Spring Quarry contaminated water treatment plant. The plant is not completely constructed and no discharge took place during the third quarter of 1991.

3.4.1 Radiological Analysis

Gross alpha and total uranium analyses corresponded reasonably well with past data. The highest uranium levels were present in surface flow from Outfalls NP-0001, NP-0003, and NP-0005. The peaks for these points were 198, 253.6, and 282.7 pCi/l, respectively.

Other outfalls exhibited the following peaks of uranium concentrations. Outfall NP-0002 had a peak of 96.3 pCi/l and Outfall NP-0004 had a peak of 4.5 pCi/l. Although not required by the NPDES permit, the outfall from the administration building sanitary wastewater treatment plant (Outfall NP-0006) was also monitored for total uranium. No uranium was detected at this outfall.

3.4.2 Other Analysis

Other analyses for NP-0001 through NP-0005 included physical analysis (settleable solids and total suspended solids) and chemical analysis (nitrate, pH, and lithium). Third quarter 1991 values generally correspond to past values for the majority of parameters. Two exceptions were high total suspended solids (TSS) values for Outfalls NP-0005 and NP-0001. The TSS was higher than usual due to off-site construction activity and a 2.24 in. rainfall that ended two hours before sample collection. Settleable solids were not analyzed for Outfall NP-0004 since the sample was collected from a pooled area that was algae laden and the algae would have prevented proper settling.

The discharge from the administration building treatment plant, Outfall No. NP-0006, has effluent limitations and a requirement to monitor once per quarter. Flow must be measured once a month. The subcontractor monitors the effluent once a month to assess plant performance, thus generating two additional sample analyses a quarter. The NPDES permit specifies effluent limitations for biochemical oxygen demand (BOD), TSS, pH, and fecal coliform at this outfall. The limits for BOD are 10 mg/l monthly average and 15 mg/l weekly average; for TSS, 15 mg/l monthly average and 20 mg/l weekly average; for fecal coliform, 200 colonies per 100 ml monthly average and 1,000 colonies per 100 ml daily maximum. The pH is limited to the range of 6.0 to 9.0. NPDES permit limits were not exceeded in the third quarter of 1991 at this outfall.

A characterization sample was collected from Outfall NP-0006 on August 27. The sample was analyzed for the following parameters and the results are shown in parentheses: lithium (ND), nitrate (15.7 mg/l), uranium-natural (ND), TSS (7.0 mg/l), gross alpha (ND).

4 AIR MONITORING

4.1 Radon Gas

The radon gas monitoring program utilizes a pair of radon detectors at each of 22 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, six locations at the Weldon Spring Quarry, four locations at the Weldon Spring raffinate pits, and six off-site locations. Radon monitoring locations are shown in Figures 4-1, 4-2, and 4-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, and RD-4006 were used to monitor background levels near the site.

Table 4-1 summarizes the third quarter 1991 radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in Table 4-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (110 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the four background locations. This data yielded an average ambient background radon concentration of 0.6 pCi/l for the third quarter of 1991. This concentration was then subtracted from the concentration for each monitoring station, and compared to the DOE guideline of 3 pCi/l above background.

Radon concentrations at the site and quarry perimeters and at off-site locations for the third quarter of 1991 were within the typical range expected during periods of below normal precipitation as was the condition for this period. The quarterly radon concentrations (background included) ranged from 0.5 pCi/l at RD-4001 to 2.0 pCi/l at monitoring location RD-1001 and RD-1002.

Radon concentrations found in the quarry are higher than concentrations measured at other locations because the radium concentrations in quarry wastes are typically much higher than other areas, and because the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high. In conjunction with stable meteorological conditions,

(a) Results include natural background.
(b) Percent of guideline calculated by taking the quarterly average minus the average of the background stations divided by the DOE concentration guideline for RN-222 which is 3 pCi/l (100 Bq/m^3)(Annual average above background) for uncontrolled areas.
* Denotes Background Station

this configuration tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

4.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, spherical environmental thermoluminescent dosimeters (TLDs) were deployed at 22 locations. The gamma monitoring station locations are the same as the ambient radon monitoring locations (see Section 4.1).

Table 4-2 summarizes the first, second, and third quarter results of total gamma radiation monitoring at the 16 Weldon Spring site (WSS) perimeter monitoring stations, the Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the four background monitoring stations.

The annual average background gamma exposures measured with TLDs in 1989 and 1990 were 68 mR/year and 62 mR/year, respectively. The gamma exposures measured with TLDs in the first, second, and third quarter of 1991 were consistent with 1989 and 1990 data. This was expected because no significant changes in the configuration or location of the wastes have occurred.

4.3 Radioactive Air Particulates

Eleven low volume air particulate samplers monitor the Weldon Spring site continuously. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter as shown in Figure 4-3. Three monitoring stations (AP-4006, AP-4008, and AP-4011) are located off site at sensitive receptor locations; including Francis Howell High School, the Army Reserve property, and near a residential site west of the quarry. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown in Figure 4-2.

(a) Results include natural background.
\- Denotes loss of TLD.
* Denotes background station.

The sampling station near the August A. Busch Wildlife Area (ABWA) headquarters is used as a background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/Weldon Spring raffinate pits (WSRP).

Table 4-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging either the weekly air particulate analysis results or the counting instrument's lower limit of detection (LLD), whichever was greater. The "<" sign in Table 4-3 appears when the actual average is less than the calculated average due to the use of LLD values in the calculation. The standard deviation for each of the monitoring locations was calculated using only results that were above the LLD. Due to maintenance, all monitors were not operating the entire 13 weeks as indicated in Table 4-3. However, the sensitive receptor monitoring stations (AP-4006, AP-4008, and AP-4011) were in operation the majority of the time and these stations are also equipped with high volume air monitoring. The high volume air monitors are part of the WSS radionuclide National Emissions Standards for Hazardous Air Pollutants (NESHAPs) requirements and were in operation the third quarter. The high volume monitoring results will be presented in the *Annual Site Environmental Report.*

The third quarter net alpha concentrations ranged from $<1.20 \times 10^{-15}$ µCi/ml to $<1.60 \times 10^{-15}$ µCi/ml with 1.22×10^{-15} µCi/ml detected at the background station.

4.4 Asbestos

No environmental asbestos monitoring was performed in the third quarter of 1991.

CHEMICAL PLANT SITE REMEDIAL INVESTIGATION/FEASIBILITY STUDY DATA VALIDATION REPORT, FEBRUARY 1992

Enclosed is a copy of the Chemical Plant Site Remedial Investigation/Feasibility Study Data Validation Report. This report culminates approximately two years of intense activity by DOE to assess the validity and useability of the data in the Weldon Spring Site Remedial Action Project (WSSRAP) Remedial Investigation database.

The work associated with this effort began in December 1989 and required laboratory documentation to verify the database for transcription errors and to validate the database for useability.

The appendices associated with this document are not included due to their volume (2,296 pages). A copy of the document, including appendices, will be available in the WSSRAP public reading room.

Sincerely,

Stephen H. McCracken
Project Manager

1 INTRODUCTION

1.1 Purpose

The purpose of this report is to define the quality of the data which were used as the basis of the remedial investigation, risk assessment and feasibility study for the site operable unit at the Weldon Spring Site Remedial Action Project (WSSRAP).

1.2 Scope

This report addresses the results of the data validation program established to validate the characterization and environmental monitoring data and supporting check sample data collected by the Project Management Contractor (PMC) and analyzed by the PMC's primary subcontract laboratories, metaTRACE, Inc., and IT Analytical Services (ITAS); and the secondary subcontract laboratories, JTC Environmental Consultants, Inc. (JTC) and Accu-Labs Research, Inc. (Accu-Labs).

This report addresses the data used as the basis for the site remedial investigation and feasibility study from samples that were collected and analyzed prior to March 31, 1990, and from supporting check samples collected between July 1990 and September 1990.

1.3 Background

1.3.1 Data Quality Requirements

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) requires that remedial action decisions be based on data of known quality so that decision makers can make informed decisions and so additional data needs can be identified.

Procedures for validating data vary considerably nationwide. At WSSRAP, the process of evaluating data quality involves establishing data quality requirements (DQRs) and verifying and validating the analytical results received from subcontract laboratories.

DQRs are quantitative statements of accuracy and precision that specify the quality of the data needed to support specified data uses. The WSSRAP DQRs used in the CERCLA decision making process and for routine environmental monitoring are shown in Attachment A.

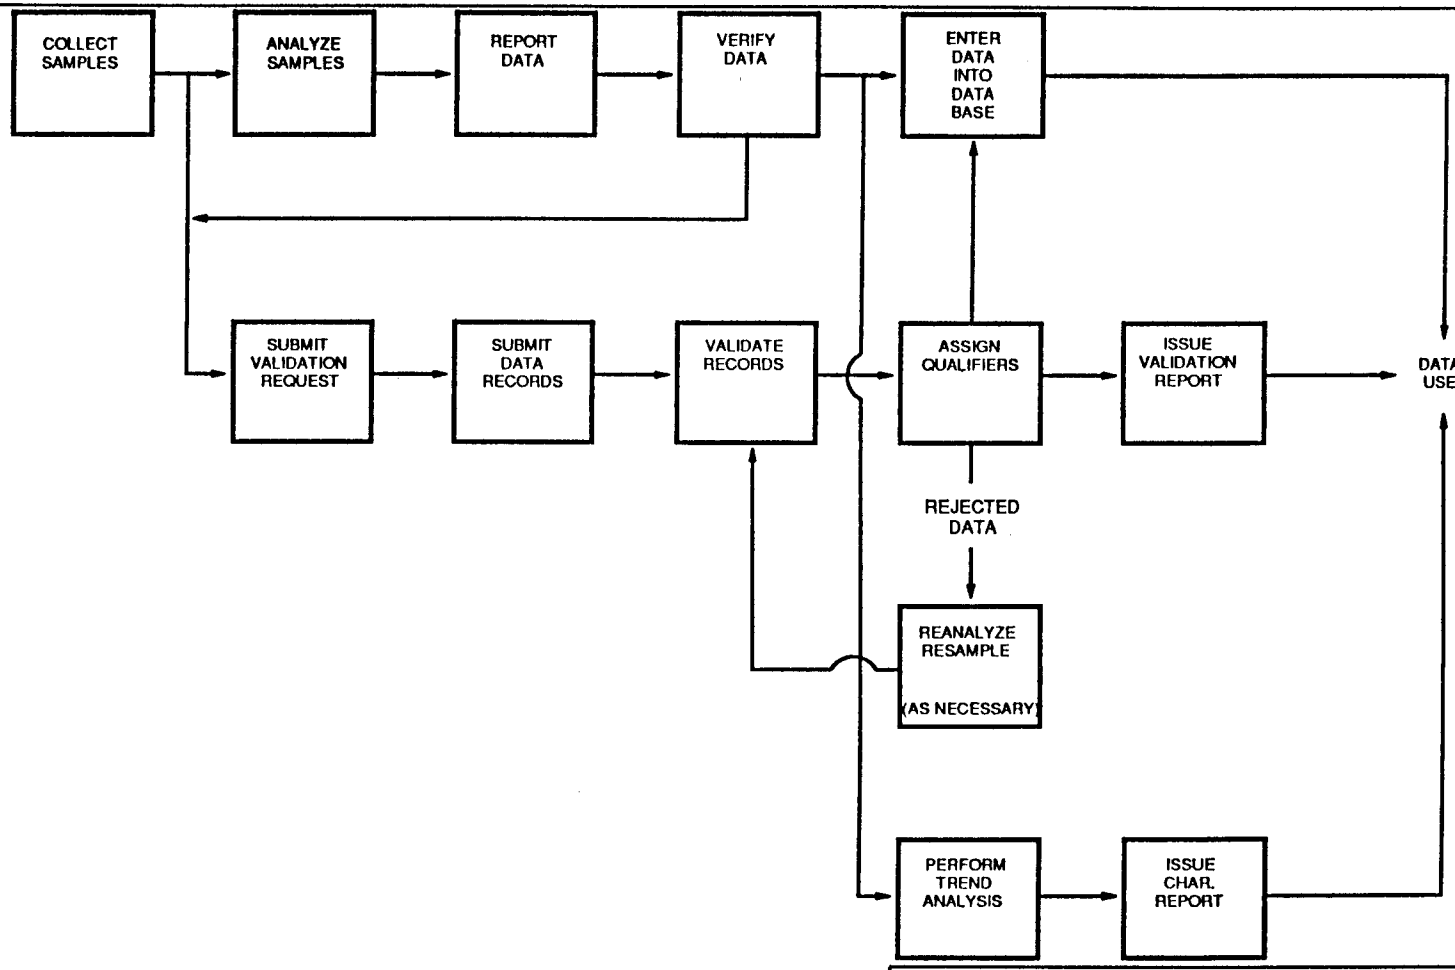
Data verification is a nonanalytical preliminary review of laboratory data and associated documentation to ensure that the samples were collected, preserved, shipped, maintained, analyzed, and reported in accordance with specified procedures. The WSSRAP data verification procedure is included in Attachment B.

Data validation involves a thorough analytical review of the data using laboratory records to assess laboratory performance relative to quality control criteria, DQRs, and other procedural and contractual requirements. Laboratories are also audited while they are analyzing the WSSRAP samples. If data quality problems or questions arise during the validation process, the PMC may require reanalysis of certain samples or may collect check samples to further define data quality. The WSSRAP procedure for the analytical review of laboratory data is shown in Attachment C.

The data verification and validation program is shown in Figure 1-1. These procedures are in-place and are routinely performed for newly acquired data, but a comprehensive and routine validation program was not performed on the data obtained prior to March 31, 1990. This report presents the results of the validation program for this previously collected data.

1.3.2 Validation Activities

In March 1989, the PMC began a formal data validation program by issuing a data validation work plan that described how the WSSRAP data would be validated. A key component of that work plan was the analytical review of approximately 4000 data points. This review included a review of the custody transfer records, a review of the laboratory's transcription of records that were merged into the WSSRAP electronic database, and of the laboratory and field quality control data. In February 1990, the final report addressing this review was submitted. The report indicated that a substantial number of data entry errors had occurred during the transcription of the data from the laboratory records into the electronic database by the subcontract laboratory. The report also indicated that a more thorough assessment of the database was necessary.



DATA VERIFICATION AND VALIDATION PROGRAM

FIGURE 1-1

REPORT NO.:	DOE/OR/21548-256	EXHIBIT NO.:	A/PI/008/0192		
ORIGINATOR:	JJC	DRAWN BY:	GLN	DATE:	1/92

In response to this report the PMC implemented an expanded data validation program for the data collected prior to March 31, 1990. This program included:

- Establishing procedures for the verification and validation of WSSRAP data.
- Obtaining all available laboratory analytical records.
- Correcting the transcription of the data from the laboratory records into the electronic database.
- Performing a thorough analytical review of approximately 5,500 key data points from metaTRACE, JTC, and Accu-Labs.
- Performing a thorough analytical review of an additional 2,500 data points from metaTRACE to provide a more even distribution of sample matrix types included in the data population.
- Comparing the results of duplicate and split samples.
- Collecting check samples to resolve data quality questions.
- Performing a thorough analytical review of the approximate 4,000 check sample data points.
- Preparing an Environmental Data Administration Plan (EDAP).

The key data points were selected by technical specialists who prepared the site characterization reports. The initial 5,500 points are those values that were key data to the interpretation of the extent and distribution of the contaminants found at the site and were selected for all environmental media, all parameters analyzed, and the full range of contamination. Therefore the 5,500 points represent the data that are key data to preparation of the site remedial investigation and feasibility study. The initial 5,500 key data points, along with the additional 2,500 metaTRACE datapoints to even out the matrix distribution and the 4,000 check sample data points make up the 12,000 (or 12K) data points referenced in this report.

Other data validation efforts included performing trend analysis for the data from the routine water monitoring program, and validating data points specifically identified by data users. Table 1-1 shows the approximate number of data points that have been validated. As shown, WSSRAP did not validate 100% of the data points but rather validated a significant percentage of the data. This was then used to define the quality of the entire data base. This process is consistent with U.S. Environmental Protection Agency (EPA) CERCLA guidance on data validation procedures. WSSRAP had previously proposed to validate an additional 7000 data points, but based on the review of the results of the validation work on the 12K points and the recommendation of the EPA, the validation of the 7000 points was determined to be unnecessary. The results of the program are described in the following sections of this report. This data validation program was reviewed and approved in an August 16, 1990, memorandum from EPA, Region VII.

Table 1–1 Data Validation Data Point Summary

VALIDATION ACTIVITY	TYPE OF VALIDATION	APPROXIMATE NO. OF DATA POINTS	STATUS
Duplicate Samples	Sample Duplication	20,000	Complete
Initial Validation (March 1990)	Analytical Review	4,000	Complete
Key Data Points[1]	Analytical Review	5,500	Complete
Add'l metaTRACE Data Points	Analytical Review	2,500	Complete
Check Sample Data Points[2] (direct)	Analytical Review	4,000	Complete
Check Sample Data Points (reference)	Reference	4,000	Complete
Routine Water Monitoring Trend Analyses	Reference/Trend Analysis	45,000	Complete
Special Validation Requests	Analytical Review	1,000	Complete

[1] Consists of data generated from metaTRACE, JTC, and Accu–Labs.

[2] Consists of data generated from ITAS.

2 DATA VERIFICATION REVIEW

2.1 Introduction

In 1987, the effort to computerize analytical data from characterization and routine monitoring activities was initiated. Analytical data were received from metaTRACE, Inc. in hard copy and in electronic copy format. As sampling activities continued and analytical results were received, a computerized database was developed from the electronic records received from metaTRACE. The data were separated into files by sample matrix and programmatic scope such as groundwater and Phase 2 soils. The computerized Weldon Spring Site Remedial Action Project (WSSRAP) database was developed to provide an organized, retrievable format with which project personnel could utilize data for various reports and documents.

As a result of the initial inquiry into the validity of data analyzed by metaTRACE, it was determined that the electronic data records contained errors. The electronic records created by metaTRACE were not adequately verified or reviewed prior to shipment to WSSRAP and a lack of consistency in the reporting methods was noted. As a result, the review of the database records by the PMC was determined to be a requirement in the validation of data for use at WSSRAP.

2.2 Verification Procedures

The verification of records in the WSSRAP databases had two aspects. The verification review included a standardization of all data in the database sampled prior to March 31, 1990, and secondly, a transcription review of all metaTRACE data with detectable concentrations was performed. All data received for samples collected after March 31, 1990, were standardized and verified, as described in Section 2.2.1.

2.2.1 Data Standardization

The standardization of the databases included review of chemical categories, chemical parameters, units of measure, sample identification assignment, laboratory identification assignment, and format of non-detect values. Each data record was reviewed to determine if it met the standardization requirements.

These standardization requirements include a list of chemical categories, parameters and units of measure, matrix types, analytical methods and a format for the concentration value and was applied to all data (Attachment D). Unique listings of the sample identification numbers were created from the database records and reviewed by two WSSRAP personnel for accuracy according to ES&H 4.1.1, *Environmental Numbering System Procedure*. Corrections made to sample identification numbers were then checked by comparing the sample ID to the sample chain-of-custody (COC) form.

Unique laboratory identification numbers are assigned to the sample by the subcontractor laboratory when it arrives at the laboratory. This unique laboratory ID number was used throughout the course of sample analysis to identify and report sample results. A review of the accuracy of the laboratory identification number was also conducted. A unique listing of the sample identification number and laboratory identification number was produced and reviewed by two WSSRAP personnel. Corrections made to the database records based on the laboratory identification review were made by comparing database records to the laboratory's sample COC form.

The values held in the concentration field for each record were also reviewed for variation of non-detect codes. The databases contained such characters as "ND", "NA", "BQL", "----"," < DL" and blank fields to represent non-detectable concentrations. The standard "ND" code was used to replace other codes.

2.2.2 Transcription Review

The transcription review was directed at verifying all detect values reported by metaTRACE and comparing the values to the records held in the database files. Copies of the original data summary sheets or raw bench sheets were recovered from metaTRACE laboratories. The sheets were reviewed for positive or detect results of the analytical test. All detectable data results were then entered into two separate databases termed DATA1 and DATA2, thus providing double-key entry of data.

After all data were entered, the two "rekeyed" databases were compared to determine the accuracy of the double-key entry effort. A compiled dBASEIII+ software program called M-COMP was used to test the exactness of the two databases. Individual records from each database were written to secondary database files based upon the results of the test. Errors in

the double-key entry databases were manually reviewed and compared to the original data summary sheets. Corrections were made to the appropriate records in the associated data file and the M_COMP program was rerun. The comparison program and data review was repeated until all records matched and a single rekeyed database was created.

The double-key entry rekeyed database was used to verify the values held in the WSSRAP database files. As each record was compared, a change indicator was used to flag the differences between data records. The records held in the WSSRAP data files were modified (if needed) to reflect the rekeyed values found in the double-key entry database. Change indicators were copied into the COMMENTS field of each modified database record to document the modification. A listing of the change indicators and their interpretation is contained in Attachment E.

The WSSRAP database was also reviewed for duplications of records as a result of data records reported by metaTRACE. A compiled dBASEIII+ program called TRUDUPS was used to identify and segregate exact duplicates from the databases. In addition, a second program (DUPS) was used to identify duplicate records based on sample ID and parameter. The DUPS program created a new file that contained any duplicated records. These records were manually reviewed and compared to the hard copy records. The records that were determined to be correct were maintained in the database files, while duplicate incorrect records were deleted. The DUPS program was rerun until all duplicate records were eliminated or corrected.

2.3 Verification Results

Prior to first quarter 1991, the WSSRAP data bases contained approximately 140,000 data records of which approximately 136,000, or 97%, are data sampled prior to March 31, 1990. Of those records, approximately 131,000, or 96%, are data analyzed by metaTRACE during the 1987 to 1989 sampling years. The majority of the records (55%) are soil samples collected during the site characterization effort in 1988. The groundwater and sludge database comprise 31% of the data; the remaining records are held in various smaller databases and include spring, lake sediment, National Pollutant Discharge Elimination System (NPDES), industrial hygiene, radiation protection and air particulate data. Table 2-1 shows the distribution of data records in the various WSSRAP databases.

[1] as of 12/12/90

[2] all records sampled prior to 03/31/90

[3] all radiological QA samples were analyzed by another lab besides metaTRACE. Therefore, there were no radiological QA data obtained from metatTRACE for verification review.

Concentration values were used to classify data into detectable and non-detect populations. Sixty-nine percent of the pre-March 31, 1990, records (or reviewed records) were found to be non-detect concentrations and 31% were detectable values. The majority of detects reported were metals and anions while nitroaromatics, semi-volatiles, volatiles and pesticides/PCBs contained the majority of the non-detect values. The distribution of detects and non-detect populations compared to chemical categories is shown in Table 2-2.

Change indicators, as discussed in Section 2.2, were assigned to modified data records to document the type of modifications made. The indicators were tallied by database, concentration type and chemical category to determine trends found in the verification review process. Table 2-3 summarizes the modifications made based on detect and non-detect populations.

Overall, the results of the verification review indicate that modifications to the database were due primarily to standardization of field information. Information gathered during the review process also showed that specific types of typographical errors were made in the data entry process by metaTRACE. Other modifications were attributed to the U.S. Environmental Protection Agency (EPA) Contract Laboratory Program (CLP) requirements for adjusting the concentration values of soil data for percent moisture. Percent moisture adjustments were not consistently calculated on the metaTRACE laboratory bench sheets. Percent moisture adjustments typically increased concentration values by 10% to 15% for soils.

2.3.1 Standardization of Data

The verification review showed that many modifications were attributed to the standardization test conducted. Use of computerized data requires the standardization of field information in order to consistently retrieve and present data for use at the WSSRAP. Of the total number of modifications made, the category and parameter checks resulted in a large percentage (23%) of modifications overall and they occurred in each of the databases. Differences in the use of units of measure also were noted (3%).

The use of the category "Metals" versus "EP Tox Metals" attributed to the many of the category modifications. Data records were erroneously classified into the EP Tox Metals category. Data analyzed under routine EPA CLP methods should be classified to the METALS

category. EP Toxicity is an extraction procedure and is documented in the database in the Method field as 3010/6010 and is given the category assignment of "EP Tox Metals. Records with the EP Toxicity designation were reviewed with chain-of-custody records to confirm extraction methods requested. As a result of the review, only the industrial hygiene database contains samples extracted by the EP Tox method.

The category "Miscellaneous" is used for classification of analytical measurements such as total organic carbon, flashpoint and percent moisture. Prior to this review, each of these miscellaneous parameters carried its own category name. The grouping of these parameters into the miscellaneous category assists users in accessing data.

Modifications were also made to records for parameter or analyze misspellings. Radiological data were classified in various manners. For example, total uranium was shown as "Total Uranium," "Natural Uranium" and other variations. Again, the computerized data resulted in some difficulty in the use of data based upon misspellings and classification errors. All records were modified to the parameter standards as listed in Attachment D.

The addition of other subcontract laboratories in October of 1989 also contributed to standardization errors. Units of measure were reported differently between laboratories and accounted for 3% of the changes. MetaTRACE reported Fluoride as mg/l while other laboratories reported fluoride in μg/l. Radiological data were reported as pCi/l and mg/l. Units were standardized according to data quality requirements (DQRs) during the verification review.

2.3.2 Transcription Review

The second review of database records assessed the types of transcriptional errors made by metaTRACE during the data entry process. This review effort was directed at determining the accuracy of transcribing data results of detectable concentrations. Values for concentration, detection limits, units and radiological errors were reviewed under the transcription process.

A change indicator of "V" was used to mark database records based on changes in concentration values. Eight percent of the total modifications made (or 8% of the records held in all databases) were modified for concentration values. While the modification of concentration field was noted during the review process, the degree of change of the concentration values was not. A separate analysis was done to determine the magnitude of the

differences between values previously held in the database and those held after transcription review. The detection limit and radiological error fields were also analyzed for percent change under the screening levels. The general finding was that relatively few values were statistically significant in concentration between the re-keyed data and records held in the database.

Most of the changes made to the concentration field were attributed to extraneous characters, such as quotes, CLP qualifiers, etc. However, most numerical changes made to the concentration values were attributed to rounding and significant figures. EPA CLP protocol indicates that three significant figures should be used in reporting concentrations. MetaTRACE did not consistently report to three significant figures and/or did not round to the closest integer. Most of these changes resulted in concentration value differences of $<0.5\%$.

Data quality requirements set for the WSSRAP designate specific reporting requirements for units of measure for each analyte. In the review of reporting units held in the databases, it was found that errors in unit conversion and appropriate sample matrix units were made. During the re-key effort, the review of laboratory bench sheets showed analytical results reported in various units for certain analytes. This was particularly true for metals analysis where data were analyzed in mg/l but reported in μg/l. For approximately 1% of all data records, the conversions of concentrations for units were either not made or were calculated erroneously by metaTRACE during the data entry process. More typical was the misuse of the proper units in the reporting of data. Most of the records with incorrect units were the site-designated quality control samples. The field and equipment water blanks were shipped to metaTRACE with soil samples for analysis. The bench sheets reflected the proper units of measure for each matrix but during the reporting phase, errors were made in reporting water blanks in weight-to-weight measurements (i.e., μg/g) instead of weight-to-volume measurements (i.e., mg/l).

Other types of transcription errors noted were caused by inappropriate data entry procedures used by metaTRACE. MetaTRACE consistently reported radiological error values as a value of 10% of the concentration instead of the calculated radiological error. During the re-key process, the calculated error values reported on the laboratory bench sheet were used to update the WSSRAP database records. Some other analytical categories show a high percentage of modifications in the error field. These changes are due to metaTRACE entering CLP qualifier values in the error field where no value was needed or expected. CLP qualifiers are

not held in the WSSRAP database and only radiological error values are held in the error field. All non-radiological records were standardized to blanks in the error field.

Detection limits were reported by metaTRACE using the standard EPA CLP CRDL values in some cases, and not provided at all in others. According to CLP protocol, detection limits should be corrected to account for dilutions and percent moisture adjustment made during the analytical testing. During manual review of the data records, some concentration values required correction to reflect dilutions and percent moisture adjustments. Adjustments to detection limits for percent moisture and dilution were only made when the WSSRAP data validation group requested changes be made based on their technical reviews.

All of the corrections described on the preceding pages were made to the database prior to use as the basis for the chemical plant remedial investigation, risk assessment, and feasibility study.

3 DATA VALIDATION

The major objectives of the data validation program are:

- To assess laboratory performance and data to quality control criteria, data quality objectives, and procedural requirements.
- To assess analytical data and qualify data for useability.
- To report data validation findings to the data users.

In support of the Weldon Spring Site Remedial Action Project (WSSRAP) remedial investigation, approximately 12,000 data points (12K data) were selected for a detailed data validation review. The samples and analyses associated with this validation effort are listed in Attachment F. Seven thousand two hundred ninety-nine data points (or 61.6%) were from analyses performed by metaTRACE, Inc.; 570 data points (4.8%) were from JTC; 101 data points (0.9%) were from Accu-Labs; and 3,878 data points (32.7%) were from ITAS. Table 3-1 provides a data point distribution of the 12K data by sample matrix and by laboratory.

3.1 Validation Procedures

The data validation process involved retracing the laboratory analyses from beginning to end and comparing the results of that validation "retracing" with those that were reported by the laboratories. In addition, sample custody transfer records and analytical holding times were reviewed to assess sample integrity. Any deviations from protocol, quality control deficiencies, compromises to sample integrity, or mathematical/transcription errors were noted and used to qualify or reject the data.

In order to accomplish the validation "retrace", the analytical documentation that pertained to the analysis (such as instrument printouts, standard preparation logs, sample preparation logs, sample data summary/calculation sheets, quality control (QC) control charts, chain-of-custody records) were reviewed for the samples of interest, instrument calibrations and tunes, and for the associated quality control samples and standards.

Table 3–1 Data Point Distribution for 12K Data

DISTRIBUTION BY SAMPLE MATRIX

MATRIX	ANIONS	METALS	MISC	NITROS	PEST/ PCBs	RAD	SEMI– VOA	VOA	TOTALS	%

Totals	254	1,472	42	654	919	317	5,265	2,924	11,847	100.0%

[1] With the exception of a few samples analyzed for lead, all air particulate analyses were limited to radiochemical parameters.

[2] metaTRACE = metaTRACE, Inc. JTC = JTC Environmental Consultants, Inc. Accu–Lab = Accu–Labs Research, Inc. ITAS = IT Analytical Services, Inc.

[3] Accu–Labs provided only radiochemical services to WSSRAP.

Calculations were repeated; accuracy and precision were measured; and the analytical process (preparatory and instrumental) was reviewed.

The analytical documentation was grouped and cataloged into data sets synonymous to the laboratory analytical lot and assigned a unique data set number. Within each data set, all analyses or injections were further cataloged chronologically and assigned a sequence number. Using this approach, each analysis or injection could be referenced by the combined data set and sequence numbers. No two analyses or injections would have the same combined numbers. An analysis-specific worksheet was maintained with each data set and was used for maintaining validation notes and comments, and as a checklist to ensure critical items for each analysis were reviewed. Calculation checks for each data set were performed and documented by computerized spreadsheet and were maintained with each data set.

The results from each validation review were compared with those that have been reported by the laboratories and/or were maintained in the WSSRAP database. This comparison included not only the reported parameter concentration values, but also the reported error values (for radiochemical analyses only), the units, and the detection limits. Discrepancies associated with these comparisons were noted.

The analyses were evaluated for useability based on the requirements established for the analytical protocol or method (i.e., U.S. Environmental Protection Agency (EPA), Contract Laboratory Program (CLP), U.S. Army Toxic and Hazardous Materials Agency (USATHAMA)) used to obtain the resulting data. However, there are numerous accepted protocols available for a given parameter, and a simple deviation from the intended protocol would not necessarily lessen the degree of confidence to a level where the data would not be usable. As such, if a sufficient amount of quality control and analytical checks were performed during an analysis (which is standard analytical practice), then the accuracy and precision for the analysis could be measured, the degree of confidence assessed, and an informed decision about the analysis and its data could be made. Such data would not be automatically rejected as unusable, but would be flagged as data from an analysis not following the intended protocol.

The results from the data validation review were summarized in the form of validation qualifiers. The use of qualifiers is similar to the technique used by the EPA with its CLP program, and provide a means for incorporating validation results into the WSSRAP database. The list of qualifiers adopted for WSSRAP and their meaning is provided in Table 3-2.

For each parameter in a given data set, the analytical accuracy and precision was calculated. In general, accuracy was calculated from the recovery of the parameter of interest in the laboratory control spike sample (or blank spike) or from the matrix spike sample. In cases were several control samples were available per data set, the recoveries were averaged. For volatiles, semi-volatiles, and pesticide/PCBs, accuracy was measured from the recovery of the analytical surrogate compounds included in each sample for analysis. Precision was measured as the relative percent difference between duplicate analyses of the same sample for the same parameters. Such precision measurements were made from laboratory duplicates, field duplicates, or matrix spike duplicates. In cases where duplicates or control samples were not available, no accuracy and/or precision determinations could be made and the resulting data were qualified accordingly. In as much as duplicate data are often matrix specific and such precision measurements are not used as a rejection criteria in the EPA CLP program, poor or missing precision measurements were not automatically taken as cause for rejection of the WSSRAP data.

3.2 Validation Criteria

Listed below are the evaluation criteria that were used during data validation. Several evaluation criteria were general and were applied to all analyses. These general criteria were:

- Reject data if the analyte of interest was present in the associated analytical blank at a level that was within 10 times the level of that analyte present in the sample (per CLP).

- Accept but flag data if the analyte of interest was present in the associated analytical blank and the level in the sample of interest exceeded the level present in the blank by a factor of ten or more (per CLP).

- Accept data if the analyte of interest was present in the associated blank but was not detected in the sample of interest.

Table 3–2 WSSRAP Data Validation Qualifier List

QUALIFIER

4 (or A+)	Data meeting all QA/QC requirements.
3	Good quantitative data not meeting all objective QA/QC requirements, but are generally valid.
2	Data that are adequate for semi–quantitative comparisons (i.e. the order of magnitude of the reported value is credible, but the exactness of the value is questionable).
1	Data that are adequate for a qualitative assessment (ie. the target analyte is a real artifact, not contamination), but have no quantitative validity.
A	Acceptable, but has restrictions (has attached flags).
V	Data that appear to be valid based on good comparison to data from identical sampling locations or to data from historical records.
R	Data that are not valid.
N	Data not petitioned for validation; or validation documentation not yet received from the laboratory.
O	Validation Technical Review ON–HOLD.
P	Validation Technical Review IN–PROGRESS or PENDING.
X	Data Not Validatable.

FLAGS[1]

>	High Bias (i.e. accuracy > DQR limit)
<	Low Bias (i.e. accuracy < DQR limit)
C	Calibration/Quantitation Deficiencies
Q	Quality Control Deficiencies
I	Qualitative Deficiencies or Instrument Interferences Present
B	Contamination or High Background Present
H(#/#)	Holding Time(s) Exceeded (# days exceeded for prep/analysis)
F	Matrix–Related Interferences Present
J	Estimated Value (may be linked with other flags)
Y	Custody Deficiencies
T	Typographical or Mathematical Error Present
M	Poor Matrix Spike Recoveries (matrix accuracy)
D	Poor Duplicate RPD (precision)
?	Other (see applicable validation report)

[1] To be used in conjunction with any of the above qualifiers, except for qualifier 4 or A+, which by definition shall stand alone.

- Reject data if any analytical condition or circumstance suggested low analytical confidence (i.e. spectral interferences, poor spectral match, faulty calibrations etc.).

- Accept but flag data if any associated precision measurement exceeded the CLP 20% criteria (no flag is necessary where the analyte concentration is less than or equal to five times the applicable detection limit).

- Accept but flag any data associated with a matrix spike or matrix spike duplicate where the CLP criteria were not met ($\pm$25% recovery was used for non-CLP parameters).

- Accept but flag data if expected quality control samples (which are protocol requirements) were missing from the analytical run; reject data if the missing quality control requirements could be interpreted as standard analytical practice (i.e. control spikes, analytical blanks).

- Place on-hold any data value mismatches or omissions in the WSSRAP database that were due to transcription errors[1]. The on-hold status would be changed when the transcription error was corrected.

- Declare any data non-validatable if documentation critical to supporting the data and the analysis (i.e. instrument print-outs) were not available.

The additional analysis-specific evaluation criteria are as described in the following sections.

Anions

There were 74 samples or 254 data points involved in this validation effort for anions. These data were grouped into 66 data sets for validation purposes.

[1] If another situation existed that would reject the data or make the data non-validatable even after the transcription error or omission was corrected, the data would be rejected or declared non-validatable.

The analytical method employed by metaTRACE, Inc. was EPA 300.0, Ion Chromatography. The analytical methods employed by JTC were the EPA 300 series wet chemistry methods for the individual anions.

An analytical value for anions was accepted or rejected by data validation based on the following criteria:

- Reject data if the associated initial calibration curve was non-linear (as determined by a correlation coefficient of < 0.995).

- Reject data if the percent recovery of the daily calibration verification checks that bracket the sample of interest were $<85\%$ and the sample was non-detect (or within 10 X DL), otherwise flag. Flag if the calibration check exceeds 115%.

- Reject data if the associated analytical accuracy exceeded the WSSRAP data quality requirement (DQR) limits.

- Accept but flag data if the accuracy exceeded the laboratory control limits, as determined by QC control charts provided. If control charts are not available, use control limits of $\pm 20\%$.

- Accept but flag data if the holding time was exceeded and the sample was positive for the analyte of interest.

- Reject data if the holding time was exceeded by seven days and the sample was negative.

Metals

There were 85 samples or 1472 data points involved in this validation effort for metals. These data were grouped into 148 data sets for validation purposes.

The analytical methods employed by the laboratories were the EPA CLP inductively coupled plasma (ICAP), graphite furnace (GFAA), and cold vapor (CV) methods. Sample

preparation was in accordance with the applicable EPA CLP procedure for each particular sample matrix type.

An analytical value for metals was accepted or rejected by data validation based on the following criteria:

- Reject data if the associated initial calibration curve was non-linear (as determined by a correlation coefficient of < 0.995).

- Reject data if the daily calibration verification checks that bracket the sample of interest exceeded recovery limits of 85% to 115%; accept but flag if the checks exceeded the CLP limits of 90% to 110%.

- Reject data if the analytical accuracy exceeded the WSSRAP DQR limits or the laboratory control limits (whichever are greater).

- Accept but flag data if the accuracy exceeded the WSSRAP DQR limits or the laboratory warning limits (whichever are greater).

- Accept but flag data if the precision exceeded the DQR (and CLP) limits of 20% (or 35% for non-aqueous samples).

- Accept but flag data if the holding time was exceeded.

Miscellaneous

There were 33 samples or 42 data points in this validation effort for the miscellaneous parameters (cyanide, total organic carbon, total organic halides, grease & oil). These data were grouped into 27 data sets for validation purposes.

EPA approved methods were employed by the laboratories for these analyses. An analytical value for the miscellaneous parameters was accepted or rejected by data validation based on the following criteria:

- Reject data if the associated initial calibration curve (if applicable) was non-linear (as determined by a correlation coefficient of < 0.995).

- Reject data if the daily calibration verification checks (if applicable) that bracket the sample of interest exceeded recovery limits of 85% to 115%.

- Reject data if the associated analytical accuracy exceeded the WSSRAP DQR limits.

- Accept but flag data if the holding time was exceeded and the sample was positive for the analyte of interest.

- Reject data if the holding time was exceeded by seven days and the sample is negative.

Nitroaromatics

There were 108 samples or 654 data points involved in this validation effort for nitroaromatics. These data were grouped into 47 data sets for validation purposes.

The analytical methods employed by the laboratory were based on procedures certified by the USATHAMA, which involved sample preparation[2] and analysis by high performance liquid chromatography (HPLC).

An analytical value for nitroaromatics was accepted or rejected by data validation based on the following criteria:

- Reject data if the associated initial calibration curve is non-linear (as determined by a correlation coefficient of <0.995).

- Reject data if the daily calibration verification checks associated with the sample of interest exceeded recovery limits of 80% to 120%; accept but flag if the checks exceeded recovery limits of 85% to 115%.

---

2 A solid phase extraction sample preparation method was used by metaTRACE, Inc.; JTC used a "dilute and shoot" method, while ITAS used a solvent "shake-out."

- Reject data if the associated analytical accuracy exceeded the laboratory control limits, as determined by QC control charts provided. If control charts are not available, use control limits of ±50%.

- Accept but flag data if the accuracy exceeded the laboratory warning limits, as determined by QC control charts provided. If control charts are not available, use warning limits of ±25%.

- Accept but flag data if the holding time was exceeded by 30 days or less[3].

- Reject data if the holding time is exceeded by more than 30 days.

Pesticides/PCBs

There were 77 samples or 919 data points involved in this validation effort for pesticides/PCBs. These data were grouped into 24 data sets for validation purposes.

The analytical methods employed by the laboratory were the EPA CLP procedures for sample preparation and analysis by gas chromatography (GC). Several PCB-only samples were analyzed in accordance with EPA Method 608 or SW846 Method 8080.

An analytical value for pesticides/PCBs was accepted or rejected by data validation based on the following criteria:

- Accept but flag data if the relative standard deviation of the calibration factors in the three evaluation standard mixes exceeded the CLP 10% criteria.

- Accept but flag data if the percent breakdown for endrin or DDT exceeded the CLP 20% criteria.

---

[3] The 30 day holding time cut-off is based on a USATHAMA/EPA holding time study performed by Martin-Marietta which demonstrated parameter stability for up to 30 days if the samples are maintained at a temperature of 4° C.

- Accept but flag data if the percent difference of the calibration factors for each standard in the individual mixes A and B exceeded the CLP 15% criteria during the analytical run.

- Accept but flag data if the dibutylchlorendate (DBC) surrogate recoveries (accuracy) exceeded the CLP advisory limits.

- Reject data if a reported positive compound did not confirm during the conformational analysis.

- Reject data if the holding times were exceeded by more than 15 days; flag otherwise.

- Reject data if a reported positive multi-peak compound did not match the peak pattern from the compound's associated standard in the analytical run.

Radiochemical

There were 122 samples or 317 data points involved in this validation effort for radiochemical parameters. These data were grouped into 103 data sets for validation purposes.

The analytical method employed by the laboratories were from the EPA 900 series methods utilizing alpha, beta, or gamma spectrometry, as appropriate. Fluorometry (EPA 908.1) was employed by Accu-Labs for natural uranium.

An analytical value for radiochemical parameters was accepted or rejected by data validation based on the following criteria:

- Reject data if the associated analytical accuracy exceeded the WSSRAP DQR limits or laboratory control limits (whichever are greater). If control limits are not available use $\pm 25\%$.

- Accept but flag data if the accuracy exceeded the WSSRAP DQR limits or laboratory warning limits (whichever are greater). If limits are not available, use $\pm 20\%$.

Semi-Volatile Organics

There were 81 samples or 5,265 data points involved in this validation effort for semi-volatile organics. These data were grouped into 39 data sets for validation purposes.

The analytical methods employed by the laboratories were the EPA CLP procedures for sample preparation and analysis by gas chromatography/mass spectrometry (GC/MS).

An analytical value for semi-volatile organics was accepted or rejected by data validation based on the following criteria:

- Initial and continuing (or daily) calibrations were evaluated and qualified as described in Appendix G.
- Reject all acid compounds if the acid surrogate recoveries did not meet the CLP criteria.
- Reject all base/neutral compounds if the base/neutral surrogate recoveries did not meet the CLP criteria.
- Reject all compounds associated with an internal standard if the CLP criteria for that internal standard were not met.
- Accept but flag all associated compounds if the surrogate compounds in the associated blank were low and did not meet the CLP criteria.
- Accept but flag all associated compounds if the internal standard area counts in the associated blank exceeded the CLP upper limits.
- Reject all data if the CLP instrument tuning criteria were not met.
- Reject all data if the holding times were exceeded by more than 15 days; flag otherwise.

Volatile Organics

There were 81 samples or 2,924 data points involved in this validation effort for volatile organics. These data were grouped into 27 data sets for validation purposes.

The analytical methods employed by the laboratories were the EPA CLP procedures for sample preparation and analysis by gas chromatography/mass spectrometry (GC/MS).

An analytical value for volatile organics was accepted or rejected by data validation based on the following criteria:

- Initial and continuing (or daily) calibrations were evaluated and qualified as described in Appendix G.
- Reject all compounds if the surrogate recoveries did not meet the CLP criteria.
- Reject all compounds associated with an internal standard if the CLP criteria for that internal standard were not met.
- Accept but flag all compounds if the surrogate compounds in the associated blank were low and did not meet the CLP criteria.
- Accept but flag all associated compounds if the internal standard area counts in the associated blank exceeded the CLP upper limits.
- Reject all data if the CLP instrument tuning criteria were not met.
- Reject all data if the holding times were exceeded by more than 15 days; flag otherwise.

3.3 Validation Results

Table 3-3 summarizes the validation qualifiers that were assigned to the data points associated with the 12K data point validation project. These qualifiers are presented for all laboratories associated with these data, and independently for metaTRACE, Inc., JTC/Accu-labs, and ITAS.

Of the 11,847 total data points referenced in Table 3-3, 80.5% are accepted, 10.4% rejected, 5.9% validated by reference, and 3.2% are not validatable. The data points that were "validated by reference" consist of 486 pesticide/PCB and 217 nitroaromatic data points that were judged for useability by comparison to similar samples collected in the check sample program (discussed in Section 4 of this report). The non-validatable percentage represents analyses where essential laboratory documentation (i.e., instrument printouts associated with the analyses) could not be located. These analyses were not rejected (unless other circumstances associated with the analysis were present that would have rejected the analysis even if the missing documentation was present), but were not accepted since the supporting documentation was missing.

Table 3-4 summarizes the accuracy and precision for each parameter in the 12K data points. The accuracy and precision values are the average from all data sets for each parameter, where n is equal to each data population size. The accuracy values for aqueous, non-aqueous, and total samples are listed as a $\pm$ percentage from 100% (where 100% or $\pm$0% represents the best accuracy). The precision values for aqueous, non-aqueous, and total samples are listed as a percentage from 0% (where 0% represents the best precision). In cases where a sample of a particular matrix was not included with the 12K data points, a "None" is listed. In cases where precision or accuracy measurements are not available (i.e. due to missing analytical QC) a "****" is listed.

In general, the accuracy and precision values listed in Table 3-4 were within the DQR limits and within the range expected for the types of analyses and matrices involved. However, a number of values are worth discussion:

1. The 51% precision for nitrate in non-aqueous samples (with a data population of 17) was influenced by the 121.5% precision for five samples in dataset 41 and the 141.7%

**** – Value not available due to missing analytical QC (ie. analytical duplicates, control sample)

None – No samples of this matrix in the data group.

NA – Analysis not applicable to this matrix.

n – Data Population.

% Acc. – Based on percent recovery (subtracted from 100%) of the target compound or surrogate compounds in the control sample, matrix spike or target sample (surrogates).

% Prec. – Based on % difference of the target compound concentration or surrogate recoveries from analytical duplicates or MS/MSD pair.

[1] All accuracy and precision values relating to CLP parameters are within the acceptance range as defined by EPA CLP protocols, except for those discussed in Section 3 of this report. Attachment A contains the WSSRAP Data Quality Requirments (DQRs) for comparison to the accuracy and precision values in this table.

precision for one sample in dataset 42. These two occurrences (datasets) may reflect sample non-homogeneity that is typically seen in non-aqueous samples.

2. The 54.8% precision for chromium in non-aqueous samples (with a data population of 15) was influenced by the 124% precision for three samples and a matrix spike/matrix spike duplicate (MS/MSD) pair in dataset 277 and the 71.4% precision for one sample in dataset 273. The 39.3% precision for iron in non-aqueous samples (with a data population of 17) was influenced by the 72.7% precision for four samples and one field duplicate in dataset 278 and the 114.6% precision for one sample in dataset 1,016. In each of these cases, sample non-homogeneity is suspected.

3. The ±35.3% accuracy for lithium in non-aqueous samples (with a data population of 12) was influenced by the 23.8% recovery of the control sample for five samples in dataset 269. This probably reflects poor sample preparation and the lithium datapoints for those five samples in the dataset have been rejected by data validation.

4. The ±52.6% accuracy for silver in aqueous samples (with a data population of 25) was influenced by the 52% control sample recovery for three samples in dataset 259, by the 6.0% control sample recovery for one sample in dataset 307, and by the 4.0% control sample recovery for 10 samples in dataset 297. The poor recoveries of these control samples probably reflect poor sample preparation (i.e., loss of silver as AgCl during digestion) or reflects inductively coupled plasma (ICP) spectral interferences. All 14 data points have been rejected by data validation.

5. The ±58.9% accuracy for Lead-210 in aqueous samples (with a data population of four) was influenced by the 158.9% control spike recovery for four samples in dataset 119. Control charts were not available for this analysis and the quality of the resulting recovery is uncertain. Due to this uncertainty and the fact that the 158.9% recovery may reflect poor sample preparation, the four datapoints have been rejected by data validation.

6. The ±32.7% accuracy for Radium-226 in non-aqueous samples (with a data population of 12) was influenced by the 57% control sample recovery for two samples in dataset 91; by the 48.2% control sample recovery for two samples in dataset 87; by the 56.4% control sample recovery for one sample in dataset 89; by the 59.3% control sample

recovery for one sample in dataset 90; and by the 77.9% control sample recovery for one sample in dataset 86. All five sets of analyses were done by radon-emanation, which according to the control charts provided by the laboratory, has lower recoveries compared to gas proportional counting. All associated datapoints have been properly flagged by data validation.

7. The ±27.5% accuracy for Radium-228 in aqueous samples (with a data population of five) was influenced by the 125.6% control sample recovery for one sample in dataset 914 and the 128% control sample recovery for four samples in dataset 99. All associated datapoints have been properly flagged by data validation.

8. The 28.9% precision for Radium-228 in aqueous samples (with a data population of five) was influenced by the 144.5% precision for one sample in dataset 914. This datapoint has been properly flagged by data validation.

9. The 88.3% precision for Thorium-228 in non-aqueous samples (with a data population of six) was influenced by the 88.3% precision for two samples in dataset 919. This may reflect sample non-homogeneity; both datapoints have been properly flagged.

10. The 28.8% precision for Thorium-230 in aqueous samples (with a data population of 19) was influenced by the 285% precision for one sample in dataset 941 and by the 52.4% precision for five samples in dataset 928. Sample preparation is suspect; all six datapoints have been properly flagged by data validation.

11. The ±40.8% accuracy for Thorium-230 in non-aqueous samples (with a data population of nine) was influenced by the 179.6% control sample recovery for one sample in dataset 100, and by the 78.1% control sample recovery for two samples in dataset 919. These recoveries probably reflect the efficiency of the sample preparation for the analysis. Due to the large deviation in recovery of the control sample in dataset 100, the target Thorium-230 datapoint in that dataset had been rejected by data validation. All three associated datapoints in the discussion have been properly flagged by data validation.

12. The 55.3% precision for Thorium-232 in aqueous samples (with a data population of 16) was influenced by the 177.0% precision for five samples in dataset 928. Sample preparation is suspect; all five datapoints have been properly flagged.

13. The ±104% accuracy for pesticides and polychlorinated biphenyls (PCBs) in aqueous samples is influenced by the 204% DBC surrogate recovery in the single target sample in the aqueous population. Due to the lack of available aqueous pesticide and PCB samples, or to the lack of available complete laboratory documentation, a larger data population was not possible. For the single sample in question (from dataset 196), the DBC surrogate recovery exceeds the CLP advisory upper limit of 175%; the data for this sample have been properly flagged by data validation.

For the volatile and semi-volatile parameters, the accuracy and precision values are within the ranges typically seen for the type of analysis. For example, the accuracies listed for the acid parameters (±53.2% for aqueous and ±33.3% for non-aqueous) and for the base/neutral parameters (±9.9% for aqueous and ±33.8% for non-aqueous) are within the acceptance ranges established from CLP (which averages ±86% for acid compounds and ±63% for base neutral compounds).

During the validation of the 12K data points, numerous problems surfaced; however, most of these problems were resolved. The most widespread problem related to missing laboratory documentation. A major effort was undertaken by the PMC to gather all WSSRAP documentation from the contract laboratories, and most of this documentation was collected. However, several pieces were not located, which has resulted in some of the data points (3.2%) being declared non-validatable (X). Listed below are several other problems that were analysis-specific:

1. Numerous manual integrations were observed with the volatile and semi-volatile data. Manual integrations occurred when the instrument operator over-rode the instrument's software integration technique which could have allowed calibration bias to enter into the analysis. However, "pictures" of these manual integrations were obtained from the laboratory, which allowed the validation team to determine which integrations were acceptable and which were not. Corrections to the data were made for the improper integrations and evaluations of the data were based on the corrected analyses.

2. Only one nitroaromatic initial calibration curve was used for compound quantitation by metaTRACE for a period of at least 13 months. This single calibration curve was applied to all but two of the metaTRACE nitroaromatic data sets. Instrument stability over that span of time is extremely unusual. According to USATHAMA protocol, a new

initial calibration is required at instrument start-up, after any instrument or column maintenance, or when the daily calibration check fails to meet the laboratory established limits. For several of the affected data sets, the daily calibration checks did not meet the acceptance criteria, and instrument maintenance by a service representative was noted during that 13 month period. Since a new calibration curve was not established, the sensitivity or ability of the instrument to detect nitroaromatic compounds at the reported detection limits was uncertain to the validation team. As such, the reliability of the nitroaromatic data (and particularly the "non-detects") in 31 of 33 metaTRACE data sets were in question.

To resolve this uncertainty, additional nitroaromatic samples were collected in a check sample program that is discussed further in Section 4 of this report, and the resulting data were validated and compared to the metaTRACE data. Except for two data points, there was complete agreement among the data. The non-detects reported by metaTRACE remained as non-detects from the check sample program, thus adding confidence and support to the viability and sensitivity of the single metaTRACE initial calibration curve used over the 13 month period. The nitroaromatic data in the affected metaTRACE data sets have been validated by reference (V) to the check sample data. The qualifier summary on Table 3-3 reflects these reference approvals.

Of the two conflicting data points, both were associated with sample S2-051280, 100890-2.0,4.0. MetaTRACE reported 1.21 μg/g for 1,3,5-TNT while the check sample was a non-detect. Since the 1.21 μg/g value is on the low end of the calibration curve, this value has been determined to be too unreliable and has been rejected by the validation team. For 2,4,6-TNT, metaTRACE reported 647 μg/g while the check sample yielded a non-detect. The metaTRACE instrument chromatogram was reviewed again by the validation team, and again confirmed the presence of 2,4,6-TNT. This discrepancy may suggest sample non-homogeneity. However, due to the poor comparison to the check sample data and the qualitative uncertainty of the chromatographic peak being 2,4,6-TNT, the metaTRACE data point has been rejected by the validation team.

3. Instrument calibration and sensitivity for the metaTRACE pesticide/PCB analyses were uncertain. To resolve this uncertainty, additional samples for PCB analysis were collected in the check sample program and the resulting data validated and compared with the metaTRACE PCB data. For all sample matrices except soils, the comparisons

matched. As such, the data from the associated metaTRACE data sets have been validated by reference to the check sample data. Table 3-3 reflects these reference approvals. However for soils, the data comparisons were poor in approximately 50% of the soil samples analyzed for PCBs in the check sample program. Significant quantities (ranging from 50 μg/kg to 38,000 μg/kg) of Aroclors 1260 and/or 1254 were observed in the check samples where non-detects were reported by metaTRACE in corresponding samples. The significant quantities of PCBs and the 50% poor match does not lend support to the uncertainty associated with the metaTRACE calibrations. The poor comparison could possibly reflect sample non-homogeneity, but this fact is uncertain. As such, the metaTRACE pesticide/PCB data associated with the soils in the 12K data points have been rejected by the validation team.

4. A large percentage of the laboratory documentation needed for validating the isotopic thorium analyses by metaTRACE was not located during the documentation search performed by both metaTRACE and the PMC. In particular, most of the Thorium-229 tracer counts were missing, which directly impacts validating the efficiency of the isotopic thorium analyses. Though these data points are not validatable, their rejection is not certain since the percent acceptance of the validatable data population for isotopic thorium is high (82%).

5. For many of the metals analyses, some of the CLP required QC samples (i.e. serial dilutions, end-of-run interference check samples, post-digestion spikes) were not included in the analytical runs. Though important, their absence has not hindered evaluation of the data. These data were evaluated, but flagged as not following CLP protocol.

6. For anions, all metaTRACE analyses were done by ion chromatography which requires an unpreserved sample. The holding time for nitrate on an unpreserved sample is 48 hours (as opposed to 28 days for a preserved sample). For this reason, the holding time was generally exceeded for all nitrate analyses. In addition, the routine end-of-run calibration verification check was not always included. Those data have been flagged accordingly.

Detailed print-outs of the 12K data point validation findings are available in appendixes A through D under separate cover. These findings have been arranged by WSSRAP ID and by analytical category. For each data point, the following information has been provided.

a. WSSRAP sample ID.
b. Sample percent solids (if applicable).
c. Validation dataset number and sequence number.
d. Laboratory code and analysis request number (if available).
e. Laboratory sample ID number.
f. Parameter.
g. Analytical category.
h. Analytical concentration ($\pm$Rad. error) in WSSRAP GURU database.
i. Analytical concentration ($\pm$Rad. error) from validation review.
j. Analytical detection limit in WSSRAP GURU database.
k. Analytical detection limit from validation review.
l. Validation qualifier and flags.
m. Validation comments (if any).
n. Analytical accuracy and precision.

4 CHECK SAMPLING PROGRAM DESCRIPTION

This section contains a discussion of the results of quality assurance (QA) samples collected and analyzed by secondary laboratories as well as the rationale, procedures, and results of the check sampling program.

4.1 Quality Assurance Sample Results

Quality assurance (QA) samples were collected throughout all site characterization and routine environmental monitoring activities at the Weldon Spring Site Remedial Action Project (WSSRAP). Two types of QA samples were used to support data validation activities; duplicate samples, which were analyzed by the same laboratory as the original sample, and replicate samples which were analyzed by a different laboratory.

Duplicate and replicate samples were collected at the same time and in the same manner as regular samples. Generally, both duplicate and replicate samples were collected at the frequency of one sample per 20 regular samples. Replicate samples were not collected for raffinate sludges due to constraints on the analysis of radioactive materials. The results of QA samples were generally presented in the data reports. Numerous reports generically summarize the QA sample results by stating the general agreement between QA samples and regular samples and present the QA sample results in an appendix or table. The number of samples collected and analyzed to evaluate interlaboratory variability is summarized in Table 4-1. QA sample results were statistically evaluated in the Phase II Chemical Soil Investigation. The results are discussed in detail in the following paragraphs.

Duplicate and replicate samples were collected during the Phase II Chemical Soil Investigation. A detailed analysis was performed for those compounds with sufficient detected concentrations. Duplicate samples from this investigation yielded an average relative percent difference of 23.6% for metals analyses and 21.1% for inorganic anions. This general agreement indicates that the primary laboratory performed analyses in a consistent manner. The average relative percent difference for replicate samples was 25%. This general agreement between laboratories indicates that the analyses were performed consistent with the required analytical methods. Also, a combined total of 65 volatile organic, semi-volatile organic and pesticide and polychlorinated biphenyl (PCB) analyses performed by the secondary laboratory

agreed completely (except for laboratory contaminants) with the results from the primary laboratory.

4.2 Check Sample Procedures

The purpose of the check sampling program was to collect and analyze samples from media and locations for which the existing data were not of documentable quality to support the Remedial Investigation/Feasibility Study (RI/FS) process (see Section 3.3). This effort focused on documenting the absence of specific contaminants as well as confirming the presence and concentrations of contaminants previously detected. A sampling plan was prepared and submitted to the U.S. Environmental Protection Agency (EPA). Samples were collected from the raffinate pit sludges, on-site soils, groundwater, and surface water. The analytical parameters included volatile organic compounds, semivolatile organic compounds, PCBs, nitroaromatic compounds and radiological species.

Check samples were collected according to site-specific procedures. Samples were preserved as appropriate prior to shipment to the analytical laboratory. Chain of custody was maintained for all samples according to the site-specific chain of custody procedure. The rational for sampling locations and analytical parameters is discussed by media in the respective sections.

Samples collected under this check sampling program were analyzed according to standard EPA Contract Laboratory Program (CLP) methods for volatile organic, semivolatile organic, and PCB compounds. Samples requiring nitroaromatic compound analyses were analyzed using EPA SW846 Method 8330. Radiological analyses were performed using methods consistent with the EPA 900 series procedures.

4.3 Check Sample Results

Results from the check sampling program are discussed by medium in the following sections. The data from this program have been used to validate previous analytical results and to confirm the absence of groups of compounds. The data collected as a result of this program have been entered into the WSSRAP database.

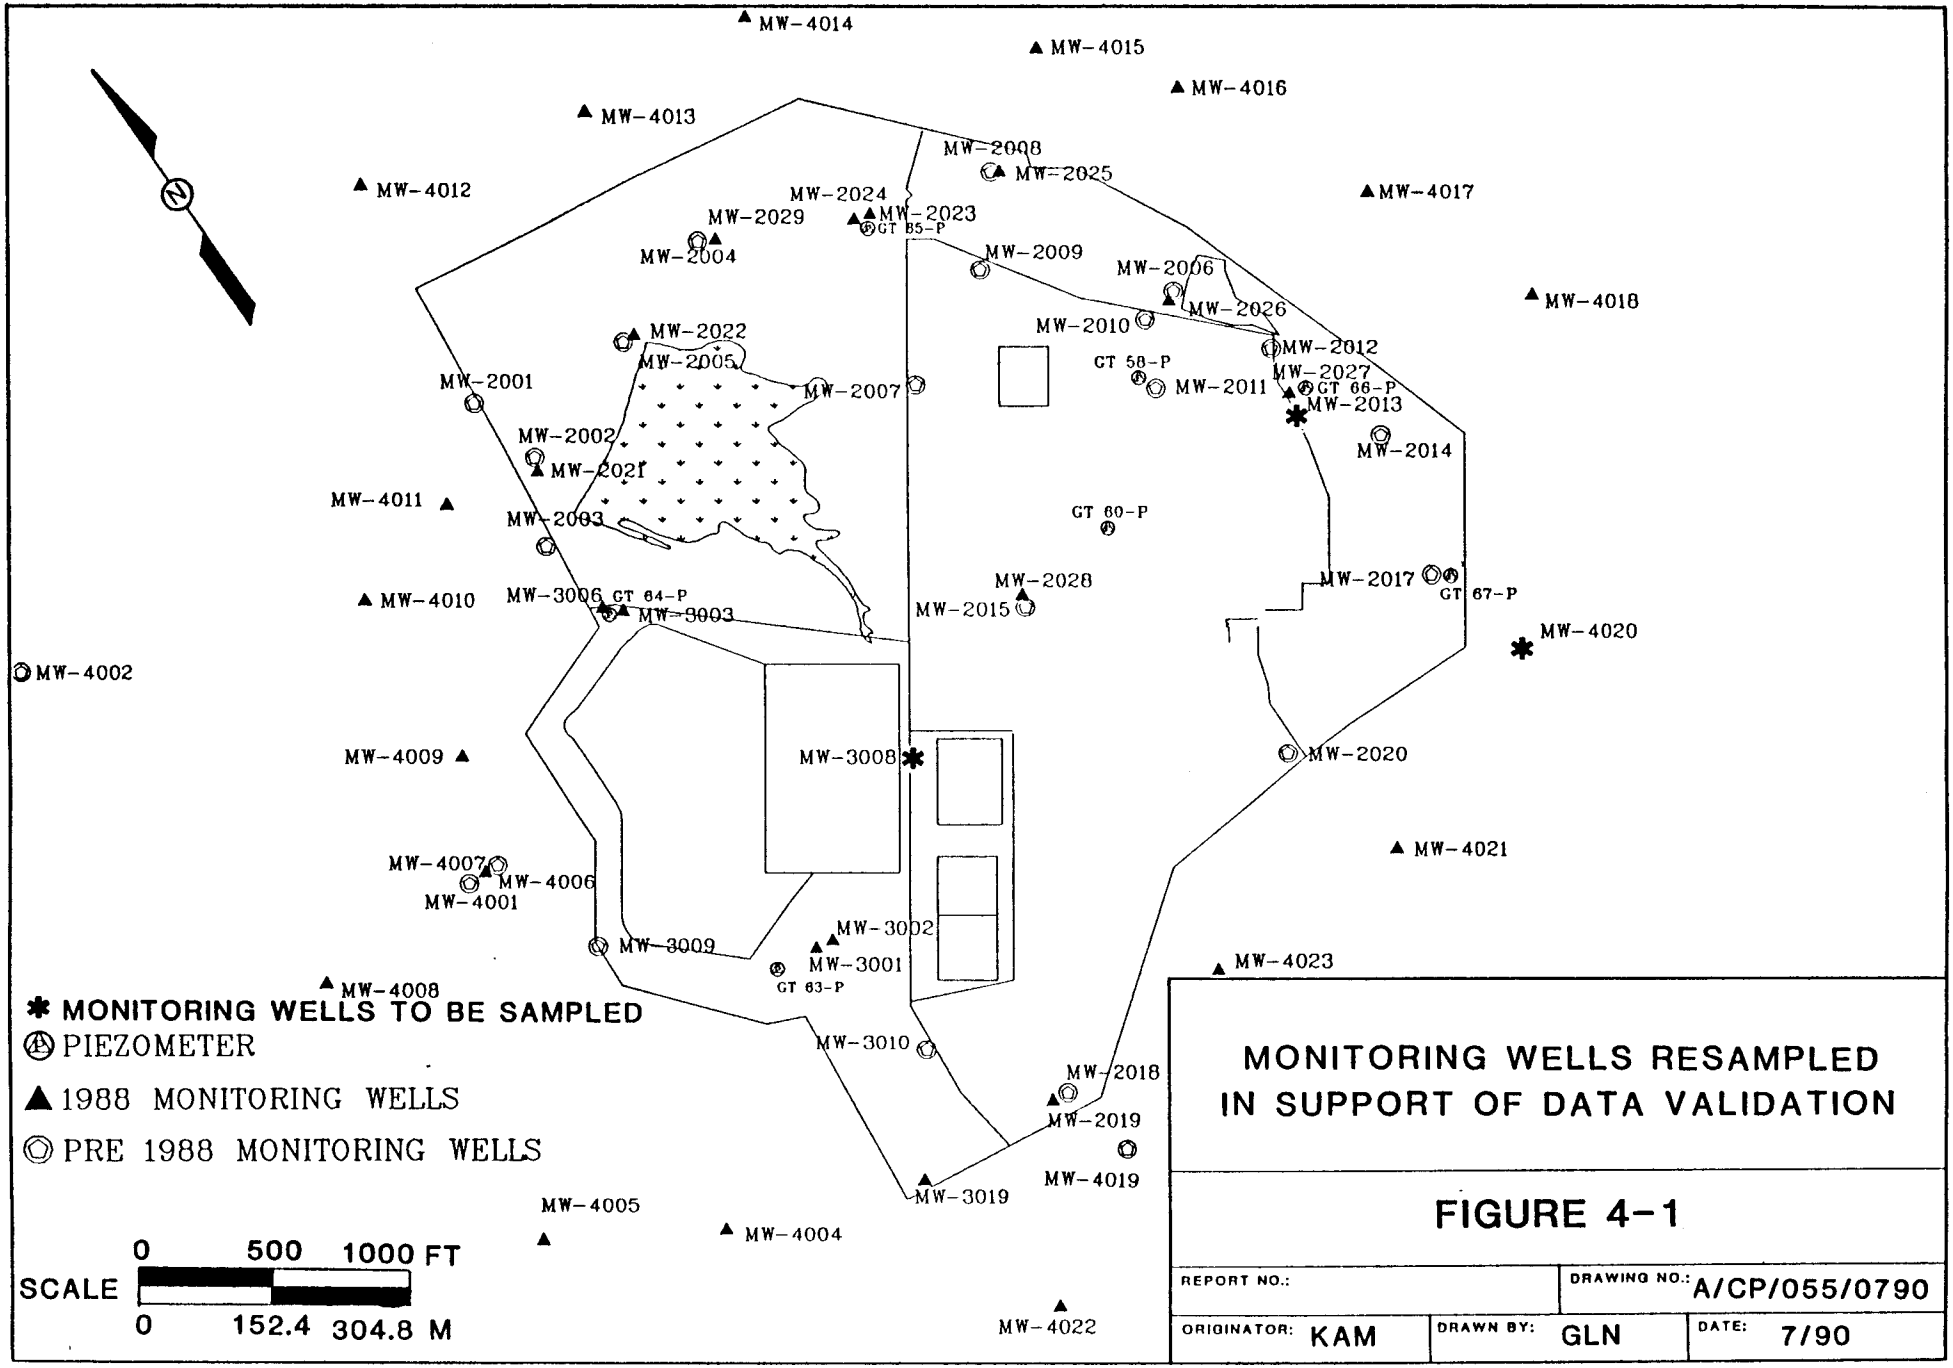
4.3.1 Groundwater

Data quality problems with the groundwater portion of the database included the inability to completely validate volatile and semivolatile organic compound results and the infrequent calibration of laboratory instruments used to perform nitroaromatic analyses. The check sampling program for groundwater consisted of resampling to provide data confirming the previous volatile and semivolatile organic results and comparing historical nitroaromatic results (performed by metaTRACE) with current environmental monitoring data performed by the U.S. Army Environmental Hygiene Agency (AEHA).

Three groundwater monitoring wells were sampled to confirm the absence of volatile and semivolatile organic compounds. These wells, MW-2013, MW-3008 and MW-4020, are located in the nitroaromatic and raffinate pit plumes and in an area not impacted by either area of contaminated groundwater. The location of these wells is shown in Figure 4-1.

Samples were collected using dedicated bladder pumps from three monitoring wells on site and analyzed for volatile and semivolatile organic compounds. The results of the check samples from these wells confirm that the groundwater is not contaminated with these compounds.

In addition to the check sampling program, nitroaromatic compound results from routine environmental monitoring performed in 1990 were compared to the historical metaTRACE results. This comparison indicates that the historical nitroaromatic concentrations observed in groundwater are consistent with the concentrations observed during recent environmental monitoring. A direct, statistical comparison is not practical due to the dynamic nature of the groundwater system. However, in 1989, 44 of 89 wells contained detectable concentrations of nitroaromatic compounds with seven wells exhibiting nitroaromatic concentrations above 10 μg/l. During the first half of 1990, 31 of 89 wells contained detectable concentrations of nitroaromatic compounds with 12 wells exhibiting concentrations above 10 μg/l. These minor differences between 1989 and 1990 are due to the fact that the 1990 numbers are based on a single sampling event, while the 1989 numbers are based on at least two sampling events. Wells with low concentrations of nitroaromatic compounds have historically varied between detecting and not detecting concentrations near the detection limit. The increase in the number of wells with



MONITORING WELLS RESAMPLED IN SUPPORT OF DATA VALIDATION

FIGURE 4-1

REPORT NO.:		DRAWING NO.: A/CP/055/0790
ORIGINATOR: KAM	DRAWN BY: GLN	DATE: 7/90

higher concentration is consistent with recent trend analyses and may be partially attributed to slight concentration fluctuations. This is supported by variation in nitroaromatic concentrations between 1987 and 1989. Overall, 1990 AEHA nitroaromatic results are consistent with 1987, 1988, and 1989 metaTRACE results.

4.3.2 Surface Water

The rational for the surface water check sampling program was similar to the groundwater check sample program. Routine monitoring confirmed the levels of contaminants present. The check sampling program was designed to confirm previous characterization efforts which documented the absence of contamination. The check sampling program consisted of sampling a spring north and a spring south of the site for both volatile and semivolatile organic compounds. The springs sampled are shown in Figure 4-2. These springs were selected because they are impacted by the WSSRAP and would indicate whether a significant problem existed. No volatile or semivolatile organic compounds were detected, confirming previous characterization data.

4.3.3 Sludge

The sludge check sampling program consisted of collecting a total of 17 samples from the four raffinate pits. The locations of these samples are presented in Figure 4-3. Analytical parameters for raffinate sludge included volatile and semivolatile organic compounds, PCBs, and nitroaromatic compounds. These analytical parameters were selected because the initial characterization indicated that these compounds were not present in the raffinate sludge. Sludge samples were also analyzed for silver and zirconium to provide data to compare with the initial results.

Sludge samples were collected using a ponar dredge from all four raffinate pits. The check samples collected confirmed the previous data which indicated that the raffinate sludges do not contain nitroaromatic, volatile organic, semivolatile organic, or PCB compounds. The check samples did detect small amounts of acetone and methylene chloride. These compounds are common laboratory solvents and their detection indicates laboratory contamination and does not represent actual values.

Check sample results from Raffinate Pit 3 indicate that silver results in the original data set may be biased low since all check sample results for silver were above the maximum observed concentration. Zirconium results were within the expected range.

4.3.4 Soil

The check sampling program for soils focused on confirming the absence of significant volatile organic, semivolatile organic, and PCB compound contamination. Samples were also collected and analyzed for nitroaromatic compounds to confirm the presence of contamination, and to confirm that the concentrations observed accurately reflect site conditions. Samples were collected from the locations shown on Figure 4-4. The coordinates, depths, and analytical parameters are presented in Table 4-2.

All soil sampling locations were surveyed prior to sample collection. Soil samples were collected using a bucket auger. Soil from the desired location and interval was placed in a clean stainless steel pan and homogenized (except for sample aliquot used for volatiles) prior to filling the samples containers. Sampling equipment was decontaminated between samples.

Thirteen soil samples from 10 locations were collected and analyzed for volatile organic compounds. The locations sampled during this effort were selected because past known practices indicated the highest probability of volatiles contamination. No detected concentrations of volatile organic compounds were detected during the resampling effort, confirming the absence of these compounds. No tentatively identified compounds other than those related to the analysis (Aldol condensation products) or those present in laboratory blanks were detected.

Thirteen soil samples were collected from 10 locations and analyzed for semivolatile organic compounds. The only compounds detected during the check sample program were common phthalate esters and low concentrations of polyaromatic hydrocarbons (PAH). Phthalates were detected during previous investigations and generally reflect laboratory contamination. The PAHs were detected in the fire training pit as originally observed during the Phase II Chemical Soil Investigation. PAHs were also observed at concentrations below the contract required quantitation limits (CRQL) at site coordinates 50040 East and 100700 North in the 2 ft to 2.5 ft depth interval. No tentatively identified compounds other than those related to the analysis (Aldol condensation products) or those present in laboratory blanks were detected.

* - ONLY PCB/PESTICIDE ANALYSES TO BE PERFORMED ON DEEPER SAMPLE

Twenty-three soil samples were collected from 14 locations and analyzed for PCBs. The results from these samples indicate that low concentrations of Aroclor-1254 and Aroclor-1260 are present near transformer pads. Check samples also confirmed that PCBs are not widely distributed in site soils. The check sample results detected higher concentrations of PCBs than the original samples. These variances were noted at site coordinants 49700 East and 100360 North. Check samples detected a total of 74 μg/g of Aroclors while the original sample did not detect PCBs. This heterogeneity may be attributed to the nature of the source. PCB contamination adjacent to transformer pads likely originated as small spills during routine transformer servicing.

Thirty-two soil samples were collected from 18 locations and analyzed for nitroaromatics. The results generally agree with historical data which determined that nitroaromatic compounds are present only in low concentration in isolated areas. The check sampling program only yielded two locations with detected concentrations of nitroaromatic compounds. A sample collected from 0 ft to 2 ft at site coordinates 51565 east and 100850 north contained 0.049 μg/g of nitrotoluene. A sample from this location originally detected 1.73 μg/g of 2,6-DNT in the 4 ft to 6 ft depth interval. The original investigations did not include analysis for nitrotoluene. A check sample collected from the 2 ft to 4 ft depth interval at site coordinants 50850 East and 100850 North detected 0.14 μg/g of trinitrotoluene (TNT). Original samples from this location did not detect contamination.

All other check samples did not detect nitroaromatic compounds, including those collected from site coordinants 51280 east and 100890 north. Samples from this location originally detected 647 μg/g of TNT and 1.21 μg/g of 1,3,5-Trinitrobenzene. The absence of contamination in the check samples indicates that the contamination is very isolated and not uniformly distributed over a large area.

4.3.5 Summary

Analytical results confirmed the absence of significant volatile organic, semivolatile organic and PCB compound contamination in raffinate sludges and soils. Minor PCB soil contamination was confirmed near transformer pads. Isolated areas of low concentrations of nitroaromatic compounds were detected in soils at former ordnance production areas. Silver results for raffinate sludges may have been biased low in the original analyses. The absence of volatile organic or semivolatile organic compounds in both groundwater and surface water was

confirmed. These results are summarized in Table 4-3. The historical concentrations and distributions of nitroaromatic compounds in groundwater were also confirmed.

In summary, the check sampling program satisfied the objectives of the sampling plan. The data collected during this program has been validated and supports the validation of the historical data.

TABLE 4-3 Summary of Check Sample Results versus Original Sample Results

Analytical Category		Percentage Identical
PCBs	- Soil	76%
	- Sludge	82%
Volatile Organics Compounds	- Soil	92%
	- Sludge	91%
	- Water	100%
Semivolatile Organic Compounds	- Soil	97%
	- Sludge	99%
	- Water	100%
Nitroaromatic Compounds	- Soil	97%
	- Sludge	100%

Percentage identical is based on number of exactly identical results (on a parameter to parameter check) in both the check sample and the original sample. Samples with detected concentrations of laboratory contaminants, with estimated concentrations, or with concentrations below the contract required detection limits (CRDL) were used in calculating these percentages.

5 CONCLUSION AND RECOMMENDATIONS

Based on the review of the comparability of the duplicate samples, the validation of the 12K data points, and the check sample program the Project Management Contractor (PMC) has concluded that the database is adequate for use as the basis for the *Chemical Plant and Raffinate Pit Remedial Investigation and Feasibility Study* (RI/FS). The database provides an accurate basis for determining which contaminants are present at Weldon Spring Site Remedial Action Project (WSSRAP) and which are not present, and also provides an accurate basis for defining the range and distribution of the contamination. The data are adequate to determine remedial action costs to a +50% and -30% accuracy as required for an RI/FS.

However, the quality of the data must be continually reassessed as the project progresses through the RI/FS phase and on to design, where a more detailed definition of the range and distribution of the contaminants is necessary. Specifically, the following tasks are recommended.

1. Additional soil samples should be collected and analyzed for pesticides and polychlorinated biphenyls (PCBs). As discussed in Section 4.0 the check sample program did not always show good agreement between the samples analyzed by metaTRACE and the samples collected for the check sample program. The lack of agreement is probably due to the fact that the exact location of the previous samples could not be duplicated (the previous sample locations were disturbed) by the check sample program. Since the PCB spills were small confined spills, any variation in the location of the samples would result in somewhat differing measured concentrations. The check sample program did confirm that PCBs are only present in low concentrations in very localized areas near former transformer locations and additional sampling will assist in more accurately defining the extent of the contamination.

2. A limited number of additional water samples should be collected and analyzed for isotopic thorium. Although there is no reason to indicate that the previous samples were improperly analyzed, a large percentage of the laboratory records could not be found and it is considered prudent to further confirm the previous analyses.

3. The accuracy and precision of the data has been evaluated against the action levels developed through the FS process. As shown in Table 3-4 the accuracy and/or precision

of certain contaminants does not meet WSSRAP data quality requirements (DQRs). These contaminants are primarily soil and sludge samples which are very difficult to analyze and improving the accuracy and/or precision may not be possible. Generally, these chemicals are not important to the site because they occur in very low concentrations. However, following the development of action levels, the PMC will evaluate whether the accuracy and precision of chemicals with concentrations near the action levels are adequate.

4. While the database is sound and has an overall estimated percent completeness of 89.2% (refer to Table 3-3), users of the data must be aware that if they choose to use a single data point or a small group of data points for a key calculation, that data point or group of points should be validated. This is necessary because WSSRAP has validated a significant percentage of the database and applied the results of this validation to define the quality of the entire database as recommended by the U.S. Environmental Protection Agency (EPA) RI/FS guidance documents. Other than this, there should be no further restrictions placed on the use of the data.

ATTACHMENT B
DATA VERIFICATION PROCEDURE

ES&H 4.9.1a ENVIRONMENTAL MONITORING DATA VERIFICATION

SET I.D. #028

1.0 PURPOSE

The purpose of this procedure is to establish the system for data verification and provide the objective evidence necessary for timely review and verification of laboratory analytical results for the Weldon Spring Site Remedial Action Project (WSSRAP).

2.0 SCOPE

This procedure applies to all environmental, waste management, health physics, and geotechnical samples collected at the WSS, and data from chemical, radiological, and physical analyses performed by off-site subcontractor laboratories. Verification includes review of hard copy, electronic data, and other documentation. This procedure excludes data collected from field measurements.

3.0 REFERENCES

3.1 EPA, SW-846, *Test Methods for Evaluating Solid Waste Physical/Chemical Methods.*

3.2 EPA, *A Compendium of Superfund Field Operations Methods*, Volume 2, Section 16.

3.3 *Environmental Data Administration Plan*, May 1990, DOE/OR/21548-119.

4.0 DEFINITIONS

4.1 Verification: A non-analytical preliminary review of analytical laboratory data and associated documentation performed to ensure that the samples are preserved, shipped, maintained, and analyzed in accordance with established data quality objectives and standard operating procedures.

4.2 Holding time: The period of time from sample collection to the time the sample is extracted and analyzed.

4.3 Validation: A thorough review of the analytical data utilizing laboratory analytical records to assess laboratory performance to quality control criteria, data quality objectives and procedural requirements.

ACRONYMS

DQO Data Quality Objectives
QC Quality Control
EDAP Environmental Data Administration Plan

5.0 RESPONSIBILITIES

The Environmental Protection Manager shall be responsible for implementing this procedure.

6.0 PROCEDURE

6.1 All laboratory data are to be received by the Procurement Department and delivered to the Verification Group.

6.2 All documentation collected as a result of data verification activities shall be retained in verification packages. The verification packages shall be filed by shipment or laboratory request number.

6.3 The Verification Group will receive hard copies and electronic copies of the analytical data. The original hard copies shall be sent to the Quality Assurance Department and copies shall be maintained in the ES&H filing system. The electronic copies shall be maintained in the ES&H filing system.

6.4 Hard copy data results shall be distributed to the designated data reviewers for review. This review process shall be documented on Form 4.9.1.1, Data Verification Data Review Sheet.

6.5 Completed Data Verification Data Review Sheets shall be returned to the Verification Department within two working days of the date distributed.

6.6 After the hard copy data has been reviewed for consistency with validated historical data, they shall be evaluated using Form 4.9.1.2, the Data Verification Checklist. The data shall be reviewed for timeliness of the report, chain-of-custody compliance, accurate sample identifications, completeness and correctness of the data report, and compliance to extraction and analytical holding time.

6.7 Electronic data records shall be compared to the verified hard copy data reports prior to incorporation into the WSSRAP computerized database system. All electronic records shall be standardized to appropriate categories, parameters, and units of measure (see Exhibit 5). Electronic records shall be compared manually on a record-by-record basis with the hard copy reports. Corrections shall be made as required and final verified printouts of the electronic data shall be attached to the Verification Checklist. The verified electronic data shall then be merged into the WSSRAP databases.

6.8 Electronic data requiring unit conversions shall be calculated using equations listed in Exhibit 6. Results of all conversions shall be shown on the hard copy report which shall be retained as part of the verification checklist package. All calculations shall be double checked by a second reviewer.

6.9 Deficiencies and/or discrepancies noted during the verification process shall be documented on Form 4.9.1.4, Verification Discrepancy Documentation Form. Corrective actions shall be made according to Standard Operating Procedures ES&H 4.1.1a, 4.1.2s, 4.4.1s, the Environmental Monitoring Plan, and data quality objectives defined in the EDAP. Corrective actions shall be reviewed by two persons and documented on form 4.9.1.4 (Exhibit 3).

6.10 Data validation shall be conducted according to SOP ENG-9a. Data reviewed during the verification process can be petitioned for validation review. Requests for data validation shall be completed by the ES&H Department or other WSSRAP participants using the Data Validation Request Form 4.9.1.5 (Exhibit 4). All validation requests shall be submitted to the validation group for processing.

7.0 RECORDS

Verification packages, including data verification data review sheets and discrepancy documentation, shall be transmitted to the Quality Assurance Department for retention as QA records in accordance with QAPP-9 for the duration of the project or as directed by DOE. Copies of data reports shall be maintained in the ES&H Department files. Data in electronic format shall be maintained in database files with access protection methods. Periodic backups of electronic data shall be made and stored in fireproof areas.

DATA VALIDATION PROCEDURE

S.T.I.D. # 048

RC-31a ENVIRONMENTAL MONITORING DATA VALIDATION

1.0 PURPOSE

The purpose of this procedure is to specify the practices and processes relating to the technical review and validation of the laboratory analytical data for the Weldon Spring Site Remedial Action Project (WSSRAP).

2.0 SCOPE

This procedure applies to all environmental and radiological analytical measurements, excluding field measurements, performed by subcontract laboratories for WSSRAP.

3.6 RC-34s, *Data Validation - Inorganic Parameters* (in preparation)
3.7 RC-35s, *Data Validation - Organic Parameters* (in preparation)
3.8 RC-36s, *Data Validation - Radiochemical Parameters* (in preparation)

4.0 DEFINITIONS

4.1 Preliminary Review - a cursory screening of the data deliverables packages to identify and correct any obvious deficiencies and to setup the validation datasets in preparation for the technical review.

4.2 Technical Review - A thorough evaluation of the analytical data utilizing the data deliverables to qualify the data quality and useability based on sample integrity, laboratory performance, procedural quality control (QC) criteria, and data quality objectives (DQOs); and to measure the accuracy, precision, and completeness of the reported analytical data.

4.3 Validation - The preliminary review and technical review of the target samples and target analyses.

4.4 Target Sample - A WSSRAP sample that has been selected for data validation.

4.5 Target Analysis - The analysis associated with a target sample that is requested for data validation.

4.6 Accuracy - A statistical measurement, expressed as a percentage, which represents how close the analytical data are to the "true" value. This measurement is based on the percent recoveries associated with the laboratory analytical control spikes (blank spikes), surrogate spikes, or matrix spikes. 100% accuracy is the best accuracy.

4.7 Precision - A statistical measurement, expressed as a percentage, which represents the repeatability of the analytical system. This measurement is based on the percent differences between laboratory duplicates. 0% precision is the best precision.

4.8 Completeness - The percentage of acceptable datapoints associated with a group of data, such as those in a validation request or those addressed in a quarterly or summary validation report. Acceptable datapoints are all datapoints that have been qualified with an A, A+, 1, 2, 3, 4, or V qualifier.

4.9 Qualifiers - A set of codes and flags which abbreviate the results and findings of the data validation technical review (See Exhibit 1).

4.10 Dataset - the minimum analytical sequence consisting of the target samples and associated QC measurements as required by the analytical protocol that can be evaluated independently; is often synonymous with the laboratory analytical lot.

4.11 Data Deliverables - laboratory analytical records including, but not limited to:

- CLP Deliverables Package (as defined in the most recent USEPA CLP Scope of Work)
- Sample custody transfer records (WSSRAP and laboratory records)
- Sample preparation/extraction/digestion logs
- Sample and QC data summary sheets/benchsheets/log-book entries
- Instrument printouts/chromatograms/spectra
- Analytical run-sequence logs
- Instrument tuning and calibration printouts and data
- Control charts
- Corrective action/exception reports
- Standards preparation logs
- Percent moisture determinations

5.0 RESPONSIBILITIES

5.1 The Environmental Compliance Manager shall be responsible for ensuring implementation of this procedure.

5.2 The Data Validation Manager shall be responsible for implementing this procedure.

6.0 PROCEDURE

6.1 Requests for Data Validation

6.1.1 Requests for data validation shall fall into one of the following three categories:

- Random requests, which are selected for validation prior to shipment of samples to the laboratory for analysis. The laboratory is not to know these data are to be validated until after the analysis is complete. These requests shall be initiated by the Data Verification Manager.

- Biased requests, which are selected for validation after the data have been reported by the laboratory. These requests shall be initiated by any user of WSSRAP data.

- Special requests, which are selected for validation based on the use of the data. These requests shall be initiated by any user of WSSRAP data.

6.1.2 All requests for validation shall be made in writing from the requestor and directed to the Data Verification Group. The Verification Group shall be responsible for requesting the validation documentation from the laboratory through the Procurement Department and shall be responsible for notifying the Validation Group of the pending request.

6.1.3 Requests for validation shall be maintained by the Data Validation Group as random, biased, or special requests. When the validation data deliverables package is received, the data package shall be logged into a Validation Tracking Record (Exhibit 2) which shall be used to track the status of the validation activity.

6.2 Datasets

6.2.1 The data from the target samples and analyses shall be grouped into datasets for the purpose of validation review and record keeping. A unique, sequential dataset number (i.e. 00001) shall be assigned to each dataset. A rubber stamp shall be utilized to maintain the next dataset number in sequence. This number shall be placed on the cover pages of all validation data documentation and validation review checklists and spreadsheets.

6.2.2 All samples (including QC samples) within each dataset shall be arranged chronologically. The date/time "stamp" from the analytical instrumentation may be used for this purpose. In cases where an instrumental date/time "stamp" is not available or in cases where samples from an analytical lot have not been provided by the laboratory (i.e. non-WSSRAP samples), the data reviewer shall use a "best guess" estimate to reconstruct the analytical order. A sequence number shall be assigned to each sample in the dataset to represent this order of analysis. The sequence number shall be identified on the raw data in such a fashion that it is clear which data are associated with which sequence number. No two analytical injections, aspirations, or measurements shall have the same combination of dataset number and sequence number.

6.2.3 A computerized database file shall be used to cross reference each target sample and target analysis with its assigned dataset number and sequence number. This database will be maintained by the data validation group.

6.3 Validation Reviews

6.3.1 The data validation technical review process for each dataset shall be directed by analysis-specific checklists and shall utilize computerized spreadsheets to confirm and document analytical calculations. The checklists and spreadsheets shall become part of the validation dataset documentation package.

Each technical review shall address as a minimum:

- Sample Integrity
- Calibration and Quantitation
- Qualitative Identification
- Background and Contamination
- Accuracy and Precision

The details associated with the technical review and the use of the corresponding checklists are described in separate SOPs for inorganics, organics, and radiochemical analyses.

6.3.2 The validation technical review requires evaluating the data and the analysis for compliance with established performance criteria (i.e. USEPA CLP). During the review of a particular dataset, it shall be appropriate for the reviewer to use the validation checklist only as a guide. Circumstances may arise that are not specifically handled by the checklist. Consequently, some degree of professional judgement will be required during the review. Since many published analytical procedures define data evaluation criteria, the mathematics involved, and the irregularities that may be intrinsic to certain types of samples, it is important that the data reviewer read and understand the analytical procedures being assessed.

6.3.3 Any changes made to any validation documentation shall be made by drawing a single line through the old entry, adding the new entry (if any), and initialing/dating the changes. Major changes (i.e. large portions of a page) may be made by drawing a single "X" through the page block, initialing, dating, and providing a brief note explaining the change.

6.3.4 All validation checklists shall be signed and dated by the reviewer, and reviewed, countersigned and dated by the Data Validation Manager.

6.3.5 An example of a validation checklist is included in this procedure (see Exhibit 5).

6.4 Reports

6.4.1 Data Validation Summary Reports shall be prepared to report the results of the validation review. Each summary report shall address the target samples and

analyses associated with an individual validation request.

6.4.2 All summary reports shall be addressed to the Data Verification Manager and shall include a copy to the Environmental Compliance Manager and to the Quality Assurance Department.

6.4.3 For Biased and Special validation requests, copies of the summary reports shall also be forwarded to the individual data requester. For Random validation requests, copies shall be forwarded to the ES&H Environmental Protection Manager.

6.4.4 Each summary report shall address at a minimum:
- WSSRAP Sample ID
- Analysis
- Lab Number
- Dataset Number
- Validation Qualifiers
- Accuracy and Precision
- Completeness for the Summary Report
- Analytical Deficiencies (if any)

6.4.5 Quarterly validation status reports shall be prepared and submitted to the Deputy Project Manager, Environmental Compliance Manager, ES&H Environmental Protection Manager, and the Quality Assurance Manager.

6.4.6 The quarterly status reports shall identify the quarterly completeness by laboratory, and shall identify the samples and analyses for which:
- validation documentation had been received during the quarter
- the validation review had been completed during the quarter
- the validation review is in progress
- the validation review is ON-HOLD, the reasons and the remedies

6.4.7 The quarterly status reports shall also calculate and report the percentages of validation requests made during the quarter for the bias and random requests. The percentage calculation shall be based on the total number of samples collected during the quarter versus the number of those samples for which validation requests have been made. If the requested percentage for a quarter falls below 5%, the Validation Manager shall notify the Verification Manager in writing in an effort to initiate additional requests to raise the percentage to at least 5%.

6.5 Qualifiers

6.5.1 Data validation qualifiers and flags shall be used to report the results of the data validation review in the WSSRAP database files (GURU). A qualifier shall be assigned to each and every parameter associated with an analysis. The qualifiers designate the validation status; the flags serve an informational purpose.

6.5.2 The validation qualifiers shall be assigned by the data reviewer and approved by the Data Validation Manager. Access rights to append, edit, or delete qualifiers in the qualifier field of the database files shall be limited to the Data Validation Group and the database administrators.

6.5.3 A list of Data Validation Qualifiers and Flags is provided as Exhibit 1. Additional qualifiers and flags may be implemented for use by the Data Validation Manager. Amendments to the qualifier list shall be issued to the data users when additions or changes are made.

6.5.4 The "N" qualifier (meaning not selected for data validation) shall be automatically assigned to the qualifier field of each new data record as it is received by the Data Verification Group from the laboratory.

6.5.5 When samples are selected for validation and their associated data deliverables are received, the "P" qualifier (meaning data validation is in progress) shall replace the "N" qualifier.

6.5.6 Upon completion of the validation review, the "P" qualifier shall be replaced with the qualifiers assigned to the data point based on the data quality determined during the review.

6.5.7 When information critical to the validation of the data is missing from the data deliverables package, or when data in the WSSRAP database files are incorrect, the data shall be placed on-hold using the "O" qualifier. Reasons for the on-hold status, actions taken to remedy the situation, and follow-up actions shall be documented Data Validation ON-HOLD Form (Exhibit 3) and maintained with the dataset.

6.5.8 In the cases where critical information needed for validation is missing and is unlikely to be retrieved from the laboratory, the affected data are to be determined non-validatable and labeled with an "X" qualifier. The non-validatable status shall be documented on the Data validation NON-VALIDATABLE form (Exhibit 4) and maintained with the dataset.

NOTE: When data are non-validatable, the data users are encouraged to take alternate means to substitute those data points with other data points (i.e., use other samples or resample and reanalyze.

6.6 Software Controls

Computerized software needed for data validation is commercially available (i.e., Quattro Pro, Lotus 1-2-3, dBase III, and dBase IV) and requires adherence to manufacturer controls only.

7.0 RECORDS

7.1 Data validation records, including checklists, spreadsheet printouts, logs, notes, and laboratory analytical records, shall be maintained on file with the data validation group

while they are active and validation reviews are in progress. Information pertaining to a specific dataset shall be filed numerically by dataset number.

Information pertaining to a specific dataset are to be filed numerically by laboratory and dataset number. Information that relates to numerous datasets (i.e. initial calibrations, instrument tunes, extraction/digestion records, custody transfer records) shall be maintained in master files and shall be filed by laboratory and type and in chronological order.

7.2 The data validation filing cabinets shall be kept locked and custody maintained by the Data Validation Manager.

7.3 Originals of the data validation records shall be transmitted to the Quality Assurance Department for retention as QA records in accordance with QAPP-9 as soon as practical upon completion of the validation review process and after the records are no longer active or in use.

8.0 EXHIBITS

Exhibit 1 - WSSRAP Data Validation Qualifier List
Exhibit 2 - Data Validation Tracking Record

Exhibit 4 - Data Validation NON-VALIDATABLE Listing Form
Exhibit 5 - Example Validation Checklist

EXHIBIT 1
WSSRAP DATA VALIDATION QUALIFIER LIST

WSSRAP DATA VALIDATION QUALIFIER LIST

QUALIFIER

4 (or A+)	-	Data meeting all QA/QC requirements.
3	-	Good quantitative data not meeting all objective QA/QC requirements, but are generally valid.
2	-	Data that are adequate for semi-quantitative comparisons (i.e., the order of magnitude of the reported value is credible, but the exactness of the value is questionable).
1	-	Data that are adequate for a qualitative assessment (i.e., the target analyte is a real artifact, not contamination), but have no quantitative validity.
A	-	Acceptable, but has restrictions.
V	-	Data that appear to be valid based on data from identical sampling locations or by comparison to historical records.
R	-	Data that are not valid.
N	-	Data not petitioned for validation; or validation documentation not yet received from the laboratory.
O	-	Validation Technical Review ON-HOLD.
P	-	Validation Technical Review IN-PROGRESS or PENDING.
X	-	Data not validatable.

FLAGS[1]

>	-	High Bias (i.e., accuracy > DQO limit)
<	-	Low Bias (i.e., accuracy < DQO limit)
C	-	Calibration/Quantitation Deficiencies
Q	-	Quality Control Deficiencies
I	-	Qualitative Deficiencies or Instrument Interferences Present
B	-	Contamination or High Background Present
H(##)	-	Holding Times Exceeded (#days exceeded for prep/analysis)
F	-	Matrix-Related Interferences Present
J	-	Estimated Value (may be linked with other flags)
Y	-	Custody Deficiencies
T	-	Typographical/Mathematical Error
M	-	Poor Matrix Spike Recoveries (matrix accuracy)
D	-	Poor Duplicate RPD (precision)
?	-	Other (see applicable validation report)

NOTE: Other flags may be added as needed.

---

1 To be used in conjunction with any of the above qualifiers, except for qualifier 4 or A+, which by definition shall stand alone.

MERCURY BY COLD VAPOR ATOMIC ABSORPTION (CVAA)

II. PRELIMINARY REVIEW

Check Action

	A. Assign Analytical Sequence Numbers to the instrument printout.
	B. Prepare Analytical Sequence Run Log if not provided by the laboratory.
	C. Prepare a Sample Qualifier Summary for each sample.

III. DOCUMENT SUBMITTAL

A. CLP Data Forms

Check the list of documents below that have been received for validation. If "Not Applicable" check "NA". If the document item is required and has not been received, place the sample ON-HOLD and request the documents from the laboratory.

Y	N		
		1. Organic Cover Page	
		2. Sample Data Sheets(FORM I)	
		3. Calibrations (FORM IIA)	
		4. Blanks (FORM III)	
		5. Matrix Spike (FORM V)	
		6. Duplicate (FORM VI)	
		7. LCS (FORM VII)	
		8. Holding Times (FORM X)	
		9. IDLs (FORM XIII)	REQUIRED
		10. Prep Log (FORM XIII)	
		11. Analysis Log (FORM XIV)	

B. Raw Data

Check the list of documentation below that have been received for validation. If "Not Applicable" check "NA". If the document item is applicable and required and has not been received, place the sample ON-HOLD and request the documents from the laboratory. If item has not been performed by lab, check "X".

Y	NA	X		
			1. Target Samples	REQUIRED
			2. Calibration Standards	REQUIRED
			3. Blanks	REQUIRED
			4. Matrix Spike	REQUIRED
			5. Duplicates	REQUIRED
			6. LCS	REQUIRED

EXHIBIT 5
EXAMPLE VALIDATION CHECKLIST

Dataset#:_____

WSSRAP DATA VALIDATION REVIEW CHECKLIST —
MERCURY BY COLD VAPOR ATOMIC ABSORPTION (CVAA)

C. True Values

Check the list of true values below that been received for validation. If "Not Applicable", check "NA". If the information is required and has not been received, place the sample ON-HOLD and request the information from the laboratory. If the item has not been performed by lab, check "X".

Y	NA	3X		
			1. Initial Calibration Verification	REQUIRED
			2. Continuing Calibration Verification	REQUIRED
			3. Laboratory Control Sample	REQUIRED

D. Other

Check the list of documentation below that have been received for validation. If "Not Applicable", check "NA". If the document is required and has not been received, place the sample ON-HOLD and request the document from the laboratory.
NOTE: The WSSRAP Custody Sheet may be retrieved from Data Verification.

Y	NA		
		1. Sample Digestion Log	REQUIRED
		2. % Solids Data	
		3. WSSRAP Custody Sheet	
		4. Laboratory Custody Sheet	
		5. Case Narrative	

COMMENTS:

IV. TECHNICAL REVIEW

A. Calculation Confirmation

When checking or confirming any calculation, place a check mark next to the data item on the form or spreadsheet to show the item has been checked. The recommended spreadsheet to confirm calculations for the related items is listed below in parentheses for each item.

Check Action

- [ ] 1. Holding Time Calculations (DV Form HG 1)
- [ ] 2. WSSRAP Sample Data Calculations (DV Form HG 2)
- [ ] 3. Calibration Verifications Calculations (DV Form HG 3)
- [ ] 4. Preparation Blank Calculations (DV Form HG 5)
- [ ] 5. Calibration Blank Calculations (DV Form HG 5)
- [ ] 6. Matrix Spike Calculations (DV Form HG 6)
- [ ] 7. Sample Duplicate Calculations (DV Form HG 7)
- [ ] 8. Laboratory Control Sample Calculations (DV Form HG 8)

For the following sections, a set of criteria are listed. If a given criterion is not met, a recommended Data Validation action is listed. These actions are only recommendations and may be changed or omitted (with comment) by the data reviewer. If an item is not applicable, enter "NA".

[ ] B. Sample Integrity

Criteria	If Criteria not met....
Sample Custody: o Documented with signatures by WSSRAP samplers and lab custodian.	o -"Y" flag the affected sample data.
Sample Preservation o Documented on custody sheet Nitric acid to pH < 2 for aqueous samples; 4°C±2°C for non-aqueous samples	o -Handled on a case-by-case basis.
Holding Times o analysis completed with 26 days or less from sample date for aqueous and non-aqueous samples.	o -"H" flag all affected data. o -If negative and exceeded by > 10 days, REJECT all affected data. o -If positive and exceeded by > 10 days, "J" flag all affected data.
Data Consistency o No improper manipulations, font changes, time gaps, auto-zeroing, etc. are present with data.	o -Handled on a case-by-case basis.

Dataset#:_____

WSSRAP DATA VALIDATION REVIEW CHECKLIST
MERCURY BY COLD VAPOR ATOMIC ABSORPTION (CVAA)

[ ] C. Wavelengths

Mercury measurements are typically made at 253.7 nm. Note if the wavelength used is other than 253.7 nm.

[ ] D. Instrument Calibration

Criteria	If Criteria not met....
Initial Calibration: o performed with each analytical run o consists of 4 stds and 1 blk o correlation coefficient ≥0.995	o -REJECT ALL ASSOCIATED DATA & "C" FLAG. o -if consists of 3 stds and blk, "Q" flag all associated data o -if 2 stds or less, REJECT ALL ASSOCIATED DATA & "C" FLAG. o -"C"flag all associated data.

Correlation Coefficient:	Y Intercept:	Slope:

Verification Checks: o performed 1 per 10 samples or per 2 hours o % recovery between 80-120%	o -"Q" flag all samples not within 6 samples of a CCV. o -if within 65-79%, "C" flag associated data. o -if within 121-135%, "C" flag positive data. o -if < 65%, REJECT DATA & "C" flag. o -If > 135%, REJECT POSITIVE DATA & "C" flag.
Calibration Blanks: o performed 1 per 10 samples or per 2 hours o absolute value ≤ CRDL	o -"Q" flag all samples not within 6 samples of a CCB. o -Evaluate closely; reject & "B" flag if necessary

[ ] E. Preparation Blank

Criteria	If Criteria not met...
o performed at least 1 prep blank per matrix o performed 1 prep blk/20 samples or batch o sample once. < 10X prep blank conc.	o -If sample data > IDL, REJECT & "B" FLAG. o -"Q" flag all positive data. o -REJECT AFFECTED DATA & "B" FLAG.

If more than 1 prep blank, use the blank with highest concentrations.

Dataset#_____

WSSRAP DATA VALIDATION REVIEW CHECKLIST
MERCURY BY COLD VAPOR ATOMIC ABSORPTION (CVAA)

[ ] F. Laboratory Control Sample

Criteria	If Criteria not met....
o performed at least 1 LCS per matrix NOTE: An aqueous LCS is not required for Mercury, per CLP. o performed 1 LCS per 20 samples or batch	o -REJECT ASSOCIATED SAMPLE DATA & "Q" FLAG. o "Q" flag all associated data.
Aqueous LCS: o % recovery between 80-120%.	o -If > 120% & sample data negative, no action o -If > 120% & sample data positive, ">" flag. o -If between 50-79%, "<" flag associated data. o -If < 50%, REJECT ASSOCIATED DATA & "<" FLAG.
Non-Aqueous LCS o % recovery within established control limits	o -If > upper limit & sample data negative, no action. o -If > upper limit & sample data positive, ">" flag. o -If < lower limit, "<" flag all associated data.

[ ] G. Sample Duplicates

Criteria	If Criteria not met....
o performed 1 dup pair/20 samples or batch (excluding field blanks)	o -"Q" flag associated data. Note that precision measurements are not available.
Aqueous Samples IF both Sample conc. ≥5X CRDL o RPD ≤ 20% ELSE either Sample conc. <5X CRDL o Diff < CRDL	 o -"D" flag associated data. o -"D" flag associated data.
Non-Aqueous Samples If both Sample conc. ≥ 5X CRDL o RPD ≤ 35% ELSE either Sample conc. < 5X CRDL o Diff < 2X CRDL	 o -"D" flag associated data. o -"D" flag associated data.

NOTE: If the sample duplicate data are rejected based on the criteria listed above AND these duplicates are the only source of precision for the analytical lot, the precision value from these duplicates are not useable and the target sample data should be "D" flagged and noted that PRECISION DATA ARE NOT AVAILABLE.

 Dataset#_____

WSSRAP DATA VALIDATION REVIEW CHECKLIST
MERCURY BY COLD VAPOR ATOMIC ABSORPTION (CVAA)

☐ H. Matrix Spike

Criteria	If Criteria not met....
o performed 1 MS per 20 samples or batch	o -"Q" flag associated data
o % recovery between 75-125% AND sample conc. < 4X spike level	o -if > 125% and sample data negative, no action. o -if > 125% and sample data positive, "M" flag associated data. o -If < 30% and negative, REJECT ASSOCIATED DATA AND "M" FLAG. o -If < 30% and positive, "M" flag associated data.

☐ I. WSSRAP Field Samples

Criteria	If Criteria not met....
o no observed transcription, mathematic, or other errors observed o all readings within the HG curve linear range o all IDLs ≤ CRDL	o -If necessary, place data ON-HOLD UNTIL ERROR IS CORRECTED o -"C" flag all data over range. o -REJECT AND "C" FLAG ALL DATA < applicable IDL.

J. Supplemental Validation Checklists/Forms

☐ 1. DV HG 1 - Holding Time Assessment
☐ 2. DV HG 2 - Sample Data Summary
☐ 3. DV HG 3 - Calibration Verifications
☐ 4. DV HG 5 - Prep and Cal Blanks
☐ 5. DV HG 6 - Matrix Spike
☐ 6. DV HG 7 - Sample Duplicates
☐ 7. DV HG 8 - Lab Control Sample (LCS)
☐ 8. DV GEN 1 - Analytical Sequence
☐ 9. DV GEN 2 - Metals Qualifiers Summary (1 per sample)
☐ 10. DV Review Checklist for EP Tox/TCLP Method of Standard Addition
☐ 11. Other (list)

Notes: (attached additional pages if necessary)

It is appropriate for the data reviewer to make professional judgements and express concerns and comments on the validity of the overall data in this dataset. This is particularly appropriate when there are several QC criteria out of specification. The additive nature of QC factors out of specification is difficult to assess in an objective manner, but the reviewer has a responsibility to inform the data users concerning data quality and data limitations in order to assist those users from inappropriate use of the data, while not precluding any consideration of the data at all. As a consequence, it may often be necessary for the data reviewer to use subjective means when assigning the final qualifiers (A, 1,2,3,4,R,V) to the data in this dataset.

Database Change Indicators

Indicator	Modification
OK	No modification - accurate as originally reported
V	Value in Concentration Field
P	Parameter spelling
C	Category spelling/assignment
E	Value in Radiological Field
U	Units of measure assignment
M	Missing or new add record
ND3	Values below CRDL to "ND" value
T	Change in record due to 12K data points validation results

ATTACHMENT F
LISTING OF 12000 DATA POINTS VALIDATED

ATTACHMENT G
CALIBRATION CRITERIA

ATTACHMENT G

Calibration Criteria for Volatiles & Semi-Volatiles by GCMS
(based on UPEPA CLP requirements)

I. Calibrations for the Control Compounds

A. Control compound present in sample

1. % RSD criteria not met in initial[1]

a. initial RRF20 closer to 1 than mean RRF

1) daily RRF closer to 1 than mean RRF
-if conc. < 20 ppb[2]; reject & flag (C)
-if conc. ≥ 20 ppb; accept & flag (CJ)

2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. initial RRF20 farther from 1 than mean RRF

1) daily RRF closer to 1 than mean RRF
-if conc. < 50 ppb[3]; reject & flag (C)
-if conc. ≥ 50 ppb; accept & flag (CJ)

2) daily RRF farther from 1 than mean RRF; reject & flag (C)

2. % RSD criteria met in the initial

a. % Diff criteria not met in daily

1) daily RRF closer to 1 than mean RRF
-if conc. < 50 ppb; reject & flag (C)
-if conc. ≥ 50 ppb; accept & flag (CJ)

---

1 Curve not linear

2 Level of the lowest initial calibration standard (use 660 ug/kg for soils)

3 Level of the daily calibration standard (use 1600 ug/kg for soils).

2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. % Diff criteria met in daily; accept

B. Control compound <u>not</u> present in sample

1. % RSD criteria not met in initial[4]

a. initial RRF20 closer to 1 than mean RRF

1) daily RRF closer to 1 than mean RRF; accept & flag (C)
2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. initial RRF20 farther from 1 than mean RRF

1) daily RRF closer to 1 than mean RRF; accept & flag (CJ)
2) daily RRF farther from 1 than mean RRF; reject & flag (C)

2. % RSD criteria met in the initial

a. % Diff criteria not met in daily

1) daily RRF closer to 1 than mean RRF; accept & flag (C)
2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. % Diff criteria met in daily; accept

[4] The non-linearity of the initial curve may not effect the ND result for the compound(s).

II. Calibrations for the NON-Control Compounds

A. Compound present in sample

1. % RSD from initial > 30%; accept & flag (CJ)
2. % RSD from initial ≤ 30%

a. % Diff from daily > 25%; accept & flag (CJ)
b. % Diff from daily ≤ 25%; accept

B. Compound <u>not</u> present in sample

1. % RSD from initial > 30%; accept & flag (C)
2. % RSD from initial ≤ 30%

a. % Diff from daily > 25%; accept & flag (C)
b. % Diff from daily ≤ 25%; accept

ATTACHMENT G
CALIBRATION CRITERIA

ATTACHMENT G

Calibration Criteria for Volatiles & Semi-Volatiles by GCMS
(based on UPEPA CLP requirements)

I. Calibrations for the Control Compounds

A. Control compound present in sample

1. % RSD criteria not met in initial[1]

a. initial RRF20 closer to 1 than mean RRF

1) daily RRF closer to 1 than mean RRF
-if conc. < 20 ppb[2]; reject & flag (C)
-if conc. ≥ 20 ppb; accept & flag (CJ)

2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. initial RRF20 farther from 1 than mean RRF

1) daily RRF closer to 1 than mean RRF
-if conc. < 50 ppb[3]; reject & flag (C)
-if conc. ≥ 50 ppb; accept & flag (CJ)

2) daily RRF farther from 1 than mean RRF; reject & flag (C)

2. % RSD criteria met in the initial

a. % Diff criteria not met in daily

1) daily RRF closer to 1 than mean RRF
-if conc. < 50 ppb; reject & flag (C)
-if conc. ≥ 50 ppb; accept & flag (CJ)

---

1 Curve not linear

2 Level of the lowest initial calibration standard (use 660 ug/kg for soils)

3 Level of the daily calibration standard (use 1600 ug/kg for soils).

2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. % Diff criteria met in daily; accept

B. Control compound not present in sample

1. % RSD criteria not met in initial[4]

a. initial RRF20 closer to 1 than mean RRF

1) daily RRF closer to 1 than mean RRF; accept & flag (C)
2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. initial RRF20 farther from 1 than mean RRF

1) daily RRF closer to 1 than mean RRF; accept & flag (CJ)
2) daily RRF farther from 1 than mean RRF; reject & flag (C)

2. % RSD criteria met in the initial

a. % Diff criteria not met in daily

1) daily RRF closer to 1 than mean RRF; accept & flag (C)
2) daily RRF farther from 1 than mean RRF; reject & flag (C)

b. % Diff criteria met in daily; accept

[4] The non-linearity of the initial curve may not effect the ND result for the compound(s).

II. Calibrations for the NON-Control Compounds

A. Compound present in sample

1. % RSD from initial > 30%; accept & flag (CJ)
2. % RSD from initial ≤ 30%

a. % Diff from daily > 25%; accept & flag (CJ)
b. % Diff from daily ≤ 25%; accept

B. Compound <u>not</u> present in sample

1. % RSD from initial > 30%; accept & flag (C)
2. % RSD from initial ≤ 30%

a. % Diff from daily > 25%; accept & flag (C)
b. % Diff from daily ≤ 25%; accept

QUARTERLY ENVIRONMENTAL DATA SUMMARY, FOURTH QUARTER 1991

Enclosed for your information and use is a copy of the Quarterly Environmental Data Summary. This document summarizes the environmental monitoring data for the Fourth Quarter 1991, highlights any potentially significant findings, and offers preliminary interpretations. Final interpretations will appear in the 1991 Annual Site Environmental Report.

The report concludes that no significant differences or changes have occurred at the Weldon Spring Site Remedial Action Project (WSSRAP) during the reporting period.

If you have any questions, please call Alan Gibson.

Sincerely,

Stephen H. McCracken
Project Manager
Weldon Spring Site
Remedial Action Project

ABSTRACT AND WELDON SPRING SITE QUARTERLY SELF ASSESSMENT FOURTH QUARTER 1991

The purpose of this Quarterly Environmental Data Summary is to provide to the public preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative intepretations. Validated data and final interpretations will appear in the 1991 Annual Site Environmental Report.

This report includes preliminary data from environmental monitoring activities at the Weldon Spring site (WSS) during the fourth quarter of 1991. Groundwater, surface water, and air were sampled in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to calculate exposure doses (where applicable) and assess the impact of the contaminants at the site on potentially exposed populations.

In summary, no significant differences were observed in off-site exposures during the fourth quarter of 1991 relative to exposures calculated in previous quarters. Contaminated groundwater did not affect the St. Charles County well field. Surface water containing elevated uranium activity continued to impact the Femme Osage Slough. Off-site gamma results are not available at this time; however, off-site radon, and air particulate exposures remained indistinguishable from background. Off-site monitoring demonstrated that exposure levels at the Francis Howell High School, the Busch Wildlife Area Headquarters, and the Weldon Spring Training Area remain indistinguishable from background levels.

1 INTRODUCTION

This document is the seventh in a series of documents designed to provide a summary of the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These documents supplement the *Annual Site Environmental Report* (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the *WSSRAP Environmental Monitoring Plan* (EMP) (MKF and JEG 1991) and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from observations made in previous reports. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1991 ASER. It is recommended that interested readers refer to previous EMPs, ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters is tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at 314-441-8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). However, because of delays in data delivery from the analytical laboratories, some of the data that was expected to be included in this report are not yet available for reporting. The unavailability of data is due to a nationwide shortage in analytical services. These data will be reported in the 1991 ASER. Sludges, soils, and biological specimens are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater and air pathways. These analyses will be presented in the 1991 ASER. Quality control (QC) data for the fourth quarter and all other quarters will be presented in the 1991 ASER.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring Quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

The groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a semi-annual basis with the exception of MW-2001, MW-2002, MW-2003, MW-3003, MW-3006, MW-3008, MW-3009, MW-3023, MW-4012, and MW-4013 which are monitored quarterly for uranium, nitrate, sulfate, and metals. Monitoring well locations are shown in Figure 2-1.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the semiannually monitored groundwater wells at the WSCP/RP/VP area. Nitroaromatic compounds were detected in seven samples for which data are currently available. Concentration levels for these compounds are within their historical range.

2.1.2 Radiological Results

The radiological results for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-2. The upper bound for natural uranium background concentration in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l (MKF and JEG 1989). The U.S. Environmental Protection Agency (EPA) has not yet established a drinking water standard for uranium; however, the proposed maximum contaminant level (MCL) currently set at 20 μg/l which is equal to 12 pCi/l using site specific conversion factors. The U.S. Department of Energy (DOE) has a health-based, derived concentration guideline (DCG) of 600 pCi/l in surface water effluent.

NA - Not Available

The highest uranium level detected from the available data was 15.3 pCi/l from a sample obtained from monitoring well MW-4020. The concentrations reported in Table 2-2 continue to indicate levels below the proposed drinking water standard for uranium.

2.1.3 Sulfate and Nitrate Results

Sulfate and nitrate concentrations are given in Table 2-2. The fourth quarter results are similar to historical ranges for these parameters.

2.1.4 Geochemical Results: Metals and Inorganic Anions

Geochemical parameters were added to the *Environmental Monitoring Plan* for the 1991 monitoring year. Results of analyses for samples from quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-3. Concentrations from most geochemical constituents are similar to their previously measured levels; however, nickel and bromide concentrations display a notable drop to NDs from previously measurable levels. These changes in nickel and bromide are thought to reflect an analytical discrepancy and are currently being investigated.

2.2 Weldon Spring Quarry

Chemical and radiological wastes at the quarry are of particular concern because of their proximity to the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mi) to the south of the Weldon Spring Quarry. Monitoring of contaminants in groundwater and the protection of the well field is a top priority at the Weldon Spring Site Remedial Action Project (WSSRAP).

Groundwater is currently being monitored in 48 wells in and around the quarry. Thirty-six monitoring wells installed by the DOE currently exist in or near the quarry. Four monitoring wells were installed by St. Charles County in 1986 and are currently included in the DOEs monitoring program. Eight St. Charles County municipal wells are also included in the DOEs monitoring program. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells draw water from both bedrock and alluvial aquifers.

WELDON SPRING QUARRY, FEMME OSAGE SLOUGH, & ST. CHARLES CO. WELL FIELD MONITORING LOCATIONS

FIGURE 2-3

REPORT NO:	DOE/OR/21548-257	EXHIBIT NO.:	A/QY/121/1291		
ORIGINATOR:	CSJ	DRAWN BY:	GLN	DATE:	12/91

Two separate groundwater monitoring programs have been developed for the quarry. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough and MW-1010 and MW-1011. Also note that MW-1035, MW-1036, MW-1037, MW-1038, and MW-1039 will be sampled monthly until operation of the Weldon Spring Quarry water treatment plant is initiated. The second program is the quarterly sampling of all wells south of the Femme Osage Slough, excluding MW-1010 and MW-1011 but including the St. Charles County well field. Both the raw and treated waters from the St. Charles County water treatment plant are also sampled.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-4, 2-5, and 2-6 for samples collected on a bimonthly and quarterly basis. The results show typical fluctuations near the average levels in the WSQ area with the exception of MW-1006. Uranium concentrations in this well were higher than recent values but did not exceed recent results for MW-1004 which appears to be hydrologically related.

2.2.2 Nitroaromatic Compounds Results

Analytical results for nitroaromatic compounds are presented in Tables 2-7, 2-8, and 2-9. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the fourth quarter of 1991. The distribution and magnitude of nitroaromatic contamination near the quarry remains unchanged.

2.2.3 Inorganic Anions Results

Two inorganic anions--nitrate and sulfate--were measured in quarry wells. The analytical results for fifth and sixth bimonthly periods and the fourth quarter are presented in Tables 2-4, 2-5, and 2-6, respectively. These results are consistent with data reported in the previous environmental monitoring reports. The WSQ groundwater samples continue to indicate no significant nitrate contamination of the groundwater. The high nitrate value of 3020 mg/l in RMW3-Q491 is attributed to a sampling error. This sample appears to have been inadvertently preserved with nitric acid.

TABLE 2-4 Fifth Bimonthly (Sept/Oct) Inorganic Anions and Radiological Results in Groundwater at the Weldon Spring Quarry

2.2.4 Metals Results

A selected group of quarry wells located south of the Femme Osage Slough are sampled for arsenic and barium. Analytical results of these metals are given in Tables 2-10, 2-11 and 2-12. Results from the fifth and sixth bimonthly and fourth quarter analyses of arsenic and barium continue to indicate elevated concentrations in a few wells. The highest levels reported are 169 μ/l for arsenic and 1050 μ/l for barium, both from MW-1017. The high Ba value (5380 μg/l) reported for GW-RMW3-Q391 in the third quarter Quarterly Environmental Data Summary (QEDS) was a typographical error and should be changed in 538 μg/l.

3 SURFACE WATER MONITORING

Routine samples were collected during the fourth quarter of 1991 from both on-site and off-site surface water and spring locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1991 Annual Site Environmental Report (ASER).

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the fourth quarter, surface water samples were collected from the 13 surface water sampling locations shown in Figure 3-1 and analyzed for uranium. The results, presented in Table 3-1, indicate that conditions remain similar to historical values.

3.2 Weldon Spring Quarry

Surface water samples were collected for uranium analyses from the 10 locations shown in Figure 3-2 and three locations in Figure 3-3. The results are presented in Table 3-2. Samples were collected from sampling locations SW-1003, SW-1004, SW-1005, SW-1007, SW-1009, and SW-1010 on a monthly basis to monitor slightly elevated uranium concentrations noted in the Quarterly Environmental Data Summary (QEDS) for the first and second quarters of 1991. Fourth quarter uranium concentrations for these locations are similar to lower pre-1991 values. The highest measured uranium concentration (1,950 pCi/l) was detected at the quarry pond (sampling location SW-1008) and is within the historical range for this site. Nitroaromatics, radionuclides, nitrate, and sulfate were measured for SW-1008 and are presented in Table 3-3. Concentrations of these constituents are similar to previously measured levels.

The fourth quarter uranium values measured for the Missouri River (SW-1011, SW-1012, and SW-1013) are similar to the third quarter values. In addition to the quarterly Missouri River samples, filtered and unfiltered samples (indicated by FI and NF in Table 3-2) were analyzed to evaluate the source of historical fluctuations in uranium concentrations at these locations as described in the Third Quarter QEDS. The fourth quarter data display little variation, either among the filtered and unfiltered samples from a single locale, or among samples from the three locales.

3.3 Springs

Nine springs around the Weldon Spring site (WSS) are sampled during fourth quarter (see Figure 3-4 for spring locations). Previous spring monitoring indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs include SP-5301 through SP-5304, SP-6301, SP-6302, and SP-6306. All spring samples are analyzed for uranium with a select few also analyzed for nitroaromatics, inorganics and metals. Available analytical results for these parameters are listed in Tables 3-4, 3-5, and 3-6. Values for these parameters remain consistent with historical values.

3.4 National Pollutant Discharge Elimination System Data Review

Surface water and effluent samples were collected and analyzed in compliance with the Weldon Spring site NPDES permits. Permit No. MO-0107701 was issued on October 1, 1990, and currently addresses the five storm water and two wastewater discharges shown in Figure 3-5. Outfalls NP-0001 through NP-0005 represent storm water discharges; Outfall NP-0006 represents the treated effluent discharge associated with the administration building sanitary wastewater treatment plant; and Outfall NP-0007 represents the site contaminated water treatment plant, which is under construction, but not yet completed. There was no discharge from NP-0007. Outfalls NP-0006 and NP-0007 have effluent limitations. The five storm water outfalls have monitoring requirements only. Fourth quarter 1991 analytical data for each outfall is presented in Table 3-6. Permit No. MO-0108987 was issued on May 5, 1989, for Outfall NP-1001 of the Weldon Spring Quarry contaminated water treatment plant. The plant construction is not completed, and no discharge took place during the fourth quarter of 1991.

3.4.1 Radiological Analysis

Gross alpha and total uranium analyses corresponded reasonably well with past data. The highest uranium levels were present in surface flow from Outfalls NP-0001, NP-0002, NP-0003, and NP-0005. The peaks for these points were 220 pCi/l, 332 pCi/l, 313pCi/l, and 614 pCi/l, respectively. Outfall NP-0004 had a uranium concentration of 9.98 pCi/l from a single sample analysis. Although not required by the NPDES permit, the outfall from the administration building sanitary wastewater treatment plant (Outfall NP-0006) was also monitored for total uranium. No uranium was detected at this outfall.

3.4.2 Other Analysis

Other analyses for NP-0001 through NP-0005 included physical analyses (settleable solids and total suspended solids) and chemical analyses (nitrate, pH, and lithium). Fourth quarter 1991 values generally correspond to past values for the majority of parameters. Four exceptions were high total suspended solids (TSS) values for Outfalls NP-0001, NP-0003, and NP-0004 and high settlable solids (SS) for Outfall NP-0005. The elevated values of TSS for outfalls NP-0001 and SS for NP-0005 were caused by surface water runoff from off-site water line construction activity and by excavation for the site water treatment plant. The elevated TSS at Outfall NP-0003 may have been due to the collection of floating debris; no other unusual circumstances were noted. The elevated value of TSS at NP-0004 may have been caused by stream bed disturbance during sample collection since very low flow in the shallow stream channel makes it difficult to collect a sample without stirring up small amounts of sediment.

The discharge from the administration building treatment plant, Outfall NP-0006, has effluent limitations and a requirement to monitor once per quarter. Flow must be measured once a month. The Subcontractor monitors the effluent once a month to assess plant performance, thus generating two additional sample analyses a quarter. The NPDES permit specifies effluent limitations for biochemical oxygen demand (BOD), total suspended solids (TSS), pH, and fecal coliform at this outfall. The limits for BOD are 10 mg/l monthly average and 15 mg/l weekly average; for TSS, 15 mg/l monthly average and 20 mg/l weekly average; for fecal coliform, 400 colonies per 100 ml monthly average and 1,000 colonies per 100 ml daily maximum. During the quarter, the effluent exceeded permitted limits four times; once for each of the four parameters. On November 13, 1991, BOD was 13.9 mg/l, which exceeded the monthly average limit of 10 mg/l; fecal coliform was 2,100 colonies/100 ml; which exceeded the daily maximum of 1,000 and the monthly average limit of 400 colonies/100 ml. On December 4, 1991, TSS was 24, which exceeded the weekly average limitation of 20 mg/l. An additional sample was collected on December 18, 1991, for TSS with a resultant value of 10 mg/l. The two samples average out to 17 mg/l, which is over the monthly average limit of 15. On October 4, 1991, pH was measured at 5.8 which is outside the permitted range of 6.0 to 9.0 (standard units). The Subcontractor added lime to the aeration compartment to increase the pH to above 6.0.

The Subcontractor will test the total residual chlorine of the effluent and inspect the chlorinator three times a week to ensure that the chlorine tablet supply is adequate. This should allow fecal coliform limits to be met. Sewage is delivered to the treatment plant by a lift station

causing an uneven flow which could cause high BOD, TSS, and fecal coliform levels. To foster a more consistent and effective treatment of the administration building wastewater, a flow equalization tank will be installed between the lift station and the sewage treatment plant. A request for specifications and an engineering proposal have been sent to an off-site A/E firm with oversight by our Engineering Department. The revised specifications for wastewater treatment facility services are under final review. The specifications will require the Subcontractor to sample the effluent during the first seven days of the calendar month and telephone or fax the results to the Project Management Contractor (PMC) as soon as they are available. The PMC will ensure that these requirements are met. This will allow time for additional sampling by the Subcontractor or the PMC if it is required.

A characterization sample was collected from Outfall NP-0006 on December 6, 1991. The sample was analyzed for the following parameters and the results are shown in parentheses: uranium-natural (ND), gross alpha (ND) and pH (5.3).

4 AIR MONITORING

4.1 Radon Gas

The radon gas monitoring program utilizes a pair of radon detectors at each of 22 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, six locations at the Weldon Spring Quarry, four locations at the Weldon Spring raffinate pits, and six off-site locations. Radon monitoring locations are shown in Figures 4-1, 4-2, and 4-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, and RD-4006 were used to monitor background levels near the site.

Table 4-1 summarizes the fourth quarter 1991 radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in Table 4-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (110 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the four background locations. This data yielded an average ambient background radon concentration of 0.2 pCi/l for the fourth quarter of 1991. This concentration was then subtracted from the concentration for each monitoring station, and compared to the DOE guideline of 3 pCi/l above background.

Radon concentrations at the site and quarry perimeters and at off-site locations for the fourth quarter of 1991 were within the typical range expected during periods of normal precipitation as was the condition for this period. The quarterly radon concentrations (background included) ranged from 0.1 pCi/l at four monitoring locations to 1.8 pCi/l at monitoring location RD-1002.

Radon concentrations found in the quarry are higher than concentrations measured at other locations because the radium concentrations in quarry wastes are typically much higher than other areas, and because the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high. In conjunction with stable meteorological conditions,

* Denotes Background Station

this configuration tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

4.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, spherical environmental thermoluminescent dosimeters (TLDs) were deployed at 22 locations. The gamma monitoring station locations are the same as the ambient radon monitoring locations (see Section 4.1).

Table 4-2 summarizes the first, second, and third quarter results of total gamma radiation monitoring at the 16 Weldon Spring site (WSS) perimeter monitoring stations, the Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the four background monitoring stations.

The annual average background gamma exposures measured with TLDs in 1989 and 1990 were 68 mR/year and 62 mR/year, respectively. The gamma exposures measured with TLDs in the first, second, and third quarter of 1991 were consistent with 1989 and 1990 data. This was expected because no significant changes in the configuration or location of the wastes have occurred.

The fourth quarter data was not available when this document was drafted. The data will be available upon request and will be included in the 1991 *Annual Site Environmental Report*.

4.3 Radioactive Air Particulates

Eleven low volume air particulate samplers monitor the Weldon Spring site continuously. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter as shown in Figure 4-3. Three monitoring stations (AP-4006, AP-4008, and AP-4011) are located off site at sensitive receptor locations; including Francis Howell High School; the Army Reserve property; and near a residential site west of the quarry. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown in Figure 4-2.

NA Not available

The sampling station near the August A. Busch Wildlife Area (ABWA) headquarters is used as a background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/Weldon Spring raffinate pits (WSRP).

Table 4-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging either the weekly air particulate analysis results or the counting instrument's lower limit of detection (LLD), whichever was greater. The "<" sign in Table 4-3 appears when the actual average is less than the calculated average due to the use of LLD values in the calculation. The standard deviation for each of the monitoring locations was calculated using only results that were above the LLD. Due to maintenance, all monitors were not operating the entire 13 weeks as indicated in Table 4-3. However, the sensitive receptor monitoring stations (AP-4006, AP-4008, and AP-4011) were in operation the entire quarter and these stations are also equipped with high volume air monitoring. The high volume air monitors are part of the WSS radionuclide National Emissions Standards for Hazardous Air Pollutants (NESHAPs) requirements and were in operation the fourth quarter. The high volume monitoring results will be presented in the *Annual Site Environmental Report*.

The fourth quarter net alpha concentrations ranged from $< 1.47 \times 10^{-15}$ μCi/ml to $< 1.81 \times 10^{-15}$ μCi/ml with 1.64×10^{-15} μCi/ml detected at the background station.

4.4 Asbestos

No environmental asbestos monitoring was performed in the fourth quarter of 1991.

QUARTERLY ENVIRONMENTAL DATA SUMMARY, FIRST QUARTER 1992

Enclosed for your information and use is a copy of the Quarterly Environmental Data Summary. This document summarized the environmental monitoring data for the first Quarter 1992, highlights any potentially significant findings, and offers preliminary interpretations. Final interpretations will appear in the 1992 Annual Site Environmental Report.

Two items were highlighted in the document. First, toluene was detected in nine samples. Toluene is not a contaminant at the WSSRAP. After data validation rejected the nine suspect data points and negative results were obtained on resampling, further investigation revealed that the tape used to secure labels to the sample vials was a likely source for the sample contamination. Second, methylene chloride was detected in one sample. Methylene Chloride, used to clean laboratory glassware, is one of the most common laboratory contaminants. Data validation rejected this suspect data point.

In summary, no significant differences were observed in off-site exposures during the first quarter of 1992 relative to previous quarters.

If you have any questions, please call Alan Gibson.

Sincerely,

Stephen H. McCracken
Project Manager
Weldon Spring Site
Remedial Action Project

ABSTRACT AND WELDON SPRING SITE QUARTERLY SELF ASSESSMENT FIRST QUARTER 1992

The purpose of this *Quarterly Environmental Data Summary* is to provide to the public preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1992 Annual Site Environmental Report.

This report includes preliminary data from environmental monitoring activities at the Weldon Spring site (WSS) during the first quarter of 1992. Groundwater, surface water, and air samples were collected in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to evaluate possible exposure scenarios and assess the impact of the contaminants at the site on potentially exposed populations.

In summary, no significant differences were observed in off-site exposures during the first quarter of 1992 relative to exposures calculated in previous quarters. Contaminated groundwater did not affect the St. Charles County well field.

1 INTRODUCTION

This document is the eighth in a series of quarterly reports which summarize the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These documents supplement the Annual Site Environmental Report (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP *Environmental Monitoring Plan* (EMP) (MKF and JEG 1992) and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from historical observations. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1992 ASER. It is recommended that interested readers refer to previous EMPs, ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters is tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at (314) 441-8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). However, because of delays in data delivery from the analytical laboratories, some of the data that were expected to be included in this report are not yet available for reporting. The unavailability of data is due to a nationwide shortage in analytical services. These data will be reported in the 1992 ASER. Sludges and soils are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater and air pathways. These analyses will be presented in the 1992 ASER. Quality control (QC) data for the first quarter and all other quarters will be presented in the 1992 ASER.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring Quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

Groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a quarterly or semi-annual basis (locations are given in Figure 2-1). The number of quarterly sampled wells has increased substantially; a complete list of wells scheduled for quarterly and semiannual sampling is given in the 1992 *Environmental Monitoring Plan* (EMP) (MKF and JEG 1992). Total uranium, inorganic anions, and nitroaromatic compounds are measured during each monitoring period for both quarterly and semiannual wells. Other radiological parameters are measured annually during the first period for all wells. Geochemical parameters (metals and inorganic anions) are measured each period for the quarterly wells only.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the quarterly monitored groundwater wells. Nitroaromatic compounds were detected in 14 of the 31 locations for which data are currently available. Concentration levels for these compounds are within their historical range. Some nitroaromatic compounds detected in monitoring wells GW-2030, GW-2032, and GW-2033 were the lowest recorded values to date.

2.1.2 Radiological Results

Total uranium results for samples from the quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-2. The upper bound for natural uranium background concentration in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l (MKF and JEG 1989). The U.S. Environmental Protection Agency (EPA) has not yet established a drinking water standard for uranium; however, the proposed maximum contaminant

level (MCL) is 20 μg/l, which converts to 13.6 pCi/l (0.50 Bq/l) using a new site-specific conversion factor of 0.68 pCi/μg (assuming isotopic equilibrum). The increase to 13.6 pCi/l (0.50 Bq/l) from the previously reported value of 12 pCi/l (0.44 Bq/l) reflects improved quantification of the average U-234/U-238 activity ratios for uranium present at the Weldon Spring Site Remedial Action Project (WSSRAP). The U.S. Department of Energy (DOE) has a health-based, derived concentration guideline (DCG) of 600 pCi/l (22.2 Bq/l) in surface water effluent.

Uranium concentrations remained within historical ranges at most locations for which data are presently available. Higher than previously detected values have been recorded for GW-2030, GW-2032, GW-2033, GW-3023, GW-4013, and GW-4014. All of these higher values are only slightly elevated above previously high levels. At present, insufficient data are available to determine whether these values are part of an upward trend or are merely extremes within the normal range of variation for these wells.

Additional radiological parameters are measured for groundwater at all WSCP/RP/VP wells during the first monitoring period of each year. The results of these analyses are given in Table 2-3. Historically, concentration levels for these parameters have been below the detection limits. In general, the increase in detectable values for 1992 predominantly reflects improved analytical sensitivity rather than high concentration levels for these parameters. Exceptions are Th-230 and both radium isotopes. The elevated Th-230 values are thought to be an artifact of analytical interferences. The source of the slightly higher radium concentrations is unclear and is currently under investigation. All locations having apparently elevated Th-230, Ra-226, or Ra-228 values have been scheduled for resampling during the third quarter to confirm these results.

2.1.3 Sulfate and Nitrate Results

Sulfate and nitrate concentrations are measured during each monitoring period. Results of these analyses are given in Table 2-2. First quarter results are within historical ranges at all locations with the exception of nitrate in GW-4016. Because historical nitrate levels for this well have been below the detection limit, the first quarter measurement of 316 mg/l is being investigated. Laboratory validation has been requested for this sample.

2.1.4 Geochemical Results: Metals and Inorganic Anions

Table 2-4 contains the first quarter geochemical data (metals and inorganic anions) for quarterly monitored wells at the WSCP/RP/VP area. In 1992, the WSSRAP increased both the number of wells and the frequency of sampling for geochemical parameters. Many of these wells (especially in the GW-40XX and GW-203X series) had been sampled only two or three times prior to 1992, with the most recent sampling event occurring in 1988 or 1989. Thus comparisons with past concentration levels are inconclusive. For the majority of the wells, concentrations for the first quarter of 1992 are consistent with previously measured values; however, notable exceptions were observed for the GW-203X wells, which contained high levels of aluminum, iron, manganese, and moderately elevated lead. The source of these elevations is unclear and is currently being investigated. Improved analytical sensitivity has resulted in an increase in the number of wells showing detectable concentrations for Ar, Ba, Ni, Cr and K and does not reflect higher concentration levels for these parameters.

2.2 Weldon Spring Quarry

Groundwater at the WSQ has become radiologically and chemically contaminated as a result of contact with or migration from wastes present in the WSQ. Monitoring of the groundwater at and near the WSQ is of particular concern because of the proximity of the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mi) to the south of the WSQ. Monitoring of contaminants in groundwater and the protection of the well field is a top priority at the WSSRAP.

Groundwater is currently being monitored at 48 wells located in and around the quarry area. Thirty-six monitoring wells installed by the DOE are currently utilized in or near the quarry. Four monitoring wells were installed by St. Charles County in 1986 and are currently included in the DOE's monitoring program. Eight St. Charles County municipal wells, and the treated and untreated water from the St. Charles County water treatment plant are also monitored for the presence of these contaminants. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells monitor groundwater in both the bedrock and alluvial aquifers associated with the WSQ.

Two separate groundwater monitoring programs have been developed for the WSQ area. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough and

MW-1010 and MW-1011 located south of the slough. In addition, wells MW-1035, MW-1036, MW-1037, MW-1038, and MW-1039 will be sampled bimonthly until operation of the Weldon Spring Quarry water treatment plant is initiated. The second program is the quarterly sampling of all wells south of the Femme Osage Slough, excluding MW-1010 and MW-1011, but including the St. Charles County well field. Both the raw and treated waters from the St. Charles County water treatment plant are sampled.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-5 and 2-6 for samples collected on the first bimonthly period and first quarter. The results show typical fluctuations near the average levels in the WSQ area with the exception of MW-1008 and MW-1032. Uranium concentrations in these wells exceeded the 1991 annual averages but do not exceed the 1991 results for MW-1004, which appear to be hydrologically related.

The monitoring wells south of the Femme Osage Slough, the St. Charles County monitoring wells, and the St. Charles County production wells are sampled annually for the radiological species of radium, thorium, gross alpha, and gross beta. The results of these samples analyses are presented in Table 2-7. The concentrations in these wells are consistent with historical values of waters in or near the WSQ.

2.2.2 Nitroaromatic Compounds Results

Analytical results for the first bimonthly period and first quarter for nitroaromatic compounds are presented in Tables 2-8 and 2-9, respectively. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the first quarter of 1992. The distribution and magnitude of nitroaromatic contamination in wells near the quarry remain consistent with historical levels.

2.2.3 Inorganic Anions Results

Two inorganic anions, nitrate and sulfate, were sampled in all the wells monitored at the WSQ. The analytical results for the first bimonthly period and the first quarter are presented in Tables 2-5 and 2-6, respectively. These results are consistent with data reported in the

previous environmental monitoring reports. The WSQ groundwater samples continue to indicate no significant nitrate contamination of the groundwater. The results indicate that elevated sulfate levels are present in groundwater within the WSQ and north of the Femme Osage Slough.

2.2.4 Metals Results

All the wells in the WSQ monitoring program are sampled for arsenic and barium. The St. Charles county production wells are also analyzed for lead, cadmium, and mercury. The results for the first bimonthly period and first quarter are presented in Tables 2-10 and 2-11, respectively. Arsenic levels were consistent with historical values for groundwater in the vicinity of the WSQ. Elevated barium levels have remained in the wells in the vicinity of the Femme Osage Slough.

2.2.5 Organics Results

The St. Charles County RMW series monitoring wells, the St. Charles County production wells, untreated and treated water from the St. Charles County water treatment plant, and monitoring well MW-1024 were sampled in the first quarter for organics; volatile and semi-volatile, pesticides, and polychlorinated biphenyls (PCBs). A listing of the parameters analyzed is in Appendix A. The results of the analyses indicated slight concentrations of toluene at nine of the 14 sampling locations. The concentration of toluene appears to be attributed to the sealing of the sample vials and labels with clear adhesive tape. Resampling of several of the wells which previously indicated toluene concentrations reported non-detects of toluene. A concentration of methylene chloride (9 μg/l) was indicated in RMW-2. This slight concentration was attributed to typical laboratory contamination as a result of container cleaning practices. No detectable concentrations of pesticides or PCBs were indicated at any of the sampling locations.

2.3 Springs

Five springs around the Weldon Spring site (WSS) were sampled during the first quarter (see Figure 2-4). Previous spring monitoring indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs include SP-5301 through SP-5304, SP-6301, SP-6302, and SP-6306. All spring samples were analyzed for uranium. Analytical results for these are not available at this time.

3 SURFACE WATER MONITORING

Routine samples were collected during the first quarter of 1992 from both on-site and off-site surface water locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1992 Annual Site Environmental Report (ASER).

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the first quarter, surface water samples were collected from the 10 of 15 surface water sampling locations shown in Figure 3-1 and analyzed for uranium. Monitoring location SW-2016 was added to the surface water monitoring plan due to an elevated uranium concentration reported by the U.S. Geological Survey (USGS) at that location. Monitoring point SW-2016 is located at the intersection of Dardenne Creek and County Highway N and is now the furthest location downstream at which to measure contaminant levels in Dardenne Creek after receiving the Schote Creek contribution. Results from SW-2002 indicated an elevated uranium concentration of 171 pCi/l (6.3 Bq/l). Although this value is greater than the 1991 annual average it does not exceed the historical high of 240 pCi/l (8.9 Bq/l) for this location. The results, presented in Table 3-1, indicated that conditions at the other sampling locations remain consistent with historical values.

3.2 Weldon Spring Quarry

Surface water samples were collected for uranium and metals (arsenic and barium) analyses from the 13 locations shown in Figures 3-2 and 3-3. The results are presented in Table 3-2. First quarter uranium and metals concentrations for the sampling locations in the Femme Osage Slough and Little Femme Osage Creek remain within historical ranges. The highest measured uranium concentration of 2060 pCi/l (76.2 Bq/l) was detected at the quarry pond (SW-1008) and is within the historical range. In addition, nitroaromatics, radionuclides, nitrate, and sulfate were measured for SW-1008. The results for the radiological parameters were not available for incorporation into this data summary. Table 3-3 presents the results of the nitroaromatic analyses which are within historical ranges. Uranium and barium values for all three Missouri River samples (SW-1011, SW-1012, and SW-1013) are higher than previously

measured values for these locations. These elevations are not related to conditions at the Weldon Spring site and likely reflect spring run-off from up-river crystalline rock terrain.

4 EFFLUENT MONITORING

The National Pollutant Discharge Elimination System (NPDES) permit process is authorized by Section 402(a)(1) of the Clean Water Act of 1977. The authority to issue permits is delegated to the State of Missouri by the U.S. Environmental Protection Agency (EPA). The State of Missouri has issued four NPDES permits to the U.S. Department of Energy (DOE) allowing the discharge of stormwater and treated wastewater to waters of the state. The permits require that samples of the wastewater be collected periodically and the results reported to the Missouri Department of Natural Resources. The following sections contain the analytical results for samples collected during January, February, and March of 1992.

4.1 National Pollutant Discharge Elimination System Data Review

Effluent samples were collected and analyzed in compliance with the Weldon Spring site NPDES permits. Permit No. MO-0107701 was issued on October 1, 1990, and currently addresses the five storm water and two wastewater discharges shown in Figure 4-1. Outfalls NP-0001 through NP-0005 represent storm water discharges; Outfall NP-0006 represents the treated wastewater discharge associated with the administration building sanitary wastewater treatment plant; and Outfall NP-0007 represents the site water treatment plant, which is under construction, but not yet completed. There was no discharge from NP-0007. Outfalls NP-0006 and NP-0007 have effluent limitations. The five storm water outfalls have monitoring requirements only. First quarter 1992 analytical data for each outfall are presented in Table 4-1.

Permit No. MO-0108987 was issued on May 5, 1989, for Outfall NP-1001 of the Weldon Spring Quarry water treatment plant. The plant construction is not complete, and no discharge took place during the first quarter of 1992.

NPDES permit No. MO-G340001 was issued on December 19, 1991. This permit is for discharge of uncontaminated water used for new tank and basin testing at the quarry water treatment plant. First quarter 1992 analytical data is presented in Table 4-2. This permit number has been changed to MO-G680001.

NPDES permit No. MO-G340002 was issued on February 7, 1992. This permit is for discharge of uncontaminated water used for new tank and basin testing at the site water treatment

plant. There was no discharge under this permit for the first quarter of 1992. This permit number has been changed to MO-G680002.

4.1.1 Radiological Analysis

Gross alpha and uranium analyses corresponded reasonably well with past data. There were higher than average uranium levels reported in samples collected from outfalls NP-0001 and NP-0003, but the levels were lower than recorded historical highs. The peak for NP-0001 was 1,090 pCi/l (1.6 mg/l) and for NP-0003, 1,680 pCi/l (2.47 mg/l). Uranium levels were similarly higher at outfalls NP-0001 and NP-0003 during the first quarter of 1991.

The stormwater outfalls had the following ranges of uranium concentrations. The process sewer outfall NP-0001 had only two sample values of 184 pCi/l (0.271 mg/l) and 1,090 pCi/l (1.6 mg/l). The Frog Pond outfall NP-0002 had values of 286 pCi/l (0.420 mg/l) to 437 pCi/l (0.643 mg/l). The Ash Pond outfall NP-0003, had values of 32 pCi/l (0.0472 mg/l) to 1,680 pCi/l (2.47 mg/l). A single sample was analyzed for outfall NP-0004 behind Raffinate Pit 4 with a value of 6.12 pCi/l (0.009 mg/l) and the southeast drainage outfall NP-0005 had values from 54 pCi/l (0.0799 mg/l) to 470 pCi/l (0.691 mg/l).

In addition to the required radiological monitoring, gross beta was quantified at 110 pCi/l (4.07 Bq/l) at outfall NP-0002 for the March 4, 1992, sample; at 630 (23.3 Bq/l) and 180 pCi/l (6.66 Bq/l) at outfall NP-0003 for the March 4 and March 25, 1992, samples; and at 11 pCi/l (0.41 Bq/l) at outfall NP-0004 for the March 2, 1992, sample.

Hydrostatic test water pumped from the quarry water treatment plant basins was analyzed for uranium in addition to the required permit parameters. The analyses showed that uranium was not present at detectable levels; see Table 4-2.

4.1.2 Other Analysis

Other analyses for NP-0001 through NP-0005 include physical analyses (settleable solids and total suspended solids) and chemical analyses (nitrate, pH, and lithium). First quarter 1992 values generally correspond to past values for the majority of parameters. Exceptions were high total suspended solids (TSS) values at NP-0003 on March 25, 1992, and at NP-0005 on February 6 and March 18, 1992; a high settleable solids (SS) level at NP-0005 on

February 6, 1992; and high nitrate values at NP-0005 on January 8, 1992, and February 24, 1992.

The elevated TSS value at NP-0003 may have been caused by runoff from the construction of the material storage area (MSA) Phase II and III; no other causes could be determined. The high total suspended solids (TSS) value at outfall NP-0005 on February 6, 1992, was the result of an off-site water line break. There was no other flow at the time and the discharge was very short term. The high TSS value at NP-0005 on March 18, 1992 can be attributed to the ongoing construction at the site water treatment plant and off site water line construction by Missouri Cities Water Company. The high settleable solids level at NP-0005 on February 6, 1992, was also caused by the water line break. The high nitrate levels at NP-0005 may also have been caused by ongoing construction at the site water treatment plant area.

The permit for the discharge from the administration building treatment plant at outfall NP-0006 has effluent limitations and a requirement to monitor once per quarter. Flow must be measured once a month. The Subcontractor monitors the effluent once a month to assess plant performance, thus generating two additional sample analyses a quarter. The NPDES permit specifies effluent limitations for biochemical oxygen demand (BOD), TSS, pH, and fecal coliform at this outfall. The limits for BOD are 10 mg/l monthly average and 15 mg/l weekly average; for TSS, 15 mg/l monthly average and 20 mg/l weekly average; for fecal coliform, 400 colonies per 100 ml monthly average and 1,000 colonies per 100 ml daily maximum. The effluent exceeded permit limits twice during the quarter. On February 12, 1992, the total suspended solids were 23 mg/l, exceeding the monthly average limit of 15 mg/l. During March BOD results were 11.6 mg/l and 13 mg/l. These results were in compliance with the weekly limit of 15 mg/l, but the monthly average of 12.3 mg/l was out of compliance with the monthly average limit of 10 mg/l. The Subcontractor is continuing to make operational changes to improve plant performance. In addition, the plans to add a flow equalization system are at the 60% design review phase. The equalization of flow will greatly improve the operation of the plant. An application for a construction permit will be submitted to the Missouri Department of Natural Resources when plans and specifications are complete. Until the flow equalization is added, the treatment plant will be monitored more frequently than would normally be required.

Hydrostatic test water pumped from the quarry water treatment plant basins was in compliance with permitted units (Table 4-2).

5 AIR MONITORING

5.1 Radon Gas

The radon gas monitoring program utilizes a pair of radon detectors at each of 25 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, eight locations at the Weldon Spring Quarry, four locations at the Weldon Spring raffinate pits, and seven off-site locations. Radon monitoring locations are shown in Figures 5-1, 5-2, and 5-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, RD-4006 and RD-4007 were used to monitor background levels near the site.

Two new monitoring stations (RD/TD-1007 and RD/TD-1008) were added to the western and northern quarry water treatment plant perimeters in addition to the relocation of monitoring station (RD/TD-1005) from the western quarry inner fence perimeter to the southern quarry water treatment plant perimeter. Another background monitoring station (RD/TD-4007) was added and is located west of Femme Osage Creek (Figure 5-3).

Table 5-1 summarizes the first quarter 1992 radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in Table 5-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (111 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the five background locations. This data yielded an average ambient background radon concentration of 0.3 pCi/l (11.1 Bq/m^3) for the first quarter of 1992. This concentration was then subtracted from the concentration for each monitoring station, and compared to the DOE guideline of 3 pCi/l (111 Bq/m^3) above background.

Radon concentrations at the site and quarry perimeters and at off-site locations for the first quarter of 1992 were within the typical range expected during periods of normal precipitation as was the condition for this period. The quarterly radon concentrations at the

(b) Percent of guideline calculated by taking the quarterly average minus the average of the background stations divided by the DOE concentration guideline for Rn-222 which is 3 pCi/l (111 Bq/m^3)(Annual average above background) for uncontrolled areas.

* Denotes Background Station.

Weldon Spring Chemical Plant/Raffinate Pit (WSCP/RP) area averaged 0.3 pCi/l (11.1 Bq/m^3) while the quarterly radon concentrations at the Weldon Spring quarry (WSQ) averaged 0.7 pCi/l (26.8 Bq/m^3). The quarterly radon concentrations (background included) ranged from 0.2 pCi/l (7.4 Bq/m^3) at three monitoring locations to 1.9 pCi/l (70.3 Bq/m^3) at monitoring location RD-1002.

Radon concentrations found at the quarry are higher than concentrations measured at other locations because the radium concentrations in quarry wastes are typically much higher than in other areas. Also, the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high which tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

5.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, spherical environmental thermoluminescent dosimeters (TLDs) were deployed at 26 locations. The gamma monitoring station locations are identified in Figures 5-1, 5-2, and 5-3 with a prefix TD-.

Table 5-2 summarizes the first quarter results of total gamma radiation monitoring at the 18 Weldon Spring site (WSS) perimeter monitoring stations, Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the six background monitoring stations.

The annual average background gamma exposure rates measured with TLDs in 1989, 1990, and 1991 were 68 mR/year, 62 mR/year, and 69 mR/year, respectively. The gamma exposure rates measured with TLDs in the first quarter of 1992 were consistent with 1989 through 1991 data. In fact, the first quarter TLD data were consistently lower than data from first quarter 1991 at all locations. This result was unexpected as the off-site laboratory increased the gamma response function by 15% prior to reporting the fourth quarter 1991 results. This increase was observed in the fourth quarter 1991 results and was expected to be reflected in the results for the first quarter 1992. However, the first quarter 1992 results at all locations were lower than those reported in the first quarter of 1991 and much lower than the results reported for the fourth quarter 1991. There were no problems identified through on-site investigations as to what caused the elevated TLD readings for the last quarter of 1991. Thus, different types of TLDs have been placed at a few locations on site for the second quarter and will be handled separately.

These experimental TLDs will likely provide insight as to whether or not laboratory handling and processing were responsible for the unusual fourth quarter results.

5.3 Radioactive Air Particulates

Eleven low volume air particulate samplers monitor the Weldon Spring site continuously. Five of these (AP–2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter as shown in Figure 5-3. Three monitoring stations (AP-4006, AP-4008, and AP-4011) are located off site at sensitive receptor locations including Francis Howell High School, the Army Reserve property, and near a residential site west of the quarry. The monitoring station at the August A. Busch Wildlife Area (ABWA) (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The off-site monitoring stations are also shown in Figure 5-2.

The sampling station near the ABWA headquarters is used as a background air monitoring station. This station is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/RP area.

Table 5-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging all weekly air particulate analysis results including results lower than the instruments lower limit of detection (LLD). The corresponding standard deviation for each monitoring location was also calculated using all weekly air particulate analysis results. Due to maintenance, all monitors were not operating the entire 13 weeks as indicated in Table 5-3. However, the sensitive receptor monitoring stations (AP-4006, AP-4008, and AP-4011) were in operation the entire quarter. These stations are also equipped with high volume air samplers which are the focus of the WSS National Emissions Standards for Hazardous Air Pollutants (NESHAPs) plan. The high volume monitoring results will be presented in the 1992 calendar year Annual Site Environmental Report.

The first quarter long-lived gross alpha concentrations ranged from 7.5×10^{-16} μCi/ml to 1.06×10^{-15} μCi/ml an average background concentration of with 1.05×10^{-15} μCi/ml detected at the background station.

ABSTRACT

The purpose of this *Quarterly Environmental Data Summary* is to provide to the public preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1992 annual site environmental report.

This report includes preliminary data from environmental monitoring activities at the Weldon Spring site (WSS) during the second quarter of 1992. Groundwater, surface water, and air samples were collected in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to evaluate possible exposure scenarios and assess the impact of the contaminants at the site on potentially exposed populations.

In summary, off-site exposures during the second quarter of 1992 did not differ significantly from exposures calculated in previous quarters. Contaminated groundwater did not affect the St. Charles County well field.

1 INTRODUCTION

This quarterly report summarizes the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These reports supplement the annual site environmental report (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP *Environmental Monitoring Plan* (EMP) (MKF and JEG 1992a) and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from historical observations. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1992 ASER. It is recommended that interested readers refer to previous EMPs, ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters is tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at (314) 441-8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). This document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1992 annual site environmental report. Because standard turnaround time to receive data from the laboratories is 45 days, not all second quarter data are available for reporting. These data will be reported in the 1992 ASER. Sludges and soils are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater, and air pathways. These analyses will be presented in the 1992 ASER. Quality control (QC) data for the second quarter, and all other quarters, will also be presented in the 1992 ASER.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring Quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

Groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a quarterly or semiannual basis (specific to each well as prescribed in the 1992 EMP). Locations are given in Figure 2-1. The number of quarterly sampled wells has increased substantially; a complete list of wells scheduled for quarterly and semiannual sampling is given in the 1992 *Environmental Monitoring Plan* (EMP) (MKF and JEG 1992a). Total uranium, inorganic anions, and nitroaromatic compounds are measured during each monitoring period for both quarterly and semiannual wells. Other radiological parameters are measured annually during the first period for all wells. Geochemical parameters (metals and inorganic anions) are measured each period for the quarterly wells only.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the quarterly monitored groundwater wells. Nitroaromatic compounds were detected in 16 of the 32 locations for which data are currently available. Concentration levels for these compounds are within their historical range.

Table 2-2 contains nitroaromatic data from samples collected from the semiannually monitored groundwater wells. Nitroaromatic compounds were detected in 10 of the 19 wells for which data are available. Concentrations for these compounds are within their historical range.

2.1.2 Radiological Results

Total uranium results for samples from the quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-3. The upper bound for natural uranium background concentration in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l (0.13 Bq/l) (MKF and JEG 1989). The U.S. Environmental Protection Agency (EPA) has not yet established a drinking water standard for uranium; however, the proposed maximum contaminant level (MCL) is 20 μg/l, which converts to 13.6 pCi/l (0.50 Bq/l) using a new site-specific conversion factor of 0.68 pCi/μg (assuming isotopic equilibrum). The increase to 13.6 pCi/l (0.50 Bq/l) from the previously reported value of 12 pCi/l (0.44 Bq/l) reflects improved quantification of the average U-234/U-238 activity ratios for uranium present at the Weldon Spring Site Remedial Action Project (WSSRAP). The U.S. Department of Energy (DOE) has a health-based, derived concentration guideline (DCG) of 600 pCi/l (22.2 Bq/l) in surface water effluent.

Uranium concentrations remained within historical ranges at most locations for which data are presently available. A higher than previously detected value was recorded for MW-2030. This higher value was only slightly elevated above previously high levels, and may be related to higher values for certain metals (see discussion in Section 2.1.4). At present, insufficient data are available to determine whether this value is part of an upward trend or merely an extreme within the normal range of variation for this well.

Table 2-4 contains uranium data from samples collected from the semiannually monitored groundwater wells. Uranium concentrations in these wells are within their historical range.

Additional radiological parameters are measured for groundwater at all WSCP/RP/VP wells during the second quarter. The results of these analyses are given in Table 2-5. Historically, concentration levels for these parameters have been below the detection limits. In general, the increase in detectable values for 1992 predominantly reflects improved analytical sensitivity rather than high concentration levels for these parameters; exceptions are Th-230 and both radium isotopes. The elevated Th-230 values are thought to be an artifact of analytical interferences. The source of the slightly higher radium concentrations is unclear and is currently under investigation. All locations having apparently elevated Th-230, Ra-226, or Ra-228 values have been scheduled for resampling during the third quarter to confirm these results.

2.1.3 Sulfate and Nitrate Results

Sulfate and nitrate concentrations are measured during each monitoring period. Results from the quarterly monitored wells are shown in Table 2-3. Second quarter results are within historical ranges with the exception of the nitrate value for MW-4012. The source of this elevation is being investigated. Sulfate and nitrate results from semiannually monitored wells are shown in Table 2-4. These concentrations are within their historical range.

2.1.4 Geochemical Results: Metals and Inorganic Anions

Table 2-6 contains the second quarter geochemical data (metals and inorganic anions) for quarterly monitored wells at the WSCP/RP/VP area. In 1992, the WSSRAP increased both the number of wells and the frequency of sampling for geochemical parameters. For the majority of the wells, concentrations for the second quarter of 1992 are consistent with previously measured values. However, notable exceptions were observed for the MW-203X wells, MW-3023, MW-4017, and MW-4022; which contained high levels of aluminum, iron, manganese, and moderately elevated lead. These wells were filtered before preservation and analysis. The failure to filter these samples resulted in metals being leached from the suspended solid material upon preservation. This leaching may also be responsible for the high uranium observed in MW-2030. Future samples from these wells will be filtered prior to preservation.

2.2 Weldon Spring Quarry

Groundwater at the WSQ has become radiologically and chemically contaminated as a result of contact with, or migration from, wastes present in the WSQ. Monitoring of the groundwater at, and near, the WSQ is of particular concern because of the proximity of the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mi) to the south of the WSQ. Monitoring of contaminants in groundwater and the protection of the well field is a top priority at the WSSRAP.

Groundwater is currently being monitored at 48 wells located in and around the quarry area. Thirty-six monitoring wells installed by the DOE are currently utilized in or near the quarry. Four monitoring wells were installed by St. Charles County in 1986 and are currently included in the DOE's monitoring program. Eight St. Charles County municipal wells, and the treated and untreated water from the St. Charles County water treatment plant, are also

monitored for the presence of these contaminants. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells monitor groundwater in both the bedrock and alluvial aquifers associated with the WSQ.

Two separate groundwater monitoring programs have been developed for the WSQ area. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough and MW-1010 and MW-1011 located south of the slough. In addition, wells MW-1035, MW-1036, MW-1037, MW-1038, and MW-1039 will be sampled bimonthly until operation of the Weldon Spring Quarry water treatment plant is initiated. The second program is the quarterly sampling of all wells south of the Femme Osage Slough, excluding MW-1010 and MW-1011, but including the St. Charles County well field. Both the raw and treated waters from the St. Charles County water treatment plant are sampled quarterly.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-7 through 2-9 for samples collected for the second and third bimonthly periods and second quarter. The results show typical fluctuations near the average levels in the WSQ area with the exception of MW-1007 and MW-1032. The uranium concentrations in MW-1007 exceeded the historic average and validation has been requested to determine whether this is a real value for uranium at this location. Results for the third bimonthly period returned to within historic ranges for this sampling location. The uranium concentration in MW-1032 exceeded the historic average and continued monitoring will be performed to determine whether this is a trend. Detectable concentrations of uranium were indicated from RMW-series wells and the St. Charles County production wells. These levels are within historic averages and representative of background levels.

The monitoring wells north of the Femme Osage Slough are sampled annually for the radiological species of radium, thorium, gross alpha, and gross beta. The results of these samples analyses are presented in Table 2-10. Calendar year 1992 is the first routine sampling of these wells for radiological species other than urnaium since 1989. Wells within the WSQ boundary show elevated levels of both gross alpha and gross beta, and are consistent with the quarry pond (SW-1008) concentrations which are the source of impact. Monitoring wells MW-1013 through MW-1016, located south of the quarry, also show elevated levels. The concentrations in the remainder of the wells are consistent with background values of waters in or near the WSQ.

2.2.2 Nitroaromatic Compounds Results

Analytical results for the second and third bimonthly period, and the second quarter for nitroaromatic compounds, are presented in Tables 2-11 through 2-13. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the second quarter of 1992. Elevated levels of nitroaromatic compounds were detected in rim wells MW-1002 and MW-1004 and alluvial monitoring well MW-1007. The distribution and magnitude of nitroaromatic contamination in the remainder of the wells near the quarry remain consistent with historical levels.

2.2.3 Inorganic Anions Results

Two inorganic anions, nitrate and sulfate, are sampled in all of the wells monitored at the WSQ. The analytical results for the second and third bimonthly period, and for the first quarter, are presented in Tables 2-7 through 2-9. An elevated level of sulfate was detected in alluvial monitoring well MW-1007 and an elevated level of nitrate was detected in rim well MW-1030. The results for the remainder of the monitoring wells are consistent with data reported in the previous environmental monitoring reports. The WSQ groundwater samples continue to indicate no significant nitrate contamination of the groundwater. The results indicate that elevated sulfate levels are present in groundwater within the WSQ and north of the Femme Osage Slough.

2.2.4 Metals Results

All wells in the WSQ monitoring program are sampled for arsenic and barium. The results for the second and third bimonthly periods, and the second quarter, are presented in Tables 2-14 through 2-16. Arsenic levels were consistent with historical values for groundwater in the vicinity of the WSQ. Elevated arsenic levels were reported for bedrock monitoring well MW-1028. Barium levels have remained elevated in the wells in the vicinity of the Femme Osage Slough. Elevated barium levels were indicated for rim monitoring wells MW-1002 and MW-1004.

2.3 Springs

Five springs around the Weldon Spring site (WSS) were sampled during the first quarter (see Figure 2-4). Previous spring monitoring indicated that waters from six perennial springs and one wet-weather spring are measurably influenced by site-related contaminants. These springs include SP-5301 through SP-5304, SP-6301, SP-6302, and SP-6306. SP-6301 and SP-6306 were to be sampled during high and low flow periods. High flow samples were not attained during second quarter, but will be collected during 3rd quarter. Unavailable analytical results will be reported in the 1992 annual site environmental report (ASER). During second quarter, spring samples were analyzed for radiological, inorganic anions, and nitroaromatics (see Table 2-17).

3 SURFACE WATER MONITORING

Routine samples were collected during the second quarter of 1992 from both on-site and off-site surface water locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1992 annual site environmental report (ASER).

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the first quarter, surface water samples were collected from 14 of the 15 surface water sampling locations shown in Figure 3-1 and analyzed for uranium and metals. Monitoring point SW-2016, not shown in Figure 3-1, is located at the intersection of Dardenne Creek and County Highway N. This is now the furthest location downstream at which to measure contaminant levels in Dardenne Creek after it has received the Schote Creek contribution. The results, presented in Tables 3-1 and 3-2, indicated that conditions at sampling locations remain consistent with historical values. The nitrate value for SW-2005 is considered suspect and full validation has been requested.

3.2 Weldon Spring Quarry

Monitoring locations SW-1001, SW-1002, and SW-1014 (Figure 3-2) monitor the Little Femme Osage Creek at points upstream and downstream of the Weldon Spring quarry (WSQ). Six sampling locations, SW-1003 through SW-1005, SW1007, SW-1009, and SW-1010, are distributed along the Femme Osage Slough in the vicinity of the WSQ. These locations within the slough were chosen to provide the most representative data of potentially impacted areas from the quarry contamination. Location SW-1008 monitors the ponded water within the WSQ and provides a rough deterination of the concentrations of the various contaminants in the WSQ pond, which may migrate to groundwater. Locations SW-1011 through SW-1013 (Figure 3-3) and SW-1015 (Howard Bend) were added to the monitoring program to provide baseline water quality data for the Missouri River at points both upstream and downstream from the WSQ and the Southeast Drainage (5300) easement.

3.2.1 Radiological Results

Surface water samples were collected for radiological analyses from the 13 locations shown in Figures 3-2 and 3-3. The uranium results for the second and third bimonthly periods are presented in Tables 3-4 and 3-5. Second and third bimonthly uranium concentrations for the sampling locations in the Femme Osage Slough and Little Femme Osage Creek remain within historical ranges. The highest measured uranium concentration of 1200 pCi/l (44.4 Bq/l) was detected at the quarry pond (SW-1008) and is within the historical range. In addition, the surface water locations were sampled for the radiological species of radium and thorium, gross alpha, and gross beta during the second bimonthly period. The results are presented in Table 3-3.

3.2.2 Nitroaromatic Compounds Results

Analytical results for nitroaromatic compounds during the second bimonthly period, are presented in Table 3-6. No nitroaromatic analyses have been performed at these sampling locations since 1989. Elevated levels of 2,4-dinitrotoluene (DNT), 2,6-DNT, and 2,4,6-trinitrotoluene (TNT) have been detected at the SW-1001 location. This location has been established as background for the WSQ. Additional sampling will be performed to determine the presence of a trend and the possible upstream source of impact.

3.2.3 Inorganic Anion Results

Surface water samples were collected from the sampling locations in the second bimonthly period for nitrate and sulfate analysis. Inorganic anions have not been analyzed at these locations since 1988 except for SW-1008 and SW-1011 through SW-1013. The results for this bimonthly period are within or below historic levels and background for nitrate and sulfate.

3.2.4 Weldon Spring Quarry Pond Results

A summary of the analytical results for the third bimonthly sampling period is presented in Table 3-7. This sampling location is summarized separately to characterize the surface waters in the WSQ which may migrate and effect groundwater. The results for this bimonthly period are within historic ranges for all parameters analyzed.

4 EFFLUENT MONITORING

The National Pollutant Discharge Elimination System (NPDES) permit process is authorized by Section 402(a)(1) of the *Clean Water Act of 1977*. The authority to issue permits is delegated to the State of Missouri by the U.S. Environmental Protection Agency (EPA). The State of Missouri has issued four NPDES permits to the U.S. Department of Energy (DOE) allowing the discharge of stormwater hydrostatic test water, and treated wastewater to waters of the state. The permits require that samples of the wastewater be collected periodically and the results reported to the Missouri Department of Natural Resources. The following sections contain the analytical results for samples collected during April, May, and June of 1992.

4.1 National Pollutant Discharge Elimination System Data Review

Effluent samples were collected and analyzed in compliance with the Weldon Spring site NPDES permits. Permit No. MO-0107701 was issued on October 1, 1990, and currently addresses the five storm water and two wastewater discharges shown in Figure 4-1. Outfalls NP-0001 through NP-0005 represent storm water discharges; Outfall NP–0006 represents the treated wastewater discharge associated with the administration building sanitary wastewater treatment plant; and Outfall NP-0007 represents the site water treatment plant, which is under construction, but not yet completed. There was no discharge from Outfall NP-0007. Outfalls NP-0006 and NP-0007 have effluent limitations. The five storm water outfalls have "monitoring only" requirements. A lack of flow due to inadequate precipitation prevented the collection of samples from outfalls NP-0003 and NP-0005 during the month of June. NP-0004 also had no discharge during the second quarter, and therefore was not sampled. Second quarter 1992 analytical data for each outfall are presented in Table 4-1.

A lack of flow due to inadequate precipitation prevented the collection of samples from outfalls NP-0003 and NP-0005 during the month of June. NP-0004 also had no discharge during the second quarter, and therfore was not sampled.

Permit No. MO-0108987 was issued on May 5, 1989, for Outfall NP-1001 of the Weldon Spring Quarry water treatment plant. The plant construction is not complete and no discharge took place during the second quarter of 1992.

* The June 22 flow value represents the total amount of water discharged from June 17 through June 22, 1992.

NPDES permit No. MO-G680001 was issued on December 19, 1991. This permit is for discharge of uncontaminated water used for new tank and hydrostatic basin testing at the quarry water treatment plant. Second quarter 1992 analytical data are presented in Table 4-2.

NPDES permit No. MO-G680002 was issued on February 7, 1992. This permit is for discharge of uncontaminated water used for new tank and hydrostatic basin testing at the site water treatment plant. There was no discharge under this permit for the second quarter of 1992.

4.1.1 Radiological Analysis

Gross alpha and uranium analyses corresponded well with past data. The storm water outfalls had the following ranges of uranium concentrations. The process sewer outfall NP-0001, had only one sample value of 450 pCi/l (0.663 mg/l). Frog Pond outfall, NP-0002, had values from 103 pCi/l (0.151 mg/l) to 173 pCi/l (0.255 mg/l). The Ash Pond outfall, NP-0003, had values of 543 pCi/l (0.799 mg/l) and 267 pCi/l (0.392 mg/l). There was no discharge from NP-0004 during the second quarter. The Southeast Drainage outfall, NP-0005, had values of 358 pCi/l (0.526 mg/l) and 509 pCi/l (0.749 mg/l).

In addition to the required radiological monitoring, gross beta was quantified for most samples. The one sample collected from NP-0001 had a gross beta count of 150 pCi/l (5.55 Bq/l). Two samples from NP-0002 were analyzed for gross beta. The sample collected on April 20 had a gross beta count of 29 pCi/l (1.07 Bq/l), and the sample collected on May 13 had a gross beta count of 61 pCi/l (2.26 Bq/l). The gross beta concentrations for NP-0003 were 190 pCi/l (7.03 Bq/l) for the April 20 sample, and 49 pCi/l (1.81 Bq/l) for the May 13 sample. The gross beta concentrations for NP-0005 were 160 pCi/l (5.92 Bq/l) for the April 20 sample, and 55 pCi/l (2.04 Bq/l) for the May 13 sample.

4.1.2 Other Analysis

Other analyses for NP-0001 through NP-0005 include physical analyses (settleable solids and total suspended solids) and chemical analyses (nitrate, pH, and lithium). Second quarter 1992 values correspond well with past values for all parameters.

The permit for the discharge from the administration building treatment plant at outfall NP-0006 has effluent limitations and a requirement to monitor once per quarter. Flow must be

measured once a month. The Subcontractor monitors the effluent once a month to assess plant performance, thus generating two additional sample analyses a quarter. The NPDES permit specifies effluent limitations for biochemical oxygen demand (BOD), total suspended solids (TSS), pH, and fecal coliform at this outfall. The limits for BOD are 10 mg/l monthly average and 15 mg/l weekly average; for TSS, 15 mg/l monthly average and 20 mg/l weekly average; for fecal coliform, 400 colonies per 100 ml monthly average and 1,000 colonies per 100 ml daily maximum. The Subcontractor is continuing to make operational changes to improve plant performance. In addition, the plans to add a flow equalization system are complete. The equalization of flow should greatly improve the operation of the plant. An application for a construction permit, as well as the plans and specifications, were submitted to the Missouri Department of Natural Resources. When the construction permit is issued, construction will begin. Until the flow equalization is added, the treatment plant will be monitored more frequently than would normally be required.

Hydrostatic test water pumped from the quarry water treatment plant basins was in compliance with permitted limits (Table 4-2). Analytical data are shown in Table 4-2.

5 AIR MONITORING

5.1 Radon Gas

The radon gas monitoring program utilizes a pair of alpha track radon detectors at each of the 25 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, eight locations at the Weldon Spring Quarry, four locations at the Weldon Spring raffinate pits, and at seven off-site locations. Radon monitoring locations are shown in Figures 5-1, 5-2, and 5-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, RD-4006, and RD-4007 monitor background levels near the site.

Beginning this quarter, a new type of alpha track monitor was used for radon monitoring. The new detector is the new Type F track etch detector. This replaces the Radtrack monitor used for radon monitoring during the first quarter of 1992. The change was made because the Radtrack monitor is designed for indoor monitoring, while the Type F is better suited for outdoor monitoring. The detection mechanism in both these monitors is identical, consisting of a track etch detector.

Table 5-1 summarizes the second quarter 1992 radon concentrations detected at all site perimeter and off-site monitoring locations. Also contained in the third column of Table 5-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (111 Bq/m^3) above background as authorized by U.S. Department of Energy (DOE) Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the five background locations. This data yielded an average ambient background radon concentration of 0.25 pCi/l (9.25 Bq/m^3) for the first quarter of 1992. This concentration was then subtracted from the concentration for each monitoring station, and compared to the DOE guideline of 3 pCi/l (111 Bq/m^3) above background.

Radon concentrations at the site and quarry perimeters and at off-site locations for the first quarter of 1992 were within the typical range expected during periods of normal precipitation. During the second quarter, the radon concentrations measured with the new type

* Denotes Background Station.

---

of detectors were also within the typical range expected during periods of normal precipitation. The quarterly radon concentrations at the Weldon Spring Chemical Plant/raffinate pit (WSCP/RP) area averaged 0.3 pCi/l (11.8 Bq/m^3), while the quarterly radon concentrations at the Weldon Spring Quarry (WSQ) averaged 0.6 pCi/l (22.2 Bq/m^3). The quarterly radon concentrations (background included) ranged from 0.03 pCi/l (1.11 Bq/m^3) to 1.2 pCi/l (44.4 Bq/m^3).

Radon concentrations found at the quarry are higher than concentrations measured at other locations, because the radium concentrations in quarry wastes are typically much higher than in other areas. Also, the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high, which tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

5.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, environmental thermoluminescent dosimeters (TLDs) were deployed at 26 locations. The gamma monitoring station locations are identified in Figures 5-1, 5-2, and 5-3 with a prefix TD-.

Table 5-2 summarizes the second quarter results of total gamma radiation monitoring at the 18 Weldon Spring site (WSS) perimeter monitoring stations, Francis Howell High School, the Weldon Spring Army Reserve Training Area, and at the six background monitoring stations.

The Weldon Spring Site Remedial Action Project (WSSRAP) is in the process of changing TLD vendors. To facilitate this change, duplicate TLDs, one from the existing vendor and one from the new vendor, were deployed at four monitoring locations during this quarter. This changeover will be effective starting with the third quarter 1992.

The average gamma radiation measured at the 26 locations during the second quarter of 1992 (30.2 mrem) was about twice that measured in the second quarter of 1991 (15.5 mrem). Based upon the readings of the control TLD (which read 14.8 mrem for the second quarter 1991, and 37 mrem for the second quarter 1992), we believe that the elevated TLD results were due either to irradiation of dosimeters after shipment to the vendor or to vendor processing problems. Also, the results of the new dosimeters that were deployed as duplicates at four locations were comparable with historical data. This further supports the contention that the elevated readings were not attributable to actual increases in environmental gamma radiation levels in the second quarter 1992. The arithmetic average of the dose measured at the five background locations is 31 mrem. This dose is not significantly different than what was seen at other locations monitored. Thus it may be concluded that the elevated readings measured at the site and quarry were not the result of work activities performed at the site. The cause of the elevated results is still under investigation. The final results will be reported in the 1992 ASER.

5.3 Radioactive Air Particulates

Fourteen low volume air particulate samplers monitor the Weldon Spring site continuously. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter. There are three sensitive monitoring stations, AP-4006, AP-4008, and

* Denotes background station.

AP-4011, located off-site at the Francis Howell high School, the Army Reserve property, and near a residential site west of the quarry, respectively. Three new monitoring stations were added during the second quarter. Two monitoring stations, AP-2013 and AP-3014, were installed at the WSCP perimeter. The other new station, AP-1017, was installed at the WSQ perimeter. The monitoring station at the August A. Busch Wildlife Area (ABWA) (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The air particulate monitoring stations are shown in Figure 5-1 and 5-3.

The background sampling station AP-4007, is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/RP area.

Table 5-3 summarizes the quarterly average concentrations and the standard deviations for the 11 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging all weekly air particulate analysis results including results lower than the instruments lower limit of detection (LLD). The corresponding standard deviation for each monitoring location was also calculated using all weekly air particulate analysis results. Due to maintenance and installation of new samplers, all samplers were not operating the entire 13 weeks, as indicated in the fourth column of Table 5-3. The WSSRAP has deployed high volume air samplers at critical receptor locations. The critical receptor locations include the Francis Howell High School, the Missouri Department of the Army

TABLE 5-3 Second Quarter 1992 Radiological Air Particulate Monitoring Results

To convert μCi/ml to Bq/m^3, multiply by 3.7E10.

Reserve property, the WSSRAP administration building, and the residential area west of the quarry. These high volume samplers are used in accordance with the *Plan for Monitoring Radionuclide Emissions Other Than Radon at the Weldon Spring Site Critical Receptors* (MKF and JEG 1992b). The high volume monitoring results will be presented in the 1992 annual site environmental report.

The second quarter average long-lived gross alpha concentrations ranged from 1.03×10^{-15} μCi/ml to 1.99×10^{-15} μCi/ml for perimeter and off site locations. The average background concentration measured at AP-4007 was 1.33×10^{-15} μCi/ml.

5.4 Asbestos

No environmental asbestos monitoring was conducted during the second quarter of 1992. As outlined in the *Environmental Monitoring Plan* (MKF and JEG 1992a), environmental asbestos monitoring is required to be performed only during asbestos removal activities. Since there were no asbestos removal operations during the second quarter of 1992, there was no need to perform environmental asbestos monitoring.

Dear Dr. Bedan:

TRANSMITTAL OF SITE SOIL PERMEABILITY DATA

A technical memorandum from the Project Management Contractor (PMC) staff is enclosed for your information and review. This document outlines the results of recent data gathering activities relating to leachate permeability of site soils at the Weldon Spring Site. Specific data collected includes:

- Laboratory permeability testing of undisturbed soils with both water and synthesized leachate as a permeant, performed to assess the effects of leachate on permeability.
- Field permeability testing of insitu site soils using a two-state borehole (TSB) procedure.

General conclusions from this effort include:

- Results of TSB testing indicate that in situ hydraulic conductivity is not affected by macropore features such as cracks or fractures.
- Logarithimic mean field permeability values (TSB results) range from 1.28 E^{-08} to 3.34 E^{-09} (cm/s).
- Hydraulic conductivity values obtained under recent efforts are consistent with prior data, and support the suitability of the proposed area for a disposal site.
- Synthesized leachate has no detectable effect on permeability. Logarithmic mean hydraulic conductivity values range from 1.26 E^{-09} cm/s (leachate) to 1.66 E^{-09} cm/s (water).
- These values indicate that a 20 ft layer of site clay soils will retard the migration of hazardous constituents contained in the waste to at least the same degree that 30 ft of material having a coefficient of permeability of 1.0 E^{-07} cm/s would retard the migration of water.

SUBJECT: Contract No. DE-AC05-86OR21548
TRANSMITTAL OF SITE SOIL PERMEABILITY DATA TO THE MISSOURI DEPARTMENT OF NATURAL RESOURCES.

Dear Mr. McCracken:

Information from recent data gathering activities relating to permeability of undisturbed site soils is attached. This data was collected at the recommendation of the MDNR/DGLS technical staff, and relates to the technical requirements for hazardous waste landfill siting standards as presented in 10 CSR 25-7. Although this regulation is not considered applicable, we have agreed to utilize these requirements to develop design criteria, including the use of engineered fill to meet these standards. Specific data collected include:

- Laboratory permeability testing of undisturbed soils with both water and synthesized leachate as a permeant, performed to assess the effects of leachate on permeability.

- Field permeability testing of insitu site soils using a two-stage borehole (TSB) procedure.

General conclusions from these data are as follows:

- Results of TSB testing indicate that *in situ* hydraulic conductivity is not affected by macropore features such as cracks or fractures.

- Logarithmic mean field permeability values (TSB results) range from 1.28 E^{-08} to 3.34 E^{-09} (cm/s).

MK-FERGUSON COMPANY
A MORRISON KNUDSEN COMPANY

 TRANSMITTAL OF SITE SOIL PERMEABILITY DATA TO THE MO. DEPT. OF NATURAL RESOURCES.

- Hydraulic conductivity values obtained under recent efforts are consistent with prior data, and support the suitability of the proposed area for a disposal site.

- Synthesized leachate has no detectable effect on permeability. Logarithmic mean hydraulic conductivity values range from 1.26 E^{-09} cm/s (leachate) to 1.66 E^{-09} cm/s (water).

- These values indicate that a 20 ft layer of site clay soils will retard the migration of hazardous constituents contained in the waste to at least the same degree that 30 ft of material having a coefficient of permeability of 1.0 E^{-07} cm/s would retard the migration of water.

A technical memorandum is attached that includes data interpretation, data tables, technical references, example calculations, and graphical presentations of the data. A formal report will be forthcoming.

Please transmit this information to the MDNR and the EPA. A draft letter of transmittal is included for your use. A copy of this letter with attachments will be placed into the administrative record. Please contact Rick Ferguson or Ken Warbritton of my staff should you have any questions.

INTER-OFFICE CORRESPONDENCE

DATE: November 23, 1992

TO: R. Ferguson

FROM: Kenyon Warbritton/Jeff Carman

SUBJECT: **TECHNICAL MEMORANDUM PRESENTING RESULTS OF RECENT LABORATORY AND FIELD PERMEABILITY TESTS.**

The PMC has recently completed Two-Stage Borehole (TSB) field permeability testing performed at the request of MDNR/DGLS personnel. These tests were performed on the Ferrelview Formation and clay till unit at locations within the Disposal Facility Study Area.

An additional testing program, triaxial permeability testing of small undisturbed samples, is nearly complete. These tests were performed using both water and a synthesized leachate as a permeant. This program is not yet finalized, however key findings are available at this time for review by interested parties.

Samples of these test programs were obtained in accordance with "Sampling Plan for Determination of Hydraulic Properties of Undisturbed Soils in the Weldon Spring Disposal Facility Study Area", Rev. 1, MK-JEG, Oct. 92. Data and conclusions from these two test programs, in addition to prior WSSRAP testing, were utilized to calculate travel times for water through a 20 ft. layer of site soil. These travel time values were compared to travel time values calculated for a 30 ft. layer of material with a hydraulic conductivity of 1.0 E^{-07} cm/s (as described in 10 CSR 25-7).

TWO-STAGE BOREHOLE FIELD PERMEABILITY TESTS

I. Please find the following attachments relating to the TSB test effort.

Attachment 1 - Figure indicating the locations of TSB tests.

Attachments 2A and 2B - Spreadsheet calculation summaries which yield initial temperature corrected hydraulic conductivity values for stage 1 (K1CT) and stage 2 (K2CT).

Attachments 3A and 3B - Plots of time versus hydraulic conductivity for stage 1 and stage 2.

Attachment 4A and 4B - Calculations of the final time-weighted average hydraulic conductivity (K1' and K2').

Attachment 5 - Spreadsheet calculation summary of the derived Kv and Kh values.

Attachment 6 - TSB Method Reference, "The STEI Two-Stage Borehole Field Permeability Test", Boutwell, March 1992.

II. Results of the TSB test program are summarized as follows:

- Table 1 provides a summary of TSB test results.

b:\mdnr.1

- Table 2 provides a summary of basic statistics generated from the TSB results presented in Table 1.

- Results of TSB testing indicate that *in situ* hydraulic conductivity is not affected by macropore features such as cracks or fractures.

- TSB no. 9 exhibited the highest permeability and also exhibited some erratic behavior early in the testing program, leading PMC staff to question the integrity of this test boring. This data is presented and is utilized in the attached data summaries. PMC staff have recently added dye to the permeameter (TSB-9) to investigate potential leakage when abandoning this hole using controlled excavation.

WATER/LEACHATE PERMEABILITY TESTING

I. Please find the following attachments relating to water/leachate permeability testing:

Attachment 7 - Figure indicating locations for undisturbed site soil samples which were subjected to permeability testing (ASTM Method D-5084).

Attachment 8 - Summary of leachate synthesis methodology.

II. Results of the water/leachate permeability testing are summarized as follows:

- Table 3 summarizes the results to date of permeability tests run using water and leachate as a permeant.

- The effect of synthesized leachate on permeability values for these undisturbed soils was not detectable. Permeability values for two samples increased slightly, values for two samples decreased slightly, and values for two samples remained essentially the same when synthesized leachate was used as the permeant after tap water. These slight differences are within the range of accuracy obtained by test measurements.

CONCLUSIONS RESULTING FROM COMBINED DATA

I. Please find the following attachments relating to water/leachate permeability testing:

Attachment 9 - Presents calculations of travel time and permittivity which compare a 20 ft. thickness with hydraulic conductivity values from various WSSRAP sampling efforts (laboratory and field efforts) to a 30 ft. layer of soil with a hydraulic conductivity of 1.0 E^{-07} cm/s (per 10 CSR 25-7).

Attachment 10 - Presents a list of pertinent reference documents associated with the data and conclusions in this technical memorandum.

II. Conclusions resulting from review of combined data are summarized as follows:

Studies conducted to date have focuses on the hydrologic performance of site soils on a conservative basis. Geochemical performance studies focusing on leachate/mineral interaction are currently being negotiated with Pacific Northwest Laboratory (PNL). The hydrologic data presented herein are considered a "worst case" assessment of the material effects of leachate/mineral interaction.

- Field hydraulic conductivity testing by the Two-Stage Borehole method indicates that macropore features such as cracks and fractures do not result in larger hydraulic conductivity values than have previously been determined for the Ferrelview Formation and clay till soil units in the Disposal Facility Study Area.

- Laboratory triaxial permeability tests have shown synthesized leachate to have an undetectable effect on hydraulic conductivity of Ferrelview Formation and clay till soil unit samples.

- Travel time and permittivity calculations are used to demonstrate that the soil units comprising the foundation of the proposed disposal facility will provide a level of protection superior to the minimum criteria specified under 10 CSR 25-7.

- The data and calculations presented herein for the Ferrelview Formation and clay till soil units satisfy the criteria set forth under 10 CSR 25-7.264 (2)(N)1.A.(III) which addressed minimum soil performance requirements relative to the movement of hazardous constituents.

This information substantiates the suitability of the WSSRAP site for location of a disposal facility. A formal report regarding this data is forthcoming, pending completion of all associated testing. If you have any questions or comments, please contact K. Warbritton (ext. 3309) or J. Carman (ext. 3506).

Logarithmic Mean (Both Units)	3.34 E^{-09}	1.28 E^{-03}	1.73 E^{-09}	6.43 E^{-09}

All hydraulic conductivity values are presented in units of cm/s.

K1′ = Arithmetic time-weighted average stage 1 hydraulic conductivity.

K2′ = Arithmetic time-weighted average stage 2 hydraulic conductivity.

Kv = Final calculated vertical component of hydraulic conductivity.

Kh = Final calculated horizontal component of hydraulic conductivity.

FF = Ferrelview Formation

CT = Clay Till unit

TABLE 3

SUMMARY
OF
WATER/LEACHATE HYDRAULIC CONDUCTIVITY DATA

	Formation	Plasticity Index	Water K	Leachate K
GT80-ST12	CT	33	1.74 E^{-09}	1.22 E^{-09}
GT83-ST06	FF	44	1.25 E^{-09}	1.2 E^{-09}
GT83-ST12	CT	35	1.0 E^{-09}	1.2 E^{-09}
GT82-ST05	FF	60	5.0 E^{-10}	6.5 E^{-10}
GT82-ST08	CT	38	1.5 E^{-08}	2.68 E^{-09}
GT84-ST07	FF	61	1.3 E^{-09}	1.3 E^{-09}

Overall natural log mean hydraulic conductivity value for water is 1.66 E^{-09} cm/s.
Overall natural log mean hydraulic conductivity value for leachate is 1.26 E^{-09} cm/s.

Sample ID	Formation	Days Water	Days Leachate	Water Pore Vol.	Leachate Pore Vol.	Total Pore Vol.
GT80-ST12	CT	5	38	0.18	0.70	0.88
GT83-ST06	FF	4	40	0.43	2.59	3.02
GT83-ST12	CT	7	23	0.53	1.79	2.32
GT82-ST05	FF	7	23	0.19	0.77	0.96
GT82-ST08	CT	8	16	3.53	3.91	7.44
GT84-ST07	FF	8	18	0.92	1.35	2.27

CT = Clay Till Soil Formation
FF = Ferrelview Clay Formation

Note: Values presented are current as of Nov. 16, 1992. Values for plasticity index are included for information. No correlations are proposed at this stage, relating PI to hydraulic conductivity. Hydraulic conductivity (K) values are shown in units of cm/s. Permeability testing with leachate will continue until all samples exceed 1.0 pore volume of leachate. Total pore volumes are estimated from calculations for total porosity for each sample.

TSB CALCULATIONS

TIME-WEIGHTED AVERAGE

HYDRAULIC CONDUCTIVITY

K1'

SUBJECT STAGE I TSB FINAL VALUES SHEET 1/5

DATE 11-13-92 BY JDC CHKD. DE Comm JOB NO. 3940-827-01-903

FROM BAITWELL (1992):

$$K1' = \Sigma(K_i * T_i) / \Sigma(T_i)$$

WHERE:

$K1'$ = ARITHMETIC TIME WEIGHTED ALERAGE HYDRAULIC CONDUCTIVITY (CM/SEC)

T_i = TIME DURATION OF TEST INCREMENT (i) (SEC)

K_i = HYDRAULIC CONDUCTIVITY MEASURED DURING TEST INCREMENT (i) (CM/SEC) (TEMPERATURE CORRECTED VALUES · KCT)

1) USING LAST 6 MEASUREMENTS FROM TSB-1 WHERE $T_i > 1000$ s:

$$K1' = \frac{(1.4E-9 * 86400) + (3.49E-9 * 87900) + (3.38E-9 * 85020) + (3.35E-9 * 82560) + (1.84E-9 * 91320) + (1.62E-9 * 76500)}{86400 + 87900 + 85020 + 82560 + 91320 + 76500}$$

$$= \frac{1.54E-03}{509700} = \boxed{3.03E-09 \text{ cm/sec}}$$

2) USING THE LAST 6 MEASUREMENTS FROM TSB-2 WHERE $T_i > 1000$s

$$K1' = \frac{(2.55E-9 * 86280) + (3.22E-9 * 87660) + (3.25E-9 * 85140) + (3.47E-9 * 82500) + (2.37E-9 * 91380) + (3.51E-9 * 76200)}{86280 + 87660 + 85140 + 82500 + 91380 + 76200}$$

$$= 1.55E-03 / 509160 = \boxed{3.04E-09 \text{ cm/sec}}$$

SUBJECT STAGE 1 TSB FINAL VALUES SHEET 215

DATE 11-13-92 BY JDC CHKD. QC Cmon JOB NO. 3940-827-01-903

3) USING LAST 6 MEASUREMENTS FROM TSB-3:

$$KI' = \frac{(2.58E-9 * 86580) + (2.18E-9 * 87660) + (2.43E-9 * 85080)}{86580 + 87660 + 85080}$$

$$+ \frac{(3.69E-9 * 82860) + (8.8E-10 * 91020) + (1.74E-9 * 83400)}{+ 82860 + 91020 + 83400}$$

$$= \frac{1.15E-3}{516600} = \boxed{2.23E-09 \text{ cm/sec}}$$

4) USING LAST 6 MEASUREMENTS FROM TSB-4:

$$KI' = \frac{(3.22E-9 * 86520) + (3.32E-9 * 87660) + (3.42E-9 * 85200) +}{86520 + 87660 + 85200}$$

$$\frac{(3.56E-9 * 82800) + (2.41E-9 * 91020) + (2.41E-9 * 82920)}{+ 82800 + 91020 + 82920}$$

$$= \frac{1.57E-03}{516120} = \boxed{3.05E-09 \text{ cm/sec}}$$

5) USING LAST 6 MEASUREMENTS FROM TSB-5:

$$KI' = \frac{(4.59E-9 * 85080) + (8.10E-9 * 82680) + (3.69E-9 * 91020)}{85080 + 82680 + 91020}$$

THE STEI TWO-STAGE BOREHOLE FIELD PERMEABILITY TEST

by: Gordon P. Boutwell, PhD, P.E.

Presented to
"CONTAINMENT LINER TECHNOLOGY AND SUBTITLE D"
Seminar Sponsored by
Geotechnical Committee
Houston Branch, ASCE
Houston, Texas - March 12, 1992

SYNOPSIS

In 1991, the Texas Department of Health began requiring field verification of the hydraulic conductivity for the waste-retention barriers under its jurisdiction. The TDH has approved two procedures: the Two-Stage Borehole (TSB) method and the Sealed, Double-Ring Infiltrometer (SDRI) method. The TSB method is discussed herein.

It is a falling-head infiltration test conducted in a cased borehole, typically 4 inches in diameter. The first stage is performed with the bottom of the hole flush with the bottom of the casing for maximum effect of vertical permeability (k_v). After steady-state is achieved, the hole is advanced some 6 to 8 inches below the bottom of the casing so that horizontal permeability (k_h) has a greater effect. The two stages yield the following:

Stage 1 - The maximum possible value for (k_v).
Stage 2 - The minimum possible value for (k_h).
Stage 1 + Stage 2 - Constants for two equations which can then be solved for the real (k_h, k_v).

Procedures are available for reduction of the data in the cases of both above and below water table testing, and for the bottom boundary conditions of a material far more permeable, equally permeable, or far less permeable than the medium being tested. The test has been successful in evaluating both compacted and natural materials with permeabilities as low as 1x10(-9) cm/sec.

The major test precautions include proper sealing of the casing along the outside, accounting for temperature effects, and correcting for sidewall smear during the second stage. The test is quick, simple, and relatively inexpensive. It allows results in days, rather than months. Multiple installations are feasible so that statistical confidence can be achieved. It is recognized in the literature, including U.S. EPA publications, and accepted by many State regulatory authorities.

I. INTRODUCTION

Clay barriers are an important component of waste retention structures. Their primary geotechnical characteristic for this use is hydraulic conductivity, which must be verified during the Construction Quality Assurance program. Until recently, practice relied on laboratory testing of small (7 to 10 cm diameter) undisturbed samples taken from the barrier or a similarly constructed test pad. Day and Daniel (1985) reported conductivities measured in the field which were 3 to 4 orders of magnitude higher than they obtained with laboratory tests. While that study was justly criticized, the horse was out of the barn and regulators all over the country galloped into field testing for hydraulic conductivity evaluation at waste facilities.

From the regulatory standpoint, a test procedure should be accurate and avoid false positives, i.e., not indicate compliance with the specified conductivity when the liner or pad truly has a higher value. This normally means testing a large soil volume searching for the elusive "macropores" which are thought to evade, somehow, even numerous laboratory tests. The regulated community wants the accuracy and avoidance of false positives for their own protection, but also wants to minimize testing times (and costs), and to avoid false negatives, both for economy.

In about the last two years, two methods have become accepted as meeting these criteria to a satisfactory degree: the Sealed, Double-Ring Infiltrometer (SDRI) and the Two-Stage Borehole (TSB) procedure. Each has its stronger and weaker points (see Daniel, 1989).

II. BASIC CONCEPTS

The vertical conductivity (k_v) governs flow, even in sidewall liners if built in the preferred manner: lifts parallel to the slope. However, the horizontal conductivity (k_h) is greater than the vertical. All field tests are affected by this anisotropy, unless flow in the horizontal direction is artificially blocked; the effect is to increase the test conductivity by factors of 2 to 5 over the real (k_v) value. Equations for flow from various source geometries in a cross-anisotropic medium are available in Hvorslev (1951). However, each equation has two unknowns: (k_v) and ($m^2 = k_h/k_v$).

The TSB procedure combines four old concepts into one new idea to find (k_v). The field procedure is taken from long-established US Bureau of Reclamation methods: their flush-bottom borehole test (E-18) and borehole packer test (E-19). Computations are based on the Hvorslev equations adapted for various bottom boundary conditions by the three-dimensional Image Potential Technique (Carslaw and Jaeger, 1959). The new idea is performing both USBR tests in the same borehole, yielding two equations which can be solved for the two unknowns, (k_h) and (k_v).

The TSB is a field infiltration test, conducted in a cased borehole so that the geometry of the infiltrating zone can be controlled. It is normally conducted as a falling-head test. The basic idea is to vary the geometry of the infiltrating area so as to vary the relative effects of (k_h) and (k_v). In the first stage, the geometry is chosen so that (k_v) has its maximum effect. The second stage geometry is such that (k_h) has its maximum effect. The results of the two stages yield two equations in two unknowns (k_h, k_v), which can then be solved. This concept is illustrated on Figure 1, below:

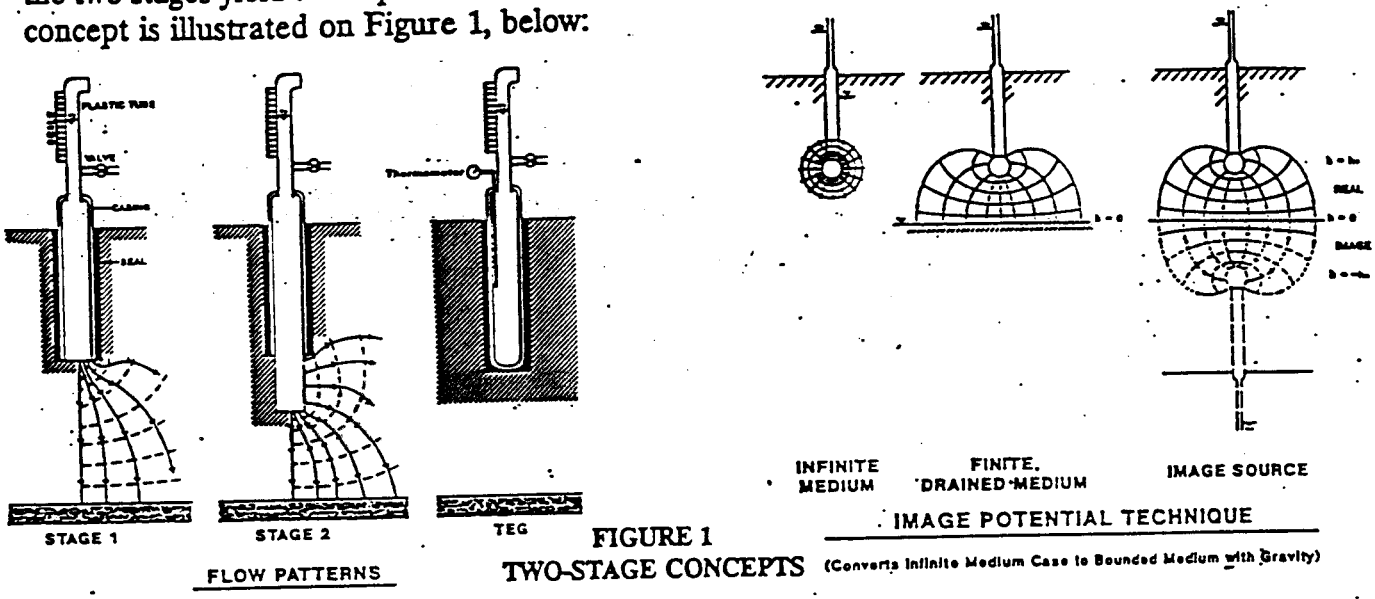

FIGURE 1
TWO-STAGE CONCEPTS

Stage 1 is normally conducted using a flat bottom flush with the base of the casing. Infiltration proceeds until a steady-state flow condition is achieved. Then, the borehole is advanced some 1.5 to 2 casing diameters (6 to 8 inches) below the bottom of the casing. The apparatus is refilled, and infiltration in this Stage 2 continues until it achieves steady-state flow.

During the test, the soil is assumed isotropic ($k_v = k_h$). Stage 1 then yields an apparent permeability (K1), and Stage 2 a different value (K2). The unknown ratio (k_h/k_v) is a unique function of the known test geometry and the known test ratio (K2/K1). When the former is determined, the real (k_v, k_h) can be computed from (K1) or (K2).

III. FIELD PROCEDURES

As is the case with virtually all field tests, and especially field permeability tests, the field procedures are of paramount importance. The most diligent office analyses cannot overcome all of the problems resulting from improper installation, inadequate monitoring, premature test termination, and the like.

3.1 Test Program Design. The test program should be designed to meet the conditions assumed in deriving the data reduction equations so that meaningful results can be obtained.

3.1.1 Vertical Boundaries. Certain clearances are required between the infiltrating surface and any boundaries, pervious or impervious. These can be summarized as:

a. **Minimum casing embedment below ground surface = 2.5D**
(Prevents uplift, minimizes hydraulic fracturing)

b. **Minimum thickness of tested material below bottom of Stage 2= 2.0D**
(Avoids violating boundary conditions of equations)

c. **Minimum recommended Stage 2 extension = 1.5D**
(Avoids theoretical problems at finite but small L/D)

D = Casing inside diameter
L = Length of Stage 2 extension

3.1.2 Horizontal Spacings. It is intuitively obvious that the tests must be spaced "far enough" apart so that their flows do not interfere with each other causing a falsely low permeability. Also, the presence of a drainage boundary (such as the edge of a test pad) which is "too close" to the test will increase the flow, yielding a falsely high permeability.

This can be avoided by maintaining at least the following clearances:

a. **Minimum horizontal distance between tests = 30D**
b. **Minimum horizontal distance to free surface = 30D**

3.1.3 Number and Size of Tests. The number of tests required for evaluation depends on the project, the acceptance criteria, and the variability of the stratum/fill being evaluated. As in virtually any other geotechnical testing, "the bigger the better".

However, the general practice has been to use 4-inch (ID) tests, with 5 tests for the typical liner or test pad.

The scale effect, if any, of test size has not been fully researched. Virtually all of the known tests have been conducted using 4-inch (10 cm) ID casings. These tests typically permeate a volume of some 0.4 - 1.1 cubic feet each, or 2 to 5 cubic feet for a 5-test group. Benson (pers. comm., 1991) indicates that the minimum representative volume for a permeability determination is on the order of 0.5 - 1.0 cubic foot. This is about the volume permeated by a typical TSB test.

3.1.4 Other Details. There are a few other details in test planning which should be considered. Among these are:

a. Protect the test area surface from desiccation, usually with clear or white plastic.
(Avoids heat-induced problems).

b. Use a "sock" to prevent collapse of the Stage 2 open hole in susceptible materials. The sock is a rigid cylinder of open-mesh plastic, lined with a filter geofabric. The cylinder is somewhat smaller in diameter than the casing ID (and thus the Stage 2 hole), and an inch or so longer than the extension for Stage 2. It is fitted with retrieving lines and not left in the hole after the test.

c. Minimize the distance (R_y) from the ground surface to the bottom of the measuring scale, especially for shallow tests. This also aids in having the longest possible reading time between standpipe refills and avoiding hydraulic fracturing.

d. Match the standpipe size to the flow rate so that accuracy is achieved but overnight readings are possible. For a 4-inch casing, this usually means a 0.5 - 0.75 inch ID standpipe.

3.2 Permeameter Installation. Proper installation and checking the permeameters are vital to obtaining a valid test. Various field techniques have been developed through experience which minimize problems. These techniques are discussed in this section.

3.2.1 Permeameter. A typical permeameter is illustrated on Figure 2. The apparatus is simple; the permeameter can be assembled with a visit to a water-well driller and a hardware store. The elements for a falling-head system are:

a. Casing. Typically 4-inch ID Schedule 40 PVC monitoring well pipe, flush-threaded, with "O"-Ring joint. Other casings can be used.

b. Cap. To fit casing, preferably domed, and drilled and/or tapped to receive the standpipe apparatus.

c. Standpipe. *Clear* Schedule 40 PVC or acrylic tube, 0.5 to 1.0 inch ID, with scale. Include elbow with cover (having air-vent) to prevent rain entry and minimize evaporation.

d. Fittings. The small fittings necessary to assemble the apparatus.

All joints which are not glued are assembled with PTFE Plumber's Tape and silicone grease (not sealant).

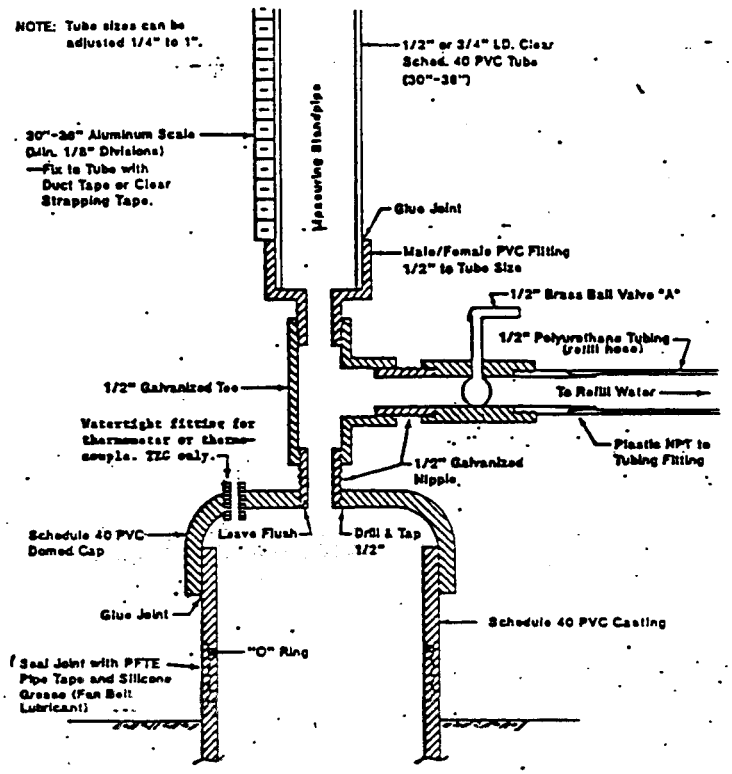

FIGURE 2
TYPICAL PERMEAMETER

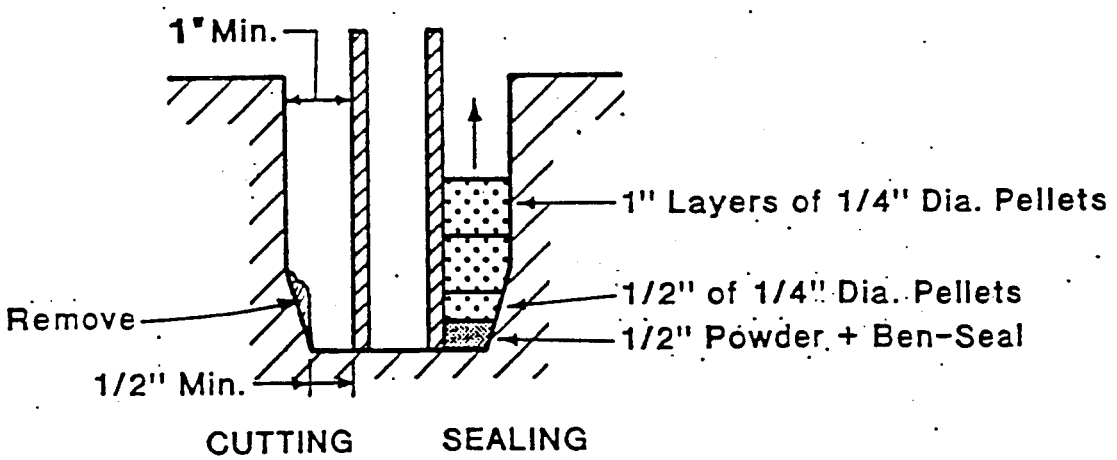

FIGURE 3
SEALING PROCEDURE

3.2.2 Borehole. The casing is set into a borehole. The holes have been drilled using rigs, power-operated hand equipment, and hand augers. The device depends on depth and hardness of material. The hole must have a large enough diameter to allow sealing the annular space between the borehole wall and the casing. Also, it must not disturb the soils below the casing bottom. The bottom must also be flat. Experience has shown the following to be acceptable:

a. Borehole diameter at least 2 inches greater than the casing OD. (To allow sealant to reach the bottom and for tamping).

b. Stop point of auger about 1 inch above proposed casing bottom. (To avoid testing in a disturbed material)

c. Ream bottom of borehole to final depth with a flat auger.

The bottom of the borehole should be flat and flush with the bottom of the casing in order to correspond with Hvorslev's (or H-I) Case "B" or "C" for Stage 1.

3.2.3 Sealing. This is the single most important step in installation. A poorly sealed test cannot be salvaged. The annular space between the casing and the wall of the borehole is sealed with bentonite. Best results have been attained using 1/4" (not 3/8" or larger) bentonite pellets or crushed bentonite (Baroid "Hole-Plug" or equivalent). The procedure, illustrated on Figure 3, is:

a. Crush sufficient pellets, "Ben-Seal", or "Hole-Plug" to fill about 1/2 inch of the annulus. This should have about 1/16" size fragments with some powder.

b. Place this material into the annular space.

c. Place about 1/2 inch of bentonite pellets or "Hole-Plug" into hole,

d. Tamp the bentonite pellets or "Hole Plug",

e. Add water until it shows above the bentonite,

f. Repeat the process (but using only the pellets or "Hole Plug") in 1 inch increments to the ground surface or a minimum of 6D above the casing bottom, whichever occurs first. Grouting above the 6D level is allowable.

g. Allow the bentonite (and grout) to hydrate at least overnight.

The casing must be steadied to prevent lateral motion while sealing. The bentonite seal is then allowed to hydrate overnight before any head is applied to the system.

3.2.4 Advancing for Stage 2. Upon completion of Stage 1, a borehole is advanced below the bottom of the casing to form the cylindrical infiltrating surface for Stage 2. The important points are:

a. **Do not disturb the casing - that can affect the seal.**

b. **Borehole diameter should equal casing ID.**

c. **Stop point of auger about 1 inch above proposed Stage 2 bottom. Ream flat and measure depth.**

d. **Roughen the sidewalls to minimize smear.**

This portion of the work is normally handled with hand equipment. The first step after removing the cap is to empty the casing of water (tests above groundwater level or where no seepage was noted during Stage 1 drilling and/or sealing). It is frequently useful to obtain an undisturbed sample during this process, using ASTM D2937 or D1587. However, undisturbed sampling should not be performed if the material being tested contains gravel-sized particles; they can disturb the sidewalls during the push or driving. After or in lieu of undisturbed sampling, the boring is augered until the point of the auger is about 1 inch above the desired bottom for Stage 2. The auger should be at least 1/2 inch in diameter smaller than the casing ID. The boring is then completed to depth and diameter with a flat-bottomed reamer.

The reamer is designed to minimize sidewall smear, having full casing ID only at the cutting edge. The sidewalls are then roughened with a wire brush or similar device, a procedure also recommended in USBR E-18. This step must not be omitted, since one of the significant problems encountered in Two-Stage testing has been artificially low values for Stage 2 due to smear. Equations to handle smear are included herein, but require some idea of the degree of smear.

After the borehole is completed and cleaned of cuttings, the depth is measured so that the correct length of the Stage 2 cylinder is known. For a typical test, a 1-inch depth error will yield the wrong Stage 2 permeability value by 7 to 8%. The cap is then reseated, and Stage 2 begins.

3.3 Ambient Condition Effects. Temperature changes cause the dominant effects of ambient conditions on this test, although there may be some contribution from barometric pressure changes. Temperature changes affect the test by:

- Volumetric changes in the water and apparatus.
- Viscosity changes with temperature.
- Freezing the test water.

The procedures for overcoming these effects are given below.

3.3.1 Volumetric Effects (TEG). At slow rates of flow, the field readings are affected by temperature, as has been noted on many such projects. Rising temperature causes the water column in the pressure/measurement standpipe to expand, so that the drop in water level is less than flow alone would produce. The net effect is a lower apparent permeability. Conversely, falling temperature produces a higher apparent permeability. A normal day's temperature variations can easily cause a 0.5 to 1 order of magnitude change in the apparent permeability of low-permeability materials.

Therefore, a complete "dummy" test setup is installed but with the bottom of the casing sealed with a cap which is normally glued on and pressure-tested. This dummy, or temperature effect gauge (TEG) is of the same construction and embedded to the same depth as the regular test setups. Since there is no flow from the TEG, any change in its readings must be due to changes in the ambient conditions (temperature and/or barometric pressure). Such changes would affect the regular test setups to exactly the same degree.

This correction is applied to the regular tests by:

- Reading the TEG at the same times as readings are taken on the regular tests.
- Determining any increase (decrease) in .water levels in the TEG between regular test readings.
- Subtracting any increase (adding any decrease) at the TEG from the readings at the regular tests for the ends of the same time increments.

3.3.2 Viscosity Effects of Temperature. Permeability is normally reported as the value for water at 20°C (68°F). The density and viscosity of liquids, including water, are affected by temperature. The effect on permeability is in direct ratio to the kinematic viscosity (U), which is the viscosity divided by the density. The kinematic viscosity decreases at higher temperatures. The net effect is that the apparent permeability is greater than the 68°F value at low temperatures. The reverse occurs with decreasing temperatures. The effects for ordinary conditions can be from -50% to +15% on the permeability value. The normal correction to the standard condition is given in ASTM D5084:

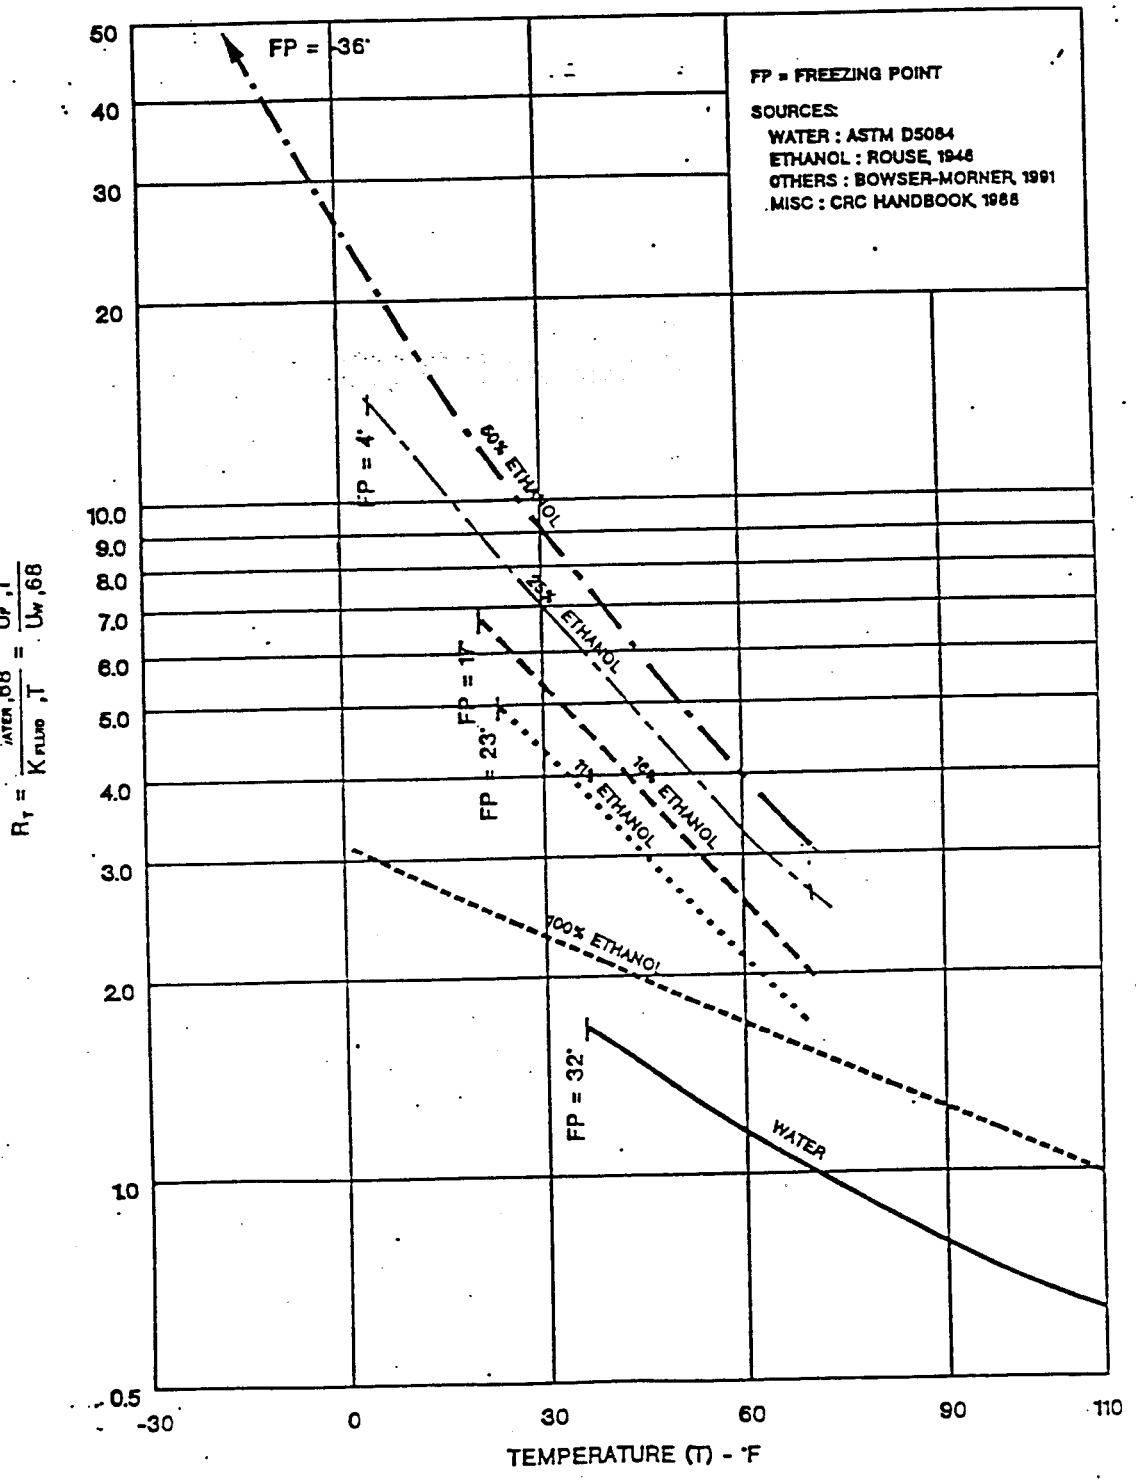

FIGURE 4
KINEMATIC VISCOSITY FACTORS

$$k_s/k_T = R_T = U_T/U_s \qquad (3.3.-1)$$

where:
k_s = Permeability for water at 68°F
k_T = Permeability observed in test
R_T = Correction Factor
U_T = Kinematic viscosity for test fluid at test temperature
U_s = Kinematic viscosity for water at 68°F

The factors (R_T) are given for water at temperatures between freezing and 120°F (0 to 49°C) in ASTM D5084. See also Figure 4 which reproduces that data.

The temperature of the exfiltrating water is measured by a thermometer or thermocouple in the TEG. It should extend to roughly the bottom of the casing. The thermometer or the leads for the thermocouple should have its own (sealed) port into the TEG cap or casing. Running either through the TEG standpipe could easily affect its function of volumetric correction.

3.3.3 Freezing Conditions. Unfortunately, field testing must sometimes proceed when the air temperatures are below freezing. Landfill operators often complete a test pad in late fall, so that they will have approval from the regulators for construction in the spring. Even if the ground temperatures stay above freezing, one cannot get decent readings from a frozen standpipe. Three procedures have been used:

a. Insulate the exposed test equipment, exposing only to make readings. (Only if mean daily air temperature exceeds freezing)

b. Use an antifreeze.
(Ethanol as Vodka is good, but needs its own R_T vs temperature graph. Does not attack clay at 25% or less alcohol).

c. Heat the test units.
(Potential for different temperatures - can invalidate the TEG).

3.4 Conducting the Test. The following discussion is applicable to both Stage 1 and Stage 2. Basically, the procedure is:

a. Fill and assemble permeameters.
(Use PTFE tape and silicone grease. Pour slowly to avoid bottom erosion).

b. **Read standpipe levels over time at the permeameter, plus level and temperature at the TEG.**
(Levels: to 1/16", temperature to 1°F).

c. **Convert these readings to apparent permeabilities.**

d. **Continue the test until these permeabilities remain steady.**

3.5 Field Calculations - Apparent Permeability. The data from each reading is converted into an apparent permeability, termed (K1) for Stage 1 and (K2) for Stage 2. Keeping up with the data in terms of a permeability has a physical meaning, and also yields a better "feel" for the behavior of the medium being tested. If that medium were isotropic ($k_h = k_v$), then (K1,K2) would be "the" permeability. Remember that the objective of most field permeability tests on regulated facilities is to determine that the vertical permeability (k_v) of the liner is not greater than some value, usually 1x10(-7) cm/sec, or to show that the horizontal permeability (k_h) of a drainage material is not less than some value, typically 1x10(-2) cm/sec. It can be shown that (K1) is the maximum possible value for (k_v) and that (K2) is the minimum possible value for (k_h). Hence, using these apparent permeabilities (K1,K2) frequently allows "pass-or-fail" determination early in the testing process. For example, (K1<Spec) within 24 hours in 90% of tests where (k_v/Spec<0.6), and 70% of all tests.

The equations for both Stage 1 and Stage 2 follow the generic falling-head test format:

$$k = R_T G \, \mathrm{Ln}(H_1/H_2)/(t_2-t_1) \qquad (3.5\text{-}1)$$

where:

k	=	Permeability
H_1	=	Initial head (at $t=t_1$)
H_2	=	Final head (at $t=t_2$)
t_1	=	Initial time
t_2	=	Final time
G	=	Geometric Constant, depends on test geometry
R_T	=	Kinematic viscosity correction to water at 68°F

In both Stages, the head is taken as the distance from the level in the standpipe to the groundwater level. The distance from the bottom of the casing to the groundwater level is limited for calculation purposes (only) to no more than 20 times the casing ID. If the depth to groundwater is less than 20 times the casing ID, the true depth is used in the calculations. However, where the depth to groundwater exceeds this criterion, it is considered to be at this 20-diameter depth in the calculations. This limitation is derived by 3-dimensional analogy with the two-dimensional "effective radius" of a well. The volumetric effects of temperature are accounted for using a corrected final head, replacing (H_2) by (H_2'), where:

$$H_2' = H_2 - c \qquad (3.5\text{-}2)$$

where: c = Increase in TEG standpipe water level during time period from t_1 to t_2

If the TEG standpipe water level goes up between readings, (c) is positive and ($H_2' < H_2$). Conversely, (c) is negative and ($H_2' > H_2$) if the TEG standpipe level drops between readings. This step is not theoretically precise, but is close enough for test purposes. The theoretical solution yields a complex implicit equation in which the true permeability is a function of its own logarithm. However, for the geometry of the test setups and the observed magnitudes of increases/decreases, the apparent permeabilities calculated in this manner differ from the true permeabilities by no more than 2 to 5 percent. The net result is to "smooth" the apparent permeabilities. This smoothing is most apparent (and most useful) when the soil's apparent permeability is less than about 2 to 5x10(-7) cm/sec and especially for small-diameter standpipes.

The kinematic viscosity factor (R_T) used in the calculation is that for the average test water temperature during the period from (t_1) to (t_2).

3.5.1 Stage 1. The nomenclature for the various terms of the Stage 1 calculations is illustrated on Figure 5. The proper equation is given below; it is the solution for (k_v) for an isotropic medium ($k_h/k_v = 1$).

$$K1 = R_T(\pi d^2/11D_1)[1+a(D_1/4b_1)]Ln(H_1/H_2')/(t_2-t_1) \qquad (3.5\text{-}3)$$

where:
- d = ID of Standpipe
- D_1 = Effective diameter of Stage 1 (Casing ID or OD)
- b_1 = Depth of tested medium below bottom of casing
- a = +1 for impervious lower boundary
- a = 0 for infinite depth of tested medium ($b_1 = \infty$)
- a = -1 for pervious lower boundary

And the other terms are as defined above. For field use, the geometric terms are combined into a single constant:

$$K1 = R_T\, G1\, Ln(H_1/H_2')/(t_2-t_1) \qquad (3.5\text{-}4)$$

where: $G1 = (\pi d^2/11D_1)[1+a(D_1/4b_1)]$

A complete example is given in the Sample Calculations, Appendix A.

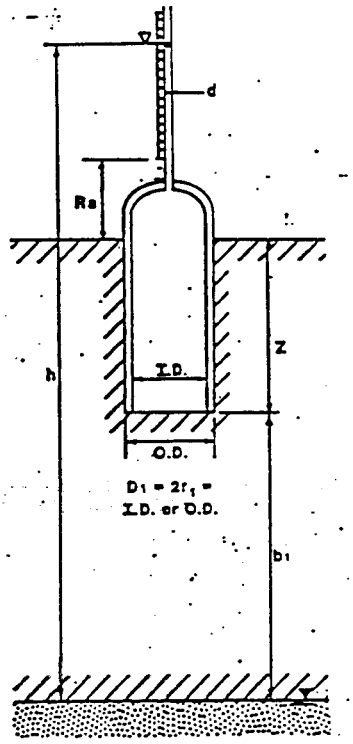

FIGURE 5
STAGE 1 NOMENCLATURE

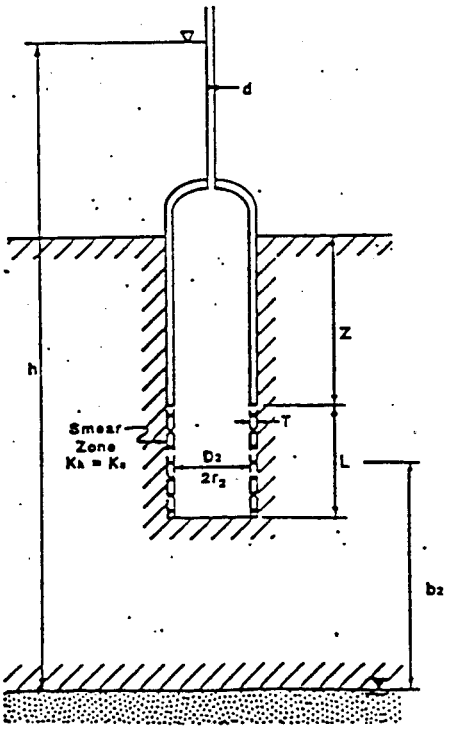

FIGURE 6
STAGE 2 NOMENCLATURE

3.5.2 Stage 2. The nomenclature for the various terms of the Stage 2 calculations is illustrated on Figure 6. The proper equation is that given below; it is the solution for (k_v) with the assumption that ($k_h/k_v=1$).

$$K2 = R_T\,(d^2/16Lf)\,\{Ln[u(1,r_o,o)]+a\,Ln[u(1,r_o,2b_2)]\}\,Ln(H_1/H_2')/(t_2-t_1) \qquad (3.5\text{-}5)$$

where:

$f = 1\text{-}0.5623\,Exp(-1.566\,L/D)$

L = Length of Stage 2 cylinder below casing

$u(1,r_o,o) = \{L/D_2 + \sqrt{1+(L/D_2)^2}\}^2$

$u(1,r_o,2b_2) = \dfrac{4b_2/D_2+L/D_2+\sqrt{1+(4b_2/D_2+L/D_2)^2}}{4b_2/D_2-L/D_2+\sqrt{1+(4b_2/D_2-L/D_2)^2}}$

D_2 = Diameter of Stage 2 extension (normally casing ID)

b_2 = Distance from center of Stage 2 extension to underlying boundary

And the other terms are as defined previously. The factor (f) was introduced to account for the non-convergence of the Hvorslev equations as ($L \rightarrow 0$). For field use, the geometric terms are combined into a single constant:

$$K2 = R_T\,G2\,Ln(H_1/H_2')/(t_2-t_1) \qquad (3.5\text{-}6)$$

where: $G2 = (d^2/16Lf)\,\{Ln[u(1,r_o,o)]+a\,Ln[u(1,r_o,2b_2)]\}$

A complete example is given in the Sample Calculation, Appendix A.

3.5.3 Time-Weighted Averaging. Whether one uses the Laplacian or the Green-Ampt model for groundwater flow, there are still transient effects at the beginning of every type of field or laboratory permeability test. The observed effect is to indicate a high permeability, gradually decreasing to some relatively constant value corresponding to a steady-state flow condition. Such an effect is usually noted in the TSB. Therefore, the test must be conducted "long enough" to achieve virtually the steady-state condition or the results will be not only too high but also erratic. In addition, a single value each of (K1) and (K2) must be used in the final data reduction (Section IV).

There is no reliable method for pre-calculating the length of time required to achieve steady-state. Rather, the observational method is used. The appropriate apparent permeability (K1 or K2) is calculated for each time-increment, and/or over longer periods of time; when these appear to be stable, they are checked using arithmetic time - weighted averages, e.g.,

$$K' = \Sigma (TiKi)/\Sigma (Ti) \qquad (3.5\text{-}7)$$

where: K' = Arithmetic Time-Weighted Average (ATWA) Permeability
Ti = Time Duration of Test Increment (i)
Ki = Permeability Measured during Test Increment (i)

This is theoretically exact for a single run (between refills). Time - weighted averaging also provides a rational basis for smoothing the (often) slightly erratic individual (K1,K2) values from the various time increments. An example of time-weighted averaging is given in the Sample Calculations, Appendix A.

3.5.4 Termination Criteria. Infiltration theory indicates that the apparent permeabilities (K1,K2) should forever decrease at an ever-and-ever decreasing rate. Observations in over 200 of these tests show that a steady-state condition or a close approximation of it is achieved in reasonable testing periods. A log-log plot of apparent permeability versus time is useful in determining when steady-state is achieved. Eventually, the (K1,K2) plots fluctuate about stable values. An example of such a plot is given in the Sample Calculation, Appendix A. This plot illustrates the importance of fairly closely spaced readings at the beginning of each stage, which allow separating the long-term behavior from the short-term fluctuations, i.e., enhance the "signal-to-noise" ratio.

In most tests, time-weighted averages become quite stable, often to within 1 to 5%. A reasonable set of criteria for terminating a stage is as follows:

* The time-weighted averages do not show an upwards or downwards trend with time,

and

* Do not fluctuate more than 10 to 20% among themselves,

and

* Maintain this behavior over a "sufficiently long" time, 12 - 72 hours depending on permeability.

IV.- DATA REDUCTION

4.1 Basic Procedure. In some cases, the (K1') or (K2') values may be adequate for the purpose of the test. More generally, the test is performed to determine the actual (k_h,k_v). This section outlines how to convert the (K1',K2') values calculated as outlined in Paragraphs (3.5.1) and (3.5.2) into the real permeabilities (k_h,k_v). Details for the common case are covered below.

4.1.1 Simultaneous Equations. The equations presented earlier for determining (K1,K2) are special cases of more general relationships. These more general equations define the degree of anisotropy by the parameter:

$$m = \sqrt{k_h/k_v} \qquad (4.1\text{-}1)$$

This parameter affects the geometric terms of the various equations. Each stage has its own equation with a different effect of (m). In a general sense, these can be written as:

Stage 1: $k_v = G1_m \, Ln(H_1/H_2')(t_2-t_1)$
$K1 = G1 \, Ln(H_1/H_2')(t_2-t_1)$

or $k_v = K1 \, (G1_m/G1)$ (4.1-2)

where: $G1_m$ = Geometric factor including (m)

Similarly, for Stage 2,

$$k_v = K2' \, (G2_m/G2) \qquad (4.1\text{-}3)$$

If the soil medium being tested is homogeneous (although cross-anisotropic and possibly bounded), the vertical permeability (k_v) must be the same in both stages. Hence, (4.1-2) and (4.1-3) provide two equations in the two unknowns ($m = \sqrt{k_h/k_v}$) and (k_v). The resulting equation is:

$$K1'(G1_m/G1) = k_v = K2'(G2_m/G2)$$

or $K2'/K1' = (G1_m/G1)(G2/G2_m)$ (4.1-4)

The standpipe area (A_p) cancels for each individual stage in (4.1-2 and 4.1-3), even though different (A_p) values may have been used for Stage 1 and Stage 2, and even for different portions of either stage. The actual equations for the geometric constants involving (m) are given in Paragraph (4.2).

The ratio (K2'/K1') is known from the test; the actual values introduced are the long-term time-weighted averages, (K1' and K2'). The geometric terms are also known. Therefore, Equation (4.1-4) is satisfied only for one value of (m). Due to the complex nature of (4.1-4), trial-and-error or graphical solution works best for specific problems.

4.1.2 Calculating (k_h) and (k_v). The value for (m) is obtained as outlined above in Paragraph (4.1.1). When (m) is known, (k_v) can be calculated directly from Equation (4.1-2), and, by the definition of (m) in Equation (4.1-1).

$$k_h = m^2 k_v \qquad (4.1\text{-}5)$$

4.1.3 Stage 1 Only Method. In some individual tests, the ratio (K2'/K1') is so low that Equation (4.1-4) fails to converge. Others may have so large a (K2'/K1') ratio that the permeability values are obviously in error: (k_v) is far too low and (k_h) is far too high. This is usually due to inhomogeneity of the tested material. Advancing Stage 2 into a zone of lower permeability will cause a low (K2'/K1'). Conversely, advancing into a zone of higher permeability (such as a poor lift joint in fill or a silt/sand seam in natural materials) yields a very high (K2'/K1').

These events are handled by using a conservative (m) from the best-behaved tests and introducing that value into Equation (4.1-2).

4.2 Image Equation with Smear. The basic Hvorslev equations apply most directly to masses of infinite depth and below the groundwater level. Neither test pads nor liners often meet these criteria. Therefore, results calculated by using the Hvorslev equations directly for such cases will not be correct. For a given permeability, both proximity to a drainage zone and the vertical gradient due to gravity cause the flow to be greater than the basic Hvorslev equations would predict. The basic Hvorslev equations therefore predict a higher permeability than the material really has. The vertical gradient effect can be overcome by using the head as from the top of the standpipe to the groundwater level. A method for accounting for the proximity effect and proving the previous assertion was needed.

The method of image wells has been used in geohydrology for years. The classic example is the solution for a well near a river, found in many textbooks. However, the method is not limited to two-dimensional situations such as this illustration. Any solution for an infinite or semi-infinite medium which describes the potential field (head distribution) can be converted to a solution for a finite medium bounded by a plane by using the Image Potential technique (Carslaw & Jaeger, 1959).

The basic idea is that halfway between a source and a sink of equal but opposite strength will be a plane of zero potential. So, if there is a plane of zero potential (head), its effect can be replaced by an "image" source/sink located twice as far away from the sink/source as is the midway plane. If the test (source) is set a distance (b) above the drainage blanket, the flow field will be the same as if there were no blanket but there was an image test (sink) with negative head at a distance of (2b) below the real test. Since the drainage blanket is at zero head, the head at the test is taken as the total head lost: (b) plus the excess pressure (ht) applied at the infiltration point of the test.

Consider also the case where both the real and image sources have equal strengths and both are sources (positive head) or both are sinks (negative head). By the same logic as given above, the midway plane will be a no-flow boundary, corresponding to an impermeable bottom boundary located at a depth (b) below the real test.

4.2.1 Stage 1. The Hvorslev-Image equation (Case "C") for the flush-bottomed portion of the test is given by:

$$k_v = (\pi d^2/11mD_1)[1+a(D_1/4mb_1)]Ln(H_1/H_2')/(t_2-t_1) \qquad (4.2\text{-}1)$$

where:

d	=	ID of Standpipe
D_1	=	Test diameter for Stage 1
b_1	=	Thickness of test medium below base of casing
H_1	=	Initial head ($t=t_1$)
H_2'	=	Corrected final head = H_2-c (see Paragraph 3.5)
t_2	=	Final time
t_1	-	Initial time
a	=	-1 for permeable bottom boundary
a	=	0 for infinite depth to bottom boundary
a	=	+1 for impermeable bottom boundary

Equation (4.2-1) can also be written as:

$$k_v = G1_m\, Ln(H_1/H_2')/(t_2-t_1) \qquad (4.2\text{-}2)$$
$$G1_m = (\pi d^2/11mD_1)[1+a(D_1/4mb_1)]$$

4.2.2 Stage 2. Similarly, for the cylindrical case (Hvorslev "G"), the Image equation (with sidewall smear) is that given by:

$$k_v = (d^2/16Lfm^2)\{Ln[u(m,r_o+T,o)] + a\, Ln[u(m,r_o,2b_2)] + p\, Ln[u(m,r_o,o)/u(m,r_o+T,o)]\}\, Ln(H_1/H_2')/(t_2-t_1) \qquad (4.2\text{-}3)$$

where: L = Length of Stage 2 extension

f = $1-0.5623\ \mathrm{Exp}(-1.566\ L/D)$

$u(m,r_o,o)$ = $[mL/D_2 + \sqrt{1+(mL/D_2)^2}]^2$

$u(m,r_o,2b_2)$ = $\dfrac{4mb_2/D_2+mL/D_2+\sqrt{1+(4mb_2/D_2+mL/D_2)^2}}{4mb_2/D_2-mL/D_2+\sqrt{1+(4mb_2/D_2-mL/D_2)^2}}$

$u(m,r_o+T,o)$ = $\{mL/(D_2+2T) + \sqrt{1+[mL/(D_2+2T)]^2}\}^2$

p = k_h/k_s

k_s = Permeability of smeared zone

T = Thickness of smeared zone (0.6cm=0.25in)

D_2 = Diameter of Stage 2 extension

b_2 = Distance from center of Stage 2 cylinder to underlying boundary

And the other terms are as defined above for Stage 1. Equation (4.2-3) can be written in the generic format as:

$$k_v = G2S\ \mathrm{Ln}(H_1/H_2')/(t_2-t_1) \qquad (4.2\text{-}4)$$

where: $G2S = (d^2/16Lfm^2)\{\mathrm{Ln}[u(m,r_o+T,o)] + a\ \mathrm{Ln}[u(m,r_o,2b_2) + p\ \mathrm{Ln}[u(m,r_o,o)/u(m,r_o+T,o)]\}$

The generic expression for (K2'/K1') as a function of the test geometry is Equation (4.1-4). Following the steps outlined in Paragraph (4.1.1),

$$K2'/K1' = (G1_m/G1) \bullet (G2/G2S) \qquad (4.2\text{-}5)$$

where:

$(G1_m/G1)$ = $(1/m)\ [1+a(D_1/4mb_1)]/[1+a(D_1/4b_1)]$

$(G2/G2S)$ = $\dfrac{m^2\{\mathrm{Ln}[u(1,r_o,o)]+a\mathrm{Ln}[u(1,r_o,2b_2)]}{\mathrm{Ln}[u(m,r_o+T,o)]+a\mathrm{Ln}[u(m,r_o,2b_2)]+p\mathrm{Ln}[u(m,r_o,o)/u(m,r_o+T,o)]}$

Equation (4.2-5) is solved by taking an appropriate (p) and determining (m) by trial-and-error or by a graphical solution such as Figure 7.

The value of (p) is not determined in the test. The normal range of (p) is from 2 to 20; (p=1) indicates no smear. The following values for (p) have yielded satisfactory results, consistent with apparently non-smeared tests on the same tested units:

K2'/K1'	p
>1.1	1
0.9 - 1.1	1,2
0.8 - 0.9	2,5
0.7 - 0.8	5,10
0.6 - 0.7	10,20
0.4 - 0.6	15,20
0.4>	*

* Use Stage 1 Only Approach - Paragraph (4.1.3).

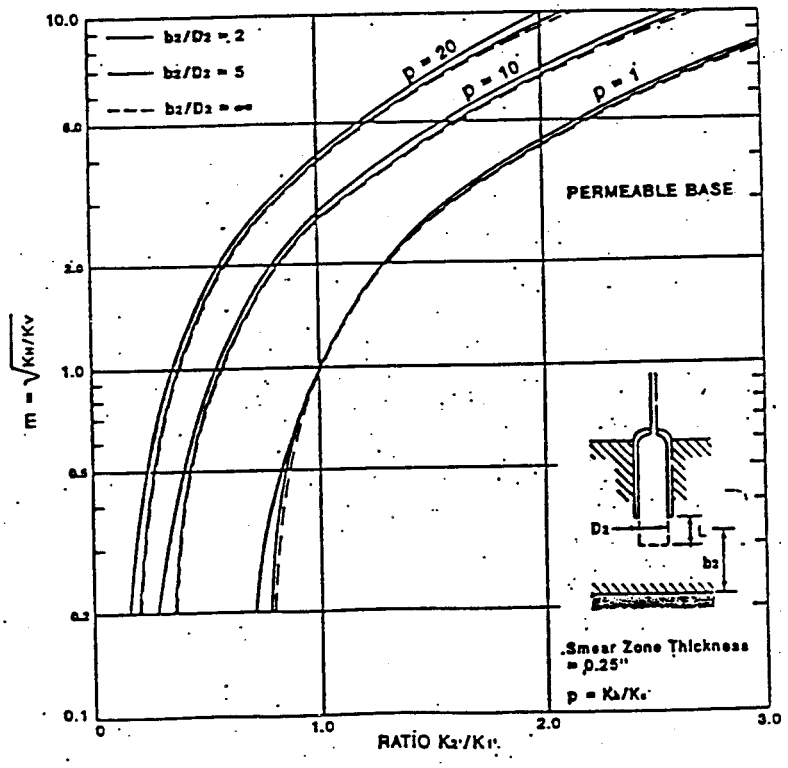

FIGURE 7
GRAPH FOR (m) - (L/D=1.5)

4.3 Non-Saturated Media. Field permeability tests are frequently performed on materials which are not fully saturated. Such materials affect the tests in two ways:

- The hydraulic head is dissipated over the (changing) distance from the point of inflow into the soil to the "wetting front", where the soil is considered fully saturated (Green-Ampt Model).
- Unsaturated clays exhibit "soil suction", which effectively adds to the hydraulic head.

In the Two-Stage test, infiltration into the soil is three-dimensional. The majority of the head loss occurs close to the inflow surface, even in a fully saturated material. About 50% of the loss occurs within one test radius of the inflow surface. For a typical Two-Stage test, disregarding wetting front distance theoretically yields a permeability 10 to 50% too high.

The effect of soil suction is roughly proportional to the ratio of suction to applied head. The effect of suction alone on a permeability test can be expressed as:

$$k_a/k_t = (1 + S/h_o) \qquad (4.3\text{-}1)$$

where:
k_a = Observed permeability
k_t = True saturated permeability
S = Soil suction
h_o = Applied head

The Two-Stage test normally operates with heads 3 to 6 times those of other test methods, minimizing the relative effect of suction.

These two effects can be handled using the graph presented on Figure 8. That figure is based on numerical solutions for the equipotential surfaces in an infinite medium (a=0). However, for the typical real test, the dimensionless flow volume is such that the equipotentials do not vary significantly from the ellipsoids in either the permeable-base (a=-1) or impermeable-base (a=+1) cases. The actual volume, which includes an allowance for the impermeable casing, has been included on Figure 8.

When using Figure 8, the initial volume (V_o) is taken as:

- Stage 1 - The volume of a hemi-ellipsoid having the diameter (D_1) and height ($D_1/4$).

$$V_{o1} = (\pi/24)\, D_1^3 \qquad (4.3\text{-}2)$$

- Stage 2 - The volume of the Stage 2 cylinder.

$$V_{o2} = (\pi/4)\, D_2^3\, (L/D_2) \qquad (4.3\text{-}3)$$

WE ALMOST NEVER USE NON-SAT EFFECTS.

The term (V_w) is the total volume of water which has infiltrated into the soil through the end of each stage, allowing for that removed in the Stage 2 extension. The (n_a) term is the soil's air porosity.

Figure 8 is applied first to the individual (K1) values from Stage 1:

$$K1_t = K1/[R(1+s/H_o)] \qquad (4.3\text{-}4)$$

where: $K1_t$ = K1 corrected for suction and wetting front
R = Permeability ratio from Figure 8

Then, Figure 8 is similarly applied to the individual (K2) values from Stage 2:

$$K2_t = K2/[R(1+s/H_o)] \qquad (4.3\text{-}5)$$

where: $K2_t$ = K2 corrected for suction and wetting front

Thereafter, ($K1_t$,$K2_t$) are used in Equation (3.5-7) for the average values ($K1'_t$,$K2'_t$). These are then introduced into Equations (4.2-5) for (m) then (4.1-2) for (k_v), and finally (4.1-5) for (k_h).

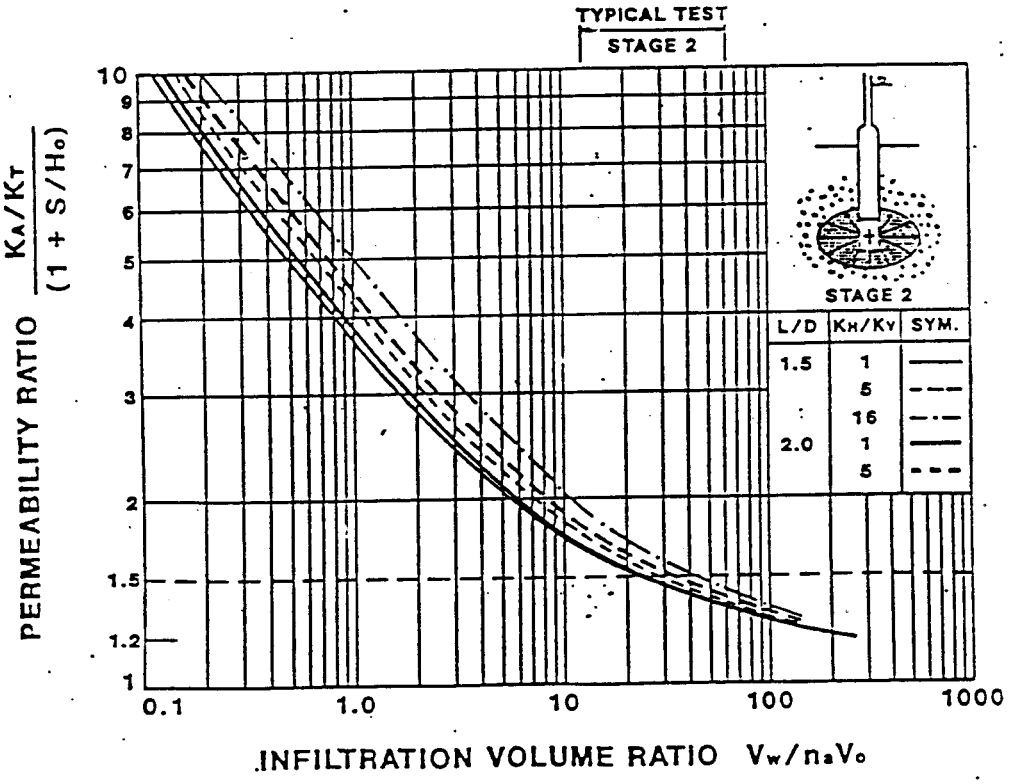

FIGURE 8
NON-SATURATION EFFECTS

V. EXPERIENCE WITH TSB TESTS

As of January, 1992, STEI alone has been involved in some 200 tests (40+ projects) on recompacted materials and 90 tests (6 projects) in natural materials. These have generally been of relatively low permeability [10(-6) to 10(-9) cm/sec]. Some conclusions from this experience are given below.

5.1 Types of Projects. The test has been successful in many types of soils:

5.1.1 Test Pads and Liners. It has been used in such conditions for test units from 20 to 60 inches thick. Materials have ranged from CH-OH (Liquid Limit 100+, clay content 70%+) to SC/GC (Liquid Limit 30-, gravel content up to 30%, clay content 12%). Vertical permeabilities have been successfully measured from the mid 10(-7)'s to the low 10(-9)'s (values in cm/sec).

5.1.2 "Natural" Deposits. It has been very successful in clays to depths of 10 to 15 feet. Where the clay does not make water, it has also been successful to about 20 to 25 feet. The test was moderately successful in soft, highly layered mine tailings clay at depths up to 30 feet. It has been used up to 7 feet deep in shales. Measured vertical permeabilities have been in the same ranges mentioned above.

5.2 Comparisons with Other Methods. The accuracy and lack of false negatives of the TSB can be evaluated by the comparisons with SDRI data shown on Figure 9 and with laboratory data from undisturbed samples given on Figure 10. Of the 11 known cases where both field methods were used on the same test pads/liners the mean ratio of their conductivities was 1.1 (TSB higher). In three known cases, the TSB proved failure defects in test pads that laboratory tests did not show, indicating the TSB avoids false positives. Experience to date can be summarized as:

5.2.1 Recompacted Clays. The vertical permeability (k_v) as obtained from laboratory tests, the TSB, and the SDRI generally agree quite well on test pads/liners (11 cases) which have had proper CQA. The laboratory tests tend to underestimate the horizontal permeability.

5.2.2 Natural Clays. Comparisons have only been made with small-scale laboratory tests. In general, there is good agreement with the TSB for vertical permeability, while laboratory tests again underestimate the horizontal permeability.

5.3 Speed. As soon as the test begins, so does the question from the client, "Does it Pass?" It is usual that (k_v) must be less than some specified value (Spec), or that (k_h) must be greater than a different (Spec). Since the maximum possible value for (k_v) is (K1), as soon as (K1<Spec), one knows the test for (k_v) must pass. Likewise, since (K2) is the minimum possible value for (k_h), if the long-term (K2) is greater than (Spec), the test for (k_h) must pass.

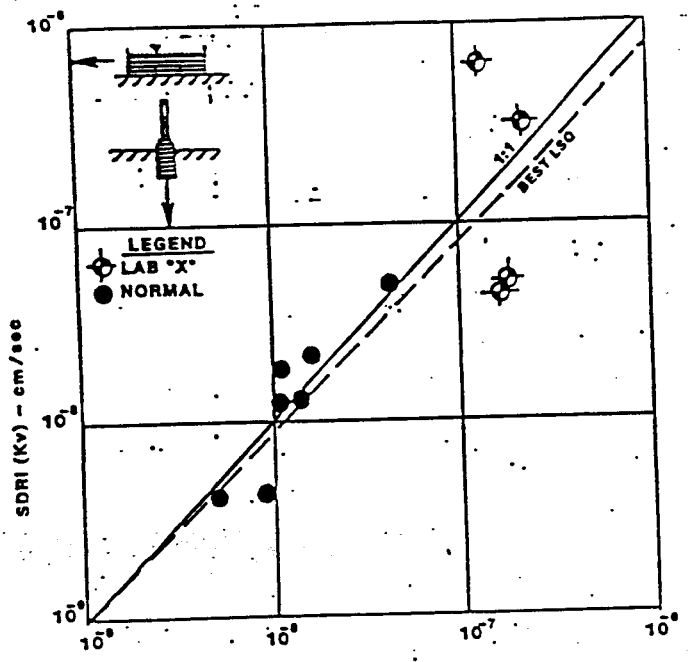

FIGURE 9
TSB AND SDRI RESULTS
(Tests on Same Liners/Test Pads)

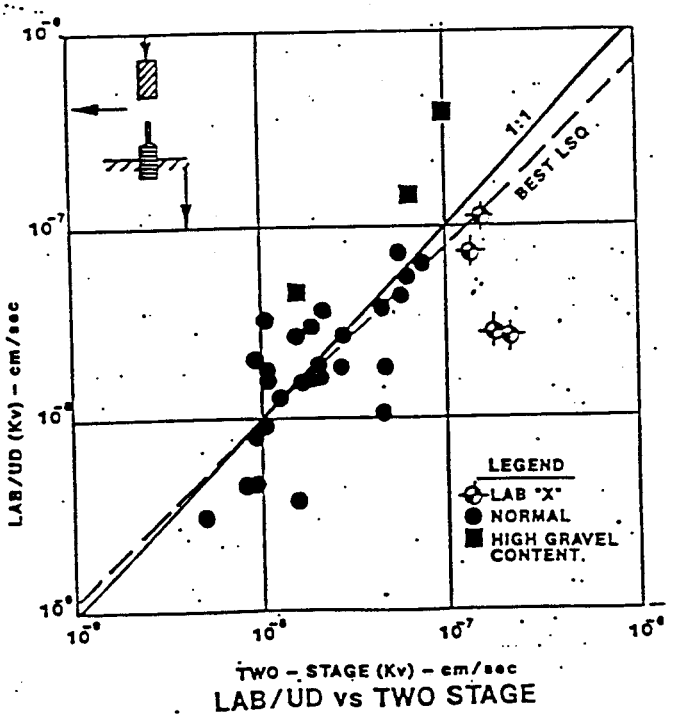

FIGURE 10
TSB AND LAB (k_v) RESULTS
(Tests on Same Liners/Test Pads)

Most of the TSB tests to date in test pads/liners have been for (k_v). The better the pad, i.e., the higher the (Spec/k_v) ratio, the sooner (K1<Spec). In 90% of the tests where (Spec/k_v>1.7), passing was indicated in 24 hours or less. Some 75% of all tests have indicated passing within 72 hours. A marginal test unit, whose (k_v) is just below (Spec), will require completing Stage 2. In general, each Stage lasts 4 to 14 days, the longer times being required to complete a test in lower permeability materials.

5.4 Volume Tested. A single typical TSB test permeates a volume around 0.6 to 1.1 cubic feet, or 60 to 200 times the volume of a typical plug tested in the laboratory (3 inch diameter, 3 inch height). The usual 5-test program thus tests about 10 to 20% the volume of an SDRI, yet yields about the same values. The TSB has a good balance of soil volume tested and speed.

3. STAGE 1

A. CALCULATE FACTOR [Eq. 3.5-4]

$$K1 = F_1 \frac{Ln(H_1'/H_2')}{t_2 - t_1} \quad \text{where } F_1 = \frac{\pi d^2}{11 D}\left(1 - \frac{D}{4b_1}\right)$$

$d = 0.50" = 1.27$ cm (See sketch on p. 1)
$D = 4.50" = 11.43$ cm (See note on p. 1)
$b_1 = 24.0" = 60.96$ cm (See sketch on p. 1)

$$F_1 = \frac{\pi (1.27)^2}{11 \times 11.43}\left(1 - \frac{11.43}{4 \times 60.96}\right)$$

$$\boxed{F_1 = 0.03841 \text{ cm}}$$

B. CALCULATIONS

i. $H1 = B + R_A + R_{W1} = 48.00 + 0.00 + R_{W1} = 57.00 + R_{W1}$
$H2' = B + R_A + R_{W2} - C = 48.00 + 0.00 + (R_{W2} - C) = 57.00 + (R_{W2} - C)$

ii. Period 1700 08/02 – 0800 08/03

$$K1 = .03841 \frac{Ln[(57.00 + R_{W1})/(57.00 + R_{W2} + C)]}{\Delta t \text{ (sec)}}$$

$H1 = 57.00 + 14.06 = 71.06$
$H2' = 57.00 + 9.06 + 1.25 = 67.31$

Note: TEG fell 1.25" in this period. 1.25' of the Test drop is purely temp.

$\Delta t = 15 hrs \times 3600 \text{ s/hr} = 54000$ sec.

$$K1 = 0.03841 \text{ cm} \frac{Ln(71.06/67.31)}{54000 \text{ sec}} = 3.86 \times 10(-8)$$

Now, apply viscosity correction
Temp $= \frac{1}{2}(74 + 68) = 71°$
From chart, Viscosity Factor $= 0.96 = R_T$

$$K1_2 = R_T \cdot K1c = 0.96 \times [3.86 \times 10(-8)] = 3.71 \times 10(-8) \frac{cm}{sec}$$

See p. 6 for Tabulation of all points

SCALE

A. STAGE 2

A. CALCULATE FACTOR [Eq. 3.5-5, with a = -1]

$$K2 = F \frac{L_N(H_1/H_2)}{z_2 - z_1}$$

where: $F = \left(\frac{1}{f}\right)\left(\frac{d^2}{16L}\right) L_N \left[\frac{U(D,0)}{U(D,2b_2)}\right]$

$f = 1 - 0.5623\, e^{-1.566(L/D)}$

L = Extension below Casing (6 inches = 15.24 cm)

D = Borehole diameter = ID of Casing (4 inches)

$r_2 = D/2$

$b_2 = B - Z + L/2 = 48.00" - 24.00" - 6.00"/2 = 21.00"$

$$U(1,D,z) = \frac{(23/D + L/D) + \sqrt{1 + [23/D + L/D]^2}}{23/D - L/D + \sqrt{1 + [23/D - L/D]^2}}$$

$L/D = 6"/4" = 1.5$

$\therefore f = 1 - 0.5623\, e^{-1.566(1.5)}$

$= 0.9463$

$$U(1,r_0,0) = U(1,D,0) = \frac{(0+1.5) + \sqrt{1 + [0+1.5]^2}}{(0-1.5) + \sqrt{1 + [0-1.5]^2}} = \frac{1.5 + \sqrt{1+1.5^2}}{-1.5 + \sqrt{1+1.5^2}}$$

[U(1,r0,0) Eq. 3.5-5]

$= [1.5 + \sqrt{1+1.5^2}]^2$

$= 10.9083$

$2b_2 = 2 \times 21 = 42"$

$$U(1,r_0,2b_2) = U(1,D,42) = \frac{(84/4 + 1.5) + \sqrt{1 + [84/4 + 1.5]^2}}{(84/4 - 1.5) + \sqrt{1 + [84/4 - 1.5]^2}} = \frac{22.5 + \sqrt{1 + 22.5^2}}{19.5 + \sqrt{1 + 19.5^2}}$$

[U(1,r0,2b2) Eq. 3.5-5]

$= 1.1537$

$\therefore F = \frac{1}{0.9463} \times \frac{1.27^2\ cm^2}{16 \times 15.24\ cm} L_N (10.9083 / 1.1537)$

$$\boxed{F = 0.01570\ cm}$$

B. EQUATION (FOR SHORTCUT, SEE p. 12)

$$K2'/K1' = \left(\frac{G1m}{G1}\right)\left(\frac{G2}{G2S}\right) \qquad [\text{Eq. } 4.2\text{-}5]$$

where $G1m/G1 = (1/m)\left[1 + a(D_1/4mb_1)\right] / \left[1 + a(D_1/4b_1)\right]$

but, $D_1 = 11.43$ cm (p. 3) $\quad a = -1$ (Perm. Base)

$b_1 = 26.924$ cm (p. 3)

$$G1m/G1 = (1/m)\left[1 - \frac{11.43}{4(m)(26.96)}\right] / \left[1 - \frac{11.43}{4(26.96)}\right]$$

$$= (1/m)\left(\frac{1}{.9464}\right)\left(1 - \frac{1}{21.33m}\right)$$

$$G2/G2S = \frac{m^2\left\{Ln\left[v(1,r_0,0)\right] + a\,Ln\left[v(1,r_0,2b_2)\right]\right\}^2}{Ln\left[v(m,r_0+r,0)\right] + a\,Ln\left[v(m,r_0,2b_2)\right] + p\,Ln\left[v(n,r_0,0)/v(m,r_0+r,0)\right]}$$

$a = -1$

$p = 1$

$$\text{Thus } G2/G2S = \frac{m^2\,Ln\left[v(1,r_0,0)/v(1,r_0,2b_2)\right]}{Ln\left[v(m,r_0,0)/v(m,r_0,2b_2)\right]}$$

$$v(1,r_0,0) = \left[L/D + \sqrt{1+(L/D)^2}\right]^2 = \left[1.5 + \sqrt{1+1.5^2}\right]^2 = 10.90833$$

$$v(1,r_0,2b_2) = \frac{4b_2/D_2 + L/D_2 + \sqrt{1+(4b_2/D_2 + L/D_2)^2}}{4b_2/D_2 - L/D_2 + \sqrt{1+(4b_2/D_2 - L/D_2)^2}}$$

$b_2 = 21''$ (See p. 1)

$D_2 = 4.0''$ (See p. 1)

$$= \frac{4(21/4) + 6/4 + \sqrt{1+(4\times 21/4 + 6/4)^2}}{4(21/4) - 6/4 + \sqrt{1+(4\times 21/4 - 6/4)^2}} = \frac{45.6622}{37.0256}$$

$$v(1,r_0,2b_2) = 1.15366$$

$$G2/G2S = \frac{m^2\,Ln\left[10.90833/1.15366\right]}{Ln\left[v(m,r_0,0)/v(m,r_0,2b_2)\right]} = \frac{2.24659\,m^2}{Ln\left[v(m,r_0,0)/v(m,r_0,2b_2)\right]}$$

$$K2'/K1' = \frac{1}{m}\cdot\frac{1}{.9464}\left(1 - \frac{1}{21.33m}\right)\cdot\frac{2.24659\,m^2}{Ln\left[v(m,r_0,0)/v(m,r_0,2b_2)\right]}$$

$$= 2.3738\,m\left(1 - \frac{1}{21.33m}\right)\frac{1}{Ln\left[v(m,r_0,0)/v(m,r_0,2b_2)\right]}$$

SCALE

C. CALCULATE K_v, K_h

Note: ONE CAN AVOID THE CALCULATIONS of pp. 10 and 11 BY USING THE ATTACHED NOMOGRAPH (Fig. 7 - Text)

The easiest calculation is using THE STRIP EQUATION:

$$K_v = \frac{G_{lm}}{G_l}\, K_1' = \frac{1}{m}\left[\frac{1 - D_1/4m b_1}{1 - D_1/4b_1}\right] K_1' \qquad \text{[Eq. 4.1-2]}$$

with $D_1 = 4.50''$
$b_1 = 24.0''$
$m = 2.27$

$$K_v = \frac{1}{2.27}\left[\frac{1 - \frac{4.5}{4(2.27)(24)}}{1 - \frac{4.5}{4(24)}}\right] \times [3.21 \times 10(-8)]$$

$$= \frac{1}{2.27}\left[\frac{.9762}{.9464}\right] 3.21 \times 10(-8)$$

$$\boxed{K_v = 1.45 \times 10(-8) \text{ cm/sec}}$$

$$K_h = m^2 K_v \qquad \text{[Eq. 4.1-5]}$$
$$= 2.27^2 [1.45 \times 10(-8)]$$

$$\boxed{K_h = 7.47 \times 10(-8)}$$

ATTACHMENT 8
SUMMARY OF LEACHATE SYNTHESIS METHODOLOGY

Permeability testing was accomplished by obtaining undisturbed samples of site soils (Ferrelview Formation and Clay Till) and subjecting these samples to triaxial permeability testing (ASTM Method D-5084). Samples were initially tested with water as a permeant, then the same samples were tested with leachate permeant.

The leachate was generated by mixing liquids generated by modified batch leach testing of chemically stabilized/solidified raffinate sludge (CSS Sludge), untreated radioactive soils, and untreated chemically contaminated soils. The liquids from these leaching tests were combined at the following ratio in order to provide a representative leachate:

2:1:1 (CSS Treated Sludge:Untreated Radioactive Soils:Untreated Chemical Contaminated Soils)

This ratio of materials is based upon proposed waste quantities including bulking factors for treated wastes. These quantities are found in the latest version of the PMC's Waste Management Quarterly Report.

Additional details relating to the leaching methodology and associated sampling of waste materials are presented in the pertinent references listed in Attachment 10.

LIST OF PERTINENT REFERENCE DOCUMENTS

The following documents are listed for reference in describing background and support activities associated with this effort. Copies of these reports have been submitted under separate cover:

Modified batch leach testing is described in the "Batch Leach Testing Plan", MK-JEG, Rev. 1, Nov. 92.

The chemical soil samples were collected in accordance with the "Soil Sampling Plan for Column Leach and Batch Tests and TCLP Analysis", Rev. 0, May 92.

The radioactive site soils were collected in accordance with the "Stabilization /Solidification/Dewatering Sampling Plan", MK-JEG, Rev. 0, May 91.

The undisturbed soil samples were obtained in accordance with the "Sampling Plan for Determination of Hydraulic Properties of Undisturbed Soils in the Weldon Spring Disposal Facility Study Area", Rev. 1, MK-JEG, Oct. 92.

Dear Mr. McCracken:

Attached for your information and review are the summaries of analytical data on 60 private drinking water wells in the vicinity of the Weldon Spring Site. This work has been carried out by the Missouri Department of Health. These data are complete through 1991.

I suggest that these data be considered and referenced in your update of the baseline assessment for the site.

Sincerely yours,

DIVISION OF ENVIRONMENTAL QUALITY

ABSTRACT

The purpose of this *Quarterly Environmental Data Summary* is to provide to the public preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1992 annual site environmental report.

This report includes preliminary data from environmental monitoring activities at the Weldon Spring site (WSS) during the third quarter of 1992. Groundwater, surface water, and air samples were collected in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, inorganic anions, and direct gamma exposure. The results are used to evaluate possible exposure scenarios and assess the impact of the contaminants at the site on potentially exposed populations.

In summary, off-site exposures during the third quarter of 1992 did not differ significantly from exposures calculated in previous quarters. Contaminated groundwater did not affect the St. Charles County well field.

1 INTRODUCTION

This quarterly report summarizes the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These quarterly reports supplement the annual site environmental report (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data. They provide data resulting from routine environmental sampling as described in the WSSRAP *Environmental Monitoring Plan* (EMP) (MKF and JEG 1992a) and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from historical observations. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1992 ASER. It is recommended that interested readers refer to previous EMPs, ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters is tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at (314) 441-8086.

These quarterly reports are intended to include data from all quarterly environmental monitoring programs conducted at the WSSRAP including groundwater, springs, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). This document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1992 annual site environmental report. Because standard turnaround time to receive data from the laboratories is 45 days, not all third quarter data are available for reporting. These data will be reported in the 1992 ASER. Sludges and soils are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater, and air pathways. These analyses will be presented in the 1992 ASER. Quality control (QC) data for the third quarter and fourth bimonthly periods, along with all other periods, will be presented in the 1992 ASER.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/RP/VP) and the Weldon Spring Quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/RP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

Groundwater at the chemical plant/raffinate pits/vicinity properties area is monitored on a quarterly or semiannual basis (specific to each well as prescribed in the 1992 *Environmental Monitoring Plan* (MKF and JEG 1992a). Locations are given in Figure 2-1. The number of quarterly sampled wells has increased substantially; a complete list of wells scheduled for quarterly and semiannual sampling is given in the 1992 EMP. Total uranium, inorganic anions, and nitroaromatic compounds are measured during each monitoring period for both quarterly and semiannual wells. Other radiological parameters are measured annually during the first period for all wells.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the quarterly monitored groundwater wells. Nitroaromatic compounds were detected in 16 of the 32 locations for which data are currently available. Concentration levels for these compounds are within their historical range, with the following exceptions: new 2,4,6-trinitrotoluene (TNT) highs were recorded in wells MW-2030, MW-2032, MW-2033, a new 2,4-dinitrotoluene (DNT) high was recorded in MW-3023, and new 1,3,5-trinitrobenzene (TNB) highs were recorded in MW-2030, MW-2033, and MW-4001. A new 1,3,5-TNB low was measured in MW-4013.

2.1.2 Radiological Results

The upper bound for natural uranium background concentration in groundwater at the WSCP/RP/VP has been determined to be 3.4 pCi/l (0.13 Bq/l) (MKF and JEG 1989). The

U.S. Environmental Protection Agency (EPA) has not yet established a drinking water standard for uranium; however, the proposed maximum contaminant level (MCL) is 20 μg/l, which converts to 13.6 pCi/l (0.50 Bq/l) using a new site-specific conversion factor of 0.68 pCi/μg (assuming isotopic equilibrum). The increase to 13.6 pCi/l (0.50 Bq/l) from the previously reported value of 12 pCi/l (0.44 Bq/l) reflects improved quantification of the average U-234/U-238 activity ratios for uranium present at the Weldon Spring Site Remedial Action Project (WSSRAP). The U.S. Department of Energy (DOE) has a health-based, derived concentration guideline (DCG) of 600 pCi/l (22.2 Bq/l) in surface water effluent.

Total uranium results for samples from the quarterly monitored wells at the WSCP/RP/VP are presented in Table 2-2. Uranium concentrations remained within historical ranges at all locations for which data are presently available.

2.1.3 Sulfate and Nitrate Results

Sulfate and nitrate concentrations are measured during each monitoring period. Results from the quarterly monitored wells are shown in Table 2-2. Third quarter results are within historical ranges with the exception of a new nitrate high in MW-3023 and a nitrate low in MW-3009. A new sulfate high was recorded in MW-2033 and a new low in MW-2003. These extreme values are thought to reflect natural fluctuation in these wells.

2.2 Weldon Spring Quarry

Groundwater at the WSQ has become radiologically and chemically contaminated as a result of contact with, or migration from, wastes present in the WSQ. Monitoring of the groundwater at and near the WSQ is of particular concern because of the proximity of the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mi) to the south of the WSQ. Monitoring of contaminants in groundwater and the protection of the well field is a top priority at the WSSRAP.

Groundwater is currently being monitored at 48 wells located in and around the quarry area. Thirty-six monitoring wells installed by the DOE are currently utilized in or near the quarry. Four monitoring wells were installed by St. Charles County in 1986 and are currently included in the DOE's monitoring program. Eight St. Charles County municipal wells, and the treated and untreated water from the St. Charles County water treatment plant, are also monitored for the presence of these contaminants. All monitoring well locations are shown in Figures 2-2 and 2-3. These wells monitor groundwater in both the bedrock and alluvial aquifers associated with the WSQ.

Two separate groundwater monitoring programs have been developed for the WSQ area. The first program is a bimonthly sampling of all wells north of the Femme Osage Slough and MW-1010 and MW-1011 located south of the slough. In addition, wells MW-1035, MW-1036,

WELDON SPRING QUARRY, FEMME OSAGE SLOUGH, & ST. CHARLES CO. WELL FIELD MONITORING LOCATIONS

FIGURE 2-3

REPORT NO.:	DOE/OR/21548-364	EXHIBIT NO.:	A/QY/121/1291		
ORIGINATOR:	CSJ	DRAWN BY:	GLN	DATE:	12/91

MW-1037, MW-1038, and MW-1039 will be sampled bimonthly until operation of the Weldon Spring Quarry water treatment plant is initiated. The second program is the quarterly sampling of all wells south of the Femme Osage Slough, excluding MW-1010 and MW-1011, but including the St. Charles County well field. Both the raw and treated waters from the St. Charles County water treatment plant are also sampled quarterly.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-3 and 2-4 for samples collected for the fourth bimonthly period and the third quarter. The results show typical fluctuations near the average levels in the WSQ area. Last quarter the uranium concentration in MW-1032 exceeded the historic average; results for this quarter are slightly below the results for the second quarter. Continued monitoring will be performed to determine whether this is a trend. Detectable concentrations of uranium were indicated from the St. Charles County RMW-series wells. In addition to being within historic averages and representative of background levels, these levels are the results of lower detection limits for uranium during analytical testing. The results for the St. Charles County production wells (PWOX series) were not available from the laboratory at the time of this report.

The St. Charles County RMW-series and production wells are sampled annually for gross alpha. The results of this analysis are presented in Table 2-4. The results for the St. Charles County production wells were not made available at the time of this report. The concentrations in the RMW-series wells are consistent with background values of waters in or near the WSQ.

2.2.2 Nitroaromatic Compounds Results

Analytical results for the fourth bimonthly period and the third quarter for nitroaromatic compounds are presented in Tables 2-5 and 2-6. No monitoring wells south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the third quarter of 1992. The elevated levels of nitroaromatic compounds detected in rim well MW-1004 remain consistent with the second and third bimonthly results. Nitroaromatic levels have increased in bedrock monitoring well MW-1027. The distribution and magnitude of nitroaromatic contamination in the remainder of the wells near the quarry remain consistent with historical levels.

2.2.3 Inorganic Anions Results

Two inorganic anions, nitrate and sulfate, are sampled in all of the wells monitored at the WSQ. The analytical results for the fourth bimonthly period and the third quarter are presented in Tables 2-3 and 2-4. An elevated level of sulfate was detected in rim well MW-1005 and alluvial well MW-1010. The results for the remainder of the monitoring wells are consistent with data reported in the previous environmental monitoring reports. The WSQ groundwater samples continue to indicate that there is no significant nitrate contamination of the groundwater. The results indicate that elevated sulfate levels are present in groundwater within the WSQ and north of the Femme Osage Slough.

2.2.4 Metals Results

All wells in the WSQ monitoring program are sampled for arsenic and barium. The results for the fourth bimonthly period and the third quarter are presented in Tables 2-7 and 2-8. Arsenic levels were consistent with historical values for groundwater in the vicinity of the WSQ. Barium levels have remained elevated in the wells in the vicinity of the Femme Osage Slough. Elevated barium levels indicated in the second and third bimonthly periods for rim well MW-1002 have remained unchanged.

2.3 Springs

Five springs near the Weldon Spring site (WSS), which are measurably influenced by site-related contaminants, were sampled during the third quarter (see Figure 2-4). During the third quarter, spring samples were analyzed for uranium and inorganic anions. Results are presented in Table 2-9. SP-6301 and SP-6306 were sampled during high and low flow to evaluate the groundwater (which is thought to predominate low flow) and surface water (which is thought to dominate high flow) components of flow. In comparison to the high flow sample from SP-6301, the low flow sample had higher levels of nitrate and sulfate, but a similar level of uranium. There was little difference between the high and low flow samples from SP-6306.

3 SURFACE WATER MONITORING

Routine samples were collected during the third quarter of 1992 from both on-site and off-site surface water locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1992 annual site environmental report (ASER).

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the third quarter, surface water samples were collected from 11 of the 15 surface water sampling locations shown in Figure 3-1 and analyzed for uranium, radium, thorium, gross alpha, and gross beta. Monitoring point SW-2016, not shown in Figure 3-1, is located at the intersection of Dardenne Creek and County Highway N. This is now the furthest location downstream at which to measure contaminant levels in Dardenne Creek after it has received the Schote Creek contribution. The results, presented in Table 3-1, indicated that conditions at sampling locations remain consistent with historical values.

3.2 Weldon Spring Quarry

Monitoring locations SW-1001, SW-1002, and SW-1014 (Figure 3-2) monitor the Little Femme Osage Creek at points upstream and downstream of the Weldon Spring Quarry (WSQ). Six sampling locations, SW-1003 through SW-1005, SW1007, SW-1009, and SW-1010, are distributed along the Femme Osage Slough in the vicinity of the WSQ. These locations were chosen to provide the most representative data for areas potentially impacted by the quarry contamination. Location SW-1008 monitors the ponded water within the WSQ and provides a rough determination of the concentrations of the various contaminants in the WSQ pond, which may migrate to groundwater. Locations SW-1011 through SW-1013 (Figure 3-3) and SW-1015 (Howard Bend) provide baseline water quality data for the Missouri River at points both upstream and downstream from the WSQ and the Southeast Drainage (5300) easement.

3.2.1 Radiological Results

Surface water samples were collected for radiological analyses from the 13 locations shown in Figures 3-2 and 3-3. The uranium results for the fourth bimonthly period are presented in Table 3-2. Fourth bimonthly uranium concentrations for the sampling locations in the Femme Osage Slough and Little Femme Osage Creek remain within historical ranges.

3.2.2 Weldon Spring Quarry Pond Results

A summary of the analytical results for the fourth bimonthly sampling period is presented in Table 3-3. This sampling location is summarized separately to characterize the surface waters in the WSQ which may migrate and effect groundwater. The results for this bimonthly period are within historic ranges for all parameters analyzed.

4 EFFLUENT MONITORING

The National Pollutant Discharge Elimination System (NPDES) permit process is authorized by Section 402(a)(1) of the *Clean Water Act of 1977.* The authority to issue permits is delegated to the State of Missouri by the U.S. Environmental Protection Agency (EPA). The State of Missouri has issued four NPDES permits to the U.S. Department of Energy (DOE) allowing the discharge of storm water, hydrostatic test water, and treated wastewater to waters of the state. The permits require that samples of the wastewater be collected periodically and the results reported to the Missouri Department of Natural Resources. The following sections contain the analytical results for samples collected during July, August, and September of 1992.

4.1 National Pollutant Discharge Elimination System Data Review

Effluent samples were collected and analyzed in compliance with the Weldon Spring site NPDES permits. Permit No. MO-0107701 was issued on October 1, 1990, and currently addresses the five storm water and two wastewater discharges shown in Figure 4-1. Outfalls NP-0001 through NP-0005 represent storm water discharges; Outfall NP-0006 represents the treated wastewater discharge associated with the administration building sanitary wastewater treatment plant; and Outfall NP-0007 represents the site water treatment plant, which is under construction, but not yet completed. There was no discharge from Outfall NP-0007. Outfalls NP-0006 and NP-0007 have effluent limitations. The five storm water outfalls have "monitoring only" requirements for permitted parameters. Third quarter 1992 analytical data for each outfall are presented in Table 4-1.

Permit No. MO-0108987 was issued on May 5, 1989, for Outfall NP-1001 of the Weldon Spring Quarry water treatment plant. The plant construction is completed, but no discharge took place during the third quarter of 1992.

NPDES permit No. MO-G680001 was issued on December 19, 1991. This permit is for discharge of uncontaminated water used for new tank and basin hydrostatic testing at the quarry water treatment plant. Third quarter 1992 analytical data are presented in Table 4-2. Waters discharged from hydrostatic testing at the quarry water treatment plant were in compliance with permitted limits, with the exception of the following occurrence.

* Detection limit.

On September 14, 1992, storm water that accumulated in the quarry water treatment plant Effluent Pond 1 was pumped to the Little Femme Osage Creek. Water sampled from this event demonstrated a total suspended solids level of 69 mg/l, which is above the permitted limit of 50 mg/l. It is believed that a small amount of algae or sediment caused this elevated solids level.

NPDES permit No. MO-G680002 was issued on February 7, 1992. This permit is for discharge of uncontaminated water used for new tank and basin hydrostatic testing at the site water treatment plant. Third quarter 1992 analytical data are presented in Table 4-3. Waters discharged from hydrostatic testing at the site water treatment plant were in compliance with permitted limits with the exception of the following occurrence.

On August 25, 1992, a sample of water being pumped from the site water treatment plant sump into the adjacent siltation basin demonstrated a total suspended solids level of 219 mg/l, which exceeds the permitted limit of 50 mg/l. This concentration is believed to have resulted from the method used to discharge the water, and not from the tanks themselves. The method used involved discharging potable water from the tanks to a concrete floor drain and collection sumps, both of which are believed to have developed an accumulation of dust and sediment from previous building construction activities.

In the future, actions will be taken to ensure that discharged waters from hydrostatic testing meet permit limits. Hydrostatic test water will no longer be discharged to secondary containments such as floor sumps. Pretesting and/or pretreating the effluent by the mobile sump treatment system prior to discharge may be a viable option. In addition, engineering controls such as effluent filtering may be used to reduce suspended solids discharge.

(a) Sample bottle was broken during shipment. No analysis was performed.

4.1.1 Radiological Analysis

Gross alpha and uranium analyses corresponded well with past data. The storm water outfalls had the following ranges of uranium concentrations. The process sewer outfall NP-0001, had two sample values of 455 pCi/l (0.669 mg/l) and 446 pCi/l (0.656 mg/l). Frog Pond outfall, NP-0002, had values from 106 pCi/l (0.156 mg/l) to 240 pCi/l (0.353 mg/l). The Ash Pond outfall, NP-0003, had values from 64.3 pCi/l (0.0946 mg/l) to 290 pCi/l (0.426 mg/l). There was no discharge from NP-0004 during the periods specified for monitoring in the permit, in the third quarter. The Southeast Drainage outfall, NP-0005, had values from 1.36 pCi/l (0.00199 mg/l) to 170 pCi/l (0.25 mg/l). These values were all below the derived concentration guideline (DCG) of 600 pCi/l.

4.1.2 Other Analysis

Other analyses for NP-0001 through NP-0005 include physical analyses (settleable solids and total suspended solids) and chemical analyses (nitrate, pH, and lithium). Third quarter 1992 values correspond well with past values for all parameters, and are displayed in Table 4-1.

The permit for the discharge from the administration building treatment plant at outfall NP-0006 has effluent limitations and a requirement to monitor once per quarter. Flow must be measured once a month. The Subcontractor monitors the effluent once a month to assess plant performance, thus generating two additional sample analyses a quarter. The NPDES permit specifies effluent limitations for biochemical oxygen demand (BOD), total suspended solids

(TSS), pH, and fecal coliform at this outfall. The limits for BOD are 10 mg/l monthly average and 15 mg/l weekly average; for TSS, 15 mg/l monthly average and 20 mg/l weekly average; for fecal coliform, 400 colonies per 100 ml monthly average and 1,000 colonies per 100 ml daily maximum. The Subcontractor is continuing to make operational changes to improve plant performance. Effluent from the administration building treatment plant was well within these limits during the third quarter 1992. In addition, a flow equalization system is being added to the treatment plant and should become operational during the fourth quarter of 1992. The equalization of flow should greatly improve the operation of the plant.

5 AIR MONITORING

5.1 Radon Gas

The radon gas monitoring program utilizes a pair of alpha track radon detectors at each of the 25 permanent locations; each detector is exchanged quarterly. These detectors are deployed at six locations at the Weldon Spring Chemical Plant, eight locations at the Weldon Spring Quarry, four locations at the Weldon Spring raffinate pits, and at seven off-site locations. Radon monitoring locations are shown in Figures 5-1, 5-2, and 5-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, RD-4006, and RD-4007 monitor background levels near the site.

Landauer Type F track etch detectors were used for radon monitoring during the third quarter of 1992. The Type F detector is designed especially for outdoor monitoring of airborne radon concentrations. The detection mechanism consists of counting tracks generated by alpha particles in detector media to determine the radon concentration.

Table 5-1 summarizes the third quarter 1992 radon concentrations detected at all site perimeter and off-site monitoring locations. These concentrations represent the average of the two radon detectors placed at each location. Also contained in the third column of Table 5-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (111 Bq/m^3)[1] above background as authorized by DOE Order 5400.5.

An average ambient background concentration was determined by calculating the arithmetic average for the five background locations. These data yielded an average ambient background radon concentration of 0.24 pCi/l (8.88 Bq/m^3) for the third quarter of 1992. This concentration was then subtracted from the concentration for each monitoring station, and compared to the U.S. Department of Energy (DOE) guideline of 3 pCi/l (111 Bq/m^3) above background.

---

(a) Results include natural background.

(b) Percent of guideline calculated by taking the quarterly average minus the average of the background stations divided by the DOE concentration guideline for Rn-222 which is 3 pCi/l (111 Bq/m^3)(Annual average above background) for uncontrolled areas.

* Denotes Background Station; therefore, percent of guideline not applicable (NA).

Radon concentrations at the site and quarry perimeters and at off-site locations for the third quarter of 1992 were within the typical range expected during periods of normal precipitation. The quarterly radon concentrations at the Weldon Spring Chemical Plant/raffinatepit (WSCP/RP) area averaged 0.3 pCi/l (11.1 Bq/m^3), while the quarterly radon concentrations at the Weldon Spring Quarry (WSQ) averaged 0.7 pCi/l (25.9 Bq/m^3). The quarterly radon
concentrations from each individual detector (background included) ranged from less than the detection limit of 0.07 pCi/l (1.11 Bq/m^3) to 1.8 pCi/l (66.6 Bq/m^3).

Radon concentrations found at the quarry are higher than concentrations measured at other locations, because the radium concentrations in quarry wastes are typically higher than in other areas. Also, the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high, which tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

5.2 Gamma Radiation Exposure

To monitor exposure from gamma radiation, environmental thermoluminescent dosimeters (TLDs) were deployed at 26 locations. The gamma monitoring locations are identified in Figures 5-1, 5-2, and 5-3 with a prefix TD-.

Table 5-2 summarizes the third quarter results of total gamma radiation monitoring at the 18 Weldon Spring site perimeter monitoring stations, Francis Howell High School (FHHS), the Weldon Spring Army Reserve Training Area, and at the six background monitoring stations.

The Weldon Spring Site Remedial Action Project changed TLD vendors starting with the third quarter of 1992. During the second quarter of 1992, duplicate TLDs, one from the old vendor and one from the new vendor, were deployed at four monitoring locations. The results from the new vendor TLDs appeared to be consistent with historical data.

The results from the third quarter of 1992 (average of 12.0 mrem) appear to be lower than would be expected when compared to the third quarter of 1991 (average 16.0 mrem). The lower than expected results for the third quarter of 1992 may be related to the results of the control TLD, which was subtracted from the results of TLDs deployed at the monitoring locations. The control TLD is used to exclude any exposures recieved by the monitoring location TLDs during transit to and from the vendor, and during storage prior to and after deployment. The lower than expected third quarter results will continue to be investigated and the outcome will be reported in the annual site environmental report.

5.3 Radioactive Air Particulates

Fourteen low volume air particulate samplers continuously monitor the Weldon Spring site. Five of these (AP-2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and two are located around the quarry perimeter. There are five critical receptor monitoring stations, AP-4006, AP-4008, AP-2001, AP-2005 and AP-4011, located off-site at the Francis Howell high School, the Army Reserve property, the highway maintenance facility, the Weldon Spring Site Remedial Action Project (WSSRAP) administration building, and near a residential site west of the quarry, respectively. Three new monitoring stations were recently added during the second quarter of 1992. Two of the new monitoring stations, AP-2013 and AP-3014, were installed at the WSCP perimeter. The

other new station, AP-1017, was installed at the WSQ perimeter. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The air particulate monitoring station locations are shown in Figures 5-1 and 5-3.

The background sampling station AP-4007, is approximately 0.8 km (0.5 mile) from the WSCP perimeter in a northwestern direction. The terrain between the WSCP and this sampling station is hilly and forested, providing a significant physical barrier to airborne particulates originating from the WSCP/WSRP area.

Table 5-3 summarizes the quarterly average concentrations and the standard deviations for the 14 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging all weekly air particulate analysis results including results lower than the instruments lower limit of detection (LLD). The corresponding standard deviation for each monitoring location was also calculated using all weekly air particulate analysis results. Due to maintenance and installation of new samplers, all samplers were not operating the entire 13 weeks, as indicated in the fourth column of Table 5-3. The WSSRAP has deployed high volume air samplers, as well as low volume air samplers, at critical receptor locations. These high volume samplers are used in accordance with the *Plan for Monitoring Radionuclide Emissions Other Than Radon at the Weldon Spring Site Critical Receptors* (MKF and JEG 1992b). The high volume monitoring results will be presented in the 1992 annual site environmental report.

* Indicates background monitor station.

The third quarter average long-lived gross alpha concentrations ranged from 1.01×10^{-15} μCi/ml to 1.52×10^{-15} μCi/ml for perimeter and off site locations. The average background concentration measured at AP-4007 was 1.28×10^{-15} μCi/ml.

5.4 Asbestos

In accordance with the *Environmental Monitoring Plan* (MKF and JEG 1992a) the WSSRAP collected environmental airborne asbestos samples. These samples were collected at both the FHHS and the WSSRAP perimeter during bulk asbestos removal operations.

The samples collected at the perimeter locations all showed results of 0.003 fibers/cc or less. Fourteen samples were collected at the perimeter of which nine had measured concentrations below the detection limit.

The samples collected at the FHHS all showed results of 0.004 fibers/cc or less. Thirty-two samples were collected at the FHHS of which 10 were less than the detection limit.

ABSTRACT

The purpose of this *Quarterly Environmental Data Summary* is to provide to the public preliminary data acquired as part of the Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring program. The document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1992 annual site environmental report.

This report includes preliminary data from environmental monitoring activities at the Weldon Spring site (WSS) during the fourth quarter of 1992. Groundwater, surface water, and air samples were collected in order to monitor potential exposure pathways. Analytical parameters included radionuclides, nitroaromatic compounds, metals, inorganic anions, and direct gamma exposure. The results are used to evaluate possible exposure scenarios and assess the impact of the contaminants at the site on potentially exposed populations.

Contaminated ground water did not affect the St. Charles County well field.

1 INTRODUCTION

This quarterly report summarizes the findings from the routine environmental monitoring programs at the Weldon Spring Site Remedial Action Project (WSSRAP). These quarterly reports supplement the annual site environmental report (ASER) by providing interested outside agencies and organizations with more frequent access to WSSRAP data (Appendix A). They provide data resulting from routine environmental sampling as described in the WSSRAP *Environmental Monitoring Plan* (EMP) (MKF and JEG 1992a) and a brief interpretation of that data.

It is the goal of this document to summarize and briefly discuss the data, highlighting data that differ significantly from historical observations. The full interpretation of these data (as well as data in other quarterly summaries) will be undertaken in the 1992 ASER. It is recommended that interested readers refer to previous EMPs, ASERs, and project documents for more information on existing site conditions, site history, transport mechanisms, and quantified contaminant levels. The monitoring scheme for every calendar year is established prior to that year in the annual EMP. Each sampling location to be monitored during the upcoming year is identified in the EMP and the schedule of analytical parameters is tabulated for easy reference. These reports may be obtained by visiting the WSSRAP reading room or contacting the WSSRAP Community Relations Manager at (314) 441-8086.

These quarterly reports are intended to include data from all environmental monitoring programs conducted at the WSSRAP including groundwater, springs, surface water, National Pollutant Discharge Elimination System (NPDES), radon gas, gamma radiation, and air particulates (including asbestos and radioactive particulates). This document summarizes the preliminary environmental data, highlights any potentially significant findings, and offers tentative interpretations. Validated data and final interpretations will appear in the 1992 annual site environmental report. Because standard turnaround time to receive data from the laboratories is 45 days, not all fourth quarter data are available for reporting. These data will be reported in the 1992 ASER. Sludges and soils are not sampled on a routine basis; therefore, analytical results for these parameters are not included in this report. Trend analyses are being prepared from historical data for surface water, groundwater, and air pathways. These analyses will be presented in the 1992 ASER. Quality control (QC) data for the fourth quarter and fifth and sixth bimonthly periods, along with all other periods, will be presented in the 1992 ASER.

2 GROUNDWATER MONITORING

The groundwater is sampled regularly at both the Weldon Spring Chemical Plant/raffinate pits/vicinity properties (WSCP/WSRP/VP) and the Weldon Spring Quarry (WSQ). Due to differences in the environmental settings and sources of contaminants, separate monitoring schedules are followed. Therefore, results of groundwater monitoring at the WSCP/WSRP/VP and WSQ will be discussed separately.

2.1 Chemical Plant/Raffinate Pits/Vicinity Properties

Groundwater at the WSCP/WSRP/VP area is monitored on a quarterly or semiannual basis. Locations are given in Figure 2-1. The number of wells sampled quarterly has increased substantially; a complete list of wells scheduled for quarterly and semiannual sampling is given in the 1992 *Environmental Monitoring Plan* (MKF and JEG 1992a). Total uranium, inorganic anions, and nitroaromatic compounds are measured during each monitoring period for both quarterly and semiannual wells. Other radiological parameters are measured annually during the first period for all wells.

2.1.1 Nitroaromatic Results

Table 2-1 contains nitroaromatic data from samples collected from the groundwater wells monitored quarterly. Nitroaromatic compounds were detected in 15 of the 34 locations. Table 2-2 contains nitroaromatic data from samples collected from the groundwater wells monitored semi-annually. Nitroaromatic compounds were detected in 9 of the 27 locations. Concentration levels for these compounds are within their historical range, with the following exceptions: a new 2,4,6-trinitrotoluene (TNT) high is recorded in well MW-2006 and a new 1,3,5-trinitrobenzene (TNB) low was measured in MW-4013.

2.1.2 Radiological Results

The upper bound for natural uranium background concentration in groundwater at the WSCP/WSRP/VP has been determined to be 3.4 pCi/l (0.13 Bq/l) (MKF and JEG 1989). The U.S. Environmental Protection Agency (EPA) has not yet established a drinking water standard for uranium; however, the proposed maximum contaminant level (MCL) is 20 μg/l, which

converts to 13.6 pCi/l (0.50 Bq/l) using a new site-specific conversion factor of 0.68 pCi/μg (assuming isotopic equilibrium). The increase to 13.6 pCi/l (0.50 Bq/l) from the previously reported value of 12 pCi/l (0.44 Bq/l) reflects improved quantification of the average U-234/U-238 activity ratios for uranium present at the Weldon Spring Site Remedial Action Project (WSSRAP).

Total uranium results for samples from the wells monitored quarterly and semi-annually at the WSCP/WSRP/VP are presented in Tables 2-3 and 2-4. Uranium concentrations remained within historical ranges at locations for which data are presently available except for wells MW-3003 and MW-2030, where a new high and low were recorded, respectively.

2.1.3 Sulfate and Nitrate Results

Sulfate and nitrate concentrations are measured during each monitoring period. Results from the wells monitored quarterly are shown in Tables 2-3 and 2-4. Fourth quarter and semi-annual results are within historical ranges with the exception of a new nitrate low in MW-2003. The nitrate level in MW-3003 and sulfate level in MW-4023 were the highest recorded values in these wells since 1989. These values are thought to reflect natural fluctuation in these wells.

2.2 Weldon Spring Quarry

Groundwater at the WSQ has become radiologically and chemically contaminated as a result of contact with, or migration from, wastes present in the WSQ. Monitoring of the groundwater at and near the WSQ is of particular concern because of the proximity of the St. Charles County well field. The well field is located approximately 0.8 km (0.5 mi) to the south of the WSQ. Monitoring of contaminants in groundwater and the protection of the well field is a priority at the WSSRAP.

Groundwater is currently being monitored at 48 wells located in and around the quarry area. Groundwater at the WSQ and surrounding areas is monitored on a bimonthly or quarterly basis as detailed in the 1992 *Environmental Monitoring Plan* (MKF and JEG 1992a). All monitoring well locations are shown in Figures 2-2 and 2-3. These wells monitor groundwater in both the bedrock and alluvial aquifers associated with the WSQ.

2.2.1 Radiological Results

Radiological data are presented in Tables 2-5 through 2-7 for samples collected for the fifth and sixth bimonthly periods and the fourth quarter. The results show typical fluctuations near the average levels in the WSQ area, except for an elevated uranium level that was reported in the sixth bimonthly period in MW-1028 (1,000 pCi/l). This value is considered to be an erroneous laboratory value based on historic averages and has been submitted for validation. Detectable concentrations of uranium were indicated from the St. Charles County RMW-series and production wells. In addition to being within historic averages and representative of background levels, these levels are the result of lower detection limits for uranium during analytical testing.

The St. Charles County RMW-series and production wells are also sampled annually for gross alpha. The results of this analysis are presented in Table 2-7. The concentrations in the St. Charles County well field are consistent with background values of waters in or near the WSQ.

2.2.2 Nitroaromatic Compounds Results

Analytical results for the fifth and sixth bimonthly periods and the fourth quarter for nitroaromatic compounds are presented in Tables 2-8 through 2-10. No monitoring locations south of the Femme Osage Slough showed detectable concentrations of nitroaromatic compounds during the fourth quarter of 1992. Nitroaromatic levels have increased in the sixth period monitoring well MW-1002 located on the quarry rim. The distribution and magnitude of nitroaromatic contamination in the remainder of the wells near the quarry remain consistent with historical levels.

2.2.3 Inorganic Anions Results

Two inorganic anions, nitrate and sulfate, are sampled in all of the wells monitored at the WSQ. The analytical results for the fifth and sixth bimonthly periods and the fourth quarter are presented in Tables 2-5 through 2-7. The nitrate and sulfate results for the WSQ groundwater samples continue to be within historic ranges. The results continue to indicate that elevated sulfate levels are present in groundwater within the WSQ and north of the Femme Osage Slough.

2.2.4 Metals Results

All wells in the WSQ monitoring program are sampled for arsenic and barium. The results for the fifth and sixth bimonthly periods and the fourth quarter are presented in Tables 2-11 through 2-13. Arsenic levels were consistent with historical and background values for groundwater in the vicinity of the WSQ. Barium levels have remained elevated, but within historical ranges in the wells in the vicinity of the Femme Osage Slough. Elevated metal concentrations have been indicated in monitoring well MW-1010 located adjacent to the Femme Osage Slough. An elevated concentration of barium has been detected in monitoring well MW-1037 during the sixth bimonthly period and is considered to be erroneous based on the historic average for this and surrounding monitoring wells.

2.3 Springs

Five springs near the Weldon Spring site (WSS), which are measurably influenced by site-related contaminants, were sampled during the fourth quarter (see Figure 2-4). During the fourth quarter, spring samples were analyzed for uranium and inorganic anions. Results are presented in Table 2-14. SP-6301 and SP-6306 were sampled during high and low flow to evaluate the groundwater (which is thought to dominate low flow) and surface water (which is thought to dominate high flow) components of flow. Results for the fourth quarter remain consistent with historical values.

3 SURFACE WATER MONITORING

Routine samples were collected during the fourth quarter and fifth and sixth bimonthly periods of 1992 from both on-site and off-site surface water locations. All surface water samples were analyzed without filtering, unless a specific comparison of dissolved versus total contaminant concentrations was desired. Some analytical results are not available at this time; however, they will be presented in the 1992 annual site environmental report (ASER).

3.1 Chemical Plant/Raffinate Pits/Vicinity Properties

During the fourth quarter, surface water samples were collected from the 15 surface water sampling locations and analyzed for uranium (Figure 3-1). Monitoring points SW-2016 and SW-5311 are not shown in Figure 3-1. Location SW-2016 is located at the intersection of Dardenne Creek and County Highway N. This is the furthest location downstream at which contaminants are sampled for in Dardenne Creek after it has received the Schote Creek contribution. Location SW-5311 is located just above the confluence of the Southeast Drainage to the Missouri River. The results, presented in Table 3-1, indicated that conditions at sampling locations remain consistent with historical values.

3.2 Weldon Spring Quarry

During fifth and sixth bimonthly periods, surface water samples were collected from 13 locations shown in Figures 3-2 and 3-3 and analyzed for uranium. Results remain within historical ranges and are presented in Tables 3-2 and 3-3.

In addition to uranium samples, the Weldon Spring Quarry pond was sampled for nitroaromatics, isotopic radium, isotopic thorium, and inorganic anions during the fifth and sixth bimonthly periods. The results for fifth and sixth bimonthly periods are within historic ranges for all parameters analyzed and are presented in Table 3-4.

4 EFFLUENT MONITORING

The National Pollutant Discharge Elimination System (NPDES) permit process is authorized by Section 402(a)(1) of the *Clean Water Act of 1977.* The authority to issue permits is delegated to the State of Missouri by the U.S. Environmental Protection Agency (EPA). The State of Missouri has issued seven NPDES permits to the U.S. Department of Energy (DOE) allowing the discharge of storm water, hydrostatic test water, and treated wastewater to waters of the state. The permits require that samples of the water be collected periodically and the results reported to the Missouri Department of Natural Resources. The following sections contain the analytical results for samples collected during October, November, and December of 1992. No NPDES permit limits were violated during the fourth quarter 1992.

4.1 National Pollutant Discharge Elimination System Data Review

Effluent samples were collected and analyzed in compliance with the Weldon Spring site NPDES permits. Permit No. MO-0107701 was issued on October 1, 1990, and currently addresses the five storm water and two wastewater discharges shown in Figure 4-1. Outfalls NP-0001 through NP-0005 represent storm water discharges; Outfall NP–0006 represents the treated wastewater discharge associated with the administration building sanitary wastewater treatment plant; and Outfall NP-0007 represents the site water treatment plant, which is under construction, and nearing completion. There was no discharge from Outfall NP-0007. Outfalls NP-0006 and NP-0007 have effluent limitations. The five storm water outfalls have "monitoring only" requirements for permitted parameters. Fourth quarter 1992 analytical data for each outfall are presented in Table 4-1.

In addition, storm water was pumped from the temporary storage area (TSA) basin to an area just west of the TSA itself. The location of the basin prevented the water from being pumped through a permitted outfall. Under the direction of the Missouri Department of Natural resources, this water was sampled as if it were flowing from the site through a permitted outfall. These results are included in Table 4-1.

Permit No. MO-0108987 was issued on May 5, 1989, for Outfall NP-1001 of the Weldon Spring Quarry water treatment plant. The first batch (approximately 541,000 gallons) of water from the Weldon Spring Quarry was treated in November 1992. Comprehensive sampling of the treated water was conducted on November 19, 1992. [a] No effluent discharge due to construction improvements to treatment plant. Influent sewage was removed daily by Ace Septic Service -- Approximately 4,000 gallons per day.

NS Not sampled.

Fourth Quarter 1992 contains all results of the treated water sampling and has been transmitted to the Missouri Department of Natural Resources. The treated water was in compliance with all applicable limits and was discharged to the Missouri River on January 7, 1992, and January 8, 1992. Analytical results for the treated water are presented in Table 4-2.

Under the NPDES permits MO-G680001, MO-G680002, MO-680004, and MO-680005, potable water used to hydrostatically test vessels, basins, and pipelines at the quarry and site water treatment plants, was discharged a total of 23 times during the fourth quarter of 1992. All discharges were within NPDES permit limits. Analytical results of these discharges will be included in the 1992 site environmental report.

4.1.1 Radiological Analysis

Gross alpha and uranium analyses corresponded well with past data with the following exception. Analysis of the December 9, 1992, sample at NP-0004 demonstrated a uranium concentration of 12 pCi/l. This concentration is slightly above the previous highest concentration at NP-0004.

The other storm water outfalls had the following ranges of uranium concentrations. The process sewer outfall NP-0001 had a sample value of 471 pCi/l (0.692 mg/l). Frog Pond outfall, NP-0002, had values from 259 pCi/l (0.381 mg/l) to 277 pCi/l (0.407 mg/l). Ash Pond outfall, MP-0003, had values from 54 pCi/l (0.0787) to 604 pCi/l (0.889 mg/l). The southeast drainage outfall, NP-0005, had values from 231 pCi/l (0.339 mg/l) to 388 pCi/l (0.571 mg/l).

4.1.2 Other Analysis

Other analyses for NP-0001 through NP-0005 include physical analyses (settleable solids and total suspended solids) and chemical analyses (nitrate, lithium, and pH). Fourth quarter 1992 values are displayed in Table 4-1 and correspond well with past values for all parameters with the following two exceptions.

Laboratory analysis demonstrated an elevated nitrate concentration of 60.5 mg/l for the December 9, 1992, sample at NP-0002. Also on December 9, 1992, laboratory analysis demonstrated a nitrate concentration of 562 mg/l at NP-0004. Previous and subsequent samples

at both locations show substantially lower nitrate levels. These two data points are under investigation and data from these locations will be closely reviewed.

The permit for the discharge from the administration building treatment plant at outfall NP-0006 has effluent limitations and a requirement to monitor once per quarter. There was no discharge from the administration building's sewage treatment plant during the fourth quarter of 1992 because construction activities were taking place during this time to improve the new flow equalization system that was recently added to the plant. During this time, all sewage was collected from the plant and disposed of by Ace Septic Services of O'Fallon, Missouri.

5 AIR MONITORING

5.1 Radon Gas

The radon gas monitoring program utilizes a pair of alpha track radon detectors at each of the 28 permanent locations; each detector is exchanged quarterly. These detectors are deployed at seven locations at the Weldon Spring Chemical Plant, eight locations at the Weldon Spring Quarry, five locations at the Weldon Spring raffinate pits, and at eight off-site locations. Radon monitoring locations are shown in Figures 5-1, 5-2, and 5-3. On-site detectors are distributed around the perimeter fences to ensure adequate detection of radon dispersing from the properties under various atmospheric conditions. Locations RD-4001, RD-4004, RD-4005, RD-4006, and RD-4007 monitor background levels near the site.

Landauer Type F track etch detectors were used for radon monitoring during the fourth quarter of 1992. The Type F detector is designed especially for outdoor monitoring of airborne radon concentrations. The detection mechanism consists of counting tracks generated by alpha particles in detector media to determine the radon concentration.

Table 5-1 summarizes the fourth quarter 1992 radon concentrations detected at all site perimeter and off-site monitoring locations. These concentrations represent the average of the two radon detectors placed at each location. Also contained in the third column of Table 5-1 is a comparison of the measured concentration with the Federally permitted radon concentration (for unrestricted areas) of 3 pCi/l (111 Bq/m^3)[1] above background as authorized by DOE Order 5400.5.

Three stations RD-3005, RD-2007, and RD-4008, were added to the radon track etch detector network for the fourth quarter of 1992. RD-2007 and RD-3005 were placed at the WSCP perimeter. RD-4008 was placed near the Femme Osage Slough where low levels of radiological contamination is known to exist.

An average ambient background concentration was determined by calculating the arithmetic average for the five background locations. These data yielded an average ambient background radon concentration of 0.14 pCi/l (5.18 Bq/m^3) for the fourth quarter of 1992. This

concentration was then subtracted from the concentration for each monitoring station, and compared to the U.S. Department of Energy (DOE) guideline of 3 pCi/l (111 Bq/m^3) above background.

Radon concentrations at the site and quarry perimeters and at off-site locations for the fourth quarter of 1992 were within the typical range expected during periods of normal precipitation. The quarterly radon concentrations at the Weldon Spring Chemical Plant/raffinate pit (WSCP/RP) area averaged 0.2 pCi/l (7.4 Bq/m^3), while the quarterly radon concentrations at the Weldon Spring Quarry (WSQ) averaged 0.6 pCi/l (22.2 Bq/m^3). The quarterly radon concentrations from each individual detector (background included) ranged from less than the detection limit of 0.06 pCi/l (2.22 Bq/m^3) to 1.5 pCi/l (55.5 Bq/m^3).

Radon concentrations found at the quarry are higher than concentrations measured at other locations, because the radium concentrations in quarry wastes are typically higher than in other areas. Also, the quarry is a large depression with side walls ranging from 3 m to 15 m (10 ft to 50 ft) high, which tends to trap emanating radon within the quarry and raise the concentrations along the quarry perimeter.

5.2 Gamma Radiation Exposure

This data is currently unavailable, however, it will be reported in the *1992 Annual Site Environmental Report*.

5.3 Radioactive Air Particulates

Seventeen low volume air particulate samplers continuously monitor the Weldon Spring site. Five of these (AP–2001, AP-2002, AP-3003, AP-3004, and AP-2005) are located around the Weldon Spring Chemical Plant (WSCP) perimeter and five are located around the quarry perimeter. There are five critical receptor monitoring stations, AP-4006, AP-4008, AP-2001, AP-2005 and AP-4011, located off-site at the Francis Howell high School, the Army Reserve property, the highway maintenance facility, the Weldon Spring Site Remedial Action Project (WSSRAP) administration building, and near a residential site west of the quarry, respectively. Three new monitoring stations were recently added during the second quarter of 1992. Two of the new monitoring stations, AP-2013 and AP-3014, were installed at the WSCP perimeter. The other new station, AP-1017, was installed at the WSQ perimeter. At the end of the fourth quarter three additional samplers were added to the low volume sampling network and one sampler was relocated. Two of the stations were added to the WSQ perimeter, AP-1015 and AP-1016. The third sampler, AP-4012 (Figure 5-4), located approximately 12 km from the WSCP will be used as the background monitoring station and replaces AP-4007 in that capacity. As a result, AP-4007 was relocated from behind the large hill which shielded the station from potential emissions from the WSCP to a location near the Busch Wildlife headquarters building and will serve as an off-site monitoring station in the future. The monitoring station at the August A. Busch Wildlife Area (AP-4007) is used to monitor background levels in the vicinity of the WSCP. The air particulate monitoring station locations are shown in Figures 5-1 and 5-3.

Table 5-2 summarizes the quarterly average concentrations and the standard deviations for the 17 air monitoring locations. The quarterly average concentration for each monitoring location was calculated by averaging all weekly air particulate analysis results including results lower than the instruments lower limit of detection (LLD). The corresponding standard deviation for each monitoring location was also calculated using all weekly air particulate

analysis results. Due to maintenance and installation of new samplers, all samplers were not operating the entire 13 weeks, as indicated in the fourth column of Table 5-2. The WSSRAP has deployed high volume air samplers, as well as low volume air samplers, at critical receptor locations. These high volume samplers are used in accordance with the *Plan for Monitoring Radionuclide Emissions Other Than Radon at the Weldon Spring Site Critical Receptors*

(MKF and JEG 1992b). The high volume monitoring results will be presented in the 1992 annual site environmental report.

The fourth quarter average long-lived gross alpha concentrations ranged from 7.96×10^{-16} μCi/ml to 1.60×10^{-15} μCi/ml for perimeter and off site locations. The average background concentration measured at AP-4007 and AP-4012 was 1.34×10^{-15} μCi/ml.

5.4 Asbestos

In accordance with the *Environmental Monitoring Plan* (MKF and JEG 1992a) the WSSRAP collected environmental airborne asbestos samples. These samples were collected at both the FHHS and the WSSRAP perimeter during bulk asbestos removal operations.

The samples collected at the perimeter locations all showed results of 0.001 fibers/cc or less. Fourteen samples were collected at the perimeter of which four had measured concentrations below the detection limit.

The samples collected at the FHHS all showed results of 0.002 fibers/cc or less. Thirty-five samples were collected at the FHHS of which 12 were less than the detection limit.

Mr. R.E. Hlavacek
Project Director
MK-Ferguson Company
7295 Highway 94 South
St. Charles, Missouri 63303

Dear Mr. Hlavacek:

PREPARATION OF ENVIRONMENTAL MONITORING SUMMARIES

With the upcoming increase in remedial action work at the site, it will be necessary to disseminate environmental monitoring data in a timely manner to the Francis Howell High School (FHHS), St. Charles Countians Against Hazardous Waste (SCCAHW), Missouri Department of Natural Resources (MDNR), U.S. Environmental Protection Agency (EPA) and others. Therefore, you are requested to prepare a plan for DOE review which would result in preparation of a document that summarizes our environmental monitoring data on a quarterly basis.

I would like the document to be brief but contain appropriate explanation and discussion of the data. Issuance of the quarterly report should begin as soon as possible and include the first two quarters of FY 90 data, in order to get caught up with this fiscal year.

Sincerely,

Stephen H. McCracken
Project Manager

WELDON SPRING SITE REMEDIAL ACTION PROJECT
HYDROGEOLOGIC INVESTIGATIONS WORK PLAN
IMMEDIATE FIELD EFFORT: INSTALLATION OF PUMPING WELLS, OBSERVATION WELLS, AND DEEP MONITORING WELLS

The attached submittal represents plans and specifications for installation of pumping and observation wells for aquifer testing at the Weldon Spring Site. Also included in this submittal are plans and specifications for installation of two deep monitoring well clusters to support related studies by the U.S. Geological Survey (USGS). Each cluster will consist of three wells penetrating the Burlington-Keokuk, Kimmswick, and St. Peter formations. These clusters will allow discrete hydraulic head measurements from deeper aquifers to calibrate a regional groundwater flow model. Sampling of these wells will confirm that these deeper aquifers have not been contaminated from the site.

This submittal is intended to support the process of drilling subcontract procurement to allow field efforts to proceed in a timely manner. Specific details of aquifer testing, sampling, and model development are subject to review following submission of the complete Hydrogeologic Investigations Work Plan. Well installation will be a relatively long field effort, approximately 3 months duration. Completion of the subsequent aquifer testing and other studies is essential to completion of site characterization. Completion of site characterization is critical to the scheduling of the Environmental Impact Statement (EIS) process leading to the Record of Decision for the Weldon Spring Site (WSS).

The attached submittal consists of subsections of the Hydrogeologic Investigations Work Plan describing the aquifer testing program and a portion of the USGS studies. An outline of the entire Hydrogeologic Investigation Work Plan is attached;

the subsections comprising this abbreviated submittal are underlined.

2.2 Aquifer Testing

DRAFT

Aquifer testing will consist of single-well hydraulic conductivity (permeability) tests, and pumping tests to define the hydraulic characteristics of the aquifer in order to predict contaminant migration and assess groundwater remediation alternatives.

2.2.1 Single-Well Hydraulic Conductivity Tests

2.2.1.1 Test Design

Single-well hydraulic conductivity tests ("slug tests") will be performed to provide information on areal variations in permeability within the Burlington-Keokuk formation. A slug test will be performed in each new monitoring well installed as described in Section 2.1. Slug tests will also be performed in selected existing monitoring wells to verify the results of packer tests performed during well installation. Existing monitoring wells selected for slug tests are:

MW - 2002
MW - 2005
MW - 2006
MW - 2008
MW - 2013
MW - 2015
MW - 2018
MW - 4001

These wells provide an evenly spaced areal distribution for confirming the packer test results. In addition, deep monitoring wells to be installed adjacent to each of these wells will also be tested, allowing for comparison of permeability values at varying depths. The existing monitoring wells are shown on Figure 2-1; the new monitoring wells to be installed to

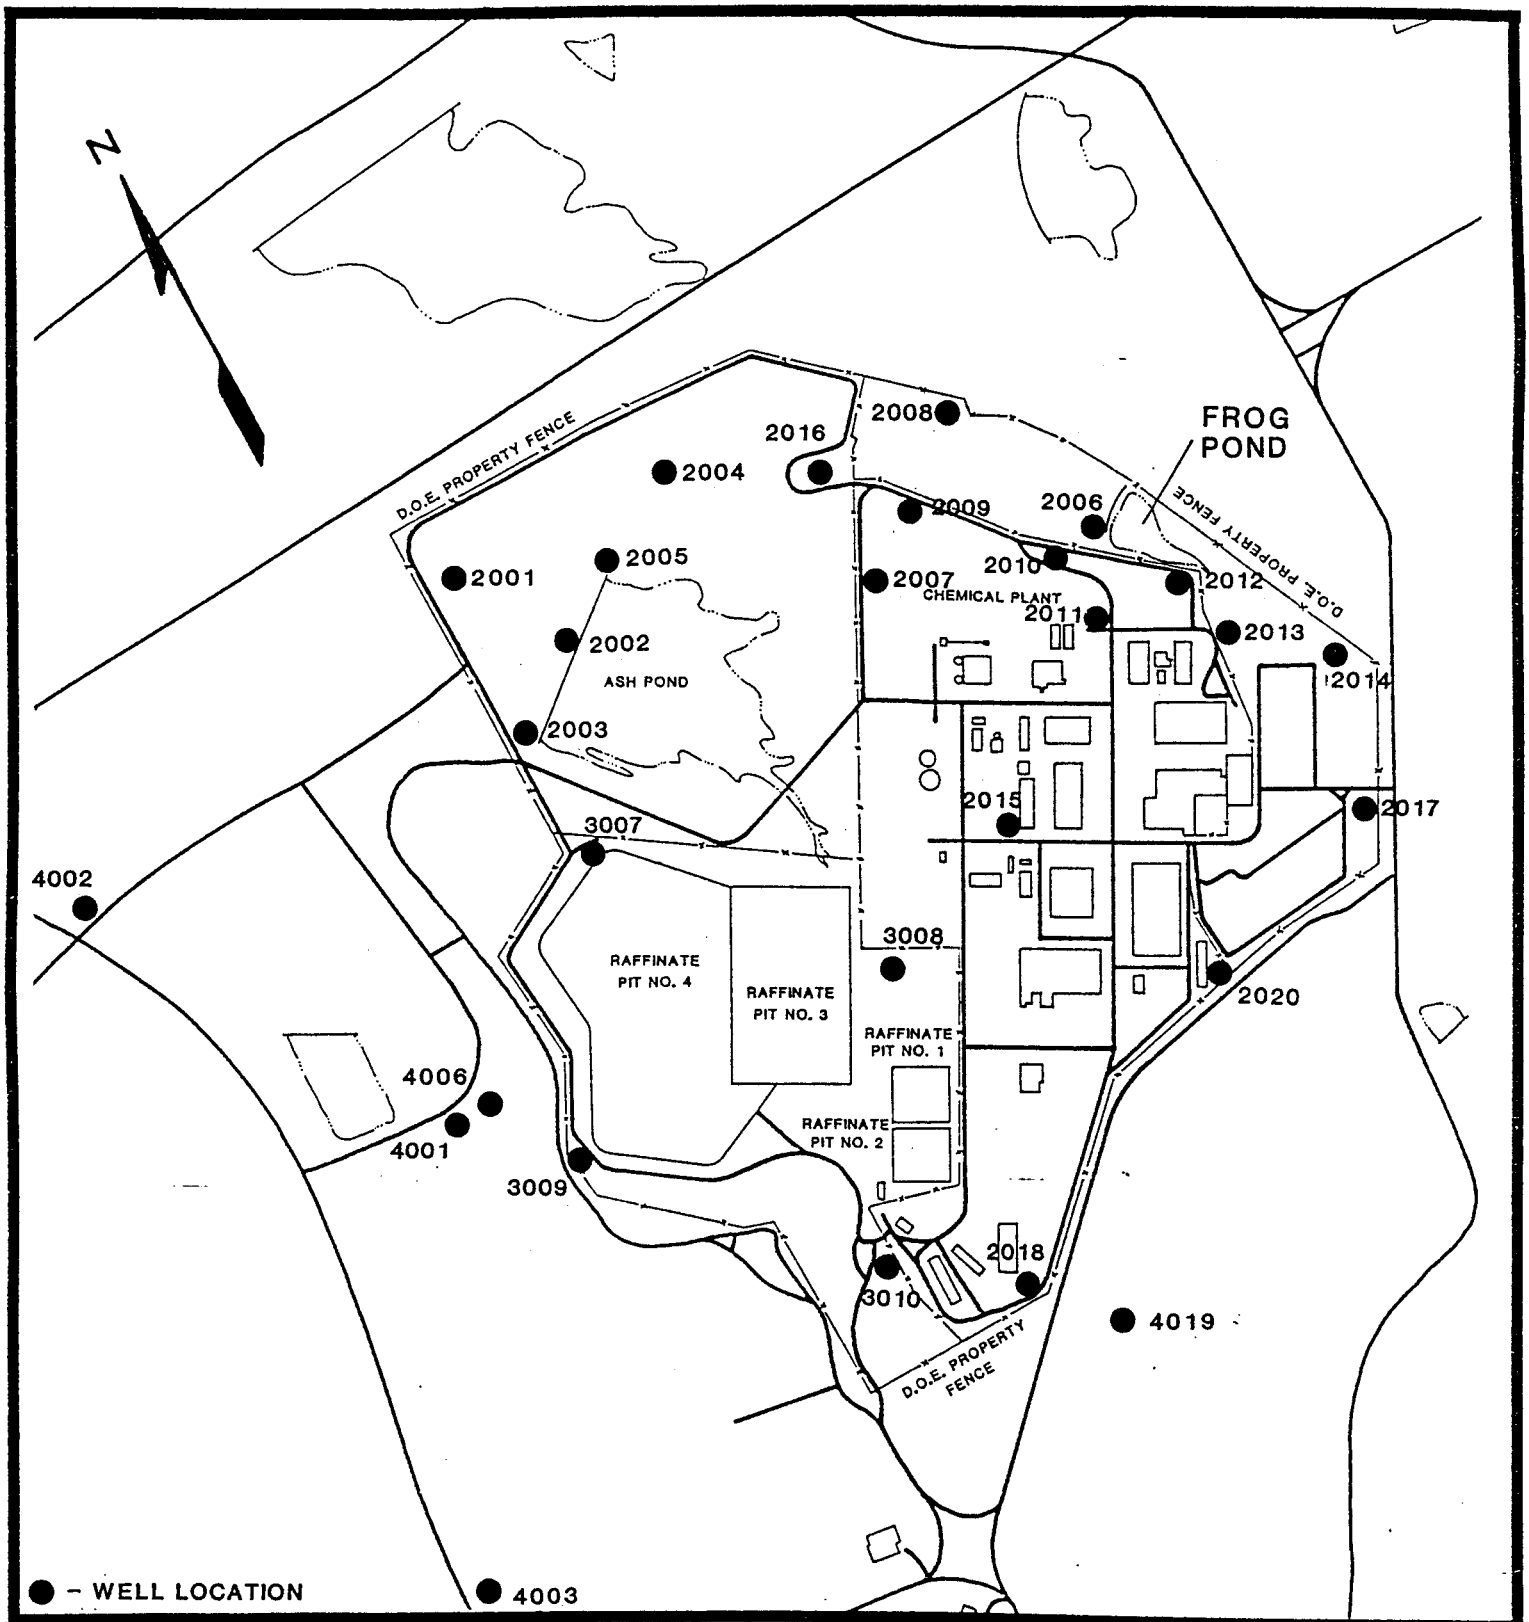

FIGURE 2-1

DRAFT

EXISTING MONITORING WELLS

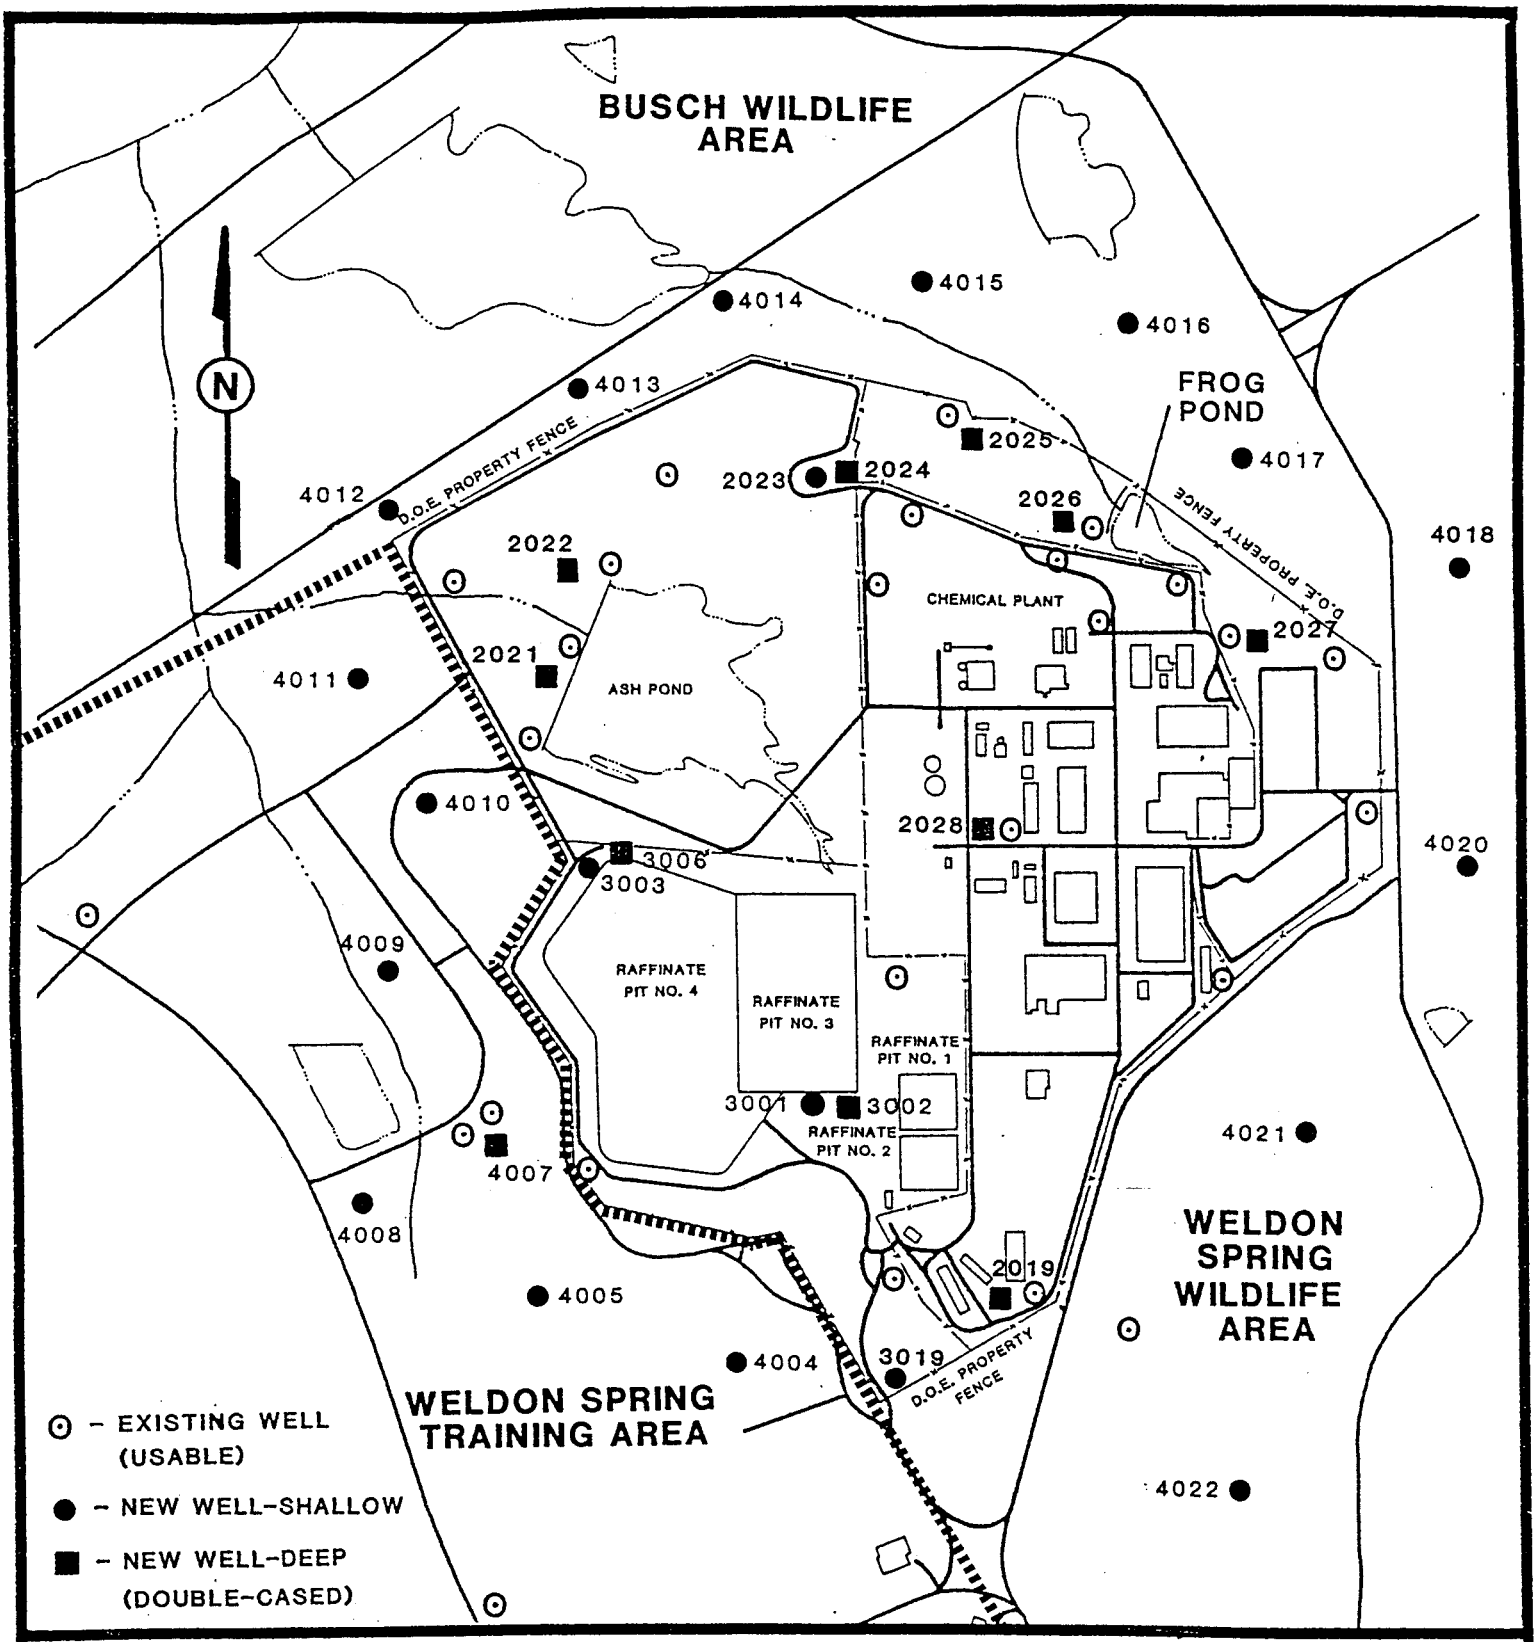

FIGURE 2-2

DRAFT

EXTENDED MONITORING WELL NETWORK

complete the extended monitoring well network are shown on Figure 2-2.

DRAFT

Slug tests are performed by displacing, adding or removing a known volume of water within the well. The test is designed to approach, to the extent possible, ideal conditions. The volume change is produced as close to instantaneously as feasible, and the volume is controlled to a premeasured amount. Readings of water levels within the well during the test will be made using a pressure transducer and electronic data logger, which will enable collection of measurements at short time intervals (1 second) during the early part of the test.

2.2.1.2 Test Performance

To begin the test, a pressure transducer is installed within the well and static water level measurements are collected. The water levels are observed to ensure that the aquifer is under steady-state conditions. The volume change is produced within the well and water levels are measured as the well recovers to the static water level.

For tests to be performed in the shallow, 2-inch diameter wells, a solid rod or similar object slightly smaller than the well diameter will be injected below water level in the well in order to displace the water to a higher level. Water levels will be measured at frequent time intervals as the water level falls to the original level. At this point the rod will be removed and water levels measured as the water level rises to the original level. The use of this test method allows for both falling head and rising head measurements. A falling head technique will be used to perform tests in the deep, 4-inch diameter monitoring wells. After monitoring static water levels, a known volume of potable water will be pumped into the well to produce an instantaneous rise in the water level. Water level measurements are collected until the water level has returned to a near

steady-state condition. Field measurements collected by the electronic data logger will be transferred to a computer data base.

DRAFT

2.2.1.3 Data Analysis

The data will be analyzed to determine a hydraulic conductivity value using a standard formula such as the Hvorslev method. The hydrologic formula will be chosen to fit the conditions in the aquifer and well being tested. A qualified groundwater professional will determine the aquifer and well conditions, the formula to be used, and the data points for the hydraulic conductivity calculation.

2.2.2 Pumping Tests

Long-term pumping tests will be performed at three (3) locations on-site in order to determine aquifer properties such as transmissivity, storativity, and anisotropy. These results will allow prediction of contaminant migration and assessment of the effects of pumping on groundwater flow patterns and contaminant levels. Pumping tests affect a much larger portion of the aquifer than the single-well tests and consequently yield more accurate hydraulic conductivity values. Transmissivity, storativity, and anisotropy can be determined accurately only from pumping tests.

2.2.2.1 Pumping Test Design

Pumping tests are designed based on the known characteristics of the Burlington-Keokuk formation. The upper, weathered zone of the formation comprises an unconfined aquifer. Yields are expected to be relatively low, based on reported yields of 5-50 gallons per minute (gpm) for wells in this formation (USGS, 1986).

DRAFT

Locations for the pumping tests are shown on Figure 2-4. Locations were selected to determine aquifer conditions in areas where contaminants have been detected in the groundwater and could potentially migrate off-site, and also at a location adjacent to the proposed disposal cell. Pumping Well 1 (PW-1) is located to the north of the apparent groundwater flow divide in the area where relatively high concentrations of nitroaromatic compounds were detected in groundwater samples. Pumping Well 2 (PW-2) is located adjacent to the proposed disposal cell area near the southern end of the site. Results from the pumping test at this location will allow for an assessment of aquifer conditions under the proposed disposal cell. The pumping and observation wells will be located adjacent to, rather than within, the proposed disposal cell area in order to minimize the number of wells and other boreholes within the disposal cell area which would need to be drilled out and grouted prior to disposal cell construction. Pumping Well 3 (PW-3) is located in the area where the highest nitrate concentrations were detected in groundwater samples from the Phase I Assessment.

The pumping wells are designed to be fully penetrating (continuously screened) over the upper forty feet (40') of saturated thickness of the Burlington-Keokuk formation. This interval has been selected to encompass the weathered, more permeable zone in which groundwater contamination has been detected. The test interval is limited to forty feet (40') to avoid producing a vertical pathway through which contaminants could migrate into deeper zones in the aquifer. The fully screened interval will allow for the most straightforward techniques for pumping test interpretation and calculations.

Each pumping test will have eleven (11) observation wells oriented to determine the distribution of drawdown due to pumping the aquifer. A set of nine (9) observation wells, labeled "a" to "i" on Figure 2-4, will be completed at the same

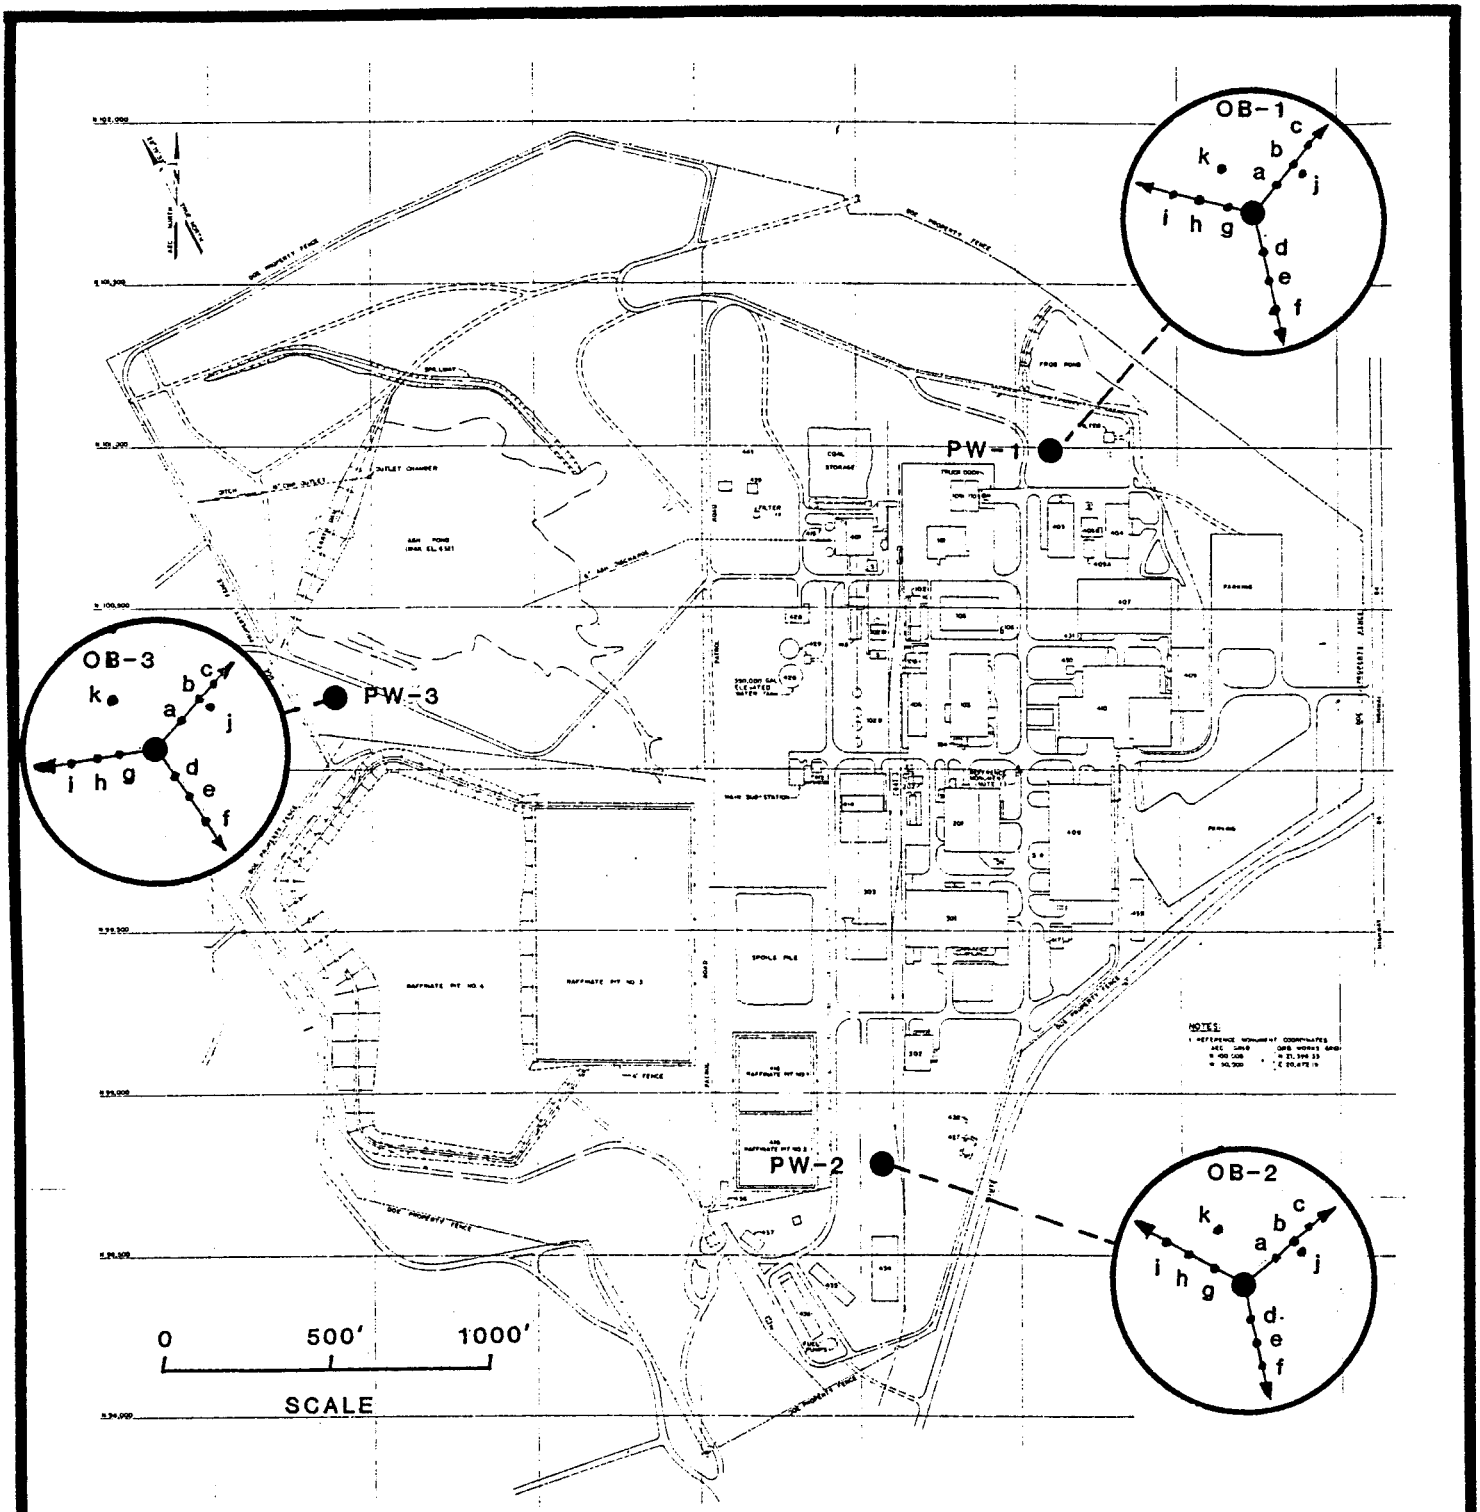

FIGURE 2-4

PUMPING AND OBSERVATION WELL LOCATIONS

DRAFT

LEGEND

PW-1 -PUMP TEST WELL

OB-1 - OBSERVATION WELL (a-k)

depth within the Burlington-Keokuk formation with the same screened interval as the pumping well. These wells will be placed on three (3) lines radiating from the pumping well with 120 degrees of arc between lines. One line will be placed on a bearing of N60^{o}E, aligned with the predominant northeastward orientation of fractures in the Burlington-Keokuk formation. The other two lines will be located relative to this primary line. Following installation and development of the pumping well, a step-drawdown pumping test will be performed to determine the optimum distance from the pumping well for placement of the observation wells and optimum pumping rate for long-term pumping tests. It is anticipated that pumping rates will be relatively low (5-10 gpm) and that all observation wells will be within 100 feet from the pumping well.

Two (2) additional observation wells will be installed in a lower zone in the Burlington-Keokuk formation, screened from 40 to 50 feet below the bottom of the pumping well. These wells will be double-cased to a depth 10 feet below the bottom of the pumping well to prevent transport of contaminants to lower zones during drilling operations. Drawdown measurments in these wells will allow for a determination of the degree of hydraulic connection between shallow and deeper zones in the Burlington-Keokuk formation. These two wells, designated "i" and "j" on Figure 2-4, will be placed approximately 40 feet from the pumping well. One well will be along the primary N60^{o}E orientation of fracturing (offset slightly if necessary to avoid interfering with other observation wells on this line), the other well will be placed an equal distance from the pumping well on a line perpendicular to the orientation of fracturing.

During the pumping tests, water levels will also be measured in monitoring wells within a radius of approximately 500 feet from the pumping well in order to observe any effects of pumping at greater distances.

DRAFT

The pumping tests will be 7 days (168 hours) in duration to allow for observation of delayed-yield effects, determination of specific yield, and observation of other effects of long-term pumping. Recovery measurements will continue until full recovery, a minimum of 24 hours under any circumstances. The duration of any individual pumping test may be modified by the project hydrogeologist as the test proceeds, based on drawdowns observed and determination of whether sufficient data has been collected.

2.2.2.2 Pumping and Observation Well Installation

The pumping wells will be installed by hollow-stem auger boring and bedrock coring to provide an accurate lithologic log of the formation at each pumping test location, followed by reaming to the final diameter by air-rotary techniques. Split-spoon samples will be collected at intervals of five feet (5') during auger drilling in the unconsolidated soils. The bedrock will be cored from the bedrock surface to the total depth of the well. The log will be recorded by a supervising hydrogeologist.

The borehole will be reamed to a final diameter of ten inches (10"). The well will be constructed using 6-inch inside diameter (ID) Schedule 40 PVC screen and casing. Screen length will be forty feet (40'), encompassing the entire saturated thickness penetrated by the pumping well. Screen slot size will be .020 inch. A filter pack consisting of 6 to 20 mesh silica sand will be emplaced through a tremie pipe to a point 2 to 4 feet above the top of the screen. A bentonite seal, a minimum of three feet (3') thick, will be emplaced above the filter pack, after which the annular space will be grouted to the surface using a tremie pipe.

Observation wells will be installed using air-rotary techniques to drill from the land surface to the total depth. Borehole diameter will be 5.5 inches. Wells will be constructed using

DRAFT

2-inch ID Schedule 40 PVC screen and casing. Screen length for the nine (9) observation wells at equal depth with the pumping well will be forty feet (40'); slot size will be .020 inch. A filter pack will be emplaced around the screen and the annular space sealed with bentonite and grounted to the surface as described above for the pumping well.

In drilling the boreholes for the deep, double-cased, observation wells, an 8.5 inch diameter borehole will be drilled to a depth of approximately ninety feet (90'), or ten feet (10') below the bottom of the corresponding pumping well. A 6-inch ID PVC casing will be placed in the borehole to the total depth. The annular space will be grouted and a grout plug at least four feet (4') thick will be emplaced to seal the bottom of the borehole. After the grout has set for a minimum of 48 hours, drilling will continue by bedrock coring to the total depth in the well located along the primary orientation of fracturing. After completion of coring, the borehole will be reamed to the final diameter of 5.5 inches using air-rotary techniques. The borehole for the well located perpendicular to the orientation of fracturing will be drilled to the final depth and diameter of 5.5 inches without coring. The observation well will then be installed as described above.

After each pumping or observation well installation is complete and the grout has set for a minimum of 48 hours, each well will be developed to produce clear, sediment-free water and to insure hydraulic communication between the well and formation for accurate drawdown and recovery measurements.

Well development will be accomplished by surging and bailing or surging and pumping, using the same procedures as used for developing monitoring wells. The 5 NTU standard for completion of development will be applied and the same decontamination procedures will be followed.

DRAFT

2.2.2.3 Pumping Test Performance

Electric submersible pumps will be used for the pumping tests. Discharge will be held at a constant rate through the use of a gate valve. Pumping rates less than 10 gpm will be measured with a calibrated container and stop watch. Flow measurements will be recorded hourly throughout the duration of the test. During pumping the well water will be discharged to a holding tank, after which it will be pumped or transported by tank truck to Raffinate Pit 4. All raffinate pit waters will be treated prior to discharge during remedial action.

Each pumping test will begin by recording static water level measurements in the pumping well, observation wells, and nearby monitoring wells. During pumping, water levels in the pumping well will be measured and recorded using a pressure transducer and electronic data logger. Water levels in observation and monitoring wells will be measured using an electrical water level indicator or wetted tapes. Multi-channel data loggers with pressure transducers in observation wells will be utilized as appropriate. Water level measurements will be recorded to the nearest 0.01 foot. Static water levels will be monitored for at least 48 hours prior to beginning each pumping test to ensure that steady-state conditions are present.

Water level measurements in the observation wells will be measured at logarithmic time intervals as pumping progresses, beginning with measurements at 1-minute intervals and increasing to 2-hour intervals after eight hours of pumping. Water levels in the pumping well will be recorded by the data logger at 1-second intervals initially, followed by logarithmically lengthening time intervals which will coincide with the observation well measurements after one hour of pumping.

After 168 hours of pumping, the pump will be shut off and recovery measurements will be collected as the aquifer recovers

DRAFT

to the initial static water levels. Measurements will be collected during recovery at the same logarithmic time intervals used during the pumping period. Measurements will continue until all wells have recovered to the original static water levels. It is expected that the recovery period will be a minimum of 24 hours.

2.2.2.4 Data Analysis

The data will be extensively analyzed to determine aquifer characteristics including hydraulic conductivity, storage parameters, anisotropy, and boundaries. Data analysis will begin by correcting the drawdown data recorded during the test for antecedent water level trends (as determined during monitoring of static water levels), dewatering, partial penetration, residual drawdown (recovery data) and barometric pressure variations. Barometric pressure data is available from a National Oceanic and Atmospheric Administration (NOAA) meterological station approximately 12 miles northeast of the WSS and from a meterological station at a utility plant approximately 10 miles to the southwest. The corrected data will be plotted on the appropriate graph paper for type curve analysis using methods such as those developed by Boulton and Neuman for unconfined aquifers. The conditions that dictate the appropriate hydrologic analyses to be done will be determined by a qualified hydrogeologist.

In addition to calculating aquifer parameters from pumping test results, a qualitative analysis will estimate the degree to which the fractured bedrock responds to pumping as an equivalent porous medium, which will indicate the reliability of the calculated parameters. Recent publications on pumping tests in fractured bedrock will be consulted and applied as appropriate to both the quantitative and qualitative analyses.

DRAFT

The combination of quantitative and qualitative analyses will allow pumping test results to be used in conjunction with groundwater monitoring data to predict contaminant migration, and also to predict the effects of pumping on groundwater flow patterns and contaminant concentrations.

2.6 Regional Hydrogeology and Water Balance

Studies of regional hydrogeology and water balance culminating in the development of a three-dimensional regional groundwater flow model will be performed by the U.S. Geological Survey. Additional USGS efforts will focus on site-related water quality issues and will serve to provide third-party verification of WSSRAP efforts.

2.6.1 Regional Groundwater Flow and Water Balance

USGS studies will include further refinement of regional hydrogeology as presented in previous USGS publications and comprehensive water balance measurements. These results will be combined with WSSRAP data to produce a regional groundwater flow model encompassing the shallow aquifer in the Burlington-Keokuk formation and the intermediate and deep aquifers in the Kimmswick and St. Peter formations.

Piezometric surface maps will be derived from water-level measurements in groundwater monitoring wells installed on-site by WSSRAP, from USGS monitoring wells located on Busch Wildlife Area to the north of the site, and from various private wells around the site which are suitable for monitoring and sampling.

Continuous water level recorders will be installed on four wells on the site near the groundwater flow divide. Daily fluctuations in the groundwater levels will be correlated with precipitation, evapotranspiration, infiltration and barometric fluctuations in order to evaluate and determine the role of each of these factors on the water balance of the plant site.

Twelve (12) steel infiltration tubes will be installed in various soils located on the Weldon Spring Site. A neutron probe will be used to measure the migration in the unconsolidated near-surface measurements. These measurements

DRAFT

will be taken by inserting the neutron probe into the steel infiltration tubes and recording the neutron response to moisture content of the soils. This data will be compared with evapotranspiration and precipitation in the determination of the water balance.

Two clusters of deep monitoring wells will be installed in order to determine vertical gradients between the shallow and deep aquifers underlying the site. Water samples will be analyzed for the determination of water quality differences at various depths and aquifers. One well cluster will be located immediately south of the site near the groundwater flow divide. The second well cluster will be located near Dardenne Creek which is at a lower topographic elevation and is considered to be a hydrogeologic boundary for shallow groundwater flow (Figure 2-7).

Each observation well cluster will consist of one well with the screened sector open opposite the Burlington-Keokuk Limestone Formation at a depth of approximately 100 feet, one well with the screened sector open opposite the Kimmswick Limestone Formation at a depth of approximately 300 feet and one well with the screened sector open opposite the St. Peter Sandstone Formation at a depth of approximately 700 feet. The cluster immediately south of the site will consist of two deep wells clustered with an existing monitoring well screened in the Burlington-Keokuk formation (MW-4019). A geologist will monitor drilling programs, collect rock samples from cores and drill cuttings and ensure compliance with Standard Operating Procedures.

Surface features which relate to groundwater accumulation, movement or quality will be investigated in depth for the purpose of developing the groundwater flow model. Springs, seeps, losing stream segments, gaining stream segments, karst features in limestone bedrock, fractures, joints, geological

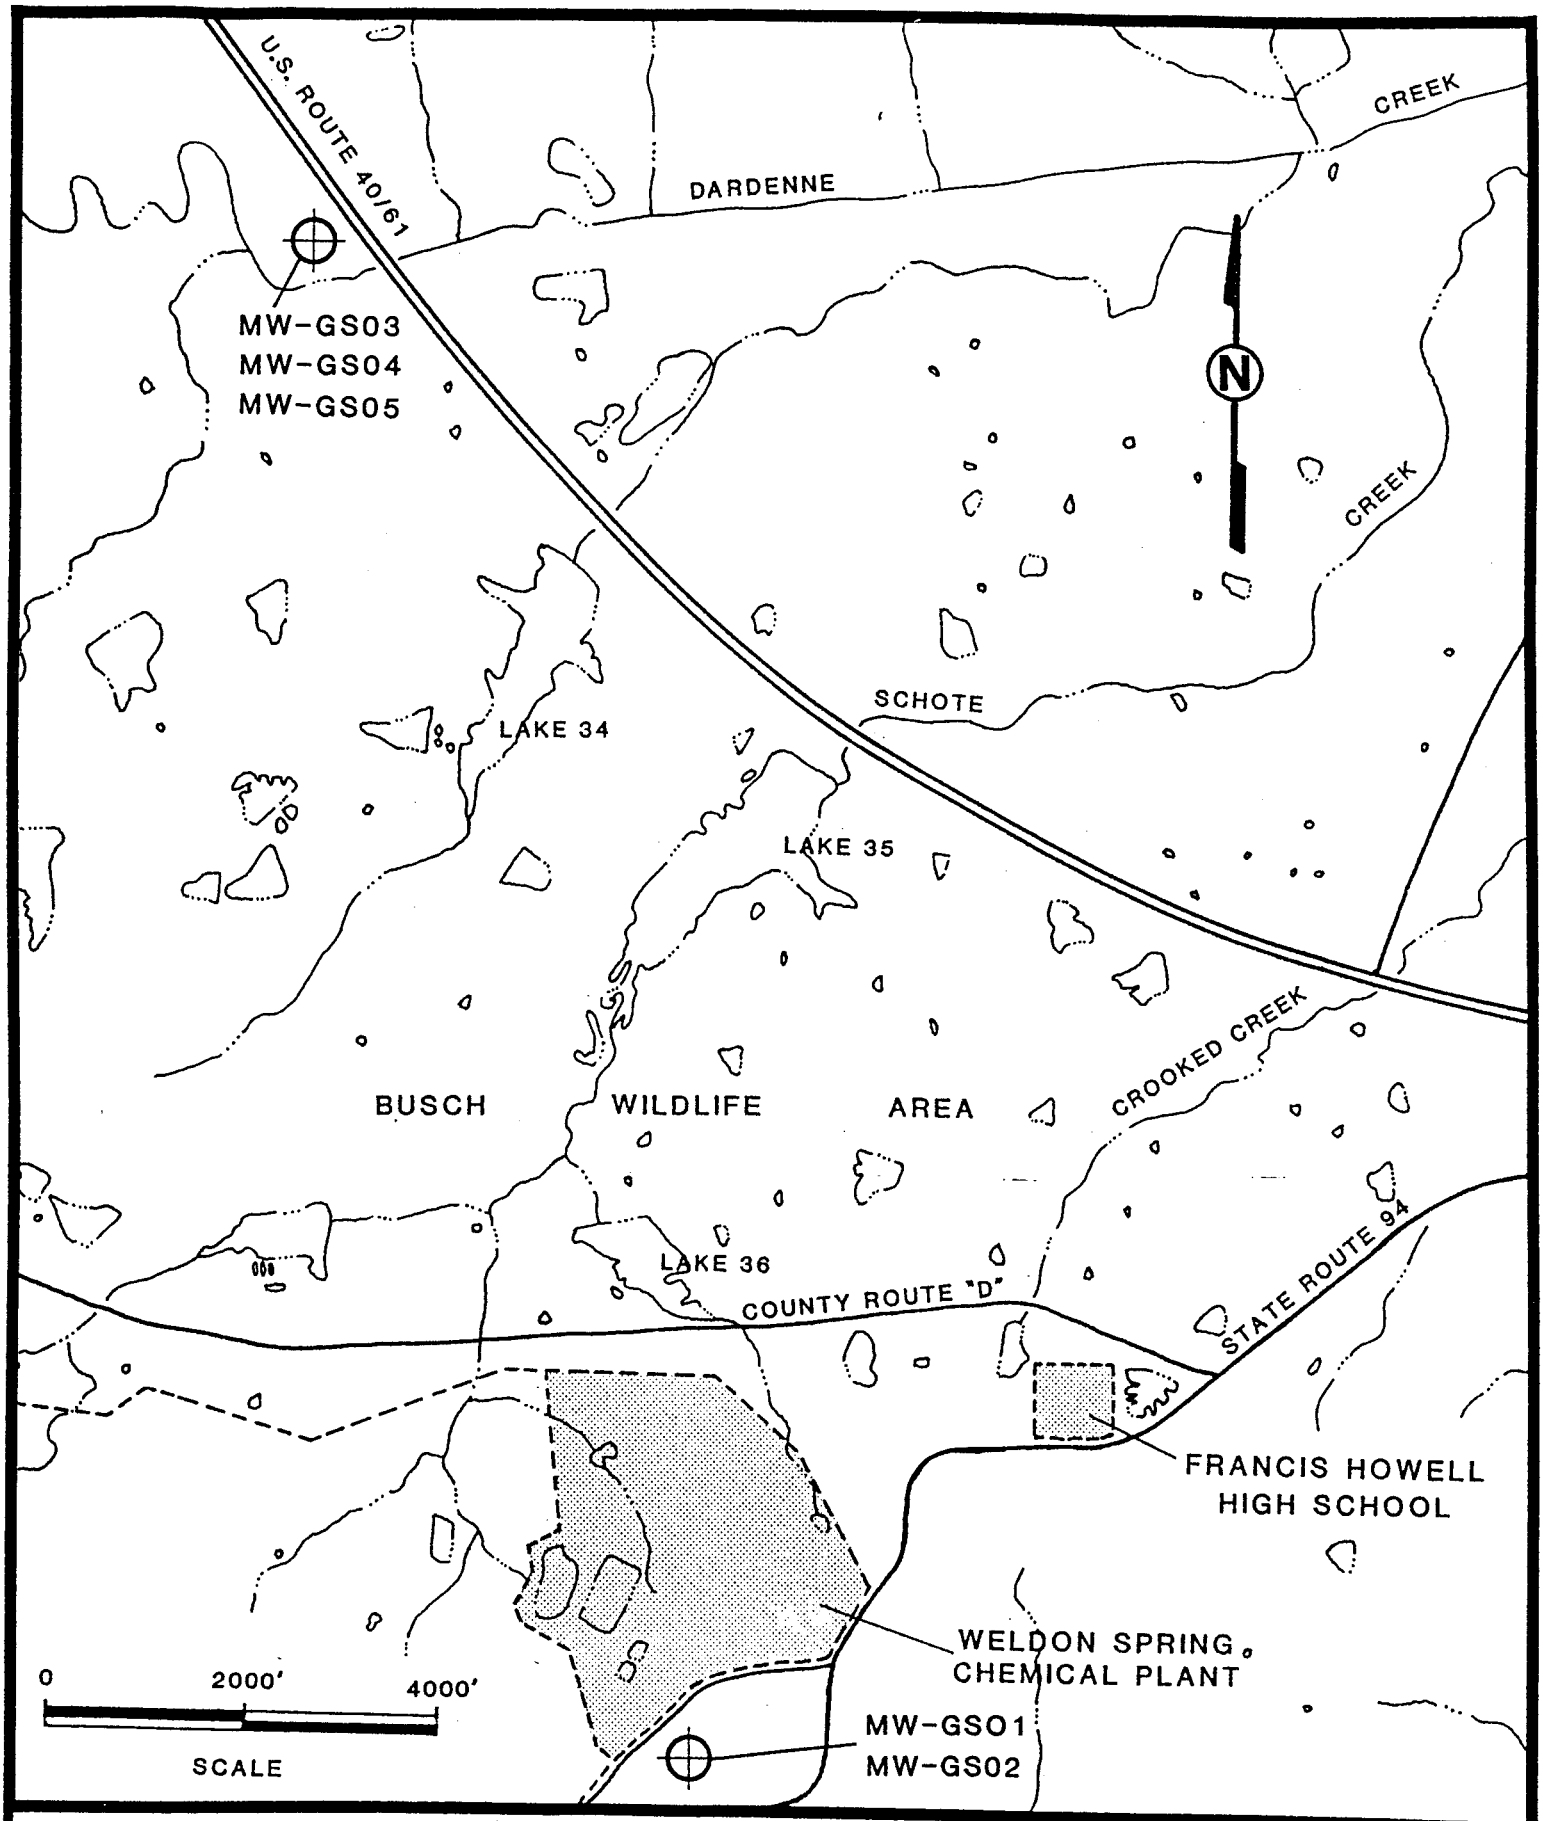

FIGURE 2-7

DRAFT

MONITORING WELL CLUSTER LOCATIONS

DRAFT

structure and any additional phenomena which may become evident during the course of field efforts will be investigated for the purpose of determining effects on water balance and flow characteristics. Remote sensing methods including air photos, side-looking radar, infrared photography and others may be employed. A field reconnaissance program will be conducted in order to locate and measure these features and to quantify their effects.

Continuously recording stream gauging stations are in place on Schote Creek and the unnamed tributary to Dardenne Creek which contains Burgermeister Spring. These gauging stations will continue in operation in order to gather flow and discharge data for use in water balance studies.

Continuous discharge monitoring of Burgermeister Spring and the adjacent wet-weather spring will be continued in order compare the effects of various weather conditions on spring discharge and chemical quality. Surface water discharge will be compared with other monitored parameters including water table fluctuations, barometric changes, precipitation, temperature, humidity, evapotranspiration and infiltration.

Nineteen (19) total catch rain gauges will be placed on-site in order to accurately determine the amount of precipitation within the study area for utilization in water balance calculations and groundwater flow modeling calibration.

The regional groundwater flow model will be constructed using the USGS 3-Dimensional Groundwater Flow Model (MOD). Vertical extent of the model will be from the surface (Burlington-Keokuk formation) to the base of the St. Peter Sandstone. Tentative horizontal boundaries are constant-head or constant-flow boundaries at the Missouri River and Dardenne Creek to the north and south and no-flow boundaries along major drainage divides to the east and west. Data used to construct the model

DRAFT

will include the piezometric surface and water balance data discussed above and aquifer testing data from WSSRAP efforts discussed above in Section 2.2.

SPECIFICATION WP059

DRAFT

WELDON SPRING SITE

DRILLING, INSTALLATION AND DEVELOPMENT

OF PUMPING TEST WELLS AND DEEP MONITORING WELLS

1.0 INTRODUCTION

Three pumping tests are planned for the Weldon Spring Site located in St. Charles County, Missouri (Figure 1). The purpose of the pumping tests is to determine aquifer characteristics of the Burlington-Keokuk Formation in order to assess contaminant migration and feasibility of groundwater restoration.

A total of three (3) 6-inch inside diamenter (ID) pumping test wells and thirty-three (33) 2-inch ID observation wells will be installed in the Burlington-Keokuk Formation at the three (3) pumping test locations (PW-1, PW-2 and PW-3) shown on Figure 2. At each pumping test area, one (1) pumping well and eleven (11) observation wells will be completed. Two (2) of the eleven observation wells at each pumping test location will be completed approximately 50 feet deeper than the rest of the wells and will be double cased through zones of known groundwater contamination. Depths of the shallow observation

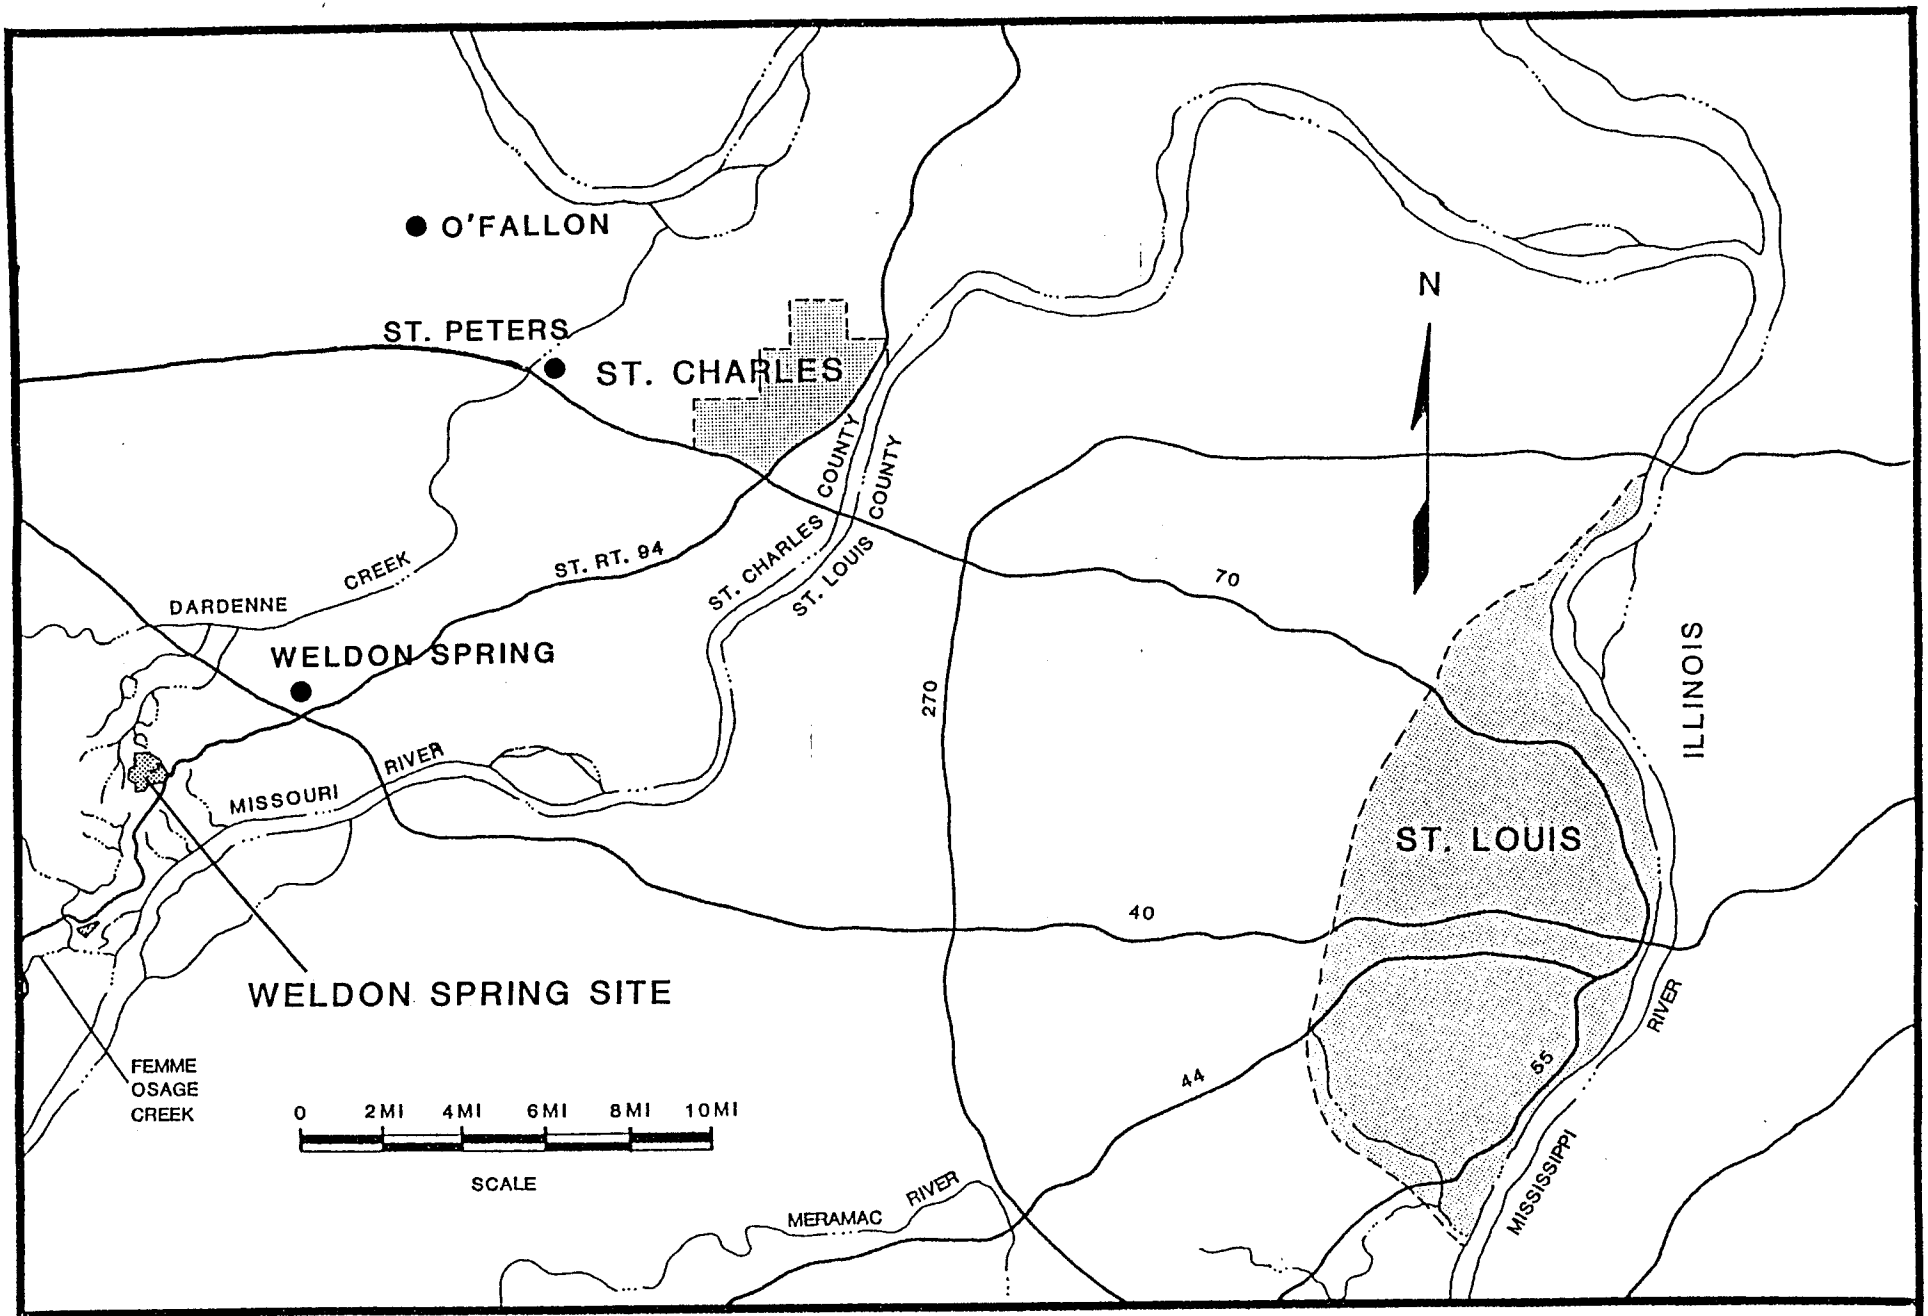

FIGURE 1

LOCATION OF WSS

DRAFT

DRAFT

wells and pumping wells will range from approximately 80 to 100 feet in depth. Double-cased observation wells will range from approximately 130 feet to 150 feet in depth. Observation wells will be placed within a radius of approximately 100 feet from the pumping well. Actual distances will be determined from step-drawdown pumping tests to be conducted by the Subcontractor prior to installation of the observation wells. Estimated quantities of materials, drilling footage, and other work are given on the Pricing Schedule.

To distinguish pumping and observation wells from other on-site wells, each pumping test area will be assigned a unique designation. The pumping test wells will be coded PW-1 in the Chemical Plant, PW-2 in the Disposal Facility, and PW-3 in the Raffinate Pits. The observation wells associated with PW-1 will be assigned OB-1a to OB-1k (Figure 2). The observation wells associated with PW-2 will be assigned OB-2a to OB-2k and the observation wells associated with PW-3 will be assigned OB-3a to OB-3k.

In addition to wells installed on the site for the pumping tests, two monitoring well clusters will be installed to support continuing groundwater studies. One of these clusters will be on the northeast side of the site, the other will be approximately 2.5 miles to the north of the site near Dardenne Creek within the Busch Wildlife Area under the administration of the Missouri Department of Conservation. The Contractor will be

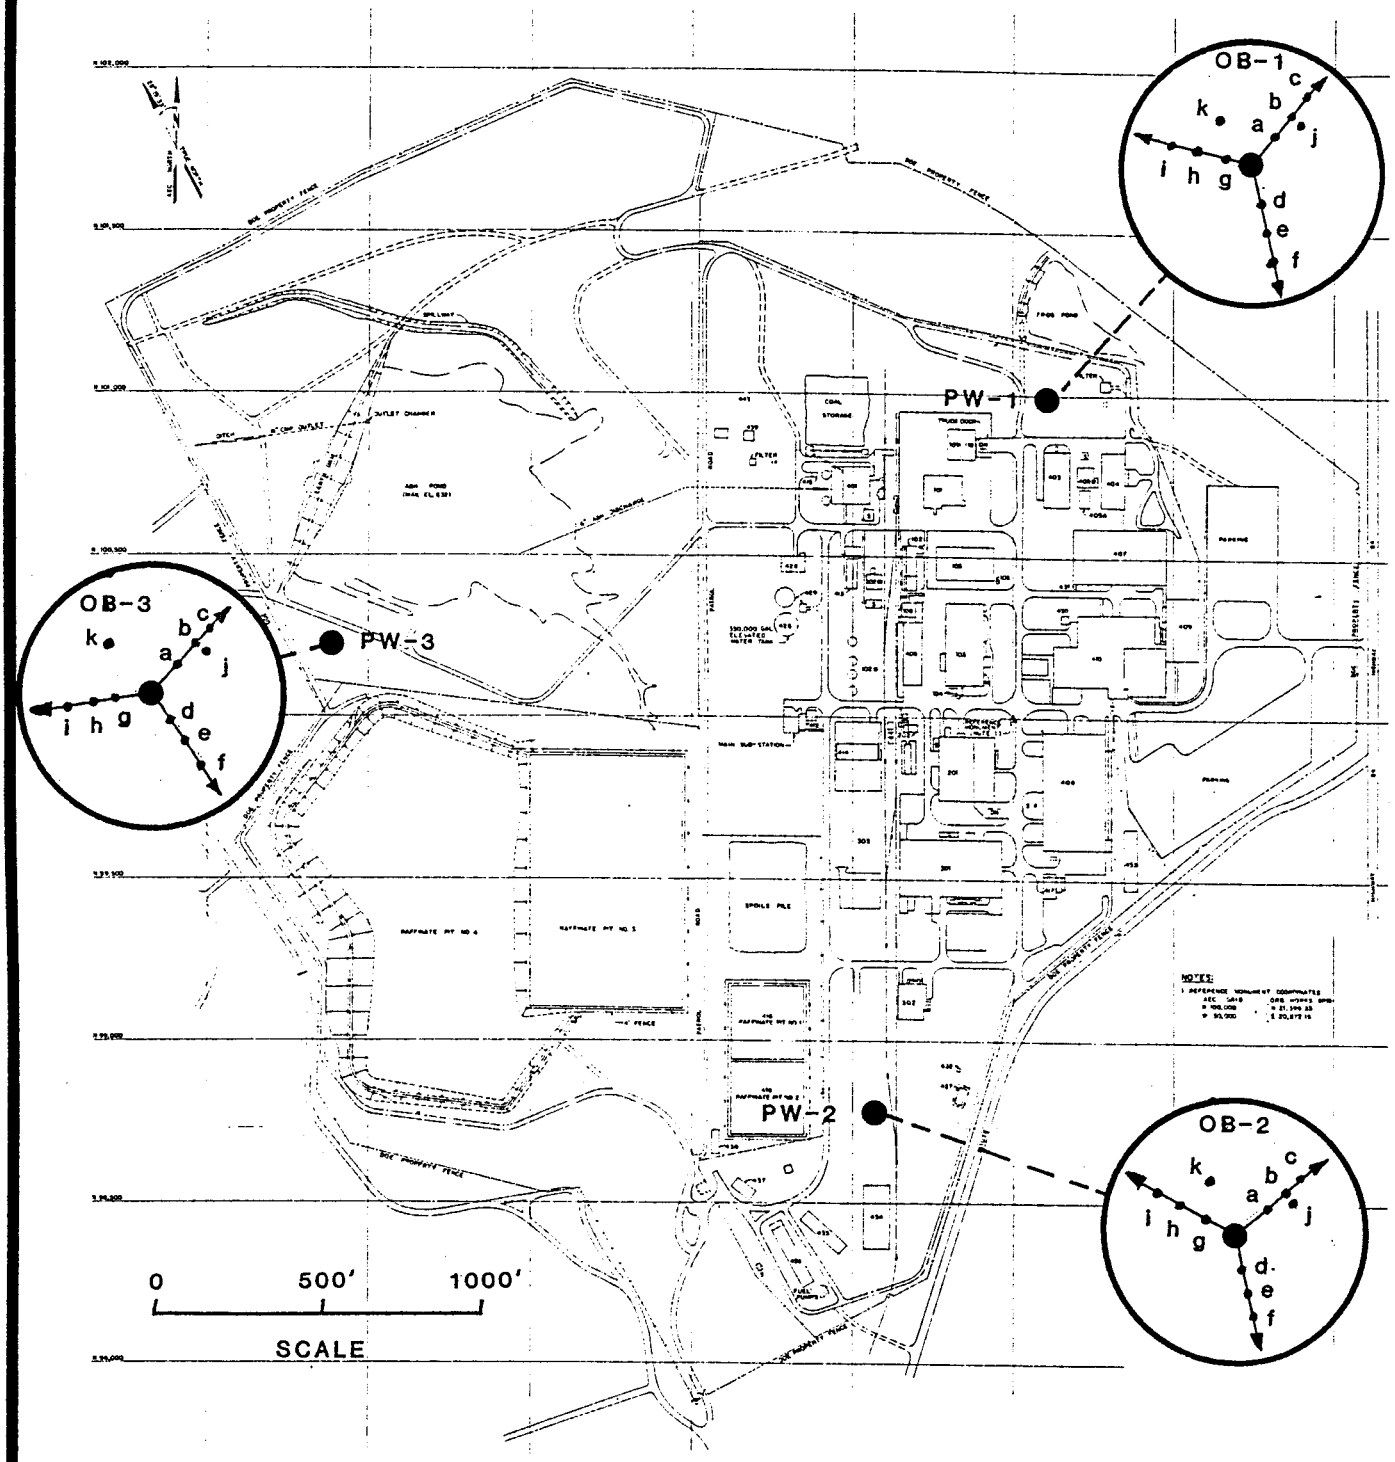

FIGURE 2

LEGEND

PW-1 -PUMP TEST WELL

OB-1 - OBSERVATION WELL (a-k)

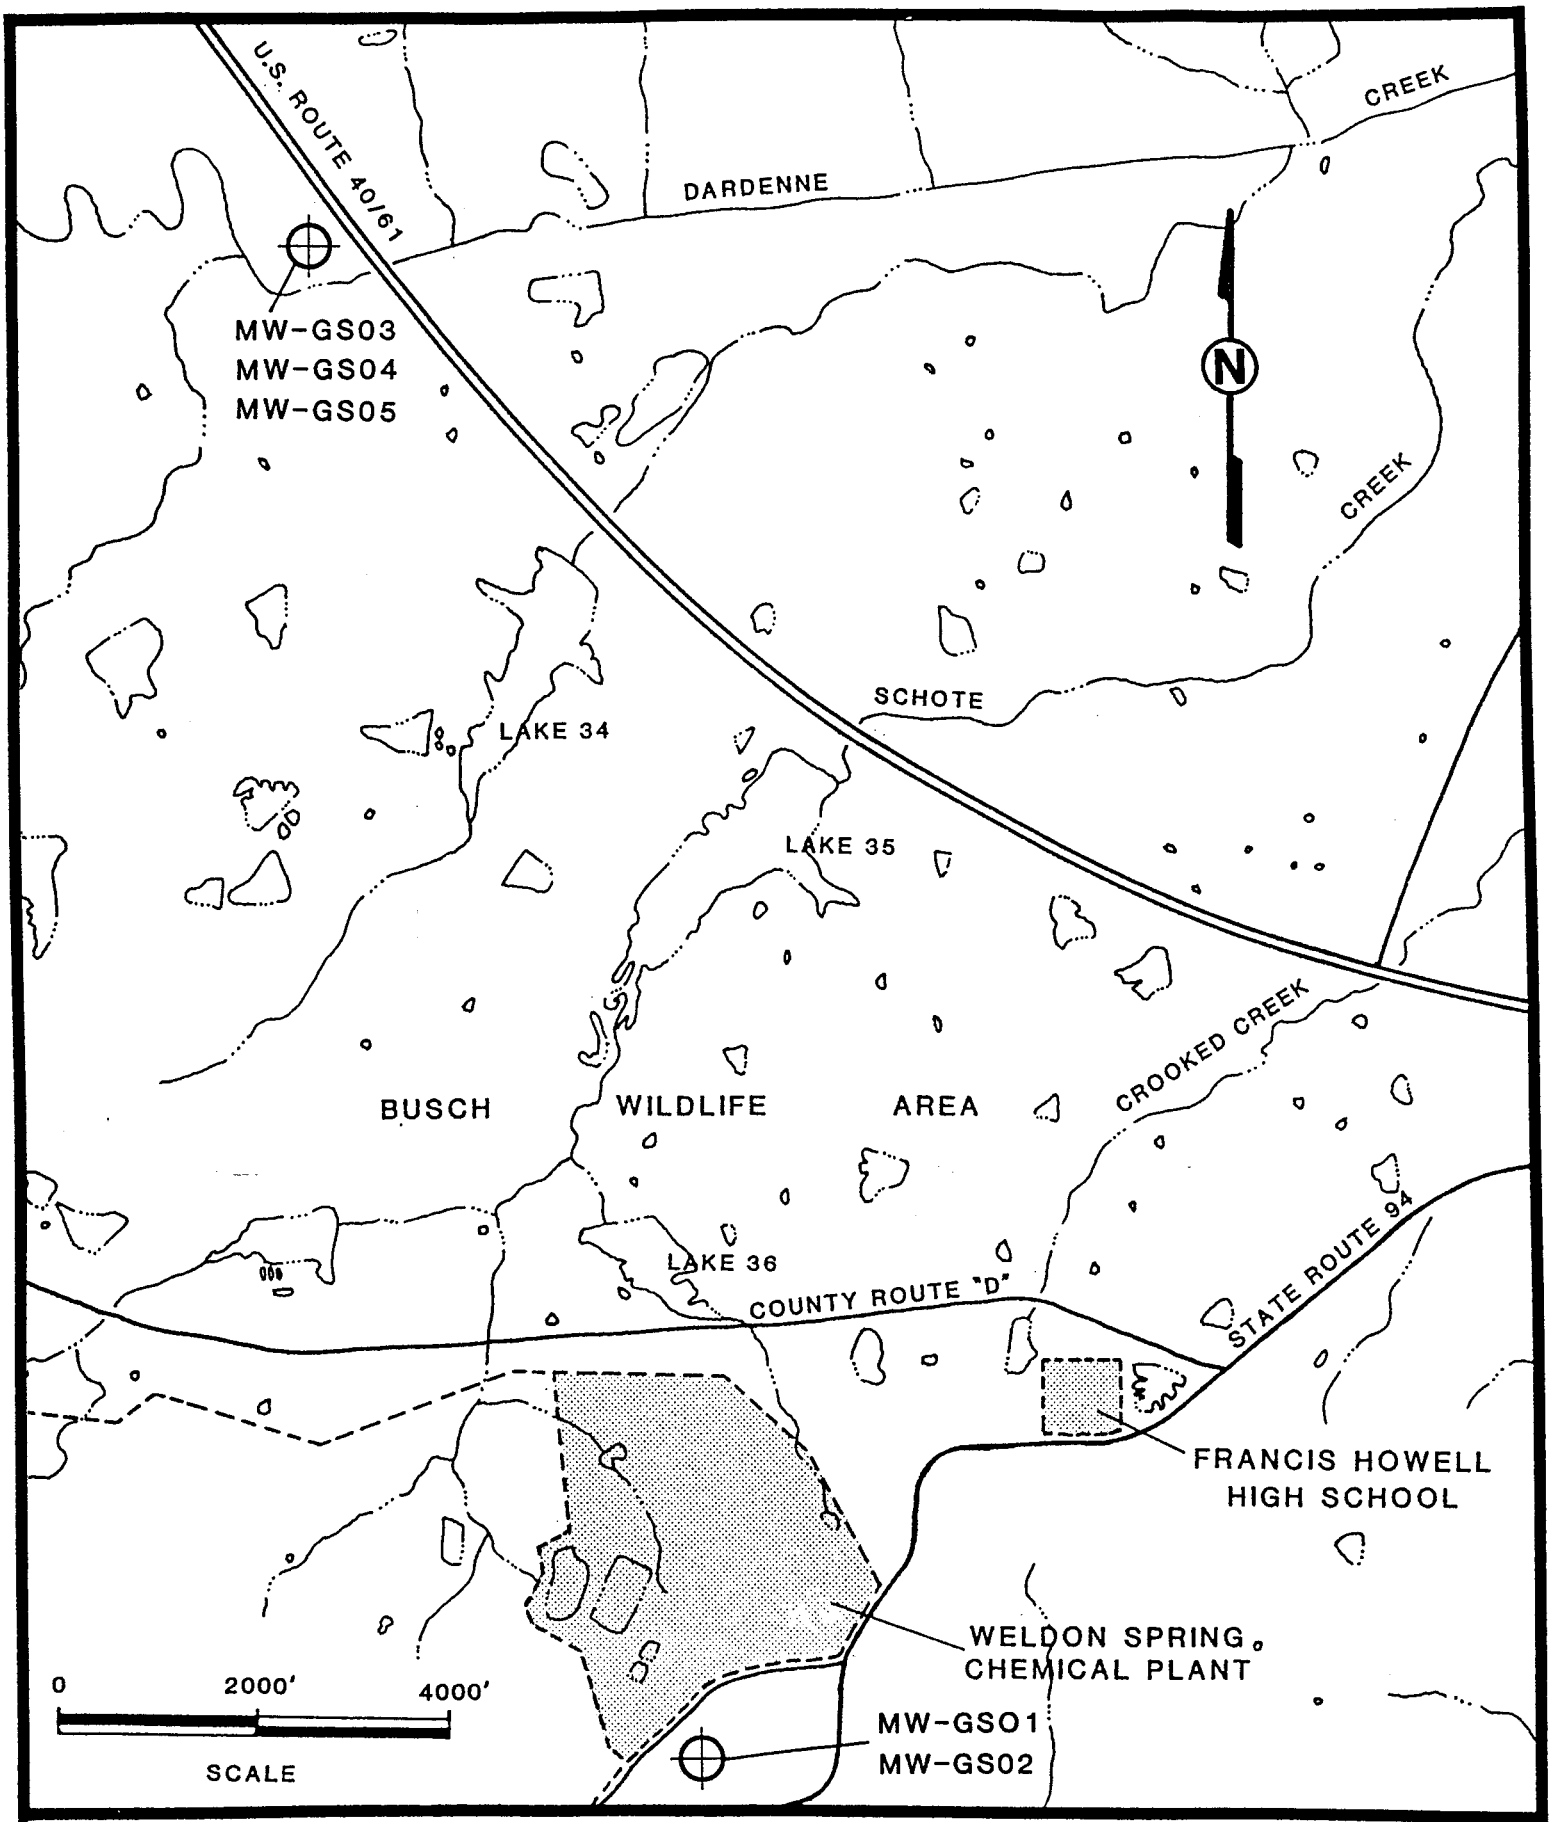

FIGURE 3

DRAFT

MONITORING WELL CLUSTER LOCATIONS

DRAFT

responsible for securing access to this area (Figure 3).

The cluster on the northeast side of the site will consist of two wells, one completed in the St. Peter formation at an approximate depth of 700 feet and the other completed in the Kimmswick formation at an approximate depth of 300 feet. The cluster near Dardenne Creek will consist of three wells: a well completed in the St. Peter formation at an approximate depth of 700 feet, a well completed in the Kimmswick formation at an approximate depth of 300 feet, and a well completed in the Burlington-Keokuk formation at an approximate depth of 100 feet. The monitoring wells will be designate MW-GS01 through MW-GS05.

A Contractor representative will be present to observe drilling and well installation operations.

DRAFT

2.0 SITE CONDITIONS

2.1 Access

The pumping test wells and observation wells will be installed at locations within the site boundary, as shown on Figure 2. The on-site locations are accessible by paved or unimproved roads. The surface soil is a silty clay which should support truck-mounted drilling equipment, but may be slippery during wet weather.

2.2 Utilities

No underground utilities are expected at any of the drilling locations. The Contractor will supply a map of known utilities and will be responsible for contacting utility companies and insuring that utilities will not be encountered during drilling operations. The Contractor will be responsible if any utilities are inadvertently encountered.

2.3 Subsurface Conditions

The best information available indicates a variable thickness of soil, consisting of approximately 20 to 50 feet of loess, glacial till and weathered bedrock, overlying the limestone bedrock.

DRAFT

The bedrock is the Mississippian Burlington-Keokuk Formation, a thickly-bedded limestone with abundant chert. Groundwater has been found to be within the limestone bedrock.

Past experience has indicated that drilling in this formation is very difficult due to the amount of chert.

A simplified stratigraphic column of the soil and bedrock formations on the site is shown on Figure 4. A geologic cross-section of the area surrounding the site is shown on Figure 5.

3.0 DRILLING

3.1 Drilling Equipment and Capabilities

The drilling rig(s) should be capable of drilling in clayey or granular soil and consolidated bedrock, above or below the water table.

Air-rotary drilling equipment shall be used for rock drilling prior to installation of the wells. The rotary rig(s) must be capable of collecting rock cores and also be capable of drilling through rock efficiently without coring. In order to avoid injecting oil into the borehole, the Subcontractor shall use in-line air filters on all air-rotary rigs.

Wireline coring apparatus with a diamond-impregnated coring bit is required for coring operations. The use of downhole hammer apparatus is an acceptable method for rock drilling in sections which are not cored and for reaming previously cored boreholes. Rig capabilities may be combined on a piece of equipment, or separate rigs with specialized functions may be used. Any change in drilling rig capabilities or other equipment must be approved in writing by the Contractor.

DRAFT

3.2 Cross-Contamination Prevention Measures

The Subcontractor shall at all times prevent the contamination or cross-contamination of all wells and borings. Prevention measures include appropriate drilling and wellsite procedures and decontamination of drilling equipment and well screens and casing. A designated representative of the Contractor will observe wellsite and decontamination activities to assure that no contamination or cross-contamination occurs. Potential contaminants include, but are not limited to oil, grease, hydraulic fluids, fuels, and contaminated soils.

To reduce the potential of contamination occurring, the drilling rigs, tools, drilling stem, and all other pertinent equipment shall be cleaned using a hot water, high-pressure washer under the direct supervision of the Contractor upon entering the site. All decontamination shall be performed at the decontamination facility located near the south end of the site. The Contractor shall supply a portable hot water, high-pressure washer and water for use by the Subcontractor. Cleaning of the entire rig and tools shall be accomplished on a one-time basis before work begins. Decontamination of the entire rig will not be required again, unless the equipment is contaminated. If the rig or any other equipment becomes contaminated due to equipment breakdown or the Subcontractor's negligence,

decontamination shall be at the Subcontractor's expense. Drill bits, drilling rod, other downhole tools, and hand tools shall be decontaminated between boreholes. Only potable water from the Contractor's source shall be used to supply the hot water high-pressure washer.

Interior portions of equipment, such as pumps and hoses, which are not accessible for cleaning with a pressure washer shall be thoroughly cleaned and flushed with potable water from the Contractor's source. Oils, greases, or pipe dope shall not be used on pipe threads or drilling rods. Non-hydrocarbon based lubricants, such as silicon or teflon, are acceptable.

In addition, all well casing and screen shall be cleaned inside and out prior to use. The well casing and screen shall be stored in a non-contaminated area, elevated off the ground, and covered with clean, new, plastic sheeting. Any well casing or screen which is subsequently contaminated by contact with the ground shall be cleaned again prior to use. Any well casing or screen which is contaminated with soil shall be thoroughly rinsed with fresh, potable water and cleaned by hot water high-pressure wash prior to installation.

Drilling equipment used in known or suspected contaminated areas shall be handled with special precautions to prevent

the introduction of any contaminants into the well or boring. No hand tools, drill bits, drill stem, casing, screen, or any other equipment other than that in use in the borehole shall be allowed to contact the ground surface at any time. An elevated platform covered with plastic sheeting shall be required for the temporary storage of such items. At no time shall this platform be walked on or allowed to have soil deposited on it in any way. If any equipment or supplies come into contact with the ground, or are otherwise contaminated, they shall be thoroughly cleaned by pressure washing at the decontamination station.

Cross-contamination shall be minimized by thoroughly cleaning all external and internal surfaces of all drilling equipment, tools, drill bits, drilling stem, mud tubs, pumps, hoses, and all other appurtenant equipment after each hole is completed and before moving to the next drilling location. Cleaning shall be accomplished by completely removing all soil from the equipment and thorough hot water high-pressure washing.

During drilling operations, the Subcontractor shall prevent soils and liquids from entering the borehole. Steel surface casing of the appropriate diameter and at least five feet (5') in length shall be used when liquids are present on the surface at a drilling location. The surface casing shall be thoroughly decontaminated by hot water

high-pressure washing prior to use at another drilling location.

3.3 Drilling Fluids

All drilling operations, with the exception of coring and drilling through unconsolidated soils, shall be performed using air-rotary techniques with no drilling fluids other than air. Uncontaminated, potable water may be used as a drilling fluid for rock coring. The water source shall be provided by the Contractor. The Subcontractor shall be responsible for providing hoses, tanks, and other equipment as well as the transport of water to drilling locations. All tanks, hoses, and other water-handling equipment shall be decontaminated by hot water high-pressure washing prior to commencing work. Hoses, valves, and other fittings shall be cleaned between drilling locations.

No other drilling fluid or additives other than those outlined above shall be used. Toxic and/or contaminating substances shall not be added to the drilling fluids, nor be permitted to enter any well or boring as a result of the Subcontractor's operations.

DRAFT

3.4 Drilling Procedures

3.4.1 Pumping Test Wells

In drilling the boreholes for pumping test wells, a borehole shall be drilled to the bedrock surface using air-rotary or hollow-stem auger techniques. Split-spoon samples, collected in accordance with ASTM D-1586, shall be taken at five foot intervals. The bedrock shall then be cored with an air-rotary drilling rig to an approximate depth of 80 feet (80') using an NX coring bit and wireline apparatus. Following completion of coring, the borehole shall be reamed to the final diameter of 10-inches using air-rotary techniques. The pumping test well shall be installed according to the specifications in Section 5.

3.4.2 Shallow Observation Wells

In drilling the boreholes for shallow observation wells, a minimum 5.5-inches diameter borehole shall be drilled to an approximate depth of 80 feet using air-rotary techniques. There will not be any sampling done for these boreholes. The observation well shall then be installed according to the specifications in Section 5.

3.4.3 Double Cased Deep Observation Wells

In drilling the boreholes for installation of the deep monitoring wells shown on Figure 2, an 8.5-inch diameter borehole shall be drilled to an approximate depth of 80 feet (80'). A 6-inch (ID) PVC casing shall be placed in the borehole to the total depth of the borehole. The casing shall be decontaminated by hot water high-pressure washing prior to emplacement. The outside of the casing shall be grouted to the surface using a grout mixture as specified in Section 4.7. A minimum of four feet (4') of grout shall be emplaced to seal the bottom of the borehole.

After the grout has set for a minimum of 48 hours, drilling shall continue on observation wells labeled "j" by coring using an NX coring bit and wireline apparatus to an approximate depth of 130 feet (130'). From 80 to 130 feet the borehole will be reamed to an approximate final diameter of 5.5-inches using air-rotary techniques. Observation wells labeled "k" will not be cored but will instead be drilled to a depth of 130 feet (130') with an approximate final diameter of 5.5-inches using air-rotary techniques. The well shall then be installed according to the specifications in Section 5.

DRAFT

3.4.4 Monitoring Well Clusters

At each cluster location the deepest borehole penetrating the St. Peter Sandstone shall be drilled first. A borehole approximately 8.5 inches in diameter shall be drilled using air-rotary methods to a depth 10 feet (10′) below the top of the St. Peter formation, estimated to be 700 feet (700′) below the surface. Lithologic samples shall be collected during drilling as described below in Section 3.5. Well materials and completion methods are specified in Section 6.

The final depths of the adjacent monitoring wells to be completed in the Burlington-Keokuk and Kimmswick formations will be determined by the Contractor from the lithologic log of the borehole penetrating the St. Peter formation. Estimated depths are 300 feet (300′) for the wells in the Kimmswick formation and 100 feet (100′) for the wells in the Burlington-Keokuk formation. Borehole diameter for these wells shall be approximately 8.5 inches, drilled by air-rotary methods as specified above for the deep borehole penetrating the St. Peter formation. Well materials and completion methods are specified in Section 6.0.

DRAFT

3.5 Lithologic Sampling

A representative of the Contractor will be responsible for maintaining a continuous written lithologic log of the boreholes.

Lithologic sampling will be performed during drilling for the pumping wells, the deep, double-cased observation wells, and the deepest well in each of the two monitoring well clusters.

3.5.1 Sampling During Drilling in Unconsolidated Soils

Split-spoon soil samples shall be collected at depth intervals of five feet (5'), with the initial sample collected at a depth of five feet. After the split-spoon sampler is removed from the drill string and opened, the Contractor representative will handle logging, labeling, and storage. Additional split-spoon samples shall be collected at the discretion of the Contractor. Six (6) of these additional samples are estimated.

3.5.2 Sampling During Rock Drilling

Lithologic sampling during rock drilling will consist

of a program of continuous coring in the boreholes for pumping and selected observation wells. During drilling of the deepest monitoring wells, lithologic sampling will consist
of sampling drilling cuttings.

The coring shall be accomplished using wireline methods. The core obtained shall be 1.875 inches in diameter (NX). A diamond-impregnated core bit and solid inner barrel shall be used.

Approximately 270 feet (270') of core will be collected from boreholes drilled for pumping test wells in order to obtain bedrock lithology, mineralogy, permeability, porosity, and evidence of bedrock contamination. Cores will be collected by continuous coring from the top of bedrock to the bottom of the hole in the pumping test wells and from the bottom of the cased interval to the total depth in the deep observation wells labeled "j".

Each core run shall be attempted to be a minimum of five feet (5') and a maximum of ten feet (10') in length. The Subcontractor shall supply pre-manufactured and treated cardboard core boxes capable of holding at least 10 feet of rock core. The cores will be delivered to the Contractor for logging

DRAFT

and storage of the boxes. The Subcontractor will be required to use a 10-foot barrel and use his workman-like "best" techniques to obtain full runs. Rock coring shall be performed in accordance with the ASTM D-2113 standard.

Competent core will be stored in the cardboard core boxes. Unconsolidated, very friable, or clayey sections of core will be placed in clear, plastic-sheeting core tubing or bags, sealed, and stored along with the competent core in the core boxes. Some sections of core chosen by the Contractor may also be sealed in the core tubing for subsequent chemical analysis.

During drilling of the deepest monitoring wells, "grab" samples of drilling cuttings shall be collected at depth intervals of five feet (5') or distinct changes in lithology as noted by the Contractor representative.

The Subcontractor will assist the Contractor in collecting, sealing, and storing samples.

DRAFT

3.6 Lost Equipment, Lost Boreholes, and Borehole Abandonment

A hole shall be termed "lost" if the Contractor determines that the condition of the hole will prevent its successful completion, or if for any reason it is impractical to continue operations. The term "abandonment" shall mean abandonment to suit the convenience of the Contractor.

A hole which is determined to be lost shall be grouted from its total depth to land surface using a cement-bentonite grout as specified in Sections 4.7 and 5.5 of these specifications.

If the Contractor determines that a hole has been lost for reasons within the control of the Subcontractor, or because of negligence, incompetence, or malpractice on the part of the Subcontractor or Subcontractor's personnel, or because of the use of defective or unsuitable equipment, the Subcontractor shall not be paid for any drilling, demobilization, or other services performed in the lost hole. This includes boreholes lost in the event drill bits, drill rod, or other downhole tools are lost in the borehole and cannot be recovered by the Subcontractor's efforts. In addition, the Subcontractor shall be required to grout the hole from its bottom to land surface, and then move over and drill a new hole in the proper manner to

replace the abandoned one. The Subcontractor shall be notified in writing of this decision.

3.7 Standby Time

Standby time shall be defined as time during which the Subcontractor has been instructed by the Contractor to cease working pending further instructions.

Decontamination time shall be defined as time spent decontaminating drilling equipment, well screens, and casing as specified in Section 3.2 and is not considered standby time.

Time spent for clean-up and restoration of drilling locations or for other routine housekeeping or equipment maintenance is not considered standby time.

All standby time shall be recorded on the Daily Field Activity Report discussed below.

3.8 Field Documentation

The Contractor will maintain a "Daily Field Activity Report" (a sample copy is attached as Figure 6) detailing Subcontractor activities. The Subcontractor is required to sign this report on a daily basis and note any differences

DRAFT

that cannot be resolved. Any differences shall be documented for future reviews and resolution between the Contractor and Subcontractor. This is the only form that will serve to document quantities of work.

A designated Contractor representative will be assigned to each drilling rig to document the activities. The Contractor representative will assure that work is performed in accordance with these specifications.

3.9 Site Restoration

DRAFT

The Subcontractor shall reclaim areas disturbed by drilling activities performed under this Subcontract. As a minimum the Subcontractor shall:

- Recontour all disturbed areas to approximate original contours.

- Purchase grass seed mix and reseed disturbed areas. The seed mix shall be one of the following, as appropriate for the time of year when seeding occurs:

Seeding between August 1 - April 15

Annual Ryegrass	38%
Orchard Grass	18%
Korean or Kobe Lespedeza	18%
Ladino Clover	2%
Switch Grass	15%
Timothy	9%

Seeding between April 16 - July 31

Big Blue Stem	33%
Indian Grass	25%
Little Blue Stem	25%
Sideouts Grama	17%

DRAFT

- Any variations in the seed mixture must be approved by the Contractor.

- Seeding shall be accomplished by broadcast and raking into the soil.

- Following seeding, the Subcontractor shall apply a mulch consisting of clean straw to the area.

- Remove drilling cuttings from the well location and transport them to a location designated by the Contractor.

DRAFT

4.0 WELL CONSTRUCTION MATERIAL

Pumping and observation wells shall be constructed using materials as specified below.

4.1 Well Casing

Well casing shall consist of new, decontaminated, threaded, flush-joint, Schedule 40 PVC casing with a nominal six inches (6") inside diameter (ID) for the pumping test wells and the outer casing of the double cased observation wells, and two inches (2") ID for the observation wells. All well riser pipe shall, as a minimum, conform to the requirements of ASTM Schedule 40 pipe. All riser pipe shall bear markings that will identify the material. There shall be no obstructions on the inside of the casing. The Subcontractor shall furnish data from the casing supplier prior to purchase.

4.2 Well Screen

The Subcontractor shall be responsible for supplying a decontaminated, factory constructed, flush-joint threaded, well screen. The well screen shall be constructed of ASTM Schedule 40 PVC with a nominal six inches (6") inside diameter for the pumping test wells and two inches (2") (ID) for the observation wells. Slot size shall be

0.020-inch. Well screen shall be supplied in lengths of 10 feet (10') each. It is estimated that forty feet (40') of 6" ID screen will be necessary for each pumping well. Forty feet (40') of 2" ID screen is estimated for each shallow observation well. Ten feet (10') of 2" ID screen is estimated for each deep observation well.

The Subcontractor shall supply data from the screen supplier prior to purchase.

4.3 Bottom Plug and Top Cap

The casing shall have a threaded PVC plug or end cap securely attached to its lower end. This will complete the well string, providing a sealed bottom.

The Subcontractor shall supply a threaded PVC top cap. A one-sixteenth inch (1/16") hole shall be drilled in the side of the cap.

4.4 Method of Joining Well Screen and Well Casing Sections

Well screen and well casing sections shall be joined by threaded, flush-jointed couplings, to form straight, water-tight unions. No threaded couplings shall be above land surface. Absolutely no solvents or glue shall be used

DRAFT

in construction of the wells.

4.5 Filter Pack

The Subcontractor shall supply clean, inert materials (silica sand) from which to construct a filter pack which shall ensure continuous flow capability.

The sand shall have a gradation which will allow no more than five percent of the sand to pass through the well screen slots (6 to 20 mesh sand). The Subcontractor shall furnish the Contractor with written documentation including a test report that the sand meets these specifications.

Any unused bulk portions or opened bags of sand remaining after completion of a pumping test well location shall be properly disposed of as stated in Special Condition 9 rather than being transported to the next pumping test well location.

4.6 Bentonite Seal

The bentonite seal shall consist of a minimum thickness of three feet (3') of 1/2- to 3/8-inch bentonite pellets. The pellets shall have a minimum purity of 90 percent montmorillonite clay and a minimum dry bulk density of 75 pounds per cubic foot. The bentonite pellets shall not

DRAFT

contain toxic or potentially hazardous compounds (such as kerosene, diesel fuel, etc.) The Subcontractor shall supply manufacturer's data certifying purity and composition of the pellets prior to purchase.

4.7 Grout Seal

A grout seal shall be installed from the top of the bentonite seal to land surface.

The grout shall consist of Portland cement (ASTM C150) mixed with six pounds of commercial bentonite powder and approximately 7-1/2 gallons of water added to each 94-pound bag of cement. An optional material is the use of Volclay grout by American Colloid. The grout mix can be adjusted or changed as dictated by the field conditions upon approval by the Contractor. A Contractor representative will be present during grouting operations and will verify that the grout has the proper consistency prior to installation.

DRAFT

5.0 OBSERVATION AND PUMPING TEST WELL INSTALLATION

Observation and pumping test well installation shall begin as soon as practicable after completion of drilling. Typical well construction is illustrated on Figure 7. After beginning well installation, operations shall not be stopped for breaks, end of regular work shift, or darkness until the bentonite seal has been emplaced above the filter pack. The Subcontractor shall be prepared to arrange the work as needed to comply with this restriction. Well installation work may be stopped prior to placement of the bentonite seal if conditions exist which would prevent the successful completion of the well or if, in the opinion of the Contractor's Safety Supervisor, a safety hazard is present. The footage for this line item for each well shall be measured from the total depth of the well to the top of the Schedule 40 PVC casing.

5.1 Well String Installation

The final well depth and screened interval shall be determined by the Contractor before the borehole is reamed to the final diameter. Estimated depths are 130 feet (130') for deep observation wells and 80 feet (80') for the shallow observation and pumping test wells.

The well string (casing and screen) is to be lowered slowly into the borehole using clamps, elevators, or other

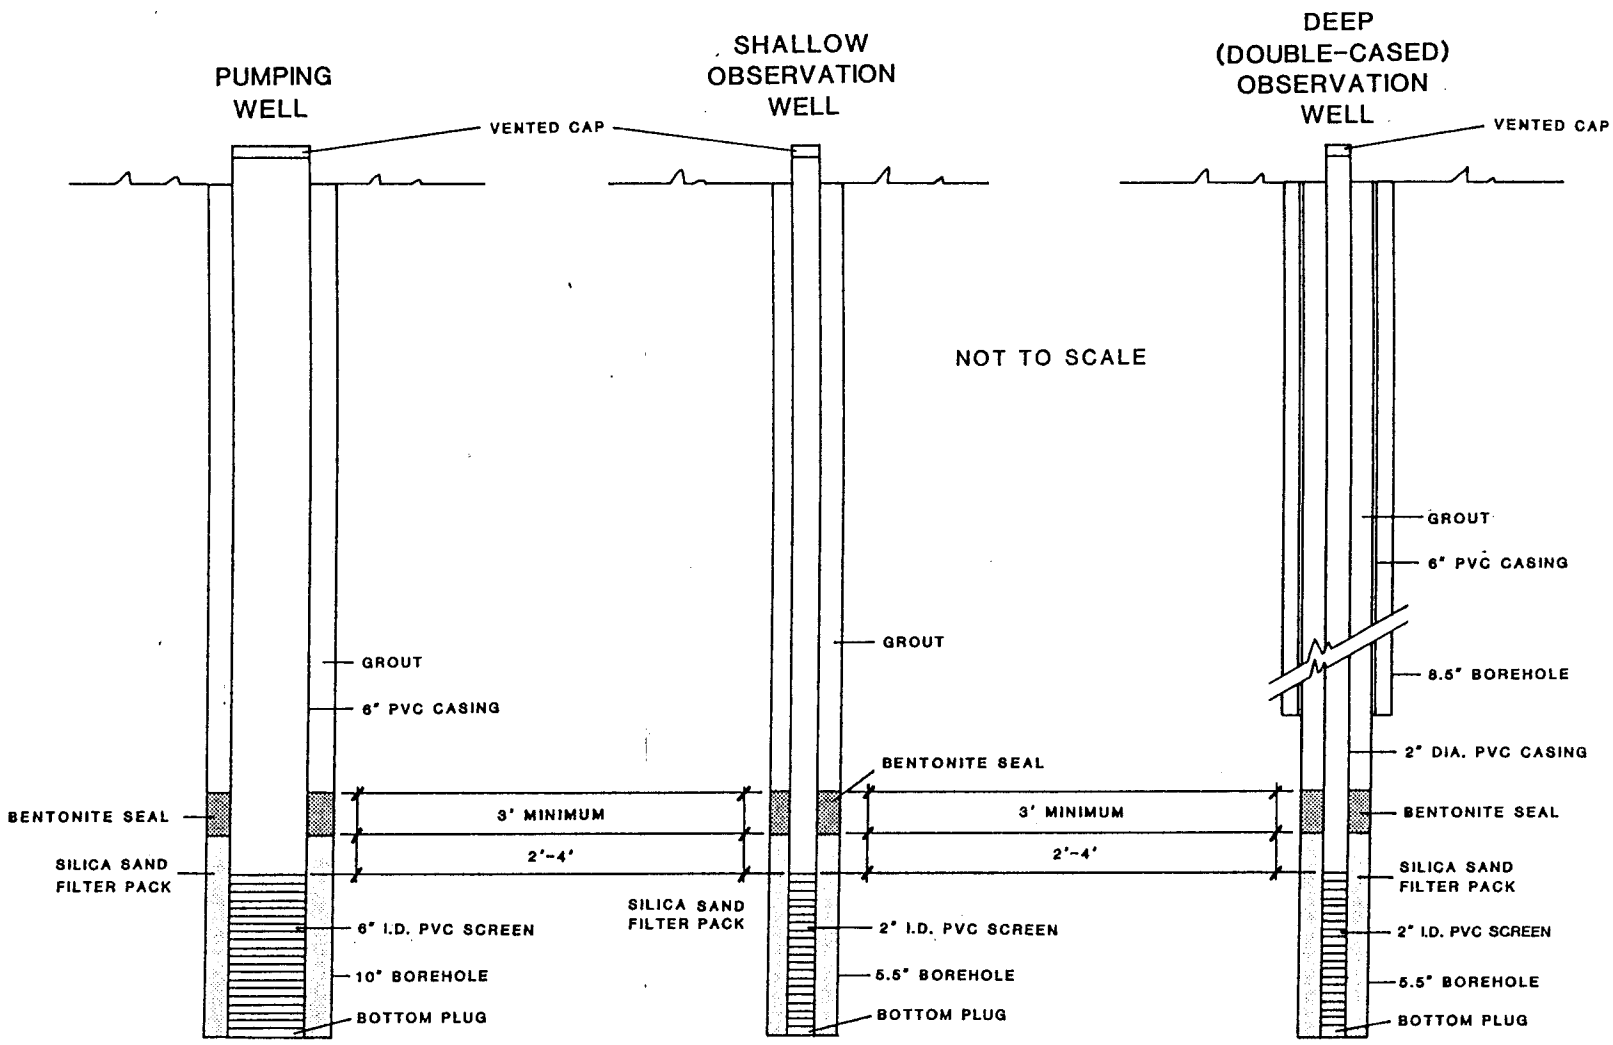

FIGURE 7

PUMPING AND OBSERVATION WELL CONSTRUCTION

DRAFT

mechanical devices to ensure the well shall maintain alignment, plumbness, and roundness during installation. The well string shall not be dropped into place, or lowered by hand in an uncontrolled manner. The casing shall be fully supported from the top and held in tension during the placement of filter pack, seal, and grout.

The well shall be set with approximately two feet (2') of casing above the ground surface. The threaded cap shall be placed on the top of the well as soon as the well string is set to the final depth.

5.2 Casing Alignment

All wells shall be constructed, and all well casing and screen set round and true-to-line.

PVC centralizers shall be used to assure alignment of the well string in the lower portion of the boreholes. The centralizers shall be placed at the bottom of the well screen and at the top of the screen. One centralizer shall be placed halfway between these two if the screen length is greater than 20 feet (20'). This will allow the uniform and complete filling of the annular space by filter pack, seal, and grout materials.

Centralizers shall be fastened to the well casing and

DRAFT

screen by using clamps and be radially spaced about the casing at 120°. No bonding agents shall be used to attach centralizers. Fasteners which penetrate the casing and extend into the well shall not be allowed since downhole sampling equipment may be hampered in its operation. Centralizers shall be placed such that the screen and casing are centered in the hole and in a manner which will not hinder the use of the tremie pipe while emplacing backfill materials.

5.3 Filter Pack Installation

The filter pack shall be installed using a 1.25 inch ID tremie pipe. The tremie pipe shall be initially placed near the bottom of the well and gradually raised. The filter pack shall be emplaced to a point at least two feet (2′) and not more than four feet (4′) above the top of the screen. The top of the filter pack shall be verified by measuring with a measured tremie or weighted tape measure.

5.4 Bentonite Seal Installation

The bentonite seal shall be installed via tremie pipe by slowly pouring the bentonite pellets from the surface. A minimum thickness of three feet (3′), measured before the pellets have expanded, shall be emplaced and measured with a tremie pipe or weighted tape measure.

DRAFT

5.5 Grouting

The grout shall be pumped into the annular space using a minimum one-half inch (0.5") ID tremie pipe. The tremie pipe shall be set at the top of the bentonite seal. The grouting shall be performed in a continuous manner until the annular space is completely filled. After the grout has settled for 24 hours, it shall be "topped-off" as necessary until the annular space is completely filled.

5.6 Well Development

After the well installation is completed and the cement grout (or Volclay grout) has set for a minimum of 48 hours, each well shall be fully developed.

Development shall be accomplished by surging and bailing or surging and pumping. All surge blocks, bailers, and other development equipment shall be decontaminated by hot water, high-pressure washing before development begins and between each well. Pumps and hoses shall be thoroughly flushed with potable water from the approved source.

Each well shall be developed for a minimum of four (4) hours. Development shall be considered complete when the water yielded from the well has a measured turbidity of no greater than five (5) Nephelometric Turbidity Units (NTU).

The Subcontractor may supply a turbidity meter to make field measurements, or may collect visually clear water samples at the end of the four (4) hour minimum and submit these samples to a laboratory for confirmation that the five (5) NTU standard has been met.

A minimum of five (5) volumes of standing water in the well casing and annular space shall be removed from each well during development. In the event that a well is pumped or bailed dry and recharges slowly, the Subcontractor may move to another well and return to complete development at the original well after it has recharged. If the five (5) NTU standard or the five (5) well volume standard cannot be achieved after a total of four (4) hours, the Contractor may set an alternative standard. If additional efforts by the Subcontractor are necessary, the Subcontractor shall be compensated according to the provisions of the Changes clause.

During and after development all sediment collected in the bottom of the well shall be removed using a bailer. Absolutely no acids, dispersive agents, or explosives shall be permitted for well development.

5.7 Aquifer Step-Drawdown Test

Following installation and development of the pumping

wells, and prior to the installation of observation wells, the Subcontractor shall furnish and install an appropriate test pump and conduct a step-drawdown pumping test. The purpose of this pumping test will be to determine observation well spacing and the pump size and sustained pumping rate for the pumping wells. The pumping unit shall be complete with an ample power source, controls and appurtenances and shall be capable of being operated for a minimum period of 8 hours without interruption. The pump shall be removed at the completion of the step-drawdown test.

Prior to starting the pump, water level measurements shall be taken in the pumping test well. The well shall be "step" tested at rates of 0.5 gpm, 1 gpm, 2.5 gpm, 7.5 gpm, 10 gpm, 15 gpm, 20 gpm, and 25 gpm. It is estimated that each step will take one hour. The Subcontractor shall operate the pump. When the drawdown in the well reaches a stable level the Subcontractor shall increase the discharge. A Contractor's representative shall be present during the step-drawdown test. Discharge of the pump shall be controlled by a gate valve, if driven by an electric motor, and both gate valve and engine throttle if driven by a gasoline or diesel engine. The discharge shall be controlled and maintained at approximately the desired discharge for each step with an accuracy of plus or minus 5 percent. Pump discharge to the nearest one-tenth gallon

DRAFT

per minute (0.1 gpm) shall be measured with a totalizing meter and stop watch, circular orifice meter, or Venturi meter. A 2-wire electric sonde (m-scope) shall be supplied by the Subcontractor to measure the static water level and drawdown in the well. The pump and hoses shall be thoroughly decontaminated between wells.

The Subcontractor shall convey and discharge all pumped water from the pumping wells to Raffinate Pit 4 on the west side of the site. Pumping through hoses or temporary piping or transport by tanker truck are acceptable methods of conveying the water from the pumping well to the raffinate pits. The Subcontractor shall supply all hoses, pipes, pumps, tanks, and vehicles necessary for these operations.

DRAFT

6.0 MONITORING WELL MATERIALS, INSTALLATION AND DEVELOPMENT

6.1 Well Installation in St. Peter and Kimmswick Formations

The monitoring wells completed in the St. Peter and Kimmswick formations shall be constructed using steel casing having an outside diameter (OD) of 6.625 inches and wall thickness not less than 0.188 inch, conforming to specifications for ASTM A-53 Grade B pipe. The ends of each section shall be cut square with beveled edges. Casing sections shall be joined by welding as the casing is installed. Each length of casing shall be decontaminated by hot water high-pressure washing prior to installation as described above in Section 3.2. Typical monitoring well construction for wells in the individual formations is shown on Figure 8.

To install each well in the St. Peter formation, a borehole approximately 8.5 inches in diameter shall be drilled to a depth 10 feet (10′) below the top of the St. Peter formation as specified above in Section 3.4.4. Casing shall then be installed to the total depth of the borehole with approximately two feet (2′) extending above the ground surface. The annular space shall be sealed to the total depth using a cement bentonite grout mixture as specified in Section 4.7. After the grout has set for a minimum of

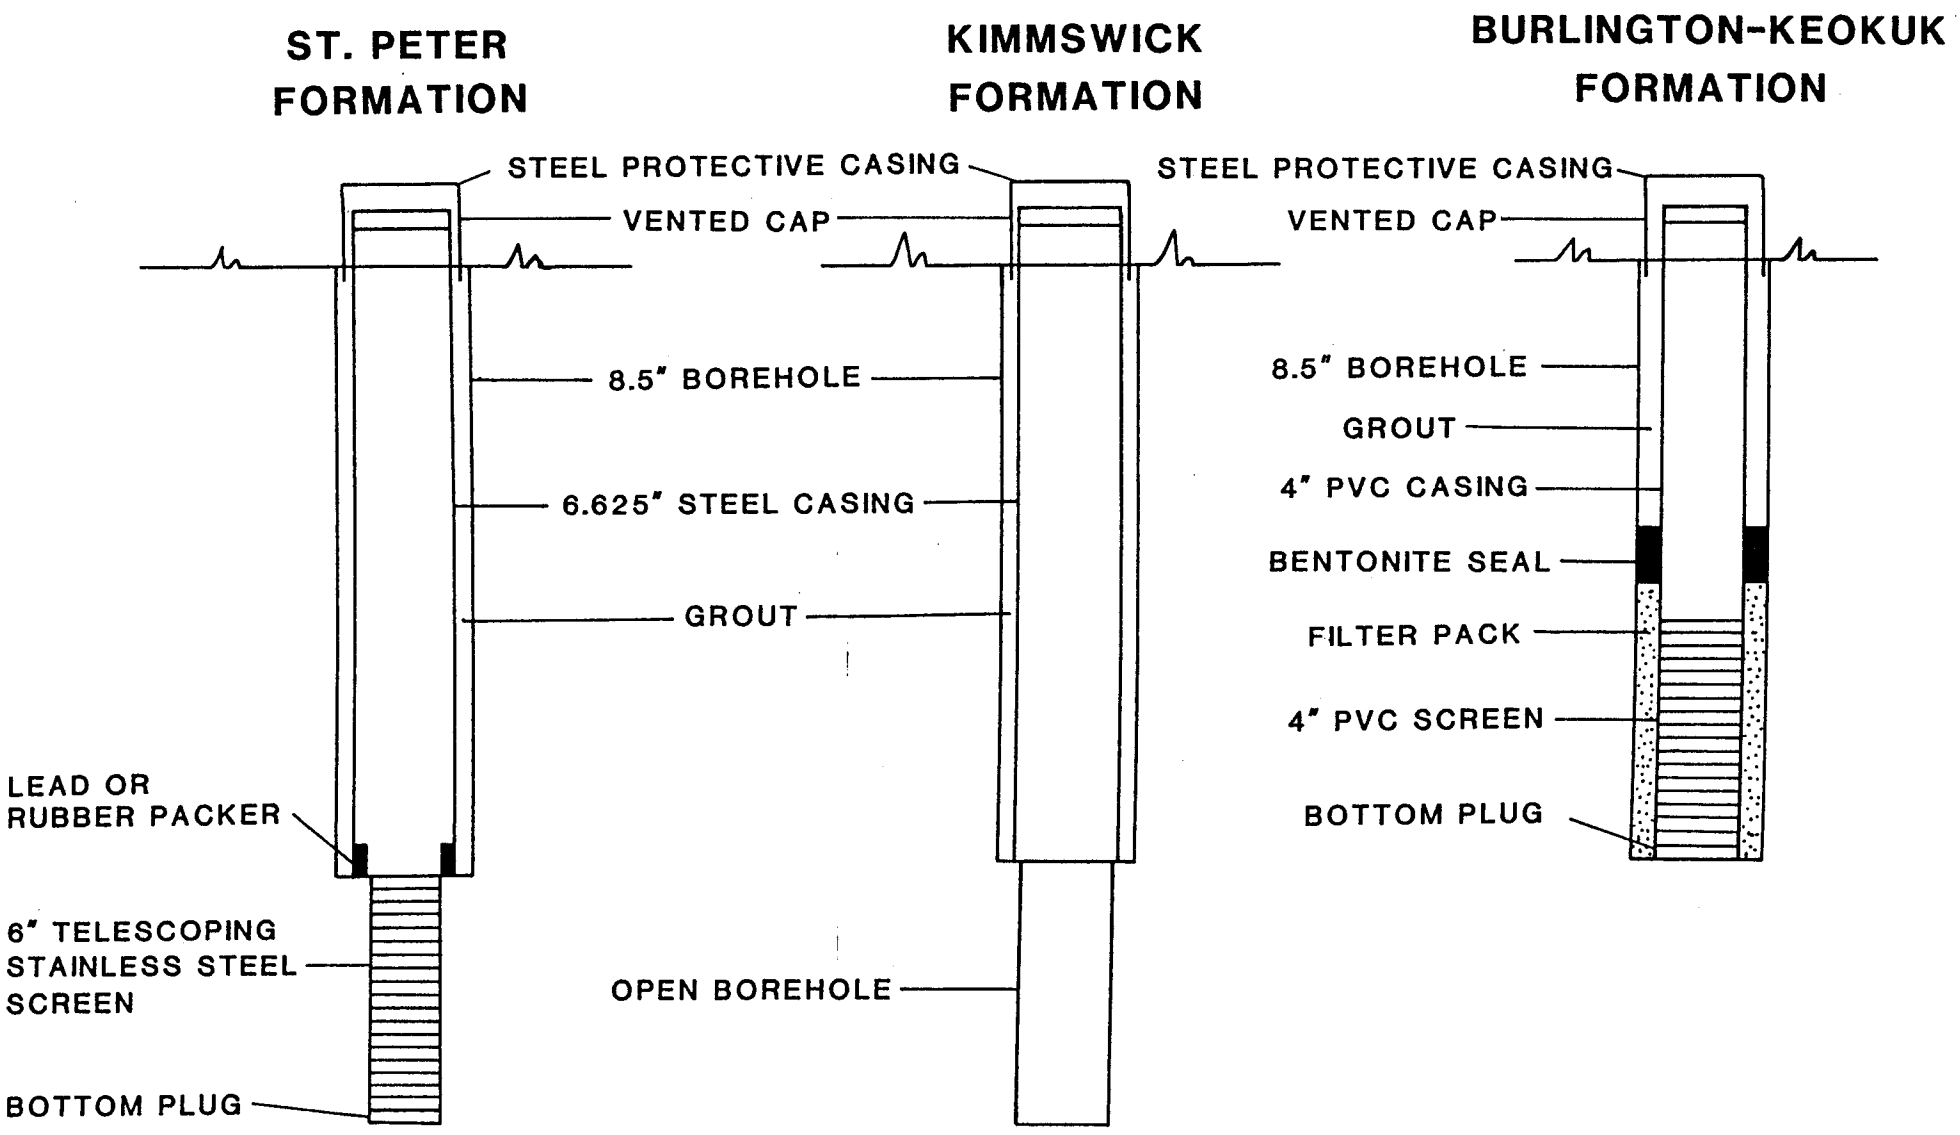

FIGURE 8

MONITORING WELL CONSTRUCTION

DRAFT

72 hours, a borehole approximately 6 inches in diameter shall be drilled through the casing to a depth 20 feet (20') below the end of the casing. A six inch (6") nominal diameter telescoping screen 20 feet (20') in length shall then be installed below the casing. The screen shall be constructed from Type 304 stainless steel using wire-wound construction techniques. Screen slot size shall be 0.010 inch. The screen shall be fitted with a bottom seal and a lead or rubber packer to seal the top of the screen to the casing.

The wells in the Kimmswick formation shall be constructed by drilling a borehole approximately 8.5 inches in diameter to a depth 10 feet (10') below the top of the Kimmswick formation, then setting and grouting casing as described above for the wells completed in the St. Peter formation. After the grout has set for a minimum of 72 hours, a borehole approximately six inches (6") in diameter shall be drilled through the casing to a depth 20 feet (20') below the bottom of the casing. These wells shall be constructed as open-hole completions.

The Subcontractor shall assure that the open borehole interval is free of obstructions to the full depth and diameter.

The Subcontractor shall supply a threaded or loose-fitting

slip cap for each monitoring well. A one-sixteenth inch (0.0625") hole shall be drilled in the side of the cap or in the casing not more than two inches (2") below the cap.

6.2 Monitoring Well Installation in the Burlington-Keokuk Formation

The monitoring well completed in the Burlington-Keokuk formation shall be constructed using four inches (4") inside diameter, threaded, flush-jointed Schedule 40 PVC casing, screen, cap and bottom plug. Screen length shall be 20 feet (20'), slot size shall be 0.020 inch. All casing and screen shall be decontaminated by hot water high-pressure washing prior to installation as described above in Section 3.2. A borehole approximately 8.5 inches in diameter shall be drilled to the total depth 25 feet (25') below the bedrock surface, or 25 feet (25') below the water table if the water table is below the bedrock surface. Estimated total depth is 100 feet (100'). The well shall then be installed in the same manner as the pumping and shallow observation wells as specified above in Sections 5.1 through 5.5, utilizing filter pack materials, bentonite, and grout as specified in Sections 4.5 through 4.7.

6.3 Monitoring Well Protection

DRAFT

The Subcontractor shall provide and install a steel protective casing around each monitoring well. Protective casings shall be a minimum of five feet (5′) in length and have a hinged, locking cap. Protective casings for the wells constructed with 6.625 inches (OD) casing shall be a minimum of ten inches (10") in diameter or ten inches (10") square. The protective casing for the four inches (4") diameter PVC well shall be a minimum of eight inches (8") in diameter or eight inches (8") square.

Each protective casing shall be set in a concrete pad at the surface. The concrete pad shall be two and one-half feet (2.5′) square, with a minimum thickness of six inches (6") and slope away from the protective casing. At least three inches (3") of this pad shall be below the ground surface. The minimum amount of slope from the protective casing is one inch (1") per two feet (2′). A one-fourth inch (0.25") diameter hole shall be drilled in the protective casing approximately one-half inch (0.5") above the surface of the concrete pad in order to allow drainage of the protective casing. The protective casing shall be painted yellow or orange using a weather-resistant enamel prior to installation.

The Subcontractor shall install three (3) protective posts

DRAFT

around each well, one hundred twenty degrees (120°) apart. These posts shall be iron posts at lest four inches (4") in diameter, extending at least two feet (2') below the ground surface and at least four feet (4') above grade. The protective posts shall be between three and one-half feet (3.5') and four feet (4') from the protective casing. The posts shall be filled with concrete and all sharp edges removed. The posts shall be painted yellow or orange using a weather-resistant enamel.

DRAFT

7.0 WELL DEVELOPMENT

After the well installation is completed and the final grout and surface concrete pad has set for a minimum of 48 hours, each well shall be fully developed.

Development shall be accomplished by surging and bailing or surging and pumping. All surge blocks, bailers, and other development equipment shall be decontaminated by hot water, high-pressure washing before development begins and between each well. Pumps and hoses shall be thoroughly flushed with potable water from the approved source.

Each well shall be developed for a minimum of four (4) hours. Development shall be considered complete when the water yielded from the well has a measured turbidity of no greater than five (5) Nephelometric Turbidity Units (NTU). The Subcontractor may supply a turbidity meter to make field measurements, or may collect visually clear water samples at the end of the four (4) hour minimum and submit these samples to a laboratory for confirmation that the five (5) NTU standard has been met.

A minimum of five (5) volumes of standing water in the well casing and annular space shall be removed from each well during development. In the event that a well is pumped or bailed dry and recharges slowly, the Subcontractor may move to another well and return to complete development at the original well after it

has recharged. If the five (5) NTU standard or the five (5) well volume standard cannot be achieved after a total of four (4) hours, the Contractor may set an alternate standard.

During and after development all sediment collected in the bottom of the well shall be removed using a bailer. Absolutely no acids, dispersive agents, or explosives shall be permitted for well development.

8.0 SURVEYING

DRAFT

After completion of monitoring well installation, the Subcontractor shall conduct land surveys to determine the horizontal coordinates of each well on the site grid system and to determine the top-of-casing elevation of each well.

Horizontal coordinates shall be measured to the nearest one foot (1').

Top-of-casing elevations shall be measured to the nearest one-hundredth of a foot (0.01'). The top-of-casing elevation shall be measured at the top of the well casing with the cap removed. Before placing the rod on the top of the casing, the surveyor shall place a clean, new plastic bag over the base of the rod. A new plastic bag shall be used at each well.

The Contractor will supply information on vertical and horizontal control points on which to base the surveys.

The survey data, including copies of the surveyor's field notes, shall be submitted to the Contractor within thirty (30) days following completion of monitoring well installation.

All surveying shall be performed under the supervision of a Registered Land Surveyor in the State of Missouri.

Dear Mr. Wall:

REMEDIAL INVESTIGATION DOCUMENTS

Enclosed are six copies of the following documents for your review:

- Quality Assurance Program Plan Weldon Spring Site DOE/OR/21548-011 (Draft Copy) February 1988.
- Community Relations Plan
- Construction Safety and Health Management Program prepared under Contract No. DE-AC05-86OR21548 April 17, 1987
- WSSRAP Procedures Manual Volume No. V - Environmental Safety and Health Contract No. DE-AC05-86OR21548 (Revision 20, January 11, 1988)
- Waste Assessment Raffinate Pit Sampling Plan Weldon Spring Site DOE/OR/21548-010 (Draft Copy) February 1988

The QAPP and its enclosures were prepared following the format and content of the Galena, Kansas QAPP provided to DOE by EPA as an example. The Waste Assessment - Raffinate Pit Sampling Plan requires your formal concurrence prior to commencement of field activities.

ABSTRACT

The Remedial Investigation Quality Assurance Program Plan (RIQAPP) for Weldon Spring Site Remedial Action Project (WSSRAP) is distinguished by purpose from the WSSRAP overall Quality Assurance/Quality Control Program Plan (QAPP). The RIQAPP is focused only on meeting EPA requirements under CERCLA whereas the QAPP is designed to meet quality assurance program requirements for nuclear facilities: NQA-1 (ANSI, 1986).

The RIQAPP specifically addresses factors, methods and criteria presented in Section 300.68 of the National Oil and Hazardous Substances Pollution Contingency Plan. Specific QC procedures are contained in existing documents incorporated into the plan by reference. These include Standard Operating Procedures, laboratory QA procedures, and activity level sampling plans. Most of the sampling and analysis activities rely heavily upon guidance in SW-846E (EPA, 1984).

The existing procedures provide many of the required QA elements: measurement, sampling, sample and document custody and control, calibration, analysis and data reduction, validation and reporting. Additional QA elements addressed in the RIQAPP include performance and system audits, surveillance, and reporting and correction of deficiencies.

System audits, on a regularly scheduled basis, will evaluate all components of measurement systems to determine capability, proper selection and use. Performance audits, on a scheduled basis, will determine adequacy and accuracy of a given measurement system and/or procedural compliance. Surveillance, both scheduled and unscheduled, of field and laboratory activities will be performed to verify conformance to specified requirements.

Audit reports will require responses from audited organizations which must include commitment dates for completion of actions

recommended to correct deficiencies. Completion of all corrective actions will be verified. Deficiencies noted during surveillance will be documented and will require responses and follow-up action.

All correspondence, plans, reports, certification and other relevant documentation will be processed through the WSSRAP Document Control Department.

Key QA positions in the PMC organization are the Project Quality Manager (PQM), reporting administratively to the Project Manager and authoritatively to the PMC's corporate QA/QC Manager, and a QA Engineer/Lead Auditor reporting to the PQM.

1.0 INTRODUCTION

The overall WSSRAP QA/QC program (including subsequent remedial action activities) is designed to meet the quality assurance program requirements for nuclear facilities: NQA-1 (ANSI, 1986). This RIQAPP is focused only on the EPA requirements under CERCLA. It is intended to meet the requirements of applicable EPA guidance documents, including Part 1 of Region VII's Quality Assurance Program Plan (EPA, 1986a) and U.S. EPA's Interim Guidelines and Specifications for the Preparation of Quality Assurance Project Plans (EPA, 1980). The primary purpose of this document is to provide a complete and accurate framework of information for assessing the amount and extent of hazardous materials present on site.

This plan incorporates the following operational plans and procedures by reference: a set of Standard Operating Procedures (WSSRAP Procedures Manual, Volumes 1 through 5); an Analytical Methods/Detection Limits Document (metaTRÀCE, Inc. Quality Assurance Manual, July 1987); WSSRAP Environmental, Safety and Health Plan, Rev. 0, January 1987; WSSRAP Spill Prevention, Control and Countermeasure Plan, January 1988; WSSRAP Community Relations Plan, Rev. 3, October 1988; and Emergency Plans and Procedures for the Weldon Spring Site Remedial Action Project, Rev. 3, June 1988. Additionally, this plan incorporates by reference the following Remedial Investigation sampling plans: WSSRAP Chemical Soil Investigation Sampling Plan for Chemical Plant/Raffinate Pits, Rev. 1, May 1988; Hydrogeologic Investigation Sampling Plan, Rev. 0, November 1988; Waste Assessment - Raffinate Pit Sampling Plan, Rev. 1, May 1988; Buildings Sampling Plan, Rev. 0, August 1988; Geophysical/ Geotechnical Investigation Sampling Plan, Rev. 1, July 1988; Radiological and Chemical Uptake by Edible Portions of Selected Biota at the Weldon Spring Site, November 1988; and Plan for the Samplng and Analysis of Lake and Stream Sediments Influenced by

the Weldon Spring Chemical PLant Drainage, November 1987.

The QA/QC program detailed in this document and within the associated sampling plans is intended to be utilized by personnel involved with the Remedial Investigation/Feasibility Study (RI/FS) at the Weldon Spring Site. Specific quality control procedures are detailed in the attached Standard Operating Procedures and in the individual remedial investigation sampling plans. This RIQAPP presents a methodology for gathering and analyzing information that will be included in the WSSRAP RI/FS-Environmental Impact Statement Report. This program is intended to fulfill DOE's commitment to meeting the requirements of the Federal Facilities Agreement signed by DOE and EPA for the Weldon Spring Site.

The RIQAPP addresses all 16 QA elements (see Table 1.1), as specified for environmentally related measurements by EPA's Office of Monitoring Systems and Quality Assurance (EPA, 1980).

2.0 PROJECT DESCRIPTION

2.1 PHYSICAL SETTING

The Weldon Spring Site is located in St. Charles County, Missouri, about 30 miles west of St. Louis. The site consists of a 3.4-hectare (9-acre) former limestone quarry, a 21-hectare (51-acre) raffinate disposal area (settling basins), a 67.8-hectare (166-acre) abandoned uranium feed materials plant, and various vicinity properties that are contaminated as a result of past Department of Army (DA) and Atomic Energy Commission (AEC) activities at the site.

Approximately 238,600 cubic meters (312,000 cubic yards) of contaminated soil, equipment, and buildings remaining on the Weldon Spring Chemical Plant (WSCP) site require cleanup to meet current DOE guidelines for unrestricted use. In addition, surveys show that radioactive contamination of the surrounding vicinity properties, which occurred during and subsequent to plant operation, would require removal of about 20,800 cubic meters (27,200 cubic yards) of soil to meet guidelines for unrestricted use.

The Weldon Spring Raffinate Pits (WSRP) contain approximately 168,200 cubic meters (220,000 cubic yards) of uranium and thorium residues. In addition, soil underlying the raffinate pits is probably contaminated and will require remedial action.

During the period 1943-1957, the DA utilized an abandoned limestone quarry, about four miles from the site (used as an ordnance works during World War II), for disposal of rubble and soils contaminated with TNT and DNT. Also the AEC later disposed of building rubble and soils contaminated with thorium, uranium, and their decay products. The quarry contains about 95,000 cubic meters (124,000 cubic yards) of waste, including quarry materials contaminated by the presence of this radioactive waste.

A detailed project description including site history, environmental setting and a summary of the known and suspected nature and extent of existing contamination is presented in the Remedial Investigation/Feasibility Study - Environmental Impact Statement (RI/FS-EIS) Work Plan.

2.2 PROJECT OBJECTIVES

Specifically, the RI activities are undertaken to define the extent of contamination at the site and surrounding area and allow the determination of the potential impacts of these hazardous substances on public health, welfare, and the environment. In addition, the RI data will allow for the formulation of strategies to develop and implement appropriate Interim Remedial Actions (IRAs), prior to the final selection of remedial actions.

The FS activities are undertaken to assess and develop, through the FS process, types of remedial and/or removal actions that should be considered. These actions must be the most economically feasible measures to mitigate threats to and provide protection for the public health, welfare, and environment. In addition, an RI/FS-EIS report will be prepared which will address the technical and demographic issues and impacts associated with selecting viable and feasible remedial measures.

2.3 DATA QUALITY OBJECTIVES

The purpose of the RI program is to ensure that all data used to support decisions made by DOE meet quality requirements imposed by Federal and state regulatory agencies. Specifically, the data collected at the Weldon Spring Site shall be of adequate quantity and quality to accurately characterize the site and to evaluate and delineate remedial measures.

The data collection, evaluation and subsequent remedial measures,

and other actions on site, are governed by a Federal Facilities Agreement (FFA) between EPA and DOE. This agreement defines the procedures and actions necessary for DOE and EPA to discharge their respective responsibilities for effective completion of WSSRAP. It specifies that all actions pursuant to the agreement shall be done in accordance with all applicable or relevant and appropriate Federal laws, regulations and executive orders, and applicable state and local laws and regulations. A preliminary identification of applicable or relevant and appropriate project requirements (ARARs) is presented in the RI/FS Work Plan.

This RIQAPP specifically addresses those factors, methods and criteria presented in Section 300.68 of the National Oil and Hazardous Substances Pollution Contingency Plan (NCP). This RIQAPP also provides a mechanism for further evaluation of the existing data for its adequacy and usability and a method for extensive monitoring of the QA/QC procedures utilized at the time of data collection and their accompanying documentation.

A three-staged Data Quality Objective (DQO) program has been delineated by EPA and will be followed on the WSSRAP. A phased investigative approach allows for a "refinement or redefinition of data collection needs at the completion of each phase" (EPA, 1987). Data collected and analyzed under the DQO process can be used to support decisions related to remedial responses at the WSS.

The three stages identified in the DQO development process are as follows:

Stage 1- Identify Decision Types
Stage 2- Identify Data Uses/Needs
Stage 3- Design Data Collection Program

The Stage 1 program identifies types of decisions needed for site remediation, designates individuals responsible for decisions and

data users, and establishes data adequacy. Data users will include the technical staff of the Project Management Contractor, DOE, EPA, Missouri Department of Conservation, Missouri Department of Health, Agency for Toxic Substances and Disease Registry, and other governmental agencies and citizen groups.

Specific data needs and uses are identified in the Stage 2 DQO process. Individual sampling plans identify uses, types, quantity, and quality of data, and establish Precision, Accuracy, Representativeness, Completeness, and Comparability (PARCC) parameter goals. Since measurement data will be used for site characterization and remedial design, goals are for the highest practical attainable level of precision and accuracy. Definitions and examples of PARCC parameters are presented in this section.

Investigative activities at the Weldon Spring Site (WSS) have progressed, for the most part, beyond Stage 1, particularly the site characterization for radiological contamination. Extensive data are available from previous investigations to allow for the development of a conceptual model of the site.

The conceptual model can be expanded, data needs and uses can be redefined, and revisions or additions to the data collection program can be implemented under the DQO program. For example, groundwater samples will be collected and analyzed under the Stage 3 program. Results of this laboratory analysis will be evaluated under the Stage 1 data evaluation process.

The RI/FS-EIS Work Plan delineates those site characterization and environmental monitoring activities that have been conducted prior to submittal of this RIQAPP. These activities have included the acquisition of extensive data relating to the chemical and physical characteristics of soil, groundwater, surface water, sludges and sediments, building waste and debris, and existing facilities at the WSS. The characterization

programs have included hydrogeological, soils, geological, meteorological, radiological and geophysical studies conducted by DOE and predecessor governmental agencies and private organizations. Aquifer parameters, extent of both soil and groundwater contamination, site geology, and the hydrologic regime have been partially defined. A summary is presented in the RI/FS-EIS Work Plan.

Sufficient preliminary data are available to delineate sources of contaminants, e.g. raffinate pits, existing contaminated buildings, transformer storage areas, overhead piping with asbestos, etc., and to define the approach to future sampling activities.

Existing data, however, are not sufficiently complete for Weldon Spring Site characterization. Additional data collection activities are required. These data will be used to further define the extent of soil, groundwater, surface water and air contamination. Those media and existing structures and facilities will be sampled in accordance with the five sampling plans listed in Section 1.0.

Data collected under these sampling and analysis plans will also be utilized to modify current health & safety plans (if required) to assure worker protection, to evaluate risk to public health and environment, to delineate remediation measures, and to modify current and proposed monitoring programs. The collection and analysis of environmental and biological samples will partially fulfill the data requirements for the preparation of an RI/FS-EIS.

2.4 SITE ASSESSMENT

The National Contingency Plan (40 CFR Part 300, Subpart F, CFR, 1988) stipulates that assessment of a hazardous waste site (conducted under CERCLA) must be a phased response action,

including preliminary assessment and removal actions, site evaluation to determine whether the site should be included on the National Priorities List (NPL), and remedial action. Included under the latter are requirements and criteria for conducting investigations and feasibility studies.

The RI process at the WSS has advanced through initial or preliminary assessment and site evaluation phases. Extensive data have been collected at the site and vicinity properties. Individual sampling plans discuss the validity, sufficiency, and sensitivity of these data, and additional data needs and uses. These sampling plans also address site history and summarize the existing data base.

Hazardous substances considered to be potentially on site have been defined after a thorough review of the site history records. This review includes a documentation of manufacturing processes, wastes deposited on site, building construction materials, and support items (e.g. transformers, storage tanks containing chemicals, etc.). These source studies have provided a basis for defining data needs as well as potential impacts to the public and environment and for determining the need for removal action.

3.0 PROJECT ORGANIZATION AND RESPONSIBILITIES

The Department of Energy (DOE) is responsible for conducting remedial actions at the Weldon Spring Site that will place the site in a radiologically and chemically safe state in accordance with guidelines by DOE and EPA. The responsibility for management and technical direction of remedial actions has been delegated to the DOE Oak Ridge Operation Office. MK-Ferguson (MK-F) is the project management contractor (PMC) assisting DOE in the planning and management of remedial action activities. Headquartered in Cleveland, Ohio, MK-F is a wholly owned affiliate of Morrison Knudsen Company, a multi-disciplinary firm located in Boise, Idaho. Joining MK-F as an integrated member of the PMC team is Jacobs Engineering Group, Inc., headquartered in Pasadena, California.

The RI/FS-EIS Work Plan describes the environmental compliance process and the role of the various organizations (including the PMC) under contract to DOE for the implementation of remedial activities at the Weldon Spring Project.

Prior to the issuance of the RI/FS-EIS, it is the responsibility of the PMC to complete a site characterization program, in accordance with EPA's RI requirements. The RI/FS-EIS will be prepared in a format consistent with the requirements of a Feasibility Study (FS) and will contain the level of detail required by EPA under CERCLA/SARA.

The Project Organization Chart, Figure 3-1, shows lines of authority, responsibility and communication assigned to key project entities.

Listed below are the reporting responsibilities and duties of key PMC personnel.

The Project Director reports to DOE and the MK-F Senior

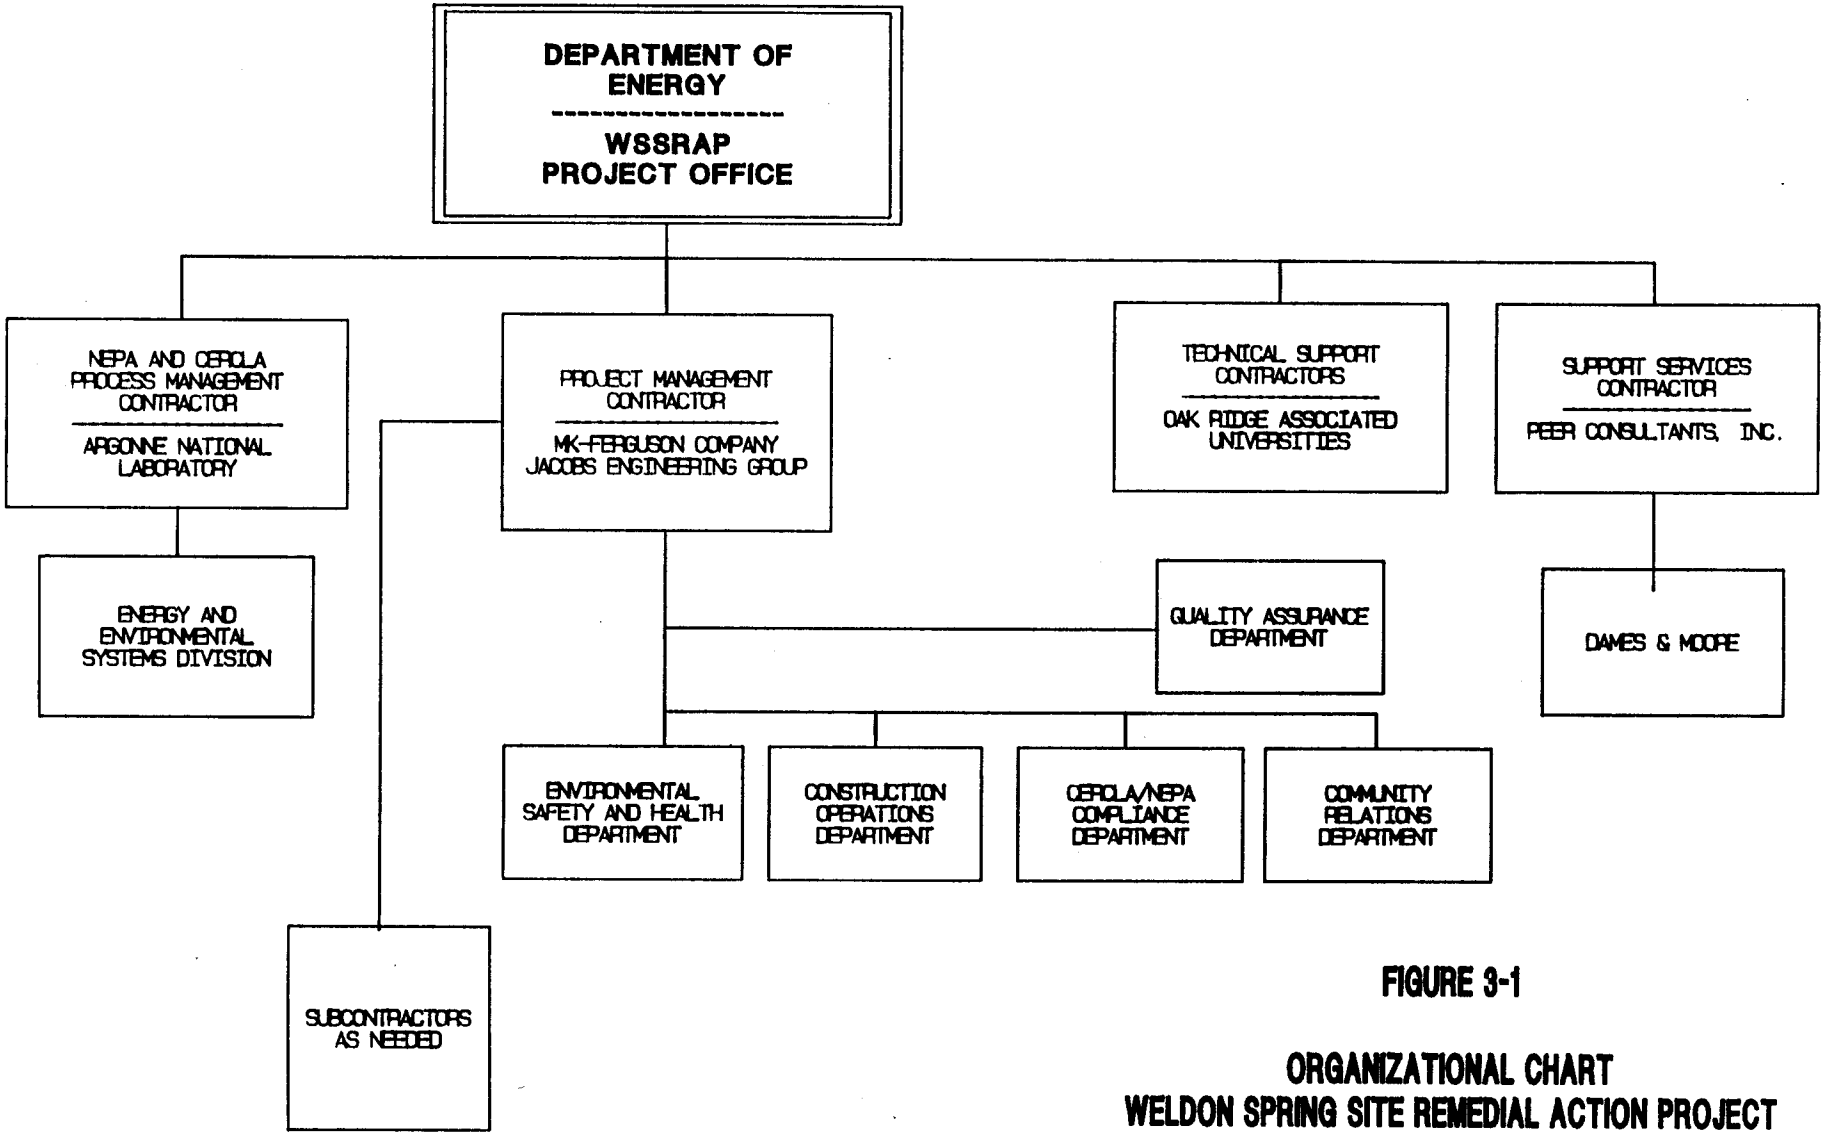

FIGURE 3-1

ORGANIZATIONAL CHART
WELDON SPRING SITE REMEDIAL ACTION PROJECT

Vice-President - Operations, and is responsible for the overall WSSRAP management. This includes completion of all contract requirements within the approved schedule and budget, and in accordance with applicable codes, standards, specifications, and the Quality Assurance Program.

The Project Manager (PM) reports to the Project Director and is responsible for regular project management and administrative duties. He directs and integrates the engineering, construction and environmental, safety and health efforts. The PM is authorized to act for the Project Director in his absence from the project office.

The Administrative Manager (AM) reports to the Project Director and is responsible for all project administrative matters, i.e. general records control, time-keeping, payroll, industrial relations, site security, property control, and all financial matters.

The Project Procurement Manager (PPM) reports to the Project Manager and is responsible for all project procurement and issuance of subcontracts, including evaluation and analysis of bids. Additional responsibilities include warehouse functions for disposal of excess property and materials.

The Community Relations Manager (CRM) reports to the Project Director and is responsible for the WSSRAP Public Information and Participation Plan. The CRM is responsible for interfaces with public groups and government agencies, arranging public presentations and all news media relations.

The Planning & Analysis Control Manager (PAM) reports to the Project Director and is responsible for the overall project management control system which includes the development of budgets and schedules, preparation of management reports and submittals, and review and analysis of progress.

The CERCLA Compliance Manager (CM) reports to the Project Manager. The CM is responsible for the preparation, review, control and distribution of all environmental compliance documentation used to perform and monitor the work. Additionally, the CM is responsible for assuring that all design documents contain all engineering information and instructions required by the contract and all applicable codes, standards and regulations.

The Environmental, Safety and Health (ES&H) Manager reports to the Project Manager. The ES&H Manager is responsible for construction safety, radiological and environmental monitoring and analysis, applied health physics, and all training required by these activities.

The Construction/Operations (C/O) Manager reports to the PM and is responsible for construction management and coordination of all subcontractors, constructability reviews, and resolution of field problems. The C/O Manager is additionally responsible for all construction type operations and maintenance functions for existing facilities, new facilities, utilities, and equipment.

The Project Quality Manager (PQM) reports to the Project Manager on an administrative and communication basis. Authoritatively, the PQM reports off-site to the corporate QA/QC Manager. The PQM is responsible for the development and implementation of the Quality Assurance Program and has the authority to stop the work or control further processing; identify the need for corrective action; initiate, recommend, coordinate and/or provide solutions and verify implementation of solutions and corrective actions related to the quality of the work. The PQM is assisted by a QA Engineer/Lead Auditor for performance and systems audits (described in Section 9.0 of this RIQAPP).

The Quality Control Supervisor (QCS) reports to the PQM and is responsible for performing and/or assigning certified inspection

personnel to perform inspections. The QCS is responsible for assuring that required inspections are performed and documented, that inspection reports identify the items inspected, and types of inspections performed, that applicable accept/reject criteria are specified, and that inspection results are indicated. The QCS is responsible for the timely performance of inspections and transmittal of inspection reports and documents to Quality Assurance Records.

Any unresolved difference between Project Quality Assurance and other project groups is first brought to the attention of the Project Manager and Project Director, and if still unresolved, it is then brought to the attention of the MK-F Senior Vice-President - Operations for resolution through the Corporate QA/QC Manager.

Names of key personnel responsible for specific components of the site characterization program and are listed below.

- **Sampling Operations**

Soils	Kenneth Meyer (JEG)
Groundwater and Surface Water	Don Penniman (JEG)
Waste Characterization	
Raffinate Pit Sludge	Rick Ferguson (JEG)
Buildings and Equipment	Steven Green (JEG)
Geophysical/Geotechnical Investigation	William Knight (JEG)
Environmental	Paul Blacker (JEG)
Other Investigations	
Lake & Stream Sediment	Kenneth Meyer (JEG)
Bio-uptake	Mark Lusk (JEG)

- **Laboratory Analysis** — Richard Manz (metaTRACE)

- **Data Processing Activities** — Yusuf Noorani (JEG)

- **Sampling and Analysis QA/QC**

Soils	Robert Hoffman (JEG)
Hydrogeology	Jim Meier (JEG)
Waste Assessment	Rick Ferguson (JEG)
Geophysical/Geotechnical Investigations	Edward Tom (MK-E)
Environmental	Karen Borkowski (JEG)
Laboratory	Kenneth Baughman (metaTRACE)
Data Processing QC	Yusuf Noorani (JEG)
Data Quality Review	Roger Nelson (JEG)
Performance Auditing	Joe Guyette (MK-F)
Systems Auditing	Joe Guyette (MK-F)
Overall QA	J.J. Hairston (MK-F)

4.0 QUALITY ASSURANCE OBJECTIVES FOR MEASUREMENT

The overall purpose of establishing quality assurance objectives for measurement data is to ensure that data of known and acceptable quality are provided for the intended data use. These objectives apply to both existing and future sampling and field measurement data. Data reviewed or generated by this project are to be of such quality that they can be used as a direct indicator of the nature and extent of radiologic and chemical contamination at the Weldon Spring Site. Most sampling and analysis activities to be performed during the conduct of the WSSRAP rely heavily upon the guidance in SW-846 (EPA, 1984).

4.1 PARAMETERS

This section describes the five major data quality objective parameters: Precision, Accuracy, Representativeness, Completeness and Comparability (PARCC). These parameters comprise the major quality assurance objectives for all measurements made as part of the WSSRAP.

4.1.1 Precision

Precision measures the reproducibility of measurements under a given set of conditions. Specifically, it is a quantitative measure of the variability of a group of measurements compared to their average value.

Sampling and analytical precision will be demonstrated respectively by:

- Collecting field replicate samples and examining replicate results for degree of variance.
- Determining if sampling error has occurred by the variance of replicates.

- Creating and analyzing laboratory replicates of field samples for degree of variance.

- Computing an overall relative standard deviation that is applicable to all the field investigation data from a particular sampling episode.

- Validating data on groups of samples that should all have the same composition by examining the variance in each group in comparison to the overall variance (invalid data are discarded).

For example, at a recent WSSRAP sampling event (3/87) duplicate groundwater samples were collected from WSS monitoring well 2003. Results from analyses in ug/l of both samples are cited below:

Well #	2,4,6 TNT	2,4 DNT	2,6 DNT	NO_3	SO_4	Cr^-	F^-
2003	<0.5	0.3	0.7	886	223	33.2	14.7
2003D	<0.5	0.4	0.7	945	232	33.0	14.6

If there is mutual agreement among the individual measurements for samples that were collected under prescribed similar conditions, then sampling precision has been demonstrated (as with the above example).

The precision values calculated from the field replicates will be used in the data interpretations to determine how sensitive the site characterizations are to the variances in the data. Any data that are being compared to a standard, criteria, or action level will be compared as the reported value, the lower bound value, and the upper bound value. If this comparison identifies data that may be either above or below the standard or criteria, it will be mentioned in the report. Subsequent

sampling of these borderline areas will incorporate appropriate frequency of QC samples to reduce the variance to the point where more definitive statements can be made.

4.1.2 Accuracy

Accuracy measures the degree of bias in a measurement system. Sample collection and preparation accuracy will be monitored by using sample container blanks, shipping and storage blanks, and field handling blanks. These samples will provide information that could detect inconsistent field procedures.

Accuracy involved in laboratory analysis will be evaluated using matrix spike/matrix spike duplicates. Analytical accuracy will be monitored using recovery of analytes from surrogate spikes, matrix spikes, reference QC samples and performance evaluation samples.

Accuracy is the degree of agreement of a measurement with an accepted reference or true value and is usually expressed as percent recovery of spiked samples, where percent recovery is:

$$\frac{\text{(spiked result) - (unspiked result)}}{\text{(amount spiked)}} \times 100$$

Errors may occur during the sampling or the analysis operation. Samples may be contaminated in the field or laboratory. Errors may result from improper use of equipment during collection and analysis, improper preservation, handling and storage. For example, improper decontamination of equipment from a previous monitor-well drilling or sampling operation may result in groundwater contamination in a newly installed well. Also, an error or inaccuracy in analytical results can be introduced by an instrument being out of calibration during a portion of the analysis. Inaccuracy can result from random error or systematic error.

The WSS sampling plans (listed in Section 1.0) have incorporated requirements for accuracy (both sampling bias and laboratory analysis) and the protocol for monitoring to determine that these requirements are met. The sampling plans also provide a method for the project staff to detect the occurrence of cross contamination or external influences.

As described in the individual sampling plans, accuracy will be determined by:

- Computing percent recoveries for performance audit samples and spiked samples.
- Calculating the standard deviation in the overall average recovery value.
- Determining the range of uncertainty at a given level of confidence.

The accuracy data will be used to determine any bias in the analytical methods. All analysis will be performed according to the methods and standards set forth in the Contract Laboratory Program (CLP), (EPA, 1986b) where appropriate. The CLP provides control limits for the laboratory spikes and the appropriate qualifications for the use of the data if the control limits are not met. For the performance audit samples, the average recovery for each compound or element will be calculated and compared to the certified values. If the performance audit sample has an acceptable range stated by the CLP, an average recovery within this range will be considered acceptable. If the average recovery falls outside the acceptable range, the field sample results will be qualified as having either a high or low bias and the amount of bias will be calculated. The field sample results will not be adjusted for bias, but the bias will be considered in the interpretation of the data.

4.1.3 Representativeness

Representativeness is a measure of how closely the measured results reflect the actual concentration or distribution of the compounds in the sampled media.

Some typical examples of representativeness consideration include:

- Sampling of media at defined and representative depths.
- Pumping tests with observation wells at select locations and screened in consistent discrete zones to define aquifer parameters, confining layers, perched zones, etc.
- Sampling procedures for water quality, asbestos, waste, and soil contamination will be in accordance with those procedures appropriate for the media being sampled.
- Adherence to approved sampling plans, e.g. radiation sampling for building characterization, will include sampling of ceilings, walls, attic, air, piping, floors and exterior to define hazards and extent of contamination.

Data collected should represent actual conditions existing at the area to be sampled. For example, a groundwater sample collected at the top of the water table would not be a representative sample if potential contaminants had a higher specific gravity than water. A soil sample to be analyzed for PCBs or nitroaromatics should be collected in known storage areas for those contaminants in order to define representative contamination of that specific area; however, it would not necessarily be representative of PCB or nitroaromatic soil

contamination throughout the entire WSS area.

During the work planning process, existing data have been reviewed and site investigations have been designed so that they will yield information representative of site conditions. The sampling plans contain proper sample collection and handling techniques, equipment decontamination procedures, sampling locations, and rationale used to determine sampling locations.

4.1.4 Completeness

Completeness is a comparison of the amount of valid data that was obtained from a measurement system to the amount that was expected and needed to meet the project data goals. Completeness is typically expressed as a percentage.

For example, assume an environmental monitoring plan requires groundwater sampling activities to be performed quarterly for a one-year period. If one sampling event is missed, or if an analytical error occurred, or samples were unusable or invalid, data may still be complete if there is little quarterly variation.

Quality assurance completeness at the Weldon Spring Site will be calculated as the total number of samples collected for which acceptable analytical data are generated divided by the total number of samples collected, then multiplied by 100.

4.1.5 Comparability

Comparability is an expression of the confidence with which one data set can be compared to another as long as precision and accuracy are known. The comparability objective is to provide assurance that the data developed during separate field investigations are comparable to each other and that data

developed during the investigation are comparable with applicable hazard identification criteria.

Comparability is addressed by assuring consistency of measuring units, standardized sampling, sample preparation, methods of analysis and data format. Comparability allows for the comparison of one set of data against another. For example, it is preferable to report all boring log depths at WSS in feet instead of meters.

Standard sampling techniques (see WSSRAP SOPs) will be used to provide consistency in subsequent sampling episodes. The WSSRAP SOPs and the Analytical Methods/Detection Limits Document used at metaTRACE Laboratory or other selected laboratories address sampling procedures and analytical methodology.

5.0 SAMPLING, ANALYTICAL AND CALIBRATION PROCEDURES

The objectives for sampling procedures and field measurements are to obtain samples and measurements that are representative and comparable. The location of the sampling and field measurements will be selected to meet the data gaps identified in the scoping process. Trace levels of contaminants from external sources and cross-contamination will be eliminated through the use of experienced field personnel, good sampling techniques, proper sampling equipment and adequate decontamination.

Operational procedures are explained in detail in the activity-specific sampling plans. The WSSRAP SOPs include descriptions of sampling techniques, sample preparation requirements, sample packaging and labeling, equipment calibration, and decontamination procedures. Substantive changes or deviations from these standard operating procedures will be approved by EPA and DOE prior to implementation.

The standard Operating Procedures contain the means for demonstrating and documenting instrument accuracy, e.g.:

- All measurement devices will be assigned individual identification numbers. Documentation will be provided for each device which identifies its use, maintenance performed, and standards used for calibration.

- Each measuring device will be calibrated against a standard of known and, if possible, higher accuracy.

- Sampling and analytical methodology is documented and referenced to federal standards.

The Standard Operating Procedures and analytical methods, then, describe operations, analyses, or actions which are thoroughly

- o Engineering Design Documents
- o Design Procedures
- o Standard Operating Procedures
- o Safety Plans

6.3.2 Field and Laboratory Data

Records generated by the site RI/FS program are, where practicable, numbered and assigned to individuals designated to perform specific tasks. They include:

- o Field logbooks
- o Field data record forms, e.g. well inventory forms, pumping test data sheets
- o Analytical logbooks
- o Lab data, calculations, graphs, etc
- o Location maps, photos, selected drawings
- o Checklists of equipment performance
- o Equipment maintenance logs including repair and calibration information
- o Photographic logs

6.3.3 Project Files

A WSSRAP filing system has been established and is under the jurisdiction of the Document Control Specialist. Project files have been assigned identifying numbers. Files will contain those controlled documents, logbooks, field data sheets, and tracking forms described above, as well as contractual documents, reports, correspondence, health and safety records, telephone conversation records, design information, notes, calculations, standard operating procedures, letters of transmittal, and other records necessary to document site activities.

6.3.4 Computerized Data

A large amount of data will be generated during site characterization. Those data collected and analyzed during the sampling and analysis program will be reduced for input into the computerized data base. These data will include logs, tracking forms, and results of laboratory analyses. Computer software is protected and documentable.

6.3.5 Document Ownership and Distribution

All project documents generated on the WSS are the property of DOE. The distribution of such documents to state agencies, federal agencies, other regulatory agencies, and citizens' groups is in accordance with DOE policies and guidelines. Distribution to third parties is upon receipt of a formal request and subsequent approval by DOE. Controlled documents, i.e. manuals, procedures, instructions and guidelines, are distributed on the basis of a written, approved Standard Distribution List. All documents distributed to parties other than DOE and PMC are inventoried and are accompanied by a document transmittal form. A return receipt is required and documented on the controlled document transmittal log.

6.3.6 Document Storage

Documents are stored in locked, secure filing cabinets. Dual document storage facilities will be provided at locations sufficiently remote from each other to eliminate the chance of simultaneous exposure to a hazard. Access to both facilities will be controlled by document control specialists. This applies to both computer generated data and hard copy documents. Copy-protected software is replaceable from the supplier.

measurement, temperature, conductivity, flow measurements, and air monitoring data are recorded in field logbooks or on field data record forms. All other samples are identified by a sample tag which delineates preservation methods and required laboratory analyses. All samples are accompanied by a chain-of-custody record.

6.2 LABORATORY SAMPLE CUSTODY

All samples are packaged and shipped to the laboratory in accordance with U.S. Department of Transportation procedures with a separate custody record accompanying each shipment. An authorized sample custodian at the laboratory facility signs for incoming field samples, obtains documents of shipment, and verifies data entered onto the sample custody records. The Analytical Methods/Detection Limits Document delineates the chain-of-custody, tracking and document control procedures employed by metaTRACE Laboratory or other selected laboratories.

6.3 EVIDENTIARY FILE AND DOCUMENT CONTROL

Documentation required for sample custody will be retained and incorporated into the WSSRAP Document Control Program. Evidentiary files will include all laboratory and field reports and will be maintained by the WSSRAP.

The goal of the WSS Document Control Program is to assure that all documents used by WSS personnel will be accounted for at the termination of project activities.

To achieve the stated goal, procedures for the identification and control of documents that specify methods of assuring data quality for WSSRAP project activities have been developed. These procedures include the establishment of a numbered document system and a document inventory procedure for accountable documents. This document control system allows for

the identification and retrieval of data for any characterization work component.

Document control for this program includes the following requirements:

- o Originals and copies of documents are kept secure and under custody where necessary.

- o Individuals holding documents.

- o Individuals holding documents receive revisions and updates when appropriate.

At the Weldon Spring Site, prescribed project activities are documented in order to meet QA/QC requirements. Documents generated from these activities can be categorized as follows:

- Controlled Documents
- Field and Laboratory Data
- Tracking Forms
- Project Files
- Computerized Data

6.3.1 Controlled Documents

Controlled documents are those documents issued by authorized personnel that, in accordance with requirements of NQA-1, are assigned a unique identifying number and logged out to selected individuals. These documents specify quality requirements on prescribed activities affecting quality. A distribution list of these documents is maintained in Document Control for each document. These documents include:

- o QA/QC Plans
- o Procurement Plans

prescribed, documented, and performed in accordance with accepted standards.

Preventive maintenance and inspection procedures for laboratory and field equipment are also prescribed. Inspection and testing of equipment will be done on a regular basis. The SOPs describe calibration procedures to be employed on all field equipment, including referenced standards, QC samples employed, and operation methods. Also included are provisions for equipment maintenance.

On-site audits of both field and laboratory procedures as described in Section 9.0 will be conducted by the QA Engineer/Lead Auditor and designated technical specialist as required. Systems audits will consist of evaluation of all components of the applicable measurement systems to determine their proper selection and use.

In order for equipment to be used effectively, the operator must demonstrate an understanding of operating principles and procedures, and be competent in calibrating, reading and interpreting the instrument. Manufacturers' operating manuals provide comprehensive guides for the use of field and laboratory equipment. The operator must also be familiar with sample preservation, equipment decontamination, health and safety procedures (as applicable), and equipment limitations to assure the acquisition and analysis of valid samples in a safe manner.

6.0 SAMPLE CUSTODY AND DOCUMENT CONTROL

A major required component of all field investigation sampling plans is the maintenance of the integrity of the sample from collection to data reporting. To maintain and document sample possession, chain-of-custody procedures are followed on the WSSRAP. Elements of the chain may include sample seals, sample labels with a sample identification number to allow for sample tracking, field logbooks, field data record forms, chain-of-custody records, sample analysis request sheets, receipts, bills of lading, and field and laboratory tracking forms. Field and laboratory sample custodians or their designated representatives are responsible for maintaining custody of samples. A sample is considered to be under a person's custody if 1) it is in the person's physical possession, 2) in view of the person, 3) secured by that person so that no one can tamper with the sample, or 4) secured by that person in an area that is restricted to authorized personnel.

Sample custody is divided into three parts as follows:

- Field sample custody
- Laboratory sample custody
- Evidentiary files

6.1 FIELD SAMPLE CUSTODY

Sampling procedures for groundwater, soil, waste, etc. are addressed in the SOPs and the five individual sampling plans. The sample custody program for the Weldon Spring Site includes the documentation of procedures for the preparation of reagents, sample identification, the recording of sampling locations, and specific considerations associated with sample acquisition. Applicable forms for recording these data, and tracking of samples, as required by the chain-of-custody procedures are presented in the SOPs. In-situ measurements, e.g. pH

- o Identity of sampling teams or team leader
- o Sampling location
- o Description of sampling location
- o Collection technique
- o Field preparation technique
- o Laboratory analytical methods
- o Laboratory detection limits

Data validation also entails a review of the QC data and the raw sample data to verify that the laboratory is operated within the required control limits, the analytical results are correctly transcribed from the instrument readouts, and which, if any, natural samples are related to any outside-of-control laboratory QC samples. The objective of the data validation is to identify any qualitative, unreliable, or invalid measurements and to also verify compliance with the CLP protocol for laboratory determination.

7.3 REPORTING

Documentation of the data collection and analysis process is an integral part of the QA/QC program. Data validation techniques require that standard operating procedures, sample tracking methods, validation formulas, QC checks on PARCC criteria, and all sampling and laboratory activities be documented. Data obtained from the sample collection and analysis operation will be recorded on standardized report forms or logbooks.

These documents include DOE, EPA and corporate management forms. Some of these documents are listed below:

- o CLP Report Forms
- o Receipt of Sample Forms
- o Chain-of-Custody Forms
- o Sample Labels
- o Field Tracking Report Forms

7.0 DATA REDUCTION, VALIDATION, AND REPORTING

Statistical parameters are used to assess the quality of data obtained. Section 4.0 addresses the procedures used to routinely assess precision and accuracy of Weldon Spring environmental monitoring and measurement data. This section presents data reduction schemes and validation criteria to be used for collected data.

7.1 DATA REDUCTION

A data reduction process has been developed for all data collected on site for WSSRAP. Generally these procedures are prescribed in the documents referenced in Section 1.0 of this document. Principal devices for field sample collection or measurement, as described in the Standard Operating Procedures (SOPs) include air, surface and groundwater, soil, and waste sample collection instruments. Associated in-situ measurements, e.g. water temperature, pH, specific conductance, meteorological, and radiation are also delineated in the SOPs. Where relevant, data reduction formulas are presented, e.g. SOP Section 2.06.05 lists formulae for computing background count rates, daily efficiency, and estimating radioactivity per unit surface area with the use of the Ludlum Model 2220/43-5 Alpha Detector.

7.2 DATA VALIDATION

Many measurement activities are underway at the WSS and large quantities of data will be obtained. A major component of the Data Quality Objective process involves the assessment of data adequacy, i.e. data validity and data sufficiency. For data validation at the WSS the following will be documented:

- Sampling date

data sets in terms of the QA/QC requirements for the current WSSRAP characterization program.

3. Utilize the existing data sets' QA/QC documentation and a retroactive data validation/evaluation program to categorize the existing data as discussed above.

- o Laboratory Tracking Report Form
- o Sample Analysis Request Forms
- o PARCC Objectives Summary Forms
- o QA/QC Report Forms for Laboratory
- o Equipment Calibration Report Forms
- o Standard Field and Laboratory Log Forms

7.4 QUALITY ASSURANCE FOR THE EXISTING DATA BASE

An important element of the WSSRAP is the validation of the large amount of data that has been collected on site at WSSRAP. The specifics of data evaluation and validation are discussed in the individual associated sampling plans listed in Section 1.0. A conceptual framework for evaluation of existing data is presented in this subsection.

Data from previous sampling and analysis programs which were used in the development of the five sampling plans were considered to fall into one of the following categories:

- o Data that are not useful
- o Data that are adequate for a qualitative assessment of contamination (i.e. contaminated or not contaminated)
- o Data that are adequate for semi-quantitative comparisons (i.e. order of magnitude)
- o Good quantitative data not meeting all QA objective requirements (but generally valid)
- o Data meeting all QA requirements

For qualitative development of the sampling plans, the following steps have been taken:

1. Determine what QA/QC documentation was available for a sampling/analysis program and obtain the documentation.

2. Evaluate QA objectives and QA/QC results of existing

Internal quality control at the laboratory also includes the utilization of matrix spikes, including EPA quality control ampules, Standard Reference Materials (SRMs) and laboratory-prepared solutions made from pure compounds.

The selected laboratory at WSS participates in EPA's Quality Control Program and utilizes those standards and guidelines prescribed by EPA for analyzing relevant chemical and radiological constituents.

The Users Guide to the Contract Laboratory Program (EPA, 1986b) presents analytical internal quality control operations which are applied at the WSS. They include:

- Inductively Coupled Argon Plasma (ICP) Interference Check Sample Analyses: Performed at least twice per eight-hour shift, to verify inter-element and background correction factors.

- Preparation Blank Analyses: Performed for each batch of samples or for each set of 20 samples, to ascertain whether sample concentrations reflect contamination.

- Spiked Sample Analyses and Duplicate Sample Analyses: Performed for each concentration and matrix within each set of 20 samples of a similar matrix, to provide information concerning sample homogeneity, analytical precision and accuracy, the effect of the sample matrix on the analytical methodology, and to allow for evaluation of the long-term precision of the method.

- Serial Dilution Analyses: Performed for each group of samples of a similar matrix type and concentration for each 20 samples received to ascertain whether significant chemical or physical interferences exist due to sample matrix.

8.0 INTERNAL QUALITY CONTROL

To achieve the highest practical attainable level of precision and accuracy, the sampling program at WSS includes the use of QC samples to measure field and laboratory performance. (Section 4.0 of this document discusses QA objectives for measurement.) QC samples are submitted to the laboratory as blind samples. To provide quality control information for interpretation of data, the following types of QC samples may be utilized:

- Background Samples: These samples are obtained from media characteristic of the site but outside of the zone of contamination; e.g. groundwater samples collected from the upper Burlington-Keokuk aquifer upgradient of the WSCP areas.

- Duplicate or Replicate Samples: These samples are collected at the same time from common collection manifolds, locations, or sampling devices, or as split samples from one sampling event, and sent to the same laboratory to verify sampling and laboratory precision. Generally, one out of every 20 investigative samples is replicated.

- Split Samples: Split or replicate samples, divided into two portions, are sent to different laboratories to assess laboratory precision.

- Field Blanks: Analyte-free deionized water is used to rinse sampling equipment that has been decontaminated, e.g. bailers, pumps, augers, split tube samplers, etc. One rinsate sample is collected per day or for every 20 investigative samples, whichever is greater. Upon analysis, these samples are used to assess the adequacy of the field decontamination process.

- Furnace Atomic Absorption QC Analysis: Required for quantification; incorporates duplicate injections and analytical spikes in order to evaluate the precision and accuracy of the individual analytical determinations on each sample.

- Laboratory Control Samples (LCS): Standards carried through sample preparation and analysis procedures to document the performance of the entire analytical process. The results for analysis of LCS are submitted with the data package. Laboratories on a quarterly basis verify their instrument detection limits, ICP linear ranges, ICP inter-element correction factors and ICP integration times.

It is the responsibility of the laboratory to document, in each data package submitted, that both initial and ongoing instrument and analytical QC requirements have been met. Any samples that have not been analyzed according to contract QC requirements are re-analyzed by the laboratory.

9.0 AUDITS AND CORRECTIVE ACTIONS

Quality assurance objectives for the Weldon Spring Site Remedial Action Project (WSSRAP) will be met in part by audits of field sampling and laboratory analysis activities. All existing and future data developed for the site will be evaluated to determine its validity and completeness. To accomplish this evaluation, audits will be conducted to insure that data of known and acceptable quality are provided. The goals or objectives of the Weldon Spring Site Characterization QA/QC audit program are to ensure that:

- Program-specific QA/QC training is provided to personnel and that QA/QC requirements are clearly established.

- Data quality meets specified goals in terms of precision, accuracy, representativeness, completeness, and comparability (PARCC) for all environmentally related measurement criteria.

- All sampling and analytical efforts are described by an approved sampling plan (listed in Section 1.0).

- Standard operating procedures are developed for each measurement activity, that qualified personnel are assigned to perform these activities in accordance with the procedures, and that proper documentation is performed in order to establish data validity.

- Audits are performed to determine compliance with the established QA/QC requirements.

- Corrective actions are proposed and implemented to address deficiencies identified during audits.

This section describes the performance, reporting and

documentation phases of the audit portion of the WSSRAP QAPP.

9.1 AUDITS-GENERAL

An audit system shall be implemented to assure compliance with the QA/QC program requirements established for the WSSRAP in the approved Project Quality Assurance Program Plan dated 02/03/87. This mechanism is intended to assess systems and procedure effectiveness. Audits will:

- Identify weaknesses and strengths.
- Dictate corrective actions as required.
- Allow for modifications and enhancement of the QA/QC program.
- Serve as a vehicle for providing necessary technical assistance.
- Measure the effectiveness of the QA/QC programs to assure quality of data.

The types of audits to be conducted during the course of actions for the WSSRAP will include performance and systems audits. These audits will be performed both internal and external to the Project Management Contractor (PMC).

System(s) audits consist of an evaluation of all components of the measurement system to determine their capability, proper selection and use. A systems audit includes a careful evaluation of field and/or laboratory quality assurance/quality control programs. Systems audits are normally performed prior to or shortly after systems are operational; however, such audits will be performed on a regularly scheduled basis for the duration of the WSSRAP.

Performance audits are conducted to determine the adequacy and accuracy of a total measurement system or on selected elements

of field or laboratory Quality Assurance/Quality Control programs to determine procedural compliance, thereby ensuring Data Quality Objectives. Performance audits are conducted periodically on a scheduled basis, generally after a system is operational and generating data.

Audits will be scheduled in intervals consistent with the schedule for accomplishing the activity and commensurate with the status and importance of the activity.

Audits shall be performed in accordance with written procedures or checklists based upon the QA/QC programs and the project's procedures manuals and conducted by appropriately trained personnel not having direct responsibilities in the areas being audited.

Audit results shall be documented by auditing personnel and reviewed by management having responsibility in the area audited.

Audits shall be performed under the direction of a certified Lead Auditor who is assisted by certified auditors and/or appropriately trained technical specialists as required to audit all components of the WSSRAP QA/QC programs.

9.2 AUDIT PREPARATION

The Lead Auditor is responsible for preparing and maintaining an audit schedule, reviewing and documenting the qualifications on all audit personnel including technical specialists, providing notification to the audited organizations, preparing and/or approving audit plans and checklists.

The Lead Auditor, after a review of applicable requirements, such as procedures, contracts, plans, standards and project schedules, prepares an audit schedule indicating the organization to be audited, subjects to be audited, schedule of

the audits and proposed Lead Auditor. The audit schedule shall be reviewed periodically and revised as necessary to assure that coverage is kept current. In advance of the scheduled audit the Lead Auditor will notify the organization to be audited of the proposed schedule and scope of the audit.

The Lead Auditor selects the audit team members including auditors, technical specialists and observers as required to best perform a comprehensive audit of the selected systems or components to be audited. The Lead Auditor will document the qualifications of audit team members selected.

The Lead Auditor is responsible for preparation of a written audit plan, when requested by the Project Quality Manager (PQM). The audit plan includes:

- Audit number
- Organization to be audited
- Subject(s) to be audited
- Scope of the audit
- Projects or activities to be audited
- Audit team members
- Audit schedule
- Applicable documents

The audit plan can be used to provide the audited organization(s) management with the proposed audit scope, audit requirements, audit personnel and the schedule for the audit.

The audit team will prepare audit checklists based on their review of applicable or relevant and appropriate requirements; documents including procedures, standards, contracts, and plans; and previous audits, if any, of the systems or tasks to be audited. The Lead Auditor is responsible for review and approval of the audit checklists. These checklists will be used to evaluate the performance of the audited activity.

The Lead Auditor provides the audit team with the audit plan and checklists, orients the team to the schedule for the audit and the internal and external organization and contractual interfaces and responsibilities of the organization to be audited.

9.3 AUDIT PERFORMANCE

The Lead Auditor conducts a pre-audit meeting at the audit site with the audit team and responsible management of the organization to be audited. The pre-audit meeting provides a means to introduce the audit team, establish contacts and interfaces, present and confirm the audit plan, scope and sequence, and schedule the post-audit meeting.

The audit will be conducted following the approved audit checklist as a guideline. The Lead Auditor may assign portions of the audit or checklist to members of the audit team commensurate with their expertise. The audit checklists are a guideline; responsible questioning or investigation may lead the audit into areas not described in the audit plan or by the audit checklist.

Audits shall include the objective examination of work areas, activities, processes and items; review of documents and records; and quality-related practices, procedures and instructions to determine compliance with the QA/QC program requirements and the project procedures manual. The audit checklists will be used by the auditors to record the results of their investigations.

Discrepancies or concerns discovered during the course of the audit by the audit team members will be presented to the Lead Auditor for review and discussion prior to formalizing. Audit discrepancies may be characterized as follows:

1) An observation is the recognition of an activity or action that might be improved but is not a significant violation of a specific requirement. Discrepancies that are corrected during the course of the audit may be addressed as observations. Isolated violations may be determined to be observations rather than findings.

2) A finding is the recognition of a specific requirement that has been significantly violated.

A post-audit meeting chaired by the Lead Auditor will be conducted at the conclusion of the audit. The objective of the post-audit meeting is to present the findings and observations to the responsible management of the audited organization. Resolution of findings and observations and commitments for corrective actions including a tentative schedule for completion of corrective actions should be discussed at this time.

9.4 AUDIT REPORTING

Audit reports will be submitted to responsible management by the PQM, or Lead Auditor. These reports will address the performance of measurement systems and data quality. Audit reports will include the dates of audit, audit procedures, names of auditors and audited organization participants, specific procedures audited, a summary of audit results including findings and observations (if any), recommendations for correcting deficiencies or improving the QA/QC programs, if necessary.

Audit findings are recorded on an Internal Quality Audit Finding Report Form and are included as part of the audit report.

Audit reports shall be issued promptly upon completion of the audit (within 30 days), and will contain the date required for response to audit findings. Audit findings require response

from the audited organization within 30 days of receipt. Audit finding responses should include a commitment date for completion of corrective actions to be taken, results of a review for potential impact on previous items or activities (if any) and the root cause of the deficiency.

Observations may or may not require a formal response depending upon the severity, type and number or specific deficiencies. The Lead Auditor will specify which of the observations require written response. Observations are recorded in the body of the audit report.

Completion of corrective actions noted in audit responses shall be verified upon receipt of the response or by the date specified on the response.

9.5 SURVEILLANCE

In addition to regularly scheduled audits, the QA Department shall perform surveillance of field or laboratory activities. Surveillance is the act of monitoring or observing to verify whether an item or activity conforms to specified requirements.

Surveillances may be planned or unplanned, scheduled or unscheduled. No checklist is required, rather the approved procedure for the operation or task will be followed to ensure adherence to the requirements. Surveillances will be documented by the individual performing the surveillance, and reviewed by the Lead Auditor.

When deficiencies are noted, the responsible department shall be notified by use of the Quality Deficiency Report (QDR).

Response to the QDR must be returned to the QA Department by the responsible department manager and appropriate follow-up actions must be prescribed at that time.

9.6 FINDING/DEFICIENCY CORRECTIVE ACTION AND CLOSURE

The Lead Auditor is responsible for the evaluation of corrective action responses to determine that the corrective action for each finding/deficiency is adequate, has been scheduled or has been completed. The Lead Auditor will ensure that responses to findings written by other audit team members such as technical specialists fully address the discrepancy identified during the course of the audit.

Follow-up may be accomplished through written communication, re-audit, surveillance or other appropriate means. Unsatisfactory responses will be addressed in writing, indicating why the response is unsatisfactory, and will specify a reply due date. Findings/deficiencies are considered open until the approved corrective action has been completed. The Lead Auditor is responsible for closing all findings/deficiencies.

9.7 QA RECORDS

All audit plans, correspondence relating to audits/surveillance, audit findings, audit reports, individual certifications, Quality Deficiency Reports and surveillance reports will be routed to Document Control for processing in accordance with Section 6 of this document.

10.0 PREVENTIVE MAINTENANCE

The preventive maintenance program at WSSRAP includes numerous tasks to prevent or minimize downtime of field sampling and laboratory analytical equipment. These measures are documented in Appendices A & B.

Operational checks and calibration procedures are prescribed in these appendices -- for example, Alpha Detector (SOP No. 2.06.01)-- and instruction manuals are referenced to show maintenance procedures. Duplicate instruments and spare parts are stocked for critical instruments in order that sampling and measurement operations can continue without delays and in an orderly manner.

Preventive and regular maintenance will be provided by trained, qualified specialists only. If feasible, maintenance responsibilities will be delegated to one or two individuals who will also bear the responsibilities of assuring proper documentation of equipment users, dates of use, maintenance and calibration, and inventory identification numbers. Preventive maintenance will be performed on a regular scheduled basis and in accordance with manufacturers' manuals and applicable SOPs.

In order to fulfill PARCC requirements, stand-by or duplicate laboratory or sampling equipment may be required.

QUALITY ASSURANCE PROGRAM PLAN
RESPONSIVENESS SUMMARY

EPA April 6, 1988

RESPONSE TO GENERAL COMMENTS: General comments are addressed in the cover letter and in the specific responses as follows:

Comment:

1. Section 3.0 - It is not made clear what role, if any, the DOE has regarding oversight of the contractor.

Response:

The responsibility for management and technical direction of remedial actions has been delegated to the DOE Oak Ridge Operation Office. MK-Ferguson (MK-F) is the project management contractor (PMC) assisting DOE in the planning and management of remedial action activities.

An organization chart is included in Section 3.0 of the RIQAPP (Rev. 0) which delineates lines of authority, responsibility and communication assigned to key project entities.

Comment:

2. Section 6.0 - It might be appropriate to establish frequency of collection of different types of QC samples used for assessing precision and accuracy in particular.

Response:

Sections 4.0 and 8.0 of the RIQAPP (Rev. 0) summarize methods for ensuring accuracy and precision. Details are presented in the Standard Operating Procedures (SOPs) and sampling plans previously published and incorporated by reference as associated documents to the RIQAPP.

Comment:

3. Section 6.3 - We feel that, on page 105, Item 6.3, or some other appropriate location, reference should be made to a needed requirement that all laboratory data should come from laboratories that participate in EPA or other quality control programs. For example, EPA operates, out of the Las Vegas Laboratory, a Radiation Quality Control Program which about 195 laboratories utilize. We feel that any lab producing quality radiation data should participate in this program, or,

an equivalent, alternate program. The EPA, from Cincinnati, offers similar programs for many other analyses.

Response:

metaTRACE Laboratory, JTC Environmental Consultants, ACCULABS Research Inc., and other WSS selected laboratories participate in EPA's Quality Control Program and utilize those standards including CLP procedures and guidelines prescribed by EPA for analyzing relevant chemical and radiological constituents. Internal quality control, as described in Section 8.0 of the RIQAPP (Rev. 0), prescribes the utilization of EPA quality control ampules, Standard Reference Materials, and pure laboratory-prepared solutions.

Comment:

4. Section 6.4 - It is not made clear in the text what level of completeness needs to be attained for the data to be valid.

Response:

The amount of valid data required to meet data goals is determined by specialists and task leaders, e.g., engineers, hydrogeologists, and geologists. The ultimate responsibility for determination of data completeness, i.e. amount of valid data obtained compared to amount of valid data needed, rests with the project director. Sampling plans delineate specific data needs, uses, and goals.

Comment:

5. Section 6.5.1 - The discussion of standard operating procedures for sampling is not consistent with the Raffinate Pit Sampling Plan.

Response:

The Raffinate Pit Sampling Plan and this section of the RIQAPP have been revised.

Comment:

6. Section 6.5.3 - The text is unclear on what points need to be considered in evaluating the representativeness of the data.

Response:

This section has been expanded and is included in Section 4.1.3 of the RIQAPP (Rev. 0).

Comment:

7. Section 7.0 - SOPs for each field operational procedure are not explained in detail in the Raffinate Pit Sampling Plan as this section prescribes.

Response:

This section has been deleted.

Refer to Table 1.1 of the RIQAPP (Rev. 0) for associated documents which provide information on sampling, calibration and analytical procedures.

Comment:

8. Section 8.0 - The text does not state who will perform all the calculations specified. Clarify who will perform the calculations (contractor, laboratory, etc.) and how the calculations will be checked and audited. If the laboratory is to perform the calculations, is this part of their standard QA/QC package?

Response:

Section 8.0 has been revised to present a synopsis of the data reduction validation and reporting process (see Section 7.0 of the revised document). Section 1.0 (Table 1.1) of the RIQAPP (Rev. 0) references documents that prescribe procedures for this QA element. The role of the laboratory is presented in Analytical Methods/Detection Limits, an associated document to the RIQAPP. The Laboratory QA/QC Manual is presented in this document.

Comment:

9. Section 8.0 - It was not clear how new data will be evaluated and reported in terms of quality.

Response:

EPA Document EPA 540/G-87/003, entitled "Data Quality Objectives for Remedial Response Activities" provides guidance for collection and evaluating the quality of data which are needed to support decisions to be made by DOE during remedial response activities. The three-stage program presented in this guidance document

is described in Section 2.3 of the RIQAPP (Rev. 0). The RI/FS-EIS Work Plan and sampling plans provide rationale and describe the data evaluation process.

Comment:

10. Section 8.5 - Why is a discussion of data quality audits provided in this section and not in Section 9.1.

Response:

This discussion has been deleted. Section 4.0 of the RIQAPP (Rev. 0) describes Quality Assurance Objectives for Measurement. Section 9.0 addresses the audits and corrective actions.

Comment:

11. Section 8.2 - The last sentence in Section 8.2 appears to be in error. In environmental monitoring, sampling error is considered to have a greater impact on variability of data than laboratory analyses.

Response:

This sentence has been deleted.

Comment:

12. Section 9.0 - It was not clear who would perform or how often audits would be performed. Mention is made of QA/QC plans on page 137, but it is unclear what these are.

15. Section 9.1 - The text is unclear on the number and type of audits that are included.

16. Section 9.1 - Field audits do not seem to include the checking of field procedures. Will this be done? Is it a separate audit?

Response to Comments 12, 15, 16:

Section 9.0 has undergone extensive revision to address concerns expressed in the above comments.

Comment:

13. Section 9.0 and Table 9-1 - QA/QC training does not include: 1) SOPs for sampling, 2) SOPs for field activities and 3) documentation of field activities.

14. Section 9.0 and Table 9-1 - It is unclear what specific items are included under 6.0 Inspection and Testing.

Response to Comments 13 and 14:

SOP training is a routine part of the WSSRAP. All employees are required to read SOPs they will implement. The employee then discusses any questions regarding specific SOPs with his supervisor. The employee then performs the SOP with oversight of a staff person familiar with the SOP. This training is documented by a sign-off form specific to the pertinent SOP being performed.

Inspection and testing is addressed in the SOPs and is in accordance with NQA-1 (ANSI, 1986). The relationship between the overall WSSRAP QA/QC program and the revised QAPP is addressed in Section 1.0.

Specific Comments:

1. In order to make Figure 2-6 (p. 30) consistent with the text (p. 32) I suggest using "pCi/l" in the title of the figure.

2. The 2nd paragraph on p. 35 refers to DOE guidelines for uncontrolled areas, but does not state what these guidelines are (see general comment 3 above).

   Special Studies in Support of Feasibility Studies (Section 4.2) should consider the following items to determine compliance with requirements of the Missouri Air Pollution Control Program within MDNR:

   - Asbestos removal from buildings and pipes,

   - Permits may be required if the remedial action is to take longer than two years or if the potential annual emissions of any criteria pollutant exceeds 100 tons,

   - Special non-attainment area regulations for volatile organic compounds apply to facilities in St. Charles County,

   - Controls for noncriteria pollutants are expected to be promulgated by the end of 1988. This may be important for the Weldon Spring project when considering the potential for radiologically contaminated airborne particles and radon-222, especially during remedial activities.

Response:

See Response to General Comments 1, 2 and 3.

Comment:

4. The list of data users (p. 99) should include the Missouri Department of Health and the Agency for Toxic Substances and Disease Registry.

Response:

Names of these data users have been added to the RIQAPP (Rev. 0).

MISSOURI DEPARTMENT OF NATURAL RESOURCES (MoDNR)

March 21, 1988

MoDNR General Comments on the QAPP.

As discussed in our meeting of March 17, 1988, the MDNR concurs that information presented in pages 1-91 more properly belongs in the Remedial Investigation/Feasibility Study (RI/FS) Work Plan.

However, in order to facilitate preparation of the RI/FS Work Plan I offer the following comments:

1. The title should indicate whether this document applies to the entire project or only the Chemical Plan/Raffinate Pit area. Section 2.4 is ambivalent since 2.4.1 includes a discussion of the Quarry while 2.4.2 does not.

2. The QAPP contains a useful presentation of characterization data. However, the data would be more useful if presented in a clearer graphic form. For example, when presenting data showing the area of contamination, I suggest using maps with isopleth showing contaminant levels.

3. The meaning of the data could better be illustrated by including an isopleth for background levels. If clean-up levels have been established then another isopleth could be included showing the clean-up levels, thereby clearly indicating the area where remedial action is needed. If this information is not available at the time the RI/FS Work Plan is prepared it can be added in the RI/FS report.

4. Will the basis for and levels of clean-up standards be included in the RI/FS Work Plan?

Response to General Comments 1, 2, and 3:

Sections 1.0, 2.0 and 4.0 (pages 1-54 and 63-91) have been revised and included in the RI/FS-EIS Work Plan. Isopleth maps will be prepared and submitted with the RI report. Background levels will be addressed in the ARAR section of this report.

Response to General Comment 4:

Applicable Relevant and Appropriate Requirements (ARARs) have been identified on a preliminary basis in the RI/FS-EIS Work Plan. As additional information becomes available, ARARs used to identify clean-up goals will be presented at the completion of the RI Phase.

Dear Ms. Biggs:

QUALITY ASSURANCE PROGRAM PLAN (QAPP) AND RAFFINATE PIT SAMPLING PLANS

Our February 25, 1988 letter transmitted copies of the Quality Assurance Program Plan (QAPP) and the Raffinate Pit Sampling Plan for your review.

In accordance with prior agreements that these types of plans be reviewed within three (3) weeks, we are requesting your comments by March 21, 1988.

Sincerely,

for Stephen H. McCracken
Deputy Project Manager
Weldon Spring Site
Remedial Action Project

Kansas City, KS 66101

Dear Ms. Biggs:

This letter contains the comments of the Missouri Department of Natural Resources (MDNR) on the draft "Quality Assurance Program Plan" (QAPP), February 1988, prepared by the U.S. Department of Energy (DOE) for the Weldon Spring Site Remedial Action Project (WSSRAP). It also contains comments on DOE's draft "Waste Assessment Raffinate Pit Sampling Plan", February 1988.

General Comments on the QAPP

As discussed in our meeting of March 17, 1988, the MDNR concurs that information presented in pages 1-91 more properly belongs in the Remedial Investigation/Feasibility Study (RI/FS) Work Plan.

However, in order to facilitate preparation of the RI/FS Work Plan I offer the following comments:

1. The title should indicate whether this document applies to the entire project or only the Chemical Plan/Raffinate Pit area. Section 2.4 is ambivalent since 2.4.1 includes a discussion of the Quarry while 2.4.2 does not.

2. The QAPP contains a useful presentation of characterization data. However, the data would be more useful if presented in a clearer graphic form. For example, when presenting data showing the area of contamination, I suggest using maps with isopleth showing contaminant levels.

RECEIVED
MAR 22 1988
EIS/404 BRANCH

RECEIVED
MAR 22 1988
EIS/404 BRANCH

3. The meaning of the data could better be illustrated by including an isopleth for background levels. If clean-up levels have been established then another isopleth could be included showing the clean-up levels, thereby clearly indicating the area where remedial action is needed. If this information is not available at the time the RI/FS Work Plan is prepared it can be added in the RI/FS report.

4. Will the basis for and levels of clean-up standards be included in the RI/FS Work Plan?

Specific Comments on the QAPP

1. In order to make figure 2-6 (p.30) consistent with the text (p. 32) I suggest using "pCi/l" in the title of the figure.

2. The 2nd paragraph on p. 35 refers to DOE guidelines for uncontrolled areas, but does not state what these guidelines are. (see general comment 3 above)

3. Special Studies in Support of Feasibility Studies (Section 4.2) should consider the following items to determine compliance with requirements of the Missouri Air Pollution Control Program within MDNR:

- Asbestos removal from buildings and pipes,

- Permits may be required if the remedial action is to take longer than two years or if the potential annual emissions if any criteria pollutant exceeds 100 tons,

- Special non-attainment area regulations for volatile organic compounds apply to facilities in St. Charles County,

- Controls for noncriteria pollutants are expected to be promulgated by the end of 1988. This may be important for the Weldon Spring project when considering the potential for radiologically contaminated airborne particles and radon-222, especially during remedial activities.

4. The list of data users (p. 99) should include the Missouri Department of Health and the Agency for Toxic Substances and Disease Registry.

General Comments on the Waste Assessment Raffinate Pit Sampling Plan

1. General comments 2 and 3 on the QAPP (above) are also relevant to this plan. Graphic presentation of contaminant levels, background levels and clean-up levels would be helpful.

2. More specific labelling of figures would be helpful, for example, figure 1.4 should indicate that this was a sampling effort by BNI in 1986.

Specific Comments on the Waste Assessment Raffinate Pit Sampling Plan

Because of potential air pollution control considerations, the plan should consider sampling for appropriate volatile and Semi-volatile chemicals. The median vapor pressure of the organic fraction would also be helpful in emission rate calculations.

Since several concerns related to air pollution control have been mentioned, I suggest contacting Mr. Doug Baker of the Air Pollution Control Program at (314) 751-4817, for further information.

Thank you for this opportunity to comment on these draft documents. Please call me at (314) 751-4533 or 4758, if you have any questions regarding this letter.

Sincerely,

DIVISION OF ENVIRONMENTAL QUALITY

Weldon Spring Site Remedial
Action Project
Route 2, Highway 94, South
St. Charles, Missouri 63303

Dear Mr. Nelson:

We have reviewed the draft Quality Assurance Program Plan (QAPP) and draft Raffinate Pit Sampling Plan. Many of our comments which follow were discussed at our meeting of March 17, 1988.

Although it is called a program plan, the QAPP basically has the elements of a project plan. However, we have no problem with using that title as long as the contents of the document are appropriate. As was discussed in our March 17 meeting, most of the information in the first 90 pages of the QAPP more appropriately belongs in the Remedial Investigation/Feasibility Study (RI/FS) work plan. The purpose of a QAPP is to provide guidelines for ensuring the quality of work conducted in a RI/FS. The QAPP should present and describe the organization, responsible personnel (including duties and responsibilities related to quality), requirements for planning document contents (i.e., sampling plan rationale, sampling procedures, sample locations, decontamination procedures, blanks, duplicates, etc.), auditing program (field and lab), reports to management and corrective action scheme.

In this case, most of these elements have been included in the QAPP; however, it is not made clear as to how each element relates to one another. The audit system is well described, but the specific responsibilities of each individual involved are not spelled out. This specific observation is representative of the entire plan. Many individual components are described, but understanding how each of the components impact one another is difficult.

In general, we suggest that the Raffinate Pit Sampling Plan provide a greater level of detail in Section 2.0, Sampling. This section should be expanded to include specific sampling locations identified by number, a table showing depth intervals and

JUL42E
4-8-88

sampling locations, and a table showing analytical parameters with the depth intervals. This is necessary since one of the primary purposes of a sampling plan is to act as a field guide for the sampling program.

Specific comments on the QAPP and Raffinate Pit Sampling Plan are enclosed. Also enclosed is a copy of the comment letter prepared by the Missouri Department of Natural Resources. Thank you for the opportunity to comment on these documents. Please call me if you have any questions.

Sincerely yours,

Katie

B. Katherine Biggs
Chief, Environmental Review Branch

Enclosure

cc: Dave Bedan, MDNR (w/enclosure)

Comments on the Quality Assurance Program Plan
Weldon Spring Site

1. Section 3.0 - It is not made clear what role, if any, the DOE has regarding oversight of the contractor.

2. Section 6.0 - It might be appropriate to establish frequency of collection of different types of QC samples used for assessing precision and accuracy in particular.

3. Section 6.3 - We feel that, on page 105, Item 6.3, or some other appropriate location, reference should be made to a needed requirement that all laboratory data should come from laboratories that participate in EPA or other quality control programs. For example, EPA operates, out of the Las Vegas Laboratory, a Radiation Quality Control Program which about 195 laboratories utilize. We feel that any lab producing quality radiation data should participate in this program or, an equivalent, alternate program. The EPA, from Cincinnati, offers similar programs for many other analyses.

4. Section 6.4 - It is not made clear in the text what level of completeness needs to be attained for the data to be valid.

5. Section 6.5.1 - The discussion of standard operating procedures for sampling is not consistent with the Raffinate Pit Sampling Plan.

6. Section 6.5.3 - The text is unclear on what points need to be considered in evaluating the representativeness of the data.

7. Section 7.0 - SOPs for each field operational procedure are not explained in detail in the Raffinate Pit Sampling Plan as this section prescribes.

8. Section 8.0 - The text does not state who will perform all the calculations specified. Clarify who will perform the calculations (contractor, laboratory, etc.) and how the calculations will be checked and audited. If the laboratory is to perform the calculations, is this part of their standard QA/QC package?

9. Section 8.0 - It was not clear how new data will be evaluated and reported in terms of quality.

10. Section 8.5 - Why is a discussion of data quality audits provided in this section and not in Section 9.1.

11. Section 8.2 - The last sentence in Section 8.2 appears to be in error. In environmental monitoring, sampling error is considered to have a greater impact on variability of data than laboratory analyses.

12. Section 9.0 - It was not clear who would perform or how often audits would be performed. Mention is made of QA/QC plans on page 137, but it is unclear what these are.

13. Section 9.0 and Table 9-1 - QA/QC training does not include: 1) SOPs for sampling, 2) SOPs for field activities and 3) documentation of field activities.

14. Section 9.0 and Table 9-1 - It is unclear what specific items are included under 6.0 Inspection and Testing.

15. Section 9.1 - The text is unclear on the number and type of audits that are included.

16. Section 9.1 - Field audits do not seem to include the checking of field procedures. Will this be done? Is it a separate audit?

ABSTRACT

The Environmental Quality Assurance Project Plan (EQAPjP) in addition to the WSSRAP Quality Assurance Program has been written to fulfill DOE Order 5700.6C requirements under the Federal Facilities Agreement between the DOE and the EPA for the Weldon Spring site. The EQAPjP addresses the 16 quality assurance elements for environmentally related measurements by the EPA QAMS 005/80 (1980) and is intended to be utilized by personnel conducting routine environmental monitoring and remedial investigation/feasibility studies (RI/FS) at the Weldon Spring site.

The primary purpose of this document is to specify Quality Assurance requirements for assessing environmental activities at the Weldon Spring site and to support the WSSRAP Quality Assurance Program as required by the DOE.

MK-FERGUSON COMPANY
STATEMENT OF POLICY

MK-Ferguson Company, a division of Morrison Knudsen Corporation, is the Project Management Contractor (PMC) for the U.S. Department of Energy (DOE) at the Weldon Spring Site Remedial Action Project (WSSRAP). The goal of the PMC is to perform all work activities in such manner that the required quality is attained or exceeded. The PMC's policy is for senior management to provide planning, organization, direction, control, and support to achieve the organization's objectives; for the line organizational units to achieve quality; and for overall performance to be reviewed and evaluated using a rigorous assessment process (DOE 5700.6C, Sec.8).

To obtain these quality assurance (QA) objectives, the PMC has developed the formal *Environmental Quality Assurance Project Plan* (EQAPjP) described in this manual. The plan is tailored for the remediation of the Weldon Spring site Chemical Plant and quarry and to meet the requirements of DOE Order 5700.6C and the guidance set forth in the QA Requirements and Description (QARD) produced by the DOE Office of Environmental Restoration and Waste Management. The EQAPjP is subordinate to the Quality Assurance Program (QAP) and expands on specific EPA/QAMS-005/80 requirements.

As Project Director, I am committed to the implementation of the WSSRAP PMC QAP. I have assigned to senior managers the responsibility and authority to implement, assess, and improve the program in their respective areas of control.

The corporate Quality Assurance/Quality Control manager has delegated to the Project Quality Manager the authority for developing and maintaining the WSSRAP PMC QAP and for ensuring its effective implementation.

Compliance with the requirements of the WSSRAP PMC QAP is mandatory for all PMC personnel, and Subcontractors are required to comply with all sections that apply to their activities.

Project Director

Deputy Project Director

Deputy Project Director

Deputy Project Director

1 INTRODUCTION

The Weldon Spring Site Remedial Action Project (WSSRAP) Quality Assurance Plan (QAP) (including subsequent remedial action activities) is written to meet the quality assurance program requirements of DOE Order 5700.6C. This *Environmental Quality Assurance Project Plan* (EQAPjP) is focused only on the U.S. Environmental Protection Agency (EPA) requirements under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA). This document replaces the existing *Environmental Quality Project Plan* that addresses the remedial investigation activities for the Weldon Spring Quarry. It meets the applicable requirements of EPA QAMS 005/80, *Interim Guidelines and Specifications for the Preparation of Quality Assurance Project Plans* (EPA 1980). The primary purpose of this document is to specify QA requirements for assessing the amount and extent of hazardous materials present on site and to support the WSSRAP Quality Assurance Program as required by the DOE.

The QAP and the EQAPjP support quality affecting activities and implement environmental activities at the WSSRAP. The EQAPjP is supported by WSSRAP Standard Operating Procedures (SOPs), Administrative Procedures, the WSSRAP Health and Safety Program, and work plans written for specific environmental tasks.

Quality assurance for the environmental program detailed in this document and within the associated work plans is intended to be utilized by personnel conducting routine environmental monitoring and remedial investigation/feasibility studies (RI/FS) at the Weldon Spring site. Specific quality control procedures are detailed in WSSRAP SOPs and in specific remedial investigation and monitoring sampling plans. This program fulfills DOE requirements under the Federal Facilities Agreement between the DOE and the EPA for the Weldon Spring site.

The Quality Assurance Program and the EQAPjP address the 16 quality assurance elements (see Table 1.1) specified for environmentally related measurements by EPA QAMS 005/80 (1980).

2 PROJECT DESCRIPTION

2.1 Physical Setting

The Weldon Spring site is located in St. Charles County, Missouri, approximately 30 mi west of St. Louis. The site consists of an abandoned limestone quarry, a raffinate disposal area (raffinate pits), a former chemical plant, and various vicinity properties that are contaminated as a result of past U.S. Department of the Army (DA) and U.S. Atomic Energy Commission (AEC) activities at the site. During World War II, explosives were manufactured at the Chemical Plant. After the war, the plant was used to process uranium.

The contaminated soil, equipment, and buildings remaining on the Chemical Plant site require cleanup to meet current U.S. Department of Energy (DOE) guidelines for unrestricted use. The raffinate pits contain uranium and thorium residues. In addition, soil underlying the pits is probably contaminated and will require remedial action.

During the period from 1943 to 1957, the DA utilized the quarry, which is about 4 mi from the site, for disposal of rubble and soils contaminated with trinitrotoluene (TNT) and dinitrotoluene (DNT). The AEC also later disposed of building rubble and soils contaminated with thorium, uranium, and their decay products in the quarry.

A detailed project description including site history, environmental setting, and a summary of the known and suspected nature and extent of existing contamination is presented in the *The Feasibility Study for Remedial Action at the Chemical Plant Area of the Weldon Spring Site* (DOE 1992) and the *Feasibility Study/Environmental Assessment for the Weldon Spring Quarry Bulk Waste Remedial Action* (ANL 1990).

2.2 Project Objectives

Environmental monitoring and characterization sampling activities are being undertaken to define the nature, extent, and magnitude of contamination at the site and surrounding area, and to determine the potential impact of these hazardous substances on public health and the environment. In addition, the data will assist in the formulation of strategies to develop and implement appropriate Interim Remedial Actions (IRAs) prior to the selection of final remedial actions.

Feasibility studies are being undertaken to assess and develop types of remedial and/or removal actions that should be considered. These actions must mitigate threats to, and provide protection for, public health and welfare and the environment. Additionally, a Remedial Investigation/Feasibility Study-Environmental Impact Statement (RI/FS-EIS) report will be prepared that will address the technical and demographic issues and impacts associated with selecting viable and feasible remedial measures.

RI/FS activities are conducted by using the U.S. Environmental Protection Agency (EPA) Total Quality Management (TQM) phased approach, which implements the Data Quality Objective (DQO) process as detailed in Section 4.0.

2.3 Site Assessment

The National Contingency Plan (NCP) (40 CFR Part 300, Subpart F) sets forth the guidelines and requirements for assessment of a hazardous waste site (conducted under the Comprehensive Environmental Response, Compensation and Liability Act [CERCLA]) including response actions, preliminary site assessments and removal actions, site evaluation to determine whether the site should be included on the National Priorities List (NPL), and remedial actions. Included in the NCP are requirements and criteria for conducting investigations and feasibility studies.

Environmental sampling activities for site characterization require sampling plans that summarize the existing database and address the validity, sufficiency, and sensitivity of the data generated.

2.4 Hazardous Materials Handling

Hazardous waste, hazardous substances, and hazardous materials will be handled, stored, and shipped in accordance with the appropriate requirements of the EPA, the State of Missouri, U.S. Department of Transportation (DOT) requirements, DOE Orders, and Weldon Spring Site Remedial Action Project (WSSRAP) Compliance Procedures. Specific procedures and requirements for handling, shipping, and storage of hazardous waste and substances will be addressed in procedures and work plans approved by the WSSRAP Project Quality Manager.

3 PROJECT ORGANIZATION AND RESPONSIBILITIES

The U.S. Department of Energy (DOE) is responsible for conducting environmental monitoring and remedial actions at the Weldon Spring site that will place the site in a radiologically and chemically safe state in accordance with guidelines established by the DOE and the U.S. Environmental Protection Agency (EPA). The responsibility for management and technical direction of these environmental activities has been delegated to the DOE Oak Ridge Operations Office. MK-Ferguson is the Project Management Contractor (PMC) assisting the DOE in planning and managing remedial action activities. Headquartered in Cleveland, Ohio, MK-Ferguson is a wholly owned affiliate of Morrison Knudsen Corporation of Boise, Idaho. Joining MK-Ferguson as an integrated subcontractor is Jacobs Engineering Group, Inc. (JEG), headquartered in Pasadena, California. Project support is also provided by Argonne National Laboratories (ANL) in the development of environmental documents. ANL serves as an independent contractor reporting directly to the DOE.

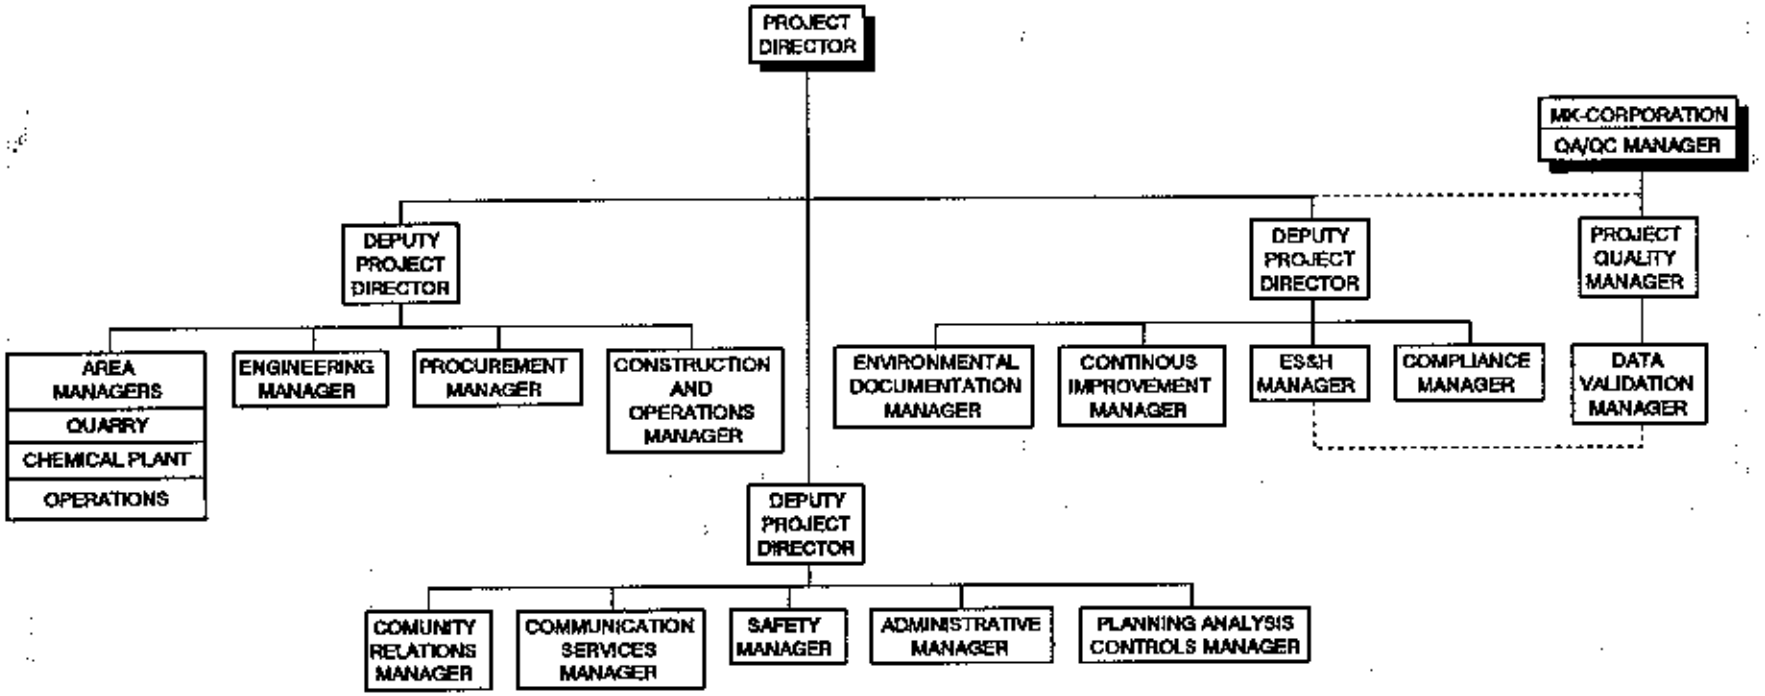
The *Remedial Investigation/Feasibility Study-Environmental Impact Statement (RI/FS-EIS) Work Plan for the Weldon Spring Site Remedial Action Project* (ANL 1988) describes the environmental compliance process and the role of the various organizations (including the PMC) under contract to the DOE for implementation of remedial activities at the Weldon Spring site.

The PMC is responsible for all on-site activities including routine monitoring and site characterization programs in accordance with EPA requirements and DOE guidelines and orders.

The Project Organization Chart, Figure 3-1, shows the lines of authority, responsibilities, and communications assigned to key project entities.

Listed below are the reporting responsibilities and duties of key PMC personnel.

The Project Director reports to the DOE and to MK-Ferguson corporate management. He is responsible for the overall management of the Weldon Spring Site Remedial Action Project (WSSRAP). The Project Director's responsibilities include completion of all contract requirements within the approved schedule and budget and in accordance with applicable codes, standards, specifications, and the WSSRAP Quality Assurance Program (QAP).



WSSRAP PROJECT
ORGANIZATIONAL CHART

FIGURE 3-1

REPORT NO.: DOE/OR/21548-352	EXHIBIT NO.: A/PI/085/0593	
ORIGINATOR: GJ	DRAWN BY: GLN	DATE: 8/9/93

The Deputy Project Directors report to the Project Director and are responsible for aiding him in accomplishing project management and administrative duties. The Deputy Directors are authorized to act for the Project Director when the latter is absent from the project office.

The Administrative Manager reports to a Deputy Project Director and is responsible for all administrative matters; i.e., time-keeping, payroll, industrial relations, property control, and all matters concerning finance.

The Project Procurement Manager reports to a Deputy Project Director and is responsible for all procurement activity including the issuing and administration of subcontracts. Additional responsibilities include evaluation and analysis of bids and warehouse functions.

The Community Relations Manager reports to a Deputy Project Director and is responsible for interfacing with public groups and government agencies, arranging public presentations, and all news media relations.

The Planning Analysis and Control Manager reports to a Deputy Project Director and is responsible for the overall project management control system which includes the development of budgets and schedules, preparation of management reports and submittals, and review and analysis of progress.

The Compliance Manager reports to a Deputy Project Director and is responsible for waste management activities and for ensuring regulatory compliance. He is also the Federal Facilities Agreement coordinator for the WSSRAP.

The Engineering Manager reports to a Deputy Project Director and is responsible for directing and coordinating on- and off-site design activities. He provides engineering support to remedial investigation/feasibility study (RI/FS), interim response action (IRA), conceptual design, and engineering evaluation/cost analysis (EE/CA) documents as well as site construction and remediation activities. He is also responsible for preparation, review, and approval of all WSSRAP engineering documents, including Title 1, 2, and 3 design drawings and construction specifications.

The Environmental Safety and Health (ES&H) Manager reports to a Deputy Project Director. The ES&H Manager is responsible for industrial hygiene, radiological protection and

environmental monitoring, radiological and chemical analysis interpretation and data verification, applied health physics, and all training required by these activities.

The Continuous Improvement Department Manager reports to a Deputy Project Director and is responsible for evaluating new DOE programs for implementation; coordinating and managing self-assessments, lessons learned, root cause analyses, and the Site Wide Audit Tracking System (SWATS); developing and maintaining document hierarchy; providing operational assessment for conduct of operations and conduct of maintenance programs; coordinating and managing independent assessments; coordinating and managing the Project Performance Indicator System; and trending and tracking SWATS reports.

The Construction Management and Operations (CM&O) Manager reports to a Deputy Project Director. The CM&O Manager is responsible for construction management and coordination of all subcontractors, constructability reviews, and resolution of field problems. The CM&O Manager is additionally responsible for all construction operations and maintenance functions including those regarding existing facilities, new facilities, utilities, and equipment.

The Project Quality Manager reports to the Project Director on an administrative basis. Authoritatively, the Quality Manager reports off site to the MK-Corporate QA Manager. The Quality Manager is responsible for development and implementation of the Quality Assurance Program. He has the authority to stop work or control further processing; identify the need for corrective actions; initiate, recommend, coordinate and/or provide solutions; and verify implementation of solutions and corrective actions related to the quality of the work.

The Environmental Documentation Manager reports to a Deputy Project Director and is responsible for preparation, review, control, and distribution of environmental documentation including the RI/FS.

The Data Validation/Verification Supervisor reports functionally to the ES&H Manager and administratively to the Project Quality Manager in order to ensure the independence necessary for this quality assurance function. The Data Validation Supervisor is responsible for evaluation and application of qualifiers to radiological and chemical data and provides technical assistance pertaining to laboratory analyses and procedures.

The Communication Services Manager reports to a Deputy Project Director. He manages the technical editing, word processing, document control, computer hardware and software support, project support, and visitor reception functions, as well as the Project Training and Improvement Program.

The Safety Manager reports to a Deputy Project Director, and is responsible for the Construction Safety Program. He promotes safety awareness and ensures that accidents are properly investigated and reported on, and that action is taken to prevent recurrence.

The Chemical Plant Manager reports to a Deputy Project Director and is responsible for all activities within the chemical plant area.

The Quarry Plant Manager reports to a Deputy Project Director and is responsible for all Quarry Bulk Waste Removal operations.

The Operations Manager reports to a Deputy Project Director and is responsible for activities associated with the water treatment plants and other administrative activities associated with labor and building construction.

4 QUALITY ASSURANCE OBJECTIVES FOR MEASUREMENT

The overall purpose of establishing quality assurance objectives for measurement data is to ensure that data of known and acceptable quality are provided for the intended uses. These objectives apply to both existing and future sampling and field measurement data. Data reviewed or generated by the Weldon Spring Site Remedial Action Project (WSSRAP) are to be of such quality that they can be used as direct indicators of the nature and extent of radiological and chemical contamination at the Weldon Spring site.

These objectives are achieved through the implementation of standard operating procedures for the following:

- Document control
- Field activities, including sample collection for routine monitoring and characterization
- Chain of custody
- Equipment calibration
- Laboratory analyses
- Data validation, verification, reduction, and reporting
- Internal quality control checks
- Audits and surveillances
- Preventive maintenance
- Corrective actions
- Document hierarchy

4.1 Data Quality Objectives

Environmental activities that support decisions (i.e., remedial investigations [RIs], risk assessments, and feasibility studies [FSs]) should be conducted by implementing the U.S. Environmental Protection Agency (EPA) Data Quality Objective (DQO) process (EPA 1990 Draft). The DQO process is a Total Quality Management approach to planning for data collection in support of environmental decision making. This planning tool utilizes seven key steps to ensure that decision makers and data collectors communicate effectively to address cleanup problems. The Project Management Contractor (PMC) recognizes that effective planning to implement the DQO process requires coordination with the Argonne National Laboratory (ANL) (an independent contractor to the DOE with responsibility for RI/FS work

plans, risk assessments, etc.) as well as U.S. Department of Energy (DOE). The PMC will make every effort to facilitate the coordination through training, reporting, and task coordination. Key players involved in each step are also identified. These steps are defined in the following subsections. They are:

(1) Define the problem.
(2) Identify alternative actions that will resolve the problem.
(3) Identify inputs affecting the decision.
(4) Specify the domain of the decision.
(5) Develop a logic statement.
(6) Establish constraints on uncertainty.
(7) Optimize the design for collecting data.

The DQO process is implemented in an iterative manner. Each iteration helps to:

- Better define the scope of the problem.
- Focus the decision.
- Clarify courses of action and inputs needed.
- Establish go/no-go alternatives.
- Identify resources constraints.
- Describe consequences of incorrect decisions.

The initial iteration of the DQO process is qualitative in nature. Each subsequent iteration clarifies and quantifies each step of the process to develop defensible design criteria for data collection. The overall benefit of implementing the DQO process can be summarized as follows:

- It helps promote effective communication with data collectors by organizing key planning issues in a thoughtful sequence.

- It helps establish objective and quantitative criteria for knowing when to stop sampling.

- It helps ensure that investigations will produce the types and amounts of data needed to decide which course of action to take, with acceptable and pre-specified measures of risks of incorrect decisions.

- It reduces overall time for investigations by decreasing the likelihood of false starts and minimizing rework.

The DQO process is implemented within all activities that support environmental decision making (e.g., RI/FS, risk assessment, site closure). Implementation is described in the *Environmental Data Administration Plan* (EDAP) (MKF and JEG 1992a). The individual sampling plans present Stage I and Stage II reports for decision making and the optimum design criteria for data collection.

Step 1: Define the Problem

The problem is defined in terms of what is known about or expected to be discovered in the affected area. This may include exposure pathways, types of contaminants, and changes to the site since original activities.

Step 2: Identify Alternative Actions to Resolve the Problem

The product of this step is a list of alternative courses of action that address the problem. Courses of action may include:

- Study the site of contamination further and develop remedial alternatives.
- Recommend "no action" based on information available.
- Recommend corrective action, such as an emergency response action, based on information indicating an immediate threat to public health.

Step 3: Identify Inputs Affecting the Decision

This step generates a list of questions that must be answered to decide which action to take, how criteria for decision making will be established, and the relevance of social and political factors.

Step 4: Specify Domain of Decision

Spatial and temporal boundaries are defined in this step to address the area and time frame required to collect data to determine the smallest area to which a separate decision will apply.

Step 5: Develop a Logic Statement

An "if/then" statement is developed from knowledge summarized in the previous DQO steps. This statement explains what actions will be taken under what circumstances.

Step 6: Establish Constraints on Uncertainty

Quantitative and qualitative statements concerning the level of uncertainty that will be allowed in the data to implement the logic statement are addressed in this step. The consequences of incorrect decisions are determined to evaluate the risk involved.

Step 7: Optimize Design for Obtaining Data

In this step a statistical approach is used to design a sampling program that will achieve the desired constraints on uncertainty.

4.2 Document Control

The goal of the Weldon Spring site document control system is to ensure that pertinent documents, including drawings, procedures, and specifications used by WSSRAP personnel, are current. To achieve this goal, procedures for identifying and controlling quality-affecting documents have been developed. These procedures include establishment of a numbered document control system and a document inventory procedure. WSSRAP Procedures ENG-5a, SQP-7a, SQP-8a, SQP-9a, SQP-10a, CID-10a, PS-6a, and PS-9a implements this system.

The document control system ensures that originals and copies of documents are kept secure and under custody, when necessary, and that individuals holding documents receive revisions and updates when appropriate.

4.2.1 Controlled Documents

Controlled documents are documents issued by authorized personnel which, in accordance with requirements of WSSRAP Standard Operating Procedures (SOPs) and Administrative Procedures, are assigned unique identifying numbers and logged out to specific individuals. These documents specify quality requirements for activities affecting quality. A distribution list for each document is maintained in the Document Control Center. These documents include:

- Quality assurance/quality control (QA/QC) plans.
- Procurement plans.
- Engineering design documents.
- Design procedures.
- SOPs/Administrative Procedures.
- Safety plans.
- Plans and procedures required by regulation.

4.2.2 Document Ownership and Distribution

All quantitative project documents generated by the WSSRAP are the property of the DOE. Such documents are distributed to State agencies, Federal agencies, other regulatory agencies, and citizen's groups in accordance with DOE approvals, policies, and guidelines. Distribution of information and documents to third parties is with concurrence of, or at the direction of, the DOE. Controlled documents (i.e., manuals, procedures, instructions, and guidelines) are distributed on the basis of a written, approved, standard distribution list. Controlled documents distributed to parties are inventoried and are accompanied by a document transmittal form. A return receipt is required and documented on the controlled document transmittal log. All quality-affecting documents submitted to the DOE are reviewed and approved by the PMC in accordance with WSSRAP Administrative Procedures.

5 SAMPLING AND ANALYTICAL PROCEDURES

The objective of field sampling and laboratory analytical procedures is to obtain defensible data that meet data quality requirements for precision, accuracy, representativeness, comparability, and completeness (PARCC) as required by characterization and monitoring sampling plans which utilize the data quality objective (DQO) process for data collection.

5.1 Field Sampling

Precision, comparability, representativeness, and completeness for field sampling activities at the Weldon Spring Site Remedial Action Project (WSSRAP) are controlled and directed by approved standard operating procedures (SOPs) and sampling plans. All SOPs and sampling plans are reviewed, approved, and controlled by appropriate WSSRAP procedures. Field sampling SOPs are developed to standardize, where possible, sampling procedures to ensure that samples are comparable to, and compatible with, other data collection activities at the WSSRAP. Sampling is conducted by trained individuals. Training of individuals is documented according to WSSRAP training requirements, including Procedure PS-14a, before any individual conducts or assists with sampling activities.

The WSSRAP SOPs include descriptions of:

- Reference of sample methods.
- Sample collection techniques.
- Sample identification.
- Sample preservation.
- Sample packaging and handling.
- Sampling quality control (QC) procedures.
- Quality assurance (QA) records.
- Equipment calibration and maintenance.

The WSSRAP has developed an *Environmental Data Administration Plan* (EDAP) (MKF and JEG 1992a) to manage the use of environmental data. The EDAP directs the implementation of the DQO process for the sampling plans where appropriate.

Field sampling plans establish the QC criteria necessary to meet the sampling precision, representativeness, comparability, and completeness required to support the data quality objective process as defined in the EDAP.

Field sampling activities that produce data (e.g., log books, field data sheets, equipment calibration records) become QA records and are maintained in accordance with the Quality Assurance Program (QAP).

Also, many geotechnical field activities and laboratory analyses are performed for the WSSRAP. The geotechnical activities also comply with the WSSRAP QAP and SOPs, when applicable, and with ASTM standards which regulate most geotechnical work such as drilling, compaction, permeability testing, etc.

5.2 Analytical Procedures

All quantitative laboratories conducting geotechnical, radiological, and/or chemical analysis for the WSSRAP are required to submit controlled copies of site-specific Quality Assurance Project Plans (QAPjPs) and SOPs to be reviewed and accepted by the Project Management Contractor (PMC). The WSSRAP and contract laboratory SOPs direct operations, analyses, and activities which are thoroughly prescribed, documented, and performed in accordance with accepted standards and methodologies. Any changes to controlled SOPs and QAPjPs must be approved by the PMC. Laboratory QAPjPs and SOPs specify QC requirements to demonstrate the precision and accuracy of methods and procedures.

All data generated by analytical activities (e.g., calculations, chromatographs, calibration curves, QC analyses) that are received by the WSSRAP are QA records and are maintained in accordance with the QAP and/or SQP-7, SQP-8, SQP-9, and SQP-10.

Maintenance and storage of completed records, charts, and logs of all pertinent calibrations, analyses, QC activities, and data generated by contract laboratories are kept in a WSSRAP-specific project file. Both electronic and hard copy data reports must be available at contract laboratory facilities for 3 yr after termination or expiration of any contract. Storage areas must keep records safe from damage by moisture or fire.

Routine audits and surveillances are conducted by the Project Quality Department on all contract laboratories to verify their conformance to their QA programs, WSSRAP contract specifications, and appropriate regulatory requirements.

6 CALIBRATION AND PREVENTIVE MAINTENANCE

To help achieve the necessary data quality, calibration and preventive maintenance procedures control the use of field sampling equipment and laboratory instruments.

6.1 Field Sampling Equipment

To ensure the precision, accuracy, and minimal down time of field sampling equipment, the Weldon Spring Site Remedial Action Project (WSSRAP) develops Standard Operating Procedures (SOPs) for operation, calibration, and maintenance of all site field sampling equipment.

These SOPs include means for demonstrating and documenting instrument precision and accuracy. Such means are:

- All measurement devices must be assigned individual identification numbers. Documentation must identify the function, calibration requirements, operating technicians, and standards used for calibration of each device.

- Each measuring device must be calibrated against a traceable standard of known accuracy.

- Sampling and analytical calibration methodologies must be documented and referenced to Federal and regulatory standards.

The SOPs also identify the type and frequency of routine preventive maintenance required for each model of field equipment used. Equipment must be maintained at least in accordance with manufacturers' recommendations. Logbooks must be maintained for each field sampling instrument. These logs must document the maintenance performed, the technician performing the maintenance, and whether maintenance was routine or for repair.

Personnel must be appropriately trained before operating field sampling equipment. Documentation of training is in accordance with WSSRAP SOP training procedures. Only trained, qualified technicians perform preventive maintenance.

All records of calibration and maintenance are quality assurance (QA) records and are maintained in accordance with QA Procedure SQP-7, *Quality Assurance Records*.

6.2 Laboratory Instruments

All laboratories conducting radiological and chemical analyses for the WSSRAP must include in their site-specific quality assurance project plans (QAPjPs), calibration and preventative maintenance requirements for all instruments used to conduct WSSRAP analyses. For each model of instrument the QAPjPs must identify:

- Calibration requirements
- Calibration acceptance criteria
- Corrective action, if required
- Routine maintenance requirements

Laboratories must, upon request, provide to the WSSRAP documentation for all calibration, maintenance, and corrective actions required. Calibration and maintenance documents are QA records and are maintained in accordance with QA procedure SQP-7, *Quality Assurance Records*.

7 SAMPLE CUSTODY

A major required component of all field investigation sampling plans is maintaining sample integrity from collection to data reporting. To maintain and document sample possession, chain-of-custody procedures must be implemented. Elements of the chain may include at a minimum:

- Sample seals
- Labels with identification numbers to allow for sample tracking
- Field log books
- Field data record forms
- Chain-of-custody records
- Sample analysis request sheets
- Bills of lading and air bills
- Field and laboratory tracking forms

Field and laboratory sample custodians or their designated representatives are responsible for maintaining custody of samples. A sample is considered to be under a person's custody if one or more of the following conditions are met:

- It is in the person's physical possession.
- It is in view of the person.
- It is secured by the person so that no one can tamper with the sample without being detected.
- It is secured by the person in an area that is restricted to authorized personnel.

Sample custody is divided into the following three parts:

(1) Field sample custody
(2) Laboratory sample custody
(3) Quality Assurance (QA) record

7.1 Field Sample Custody

Sampling procedures for groundwater, soil, waste, etc., are addressed in the Weldon Spring Site Remedial Action Project (WSSRAP) Standard Operating Procedures (SOPs) and sampling plans. The sample custody program for the Weldon Spring site includes documentation of procedures for the preservation of samples, sample identification, recording sample collection locations, and specific considerations associated with sample acquisition. Applicable forms for recording these data, and the tracking of samples as required by chain-of-custody procedures, are specified in SOPs. The chain of custody requires at a minimum, the following:

- Sample identification
- Sample location
- Sample date
- Sample matrix
- Sample preservation
- Analysis required
- Release and acceptance information; i.e., date, location, and technician's signature

In situ or field measurements (e.g., pH measurements, temperature, conductivity, flow measurements, and air monitoring data) are recorded in field log books or on field data record forms. Sample containers are labeled or tagged appropriately according to applicable SOPs. Labels or tags contain the following information:

- Organization name
- Location
- Date
- Matrix type
- Preservation
- Sample identification number
- Name(s) of sampler(s)

Samples are accompanied by chain-of-custody records. Completed chain-of-custody documents are retained as quality assurance records and maintained in accordance with the Quality Assurance Program.

7.2 Laboratory Sample Custody

Samples are packaged and shipped to the laboratory in accordance with U.S. Department of Transportation requirements and WSSRAP procedures RC-17 and RC-19 with a separate custody record accompanying each shipment. Authorized sample custodians at the laboratories sign for incoming field samples, obtain documents of shipment, and verify data entered onto the sample custody records. The laboratories are required to inform the PMC of receipt of samples within one working day. If any damage or shipping discrepancy is noted upon receipt of samples, the laboratories are required to inform the PMC immediately. Contract laboratories are required to maintain custody of samples as defined in Section 7.0.

8 DATA EVALUATION, REDUCTION, AND REPORTING

Statistical parameters are used to assess the quality of data obtained. Section 4.1 discusses the process used to establish and assess the precision, accuracy, representativeness, completeness, and comparability (PARCC) of Weldon Spring Site Remedial Action Project (WSSRAP) environmental monitoring and measurement data. This section discusses criteria to be used in handling collected data.

8.1 Data Packages

Data packages received from contract laboratories undergo several processes to evaluate the quality of the data. When the data are first received, copies are distributed to the Quality Assurance (QA) Department for storage as QA records and to the Verification Group and data users for review. If validation of sample analysis has been requested, a copy is forwarded to the Validation Group for data qualification. The following subsections further describe the evaluation process.

8.1.1 Data Verification

The WSSRAP processes all data received from contract laboratories in accordance with ES&H 4.9.1s *Environmental Monitoring Data Verification*. The following factors are reviewed to verify if a sample has been properly handled according to WSSRAP protocol:

- Chain of custody
- Holding times
- Sample preservation requirements
- Laboratory chain of custody
- Sample analysis request form
- Quality control (QC) samples
- Laboratory receipt forms

8.1.2 Data Review

Copies of the data packages are distributed to the data users for their review. The data are reviewed to identify discrepancies in the field QC samples, inconsistencies of the data in

comparison to historical data, or apparent abnormalities. Deficiencies reported by data users are reported to the verification group. Data users may request validation of any data that appear to be of questionable quality.

8.1.3 Data Validation

Randomly selected laboratory data and data selected by verification or data users undergo thorough reviews of the analytical process in accordance with WSSRAP data validation Standard Operating Procedures (SOPs). These reviews are conducted by the validation group.

The purpose of the validation procedure is to specify a consistent means for reviewing and evaluating the data resulting from laboratory analyses and for providing a consistent means for documenting the evaluation, and reporting the usefulness, of the data to the data users. This is accomplished through a thorough review of the analytical data utilizing laboratory analytical records to assess laboratory conformance to QC criteria, data quality requirements for data quality objectives, and procedural requirements.

8.2 Data Reduction

A data reduction process has been developed for all data collected on site for the WSSRAP. Generally, these procedures are described in WSSRAP SOPs.

8.2.1 Computerized Data Reduction

A large amount of data will be generated during site characterization. Those data collected and analyzed during the sampling and analysis program will be reduced for input into the computerized database. These data may include logs, tracking forms, and results of laboratory analyses. Computer software used for data reduction will be managed in accordance with Section 6 of the Quality Assurance Program (QAP).

8.3 Reporting

Documentation of the data collection and analysis process is an integral part of the QA/QC program. Data validation techniques require that SOPs, sample tracking methods, validation procedures, QC checks on PARCC criteria, and all sampling and laboratory activities

be documented. Data obtained from sample collection and analysis operations are recorded on standardized report forms or log books.

These documents include approved WSSRAP forms. Some of these documents are listed below:

- Contract Laboratory Program (CLP) report forms
- Chain-of-custody forms
- Sample labels
- Sample analysis request forms
- PARCC objectives summary forms
- QA/QC report forms for laboratory
- Equipment calibration report forms
- Standard field and laboratory log forms

8.3.1 Field and Laboratory Quality Assurance Records

Documents used to record environmental activities are, where practicable, numbered and assigned to individuals designated to perform specific tasks. They include:

- Field log books
- Field data record forms (e.g., well inventory forms, pumping test data sheets)
- Analytical log books
- Laboratory data, calculations, graphs, etc.
- Location maps, photos, selected drawings, as-builts
- Checklists of equipment performance
- Equipment maintenance logs including repair and calibration information
- Photographic logs
- Engineering calculations

8.3.2 Quality Assurance Record Storage

QA records are monitored as specified in SQP-7, SQP-8, SQP-9, and SQP-10 and are stored in locked and secure facilities. Dual document storage facilities are maintained at locations sufficiently remote from each other to eliminate the chance of simultaneous exposure

to a hazard. Access to both facilities is controlled. This applies to both computer-generated data and hard copy documents. Copy-protected software can be replaced by the supplier.

Documents are reviewed for technical adequacy by the responsible management before submittal to the Project Quality Department for retention as QA records. QA records are one-of-a-kind documents not being retained by the Document Control Center in the project correspondence or controlled document system. Appropriate documents become QA records upon completion.

9 INTERNAL QUALITY CONTROL

To achieve the highest practical attainable level of precision and accuracy, sampling programs at the Weldon Spring Site Remedial Action Project (WSSRAP) include the use of quality control (QC) samples to measure field and laboratory performance. QC samples are submitted to laboratories as blind samples. These samples are defined for aqueous media in procedure ES&H 4.1.4. To provide quality control information, the following types of QC samples may be utilized:

- Background Samples: The samples are obtained from media characteristic of the site but outside of the zone of contamination; e.g., groundwater samples collected from the upper Burlington-Keokuk aquifer upgradient of the Weldon Spring Chemical Plant area.

- Duplicate Samples: These samples are collected at the same time from common collection manifolds, locations, or sampling divides, or as split samples from one sampling event, and sent to the same laboratory to verify sampling and inter-laboratory precision. Generally, one out of every 20 investigative samples is replicated.

- Secondary Duplicate Samples: Replicate samples, divided into two portions, are sent to different laboratories to assess inter-laboratory precision.

- Equipment Blanks: Analyte-free deionized water is used to rinse sampling equipment that has been decontaminated; e.g., bailers, pumps, augers, split tube samplers, etc. When using non-dedicated sampling equipment, one rinsate sample is collected per day or for every 20 investigative samples, whichever is greater. Upon analysis, these samples are used to assess the adequacy of the field decontamination process.

- Trip Blank: This is analyte-free water taken from a laboratory to the sampling site and returned to the laboratory unopened. Trip blanks are used only when sampling for volatile organics.

- Performance Audit Sample: This is a sample containing known concentrations of analytes which is submitted to a laboratory without warning to assess its performance. See Section 10.3.

Internal QC samples at the laboratories include the utilization of matrix spikes and laboratory control samples, including U.S. Environmental Protection Agency (EPA) quality control ampules, Standard Reference Materials (SRMs), and laboratory-prepared solutions made from pure compounds and method or analytical blanks.

The laboratories selected by the WSSRAP utilize the standards and guidelines prescribed by the EPA, where appropriate, for analyzing relevant chemical and radiological constituents.

The analytical internal QC operations presented in *Users Guide to the Contract Laboratory Program* (EPA 1986b) are applied to contract laboratories performing analyses on samples generated by the WSSRAP. These operations include:

- Inductively Coupled Argon Plasma (ICP) Interference Check Sample Analysis: Performed at least twice per 8-hr shift to verify inter-element and background correction factors.

- Preparation Blank Analysis: Performed on each batch of samples or on each set of 20 samples to ascertain whether sample concentrations reflect contamination.

- Spiked Sample Analysis and Duplicate Sample Analysis: Performed on each concentration and matrix within each set of 20 samples of a similar matrix to provide information concerning sample homogeneity, analytical precision and accuracy, and the effect of the sample matrix on the analytical methodology and to allow for evaluation of the long-term precision of the method.

- ICP Serial Dilution Analysis: Performed on one of each 20 samples received in each group of samples of a similar matrix type and concentration to ascertain whether significant chemical or physical interferences exist due to sample matrix.

- Furnace Atomic Absorption Quality Assurance (QA) Analysis: Required for quantification; incorporates duplicate injections and analytical spikes in order to

evaluate the precision and accuracy of the individual analytical determinations on each sample.

- Laboratory Control Spikes (LCS): Standards carried through sample preparation and analysis procedures to document the performance of the entire analytical process. The results of LCS analysis are submitted with the data package. Laboratories verify, on a quarterly basis, their instrument detection limits, ICP linear ranges, ICP inter-element correction factors, and ICP integration times.

It is the responsibility of each laboratory to document in each data package submitted that both initial and ongoing instrument and analytical QC requirements have been met. Any samples that have not been analyzed according to contract QC requirements are re-analyzed by the laboratory or properly qualified by the Validation Group.

10 AUDITS AND CORRECTIVE ACTIONS

Quality assurance (QA) objectives for the Weldon Spring Site Remedial Action Project (WSSRAP) will be met in part by audits of field sampling and laboratory analysis activities. The goals or objectives of the Weldon Spring site characterization quality assurance/quality control (QA/QC) audit program are to ensure that:

- QA/QC requirements are clearly established.
- All sampling and analytical efforts are described by an approved sampling plan.
- Standard operating procedures are developed for each measurement activity.
- Qualified personnel are assigned to perform these activities in accordance with the procedures.
- Proper documentation is prepared to establish data validity.
- Audits are performed to determine compliance with the established QA/QC requirements.
- Corrective actions are proposed and implemented to address deficiencies identified during audits. The corrective actions are also verified and validated.

This section describes the performance, reporting, and documentation phases of the audit portion of the WSSRAP Quality Assurance Program.

10.1 Audits—General

An audit program is implemented to ensure compliance with the QA/QC program requirements established for the WSSRAP in the approved *Project Management Contractor Quality Assurance Program* (MKF and JEG 1992c). This mechanism is intended to assess systems and procedure effectiveness.

Audits:

- Identify weaknesses and strengths of overall programs.
- Dictate corrective actions as required.
- Allow for modification and enhancement of QA/QC programs.
- Serve as a vehicle for providing necessary technical assistance.
- Measure the effectiveness of QA/QC programs to ensure data quality.

Audits at the WSSRAP include performance and systems audits. These audits are performed both internally and externally to the Project Management Contractor (PMC). All audits are performed by PMC personnel that have been certified in accordance with SQP-17s, *Auditor Training and Lead Auditor Certification*.

Systems audits consist of an evaluation of all components of a measurement system to determine their capability, proper selection, and use. A systems audit includes a careful evaluation of field and/or laboratory QA/QC programs. Systems audits are normally performed prior to, or shortly after, systems are operational; however, such audits are performed on a regularly scheduled basis for the duration of the WSSRAP. Systems audits are performed in accordance with SQP-18s, *Independent Assessment*.

10.2 Audit Preparation

Audits are performed under the direction of certified lead auditors who are assisted by certified auditors and/or appropriately trained technical specialists as required to audit all components of the WSSRAP QA/QC programs. For each audit, the lead auditor is responsible for preparing and maintaining an audit schedule, reviewing and documenting the qualifications of all audit personnel (including technical specialists), providing notifications to audited organizations, and preparing and/or approving audit plans and checklists.

The lead auditor, after a review of applicable requirements such as procedures, contracts, plans, standards, and project schedules, prepares an audit schedule indicating the organization to be audited, subjects to be audited, and schedule of the audits. The audit schedule is reviewed periodically and revised as necessary to ensure that coverage is kept current. In advance of the scheduled audit, the lead auditor notifies the organization to be audited of the proposed schedule and scope of the audit.

The lead auditor selects the audit team members including auditors, technical specialists, and observers as required to best perform a comprehensive audit of the systems or components to be audited. Team personnel are appropriately trained as auditors and do not have direct responsibilities in the areas being audited. The lead auditor documents the qualifications of the audit team members.

The lead auditor is responsible for preparing a written audit plan as requested by the Project Quality Manager. The audit plan includes:

- Audit number
- Organization to be audited
- Subjects to be audited
- Scope of the audit
- Projects or activities to be audited
- Audit team members
- Audit schedule
- Applicable documents

The audit plan is used to provide the audited organization's management with the proposed scope, requirements, personnel, and schedule for the audit.

The audit team prepares audit checklists based on their review of applicable or relevant and appropriate requirements, documents, including procedures; standards, contracts, and plans; and previous audits, if any, of the systems or tasks to be audited. The lead auditor is responsible for review and approval of the audit checklists. These checklists are used to evaluate the performance of the audited activity.

The lead auditor provides the audit team with the audit plan and checklists. The lead auditor also orients the team to the audit schedule as well as the internal and external organization and contractual interfaces and responsibilities of the organization to be audited.

Audits are scheduled at intervals consistent with the schedule for accomplishing the activity and commensurate with the status and importance of the activity.

Audits are performed in accordance with written procedures.

Audit results are documented by auditing personnel and reviewed by management having responsibility in the area audited.

10.3 Performance Audits

Performance audits are used to quantitatively determine the accuracy of a laboratory's performance, using a blind quality control sample. The WSSRAP requires that laboratories generating data that are to be used for making decisions that may impact the health and safety of the public or the environment participate in the appropriate performance sample programs. The following are examples of programs that are presently used for this purpose:

- U.S. Department of Energy (DOE) Environmental Measurement Laboratory QA Program
- U.S. Environmental Protection Agency (EPA) Environmental Monitoring System Laboratory Program
- EPA Water Pollution and Water Supply Intra-laboratory Performance Program

The laboratories' performance in these programs is evaluated during annual system audits conducted by the PMC.

10.4 System Audit Performance

For each audit, the lead auditor conducts a pre-audit meeting at the audit site with the audit team and responsible management of the organization to be audited. The pre-audit meeting provides a means to introduce the audit team; establish contacts and interfaces; present and confirm the audit plan, scope, and sequence; and schedule the post-audit meeting.

The audit is conducted following the approved audit checklist as a guideline. The lead auditor may assign portions of the checklist to members of the audit team commensurate with their expertise. The checklist is a guideline; responsible questioning or investigation may lead the audit into areas not described in the audit plan or by the audit checklist.

Audits include objective examination of work areas, activities, processes, and items and review of documents, records, quality-related practices, procedures, and instructions to determine compliance with the QA/QC program requirements and the project procedures manual. The results of the investigations are recorded on the audit checklists.

Discrepancies or concerns discovered during the course of the audit are presented to the lead auditor for review and discussion prior to formalizing. Discrepancies are categorized as follows:

1. Finding: A deficiency or non-compliance to established procedures, requirements, or regulations.

2. Item of Concern: A condition or item identified during an assessment which, although currently meeting established requirements, may, if left without management attention, lead to a departure from established requirements.

3. Observation: A conclusion which is the result of a generally subjective evaluation of implementation practices or management systems related to the area under review.

At the conclusion of the audit, a post-audit meeting chaired by the lead auditor is conducted. The purpose of the post-audit meeting is to present the findings, items of concern, and observations to the responsible management of the audited organization. Resolution of discrepancies and commitments for corrective actions, including a tentative schedule for completion of corrective actions, are discussed at this time.

10.5 Audit Reporting

Audit reports are submitted to cognizant managers by either the Project Quality Manager or the lead auditor. These reports address the performance of measurement systems and data quality. Audit reports include the dates of audits, audit procedures, names of auditors, audited organization participants, specific procedures audited, a summary of audit results including findings and observations (if any), and recommendations for correcting deficiencies or improving the QA/QC programs, if necessary.

Audit findings are recorded on the Quality Finding Report Form and are included as part of the audit report as detailed in SQP-18s. Items of concern are also included in the audit report.

Audit reports are issued promptly upon completion of an audit (with 30 days), and include the date required for response to audit findings. Findings require responses within 30 days. Responses must include commitment dates for completion of corrective actions to be taken, results of a review for potential impact on other items or activities (if any), and the causes of deficiencies.

Items of concern also require responses within 30 days as appropriate and do not necessarily include corrective actions or causes of deficiencies.

Observations may or may not require formal responses, depending upon the severity, type, and number of specific deficiencies. The lead auditor specifies which of the observations require written responses. Observations are recorded in the body of the audit report.

Completion of corrective actions noted in audit responses are verified and validated upon receipt of the responses or by the dates specified on the responses.

10.6 Surveillance

In addition to regularly scheduled audits, the QA Department performs surveillances of field and laboratory activities in accordance with SQP-2s, *Quality Assurance Surveillance*. Surveillance is the act of monitoring or observing to verify whether an item or activity conforms to specified requirements.

Surveillances may be planned or unplanned, scheduled or unscheduled. No checklist is required; however, the approved procedure for the operation or task is followed to ensure adherence to the requirements. Surveillances are documented by the individuals performing them and reviewed by the lead auditor.

When deficiencies are noted, the responsible departments are notified by either Quality Finding Reports (QFRs) or items of concern as presented in the audit report.

Responses to QFRs and items of concern must be returned to the Project Quality Department by the responsible department manager and appropriate follow-up actions must be prescribed at that time.

10.7 Finding/Deficiency Corrective Action and Closure

The lead auditor is responsible for the evaluation of corrective action responses to determine if the corrective action for each finding/deficiency is adequate, has been scheduled, or has been completed. The lead auditor ensures that responses to findings written by audit team members fully address discrepancies.

Follow-up may be accomplished through written communication, re-audit, surveillance, or other appropriate means. Unsatisfactory responses are addressed in writing, indicating why they are unsatisfactory, and specifying a reply due date. Findings and deficiencies are considered open until approved corrective actions have been completed. The lead auditor is responsible for closing all findings and deficiencies.

10.8 Quality Assurance Records

All audit plans, correspondence relating to audits/surveillances, audit findings, audit reports, individual certifications, QFRs, and surveillance reports become QA records and are maintained in accordance with the WSSRAP *Quality Assurance Program* (MKF and JEG 1992c).

11 QUALITY ASSURANCE REPORTS TO MANAGEMENT

11.1 Assessment of PARCC

The Validation Group generates periodic and quarterly reports to management. The appropriate validation standard operating procedures (SOPs) clearly define the mechanism for transmitting these reports.

11.1.1 Periodic Reports

Reports generated by the Validation Group from random selection or data user requests are submitted to management upon completion. These periodic reports are submitted to the managers of the appropriate departments for their information.

11.1.2 Quarterly Reports

The Validation Group reports to management all data assessments to date on a quarterly basis. These reports are submitted, as a minimum, to the following:

- The Deputy Project Director
- The Quality Assurance (QA) Department
- Environmental Safety and Health Manager

11.2 Quality Assurance Reports

The QA Department's standard quality procedures define the disposition of all reports generated by QA activities to the appropriate management levels.

The QA Department developed the Site Wide Audit Tracking System (SWATS) to identify, track, and document closure of quality-affecting deficiencies. The SWATS has been divided into three categories:

- Extrinsic SWATS: Deficiencies that have been identified and issued to the WSSRAP from an outside source (e.g., the DOE or a PMC corporate office).

- Internal/Subcontractor SWATS: Deficiencies that were identified by QA surveillances, inspections, and audits.

- Self-assessment SWATS: Deficiencies identified by the specific department conducting a self assessment.

11.2.1 Monthly Reports

- QA monthly reports will be submitted to the MK corporate QA Manager.

- Monthly SWATS reports will be submitted to PMC management to identify open deficiencies.

11.2.2 Quarterly Reports

- Quarterly quality reports summarizing quality activities will be submitted to the DOE Project Office and MK corporate QA manager.

- The Extrinsic SWATS Reports will be submitted quarterly to the DOE project office for closure of externally identified deficiencies.

MK-Ferguson Company and Jacobs Engineering Group, 1992a. *Environmental Data Administration Plan*. Rev. 2. DOE/OR/21548-119. Prepared for the U.S. Department of Energy, Oak Ridge Operations Office. St. Charles, Missouri. December.

MK-Ferguson Company and Jacobs Engineering Group, 1992b. *Site Consolidated Transportation Activity Manual*, Rev. 0. DOE/OR/21548-309. Prepared for the U.S. Department of Energy, Oak Ridge Operations Office, Weldon Spring Site Remedial Action Project. St. Charles, MO. October.

MK-Ferguson Company and Jacobs Engineering Group, 1992c. *Project Management Contractor Quality Assurance Program*, Rev. 0. DOE/OR/21548-333. Prepared for the U.S. Department of Energy, Oak Ridge Field Office, Weldon Spring Site Remedial Action Project. St. Charles, MO. September.

U.S. Department of Energy, 1992. *Feasibility Study for Remedial Action at the Chemical Plant Area of the Weldon Spring Site*. Volume I: Main Text; Volume II: Appendixes. RI/FS-EIS Document: DOE/EIS-0185D; Feasibility Study: DOE/OR/21548-148. Oak Ridge Field Office, Weldon Spring Remedial Action Project. November.

U.S. Environmental Protection Agency, 1983. *Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans*. QAMS - 005/80; EPA-600/4-83-004. Office of Monitoring Systems and Quality Assurance, Office of Research and Development, February.

U. S. Environmental Protection Agency, 1986b. Office of Emergency and Remedial Response, *Users Guide to the Contract Laboratory Program*, Washington, D.C. December.

U. S. Environmental Protection Agency, 1987. *Data Quality Objectives for Remedial Response Activities*. EPA 540/G-87/003. Office of Emergency and Remedial Response and Office of Waste Programs Enforcement, March.

Regulations

Code of Federal Regulations 40 CFR 300 - *National Oil and Hazardous Substances Contingency Plan*.

DOE Order

DOE Order 5700.6C, *Quality Assurance*

13 DISTRIBUTION LIST

Mr. Dave Bedan (3 copies)
State of Missouri
Department of Natural Resources
Post Office Box 176
Jefferson City, Missouri 65102

Mr. Dan Wall (4 copies)
Superfund Branch
U.S. Environmental Protection Agency
Region VII
726 Minnesota Avenue
Kansas City, Kansas 66101

Dr. Margaret MacDonnell
EID Division
Argonne National Laboratory
9700 South Cass Avenue, Building 900
Argonne, Illinois 60439

H. W. Hibbitts, SE-31 (letter w/o encl)
U. S. Department of Energy
Environmental Protection Agency
Oak Ridge Operations Office
Post Office Box 2001
Oak Ridge, Tennessee 37830

Mr. Jim J. Fiore, Director
Office of Eastern Area Programs
Division of Environmental Restoration
EM-42, Room D-430
U.S. Department of Energy
104 Trevion II Building
12800 Middlebrook Road
Germantown, Maryland 20874

Project Manager U.S. Army Toxic and
Hazardous Materials Agency
Attn: CETHA-IR-A
Building E4435
Aberdeen Proving Ground, MD 21010-5401

Mr. Karl J. Daubel
Environmental Coordinator,
Weldon Spring Training Area
U.S. Department of the Army
7301 Highway 94 South
St. Charles, Missouri 63304

Mr. Marvin Sherrill
District Chief
U.S. Department of the Interior
Geological Survey, Mail Stop 200
1400 Independence Road
Rolla, MO 65401

The Honorable Eugene Schwendermann
County Executive
St.Charles County Courthouse
118 North Second Street
St. Charles, MO 63301

The Honorable Bob Fisher
County Council
St. Charles County Courthouse
118 North Second Street
